selang recognizes which command you want to execute as soon as you have typed in enough characters to distinguish it from all the other available commands. For example, you can type **ho** to run the *hosts* command as it is the only command beginning with those letters. As soon as you type **ho**, selang can recognize the intended command. On the other hand, there are several commands that begin with the string **new**. You must add enough characters to distinguish between *newusr*, *newgrp*, *newfile*, and *newres*.
- **Abbreviations**  
Each command is also associated with a one- to four-letter abbreviation. For example, because there are several commands beginning with the string *new*, you can also use the abbreviation **nu** for the command *newusr*. These abbreviations are documented as part of the command syntax for each command. You can enter commands in either uppercase or lowercase.
- **Word Completion (UNIX only)**  
Press *Tab* in the middle of a word to complete the word. Word completion is context-sensitive. If more than one word matches the specified string, selang uses the shortest word or word fragment that matches the string. For example, if you type the letter *n*, selang supplies *ew*, to form the word *new*. If this is not the required word, type another one or two characters and press *Tab* again to complete the word. Press **Ctrl+D** to see all the possible options. This is useful if you are not sure which command to use. Using the example in the previous paragraph, if you add the letter *u* to the word *new* and press *Tab*, selang supplies *sr*, giving you the command *newusr*. Words that are not part of the selang commands are stored in memory for use by the word completion feature later on in the same session. For example, if you type *newusr Mercedes*, and then later type *showusr Me* followed by *Tab*, the abbreviation *Me* is expanded to *Mercedes*, as follows:

```
showusr Mercedes
```

This assumes that you have not entered any other user name that begins with "Me".

## Wildcard Matching

selang supports the following wildcard characters:

- **\* (asterisk)**  
Any sequence of zero or more characters.
- **? (question mark)**  
Any single character (except a path separator for files).

To make a single character a do not care character that matches any other single character, use a question mark (?), as in the following examples:

Specify this...	To do this...
mmc?	mmc3, mmc4, mmc5
mmc?.t	mmc1.t, mmc2.t
mmc04.?	mmc04.a, mmc04.1

To match any string of zero or more characters, use an asterisk (\*), as in the following examples:

Specify this...	To do this...
*i*.c	main.c, list.c
st*.h	stdio.h, stdlib.h, string.h
*	All records of the specified class

## selang Command Authorization

To use selang commands that change records in the AC or native operating system (native OS) environment, you must have sufficient authority. For most commands, *one* of the following conditions must be met:

- You are the owner of the resource.
- You have the ADMIN attribute.
- The resource record is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You have CREATE or MODIFY access authority in the ACL of the record in the ADMIN class.
- (Windows) If your installation only permits management of the native Windows environment, you are a member of the Privileged Access Manager Administrators group in the Windows database.
- (UNIX) If your installation only permits management of the native UNIX environment, you are a member of the Privileged Access Manager Administrators group in the security files of the local UNIX host.

### NOTE

Exceptions to these general rules are noted in the description of each command.

## Access Control List Support

To give or deny access authority, you can use six types of access control lists:

- **ACL**  
Standard access control list that contains the user names and group names authorized to access the resource and the level of access granted to each.
- **NACL**

Negative access control list that contains the user names or group names that are not authorized to access the resource.

- **PACL**

Program access control list that depends upon the accessing program. Each PACL contains the user names and group names, the level of access, and the name of the program or shell script the user must execute to access the particular resource.

- **INET-ACL**

Internet access control list.

- **CACL**

Conditional access control list.

- **AZNACL**

The authorization ACL; an ACL that allows access to a resource based on the resource description.

Privileged Access Manager uses all relevant lists when it checks a user's authority to access a resource.

#### NOTE

You can maintain any single list with a single authorize command. To change more than one list you need to issue authorize again. You cannot define multiple access rights for multiple users and groups with one authorization rule. You must separate the rules.

The following table lists which access control lists you can use with each class. Classes that do not appear in the table have no access control lists and cannot be controlled by the authorize command.

Class	ACL/ NACL	CALACL	PACL	INET-ACL	CACL	AZNACL
ADMIN	X	X	X			
APPL	X	X				X
AUTHHOST	X	X				X
CONNECT	X	X	X			
CONTAINER	X	X	X			
DOMAIN	X	X	X			
FILE	X	X	X			
GAPPL	X	X				X
GAUTHHOST	X	X				X
GFILE	X	X	X			
GHOST				X		
GSUDO	X	X				
GTERMINAL	X	X				
HOLIDAY	X	X				
HOST				X		
HOSTNET				X		
HOSTNP				X		
LOGINAPPL	X	X				
MFTERMINAL	X	X	X			
PROCESS	X	X	X			
PROGRAM	X	X				
REGKEY	X	X	X			
REGVAL	X	X	X			

SUDO	X	X	X			
SURROGATE	X	X	X			
TCP	X	X	X		X	
TERMINAL	X	X	X			
UACC	X	X				
USER_DIR	X					X

## Access Authority by Class

Valid access values depend on the class the resource belongs to. The following table lists valid access values by class in the AC environment.

Class	Valid Access Values	Lets Accessors...
All classes	all	Perform <i>all</i> valid operations for the class.
	none	Perform <i>no</i> valid operations for the class.
ADMIN	create	Create records in this class.
	delete	Delete records in this class.
	join	Add a group to a USER record and to complete the linking of a user to a group. <b>Note:</b> The accessor must also have <i>modify</i> access.
	modify	Modify existing records. <b>Note:</b> To link a user to a group (add user names to GROUP records) the accessor must also have <i>join</i> access.
	password	Change the passwords of other users. <b>Note:</b> This access type affects only the USER class.
	read	List records in this classes
AUTHHOST	read	Login from an authenticated host.
CONNECT	read	Connect to the remote host.
CONTAINER	<i>inherited</i>	<b>Note:</b> Valid access values for this class are the valid values for the class of the contained objects.
DOMAIN	chmod	Create and delete trust relationships between one domain and another. <b>Note:</b> Both domains must have this access type.
	execute	Add or delete members from the domain.
	read	List domain members.
FILE, GFILE	chdir	Access the directory with the equivalent of read and execute permissions.
	chmod	Change file system modes. <b>Note:</b> Only applicable on UNIX hosts.
	chown	Change the owner of the record.

	control	Perform <i>all</i> valid operations except <i>delete</i> and <i>rename</i> .
	create	Create records in this class.
	delete	Delete records in this class.
	execute	Execute a program. <b>Note:</b> The accessor must also have <i>read</i> access.
	read	Use a file or directory without changing it. <b>Note:</b> On UNIX, if you want <i>read</i> privileges to control whether users can perform operations that obtain information about the file (such as <i>ls -l</i> ), set the <i>STAT_intercept</i> configuration setting to 1. For more information, see the <i>Reference Guide</i> .
	rename	Rename to a record in this class.
	sec	Change the ACL of records in this class.
	update	Perform the combined operations of <i>read</i> , <i>write</i> , and <i>execute</i> .
	utime	Change the modification time of a file. <b>Note:</b> Only applicable on UNIX hosts.
	write	Change the file or directory.
HNODE	read	List records in the class.
	write	Edit the details of the record.
HOLIDAY	read	Log in during the specified holiday.
KMODULE	load	Load a kernel module.
	unload	Unload a kernel module.
MFTERMINAL	read	Log in from the Mainframe terminal.
	write	Administer from the Mainframe terminal.
POLICY	delete	Delete the policy.
	execute	Deploy the policy.
	read	View policy details.
	write	Edit the details of the record.
	undeploy	Perform the combined operations of <i>delete</i> and <i>execute</i> .
PROCESS	read	Kill the process.
PROGRAM, SUDO, GSUDO	execute	Execute a program.
REGKEY	delete	Delete a Windows registry key.
	read	List the contents of the Windows registry key.
	write	Change the Windows registry key.
REGVAL	delete	Delete a Windows registry value.
	read	Read a Windows registry value.
	write	Change a Windows registry value.
RULESET	read	View the details of the record.
	write	Edit the details of the record.

SURROGATE	execute	Surrogate to the user.
TCP	read	Access TCP services from remote hosts or host groups.
TERMINAL, GTERMINAL	read	Log in to the terminal.
	write	Administer the terminal.
UACC	<i>inherited</i>	<b>Note:</b> Valid access values for this class are the valid values for the class it is defining.
WINSERVICE	read	View the properties of the Windows service.
	start	Start the Windows service.
	modify	Change the properties of the Windows service.
	resume	Resume a paused Windows service.
	stop	Stop a Windows service.
	pause	Pause a Windows service.

**NOTE**

The values none and all are applicable to all classes. The value all represents the entire group of access values, other than none, for a particular class. For more information about access authority, see the *Endpoint Administration Guide* for your OS.

**Windows Access Authority by Class**

Valid access values depend on the class the resource belongs to. The following table lists valid access values by class in the Windows (nt) environment.

Class	Valid Access Values	Let Accessors...
All classes	all	Perform <i>all</i> valid operations for the class.
	none	Perform <i>no</i> valid operations for the class.
COM, DISK	change	Perform the combined operations of <i>delete</i> , <i>read</i> , and <i>write</i> .
	changepermissions	Modify the ACL of the resource.
	delete	Delete the resource.
	read	Access data on the resource without changing it.
	takeownership, chown, owner	Change the owner of the specified resource.
	write	Write data to the specified resource.
FILE		<b>Note:</b> It is only possible to define access authorities for NTFS files; FAT files cannot have access authorities.
	change	Perform the combined operations of <i>delete</i> , <i>read</i> , and <i>write</i> .
	changepermissions, sec	Modify the ACL of the resource.
	chmod	Perform all operations except <i>delete</i> .
	chown	Change the owner of the specified resource.

	delete	Delete the resource.
	execute	Execute programs. <b>Note:</b> To use this access, the accessor must also have <i>read</i> access.
	read	Access a resource without changing it.
	rename	Renames the resource. <b>Note:</b> To rename a file, you must have <i>delete</i> access to the source and <i>rename</i> access to the target. The audit log reflects this order of events.
	write	Modify the resource.
	update	Perform the combined operations of <i>read</i> , <i>write</i> , and <i>execute</i> .
PRINTER	manage	Manage the printer. For example, set the data for a specified printer, pause printing, resume printing, clear all print jobs, update the ACL, or change printer properties.
	print	Print using the printer.
REGKEY	append, create, subkey	Create or modify a subkey of the registry key
	takeownership, chown, owner	Change the owner of the resource
	changepermissions, sec, dac, writedac	Modify the ACL of the resource.
	delete	Delete the resource.
	enum	Enumerate subkeys.
	link	Create a link to the registry key.
	notify	Change notifications for a registry key or for subkeys of a registry key.
	query	Query a value of the registry key
	read	Access a resource without changing it.
	readcontrol, manage	Read the information in the registry key's security descriptor, not including the information in the system (audit) ACL.
	set	Create or set a value of the registry key.
	write	Change the registry key and its subkeys.
SHARE	change	Change properties of the resource or remove sharing from the resource.
	read	Access a resource without changing it.

**NOTE**

The values *none* and *all* are applicable to all classes. The value *all* represents the entire group of access values, other than *none*, for a particular class. For more information about access authority, see the *Endpoint Administration Guide for Windows*.

## selang Environments

In addition to working on the local Privileged Access Manager database, you can use selang to modify the following:

- The native (Windows or UNIX) database
- The local Policy Model database (PMDB)
- A database on a remote host (Windows or UNIX) where Privileged Access Manager is installed
- Privileged Access Manager configuration settings

To switch environments, use the *env* (environment) command, which is available in all environments.

Some commands are the same in the different environments, but they may have different parameters and arguments. You should, therefore, check the syntax carefully when beginning to work in a new environment.

#### NOTE

When you are entering the *native* property of a command using *env*, the command is entered in both the *native* environment and current environment.

The following environments are supported:

Environment	Command	Prompt	Description
Policy Model	<code>env pmd</code>	<code>PAMSC (pmd) &gt;</code>	All <i>selang</i> commands operate on the local PMDB.
Native Windows	<code>env nt</code>	<code>PAMSC (nt) &gt;</code>	All <i>selang</i> commands modify the Windows database.
AC	<code>env ac</code>	<code>PAMSC&gt;</code>	All <i>selang</i> commands operate on the Privileged Access Manager database.  <b>Note:</b> This is the default.
Native UNIX	<code>env unix</code>	<code>PAMSC (unix) &gt;</code>	All <i>selang</i> commands operate on the security files of the local UNIX host.
Native	<code>env native</code>	<code>PAMSC (native) &gt;</code>	All <i>selang</i> commands operate in the native environment of the host.
Remote Configuration	<code>env config</code>	<code>PAMSC (config) &gt;</code>	All <i>selang</i> commands operate on the Privileged Access Manager configuration settings for the host.

## selang Configuration on UNIX

On UNIX, you can manage the way *selang* works. Most of the options are concerned with the way *selang* manages the UNIX security system (for the *selang* UNIX environment).

The *selang* utility uses the following two files for configuration options:

- **seos.ini**  
Contains the product configuration options. This is the main configuration file for the product.
- **lang.ini**  
Contains configuration information that *selang* uses.

*selang* uses the *lang.ini* files in *one or both* of the following locations:

- The directory where the seos.ini file is located.
- Home directory of the user.

If you specify a token in only one of these lang.ini files, selang uses the value from that file. If you specify a token differently in the two lang.ini files, the value in the home directory of user overrides the other one.

The values for the tokens DefaultShell and DefaultHome in the seos.ini file of server *override* the values set in the tokens DefaultShell and HomeDirPrefix in the lang.ini file.

**Note:** Sample lang.ini files are located in the directory *ACInstallDir/samples/lang.init*.

## Change the User File

The default file for updating UNIX users is /etc/passwd but you can change this default. This is normally required on the NIS server if you are working under NIS.

To change the user file modify the *YpServerPasswd* in the *passwd* section of the seos.ini file to point to your user's file full pathname.

## Change the File for Updating Groups

The default file for updating UNIX groups is /etc/group but you can change this default. This is normally required on the NIS server if you are working under NIS.

To change the file for updating groups modify the **YpServerGroup** in the **passwd** section of the **seos.ini** file to point to your user's file full pathname.

## Automatic Backup of the UNIX User and Group Files

Before the first update of a UNIX user in a session and before the first update of a UNIX group in a session, Privileged Access Manager creates a backup copy of the files /etc/passwd or /etc/group. The backup files are called /etc/passwd.SeOS.bak and /etc/group.SeOS.bak, respectively. If an error occurs when updating the UNIX system, the original information is recoverable. Backups are made only before the first change to the UNIX system in a selang command shell session.

## Get selang Help

You can get help at any time in the interactive selang command environment.

To enter selang online help, enter one of the following:

- **? or help**  
The selang online help text for the environment you are in, appears on the screen, displaying the table of contents.
- **help topic**
  - *topic*  
Defines a selang command or other topic related to the selang command shell.  
The help text that describes the topic appears.
- **help env**
  - *env*  
Defines is a selang environment.  
The help text for the specified environment appears on the screen, displaying the table of contents.

**NOTE**

On UNIX, to display the help text for a command typed in the command line without deleting the text in the command line, type Ctrl+2 (or press Esc, Esc).

## Rules Effectiveness Exceptions

Most rules created by selang command become effective shortly after creation with the following exceptions:

- **SPECIALPGM class**  
Newly created or changed SPECIALPGM rules become effective for newly executed programs or after you restart Privileged Access Manager.
- **USER Class**  
Audit, trace, and interactive attributes become effective for new login sessions.

## selang Commands Reference

The following table lists all selang commands alphabetically.

**NOTE**

Commands that operate in the same manner in all environments are documented only in the AC environment. However, some commands are valid in more than one environment but differ in the manner they operate in each environment. These commands are marked with an asterisk (\*) in the *Description* column of the table below and are documented separately in each environment they are valid in.

Command	Short	Environments	Description
alias		AC and unix <b>Note:</b> For UNIX hosts only.	Lists or defines aliases for selang commands and properties.
authorize	auth	AC and nt	*Sets the authority a specific accessor has when accessing a specific resource.
authorize-	auth-	AC and nt	*Removes the authority previously given to a specific accessor when accessing a specific resource.
backuppmd		pmd	Backs up the data in the PMDB database to a specified directory.
check		AC	Checks whether a user has access privileges to a particular resource.
checklogin		AC	Determines a user's login privileges, whether a password check is needed, and whether a terminal access check is needed.
checkpwd		AC	Checks a user's new password, without changing it, to make sure it follows password rules.
chfile	cf	AC and native	*Changes the definition of a file record in the Privileged Access Manager or native OS database.

chgrp	cg	AC and native	*Changes existing internal group settings in the Privileged Access Manager or native OS database.
chres	cr	AC and nt	*Changes an existing resource record in the Privileged Access Manager or native OS database.
chusr	cu	AC and native	*Changes an existing internal user in the Privileged Access Manager or native OS database.
chxgrp	cxg	AC	Changes existing enterprise group settings in the Privileged Access Manager database.
chxusr	cxu	AC	Changes existing enterprise user settings in the Privileged Access Manager database.
createpmd		pmd	Creates a PMDB on a remote host.
deletepmd		pmd	Removes the PMDB's selang protection files, the contents of the PMDB directory, and the PMDB directory from the remote host.
deploy	◆ ◆	AC	Executes deployment selang commands stored in a RULESET object for the particular POLICY.
deploy-		AC	Executes policy undeployment selang commands stored in a RULESET object for the particular POLICY.
editfile	ef	AC and native	*Adds or changes the definition of a file record in the Privileged Access Manager or native OS database.
editgrp	eg	AC and native	*Adds a new group to, or changes existing group settings in, the Privileged Access Manager or native OS database.
editres	er	AC and nt	*Adds a new resource record to, or changes an existing resource record in, the Privileged Access Manager or native OS database.
editres config		config	Lists the configuration settings in the source you specify.
editusr	eu	AC and native	*Adds a new user to, or changes an existing user in, the Privileged Access Manager or native OS database.

editxgrp	exg	AC	Adds a new enterprise group or changes existing enterprise group properties, in the Privileged Access Manager database.
editxusr	exu	AC	Adds a new enterprise user or changes existing enterprise user properties, in the Privileged Access Manager database.
end_transaction		AC	Completes the start_transaction command for Dual Control PMDB processes.
environment	env	all	Sets the security environment selang is operating on.
find	f	AC and native	Lists the classes in the environment or the records in a class.
findpmd		pmd	Lists all PMDBs on the computer.
find config		config	Lists sources of configuration settings (ini files or registry entries) you can manage on this host.
find file		native	Lists system files.
find xgroup		nt	Lists the names of enterprise groups in the current or trusted domains.
find xuser		nt	Lists the names of enterprise users in the current or trusted domains.
get dbexport		AC	Retrieves the rules that were exported from a Privileged Access Manager or PMD database.
get devcalc		AC	Retrieves policy deviation calculation results.
help		all	Displays selang help.
history		all	Displays the commands issued previously in the session.
hosts		all	Shows or sets the host to which selang commands are sent.
join	j	AC and native	*Joins a user to a group.
join-	j-	AC and native	*Removes a user from a group.
joinx	jx	AC	Joins an enterprise user to a group
joinx-	jx-	AC	Removes an enterprise user from a group.
list		AC and native	An alias of the <i>find</i> command.

listpmd		pmd	Lists information about the PMDB and its subscribers, update file, and error log.
newfile	nf	AC	Adds the definition of a file record in the Privileged Access Manager database.
newgrp	ng	AC and native	*Adds a new group to the Privileged Access Manager or native OS database.
newres	nr	AC and nt	*Adds a new resource record to the Privileged Access Manager or native OS database.
newusr	nu	AC and native	*Adds a new internal user to the Privileged Access Manager or native OS database.
newxgrp	nxg	AC	Adds a new enterprise group to the Privileged Access Manager database.
newxusr	nxu	AC	Adds a new enterprise user to the Privileged Access Manager database.
pmd		pmd	Clears the Policy Model error log, updates the subscriber list, releases subscribers, starts and stops the Policy Model service, truncates the update file, and reloads the initialization files.
rename		AC	Renames an object in the database.
restorepmd		pmd	Restores a PMDB on a local host.
rmfile	rf	AC	Removes a file resource record from the Privileged Access Manager database.
rmgrp	rg	AC and native	*Removes a group from the Privileged Access Manager or native OS database.
rmres	rr	AC and nt	*Removes a resource record from the Privileged Access Manager or native Windows database.
rmusr	ru	AC and native	*Removes a user from the Privileged Access Manager or native OS database.
rmxgrp	rxg	AC	Removes an enterprise group from the Privileged Access Manager database.
rmxusr	rxu	AC	Removes an enterprise user from Privileged Access Manager
ruler		AC and native	Sets the properties that display when a show command is executed.

search		AC and native	An alias of the <i>find</i> command.
setoptions	so	AC and nt	*Sets or displays the global options that control the behavior of the database.
showfile	sf	AC and native	*Lists the properties of file records in the Privileged Access Manager or native OS database.
showgrp	sg	AC and native	*Lists the properties of group records in the Privileged Access Manager or native OS database.
showres	sr	AC and nt	*Lists the properties of records in the Privileged Access Manager or native Windows database.
showres config		config	Lists the configuration settings in the source you specify.
showusr	su	AC and native	*Lists the properties of user records in the Privileged Access Manager database or the native OS database.
showxusr	sxu	AC	Lists the properties of enterprise user records in Privileged Access Manager.
source		<i>all</i>	Executes the commands in a specified file.
start dbexport		AC	Exports a Privileged Access Manager or PMD database.
start devcalc		AC	Triggers a policy deviation calculation.
start_transaction		AC	Starts recording a file that contains an unprocessed transaction for Dual Control PMDB processes, with one or more commands.
subs		pmd	Adds a subscriber to a parent PMDB or subscribes a database to a parent PMDB.
subspmd		pmd	Changes the parent of the database in the host to which you are connected.
unalias		AC and unix	Removes aliases for selang commands and properties.
undeploy		AC	An alias of the deploy-command.
unsubs		pmd	Removes subscribers from the subscriber list of a PMDB.
xaudit		nt	Sets auditing criteria and begins logging access events.
xaudit-		nt	Removes auditing criteria and stops logging access events.

**NOTE**

The native environment conforms to the rules of either the Windows (nt) or UNIX environments, depending on the operating system of the host to which you are connected.

## selang Commands in the PAM SC Environment

This section contains a complete alphabetic reference to all the selang commands that operate on the Privileged Access Manager database (commands in the AC environment).

Use the table of contents to access the topics in this section.

### alias Command Define selang Aliases

#### Valid on UNIX hosts

Use the alias command to list or define aliases for selang commands and properties. Any user can use the alias command.

**NOTE**

You can build a set of aliases to use in all selang sessions by defining those aliases in a startup file and using the *selang -r* command.

This command has the following format:

```
alias [aliasName [aliasValue]]
```

- *aliasName*  
(Optional) Defines the name you want to use as alias.  
If this option is not specified, the alias command lists all defined aliases.
- *aliasValue*  
(Optional) Defines the meaning that the selang command shell should associate with *aliasName*.  
If this option is not specified, the alias command displays the value of the specified alias.  
You can also include up to ten variables in *aliasValue* (\$0 to \$9). If *aliasValue* contains variables, you must replace each variable with the proper value in parentheses when invoking the alias.

#### Example: Use a Variable to Ease the Creation of New Administrators

To create an alias that makes adding new administrators to the database easier, enter the following command:

```
alias newadm newusr ($0) admin
```

To use this alias, simply add the names of the new administrators in brackets. For example:

```
newadm(Terri)
```

This adds a user called Terri to the database. Terri is given the ADMIN attribute which is required for administering the database. This is the same as entering the following command:

```
newusr Terri admin
```

#### Example: Simplify Property Names

To create an alias that replaces the property name *access* with the shortened alias *acc*, enter the following command:

```
alias acc access
```

You can now enter the following to use this alias:

```
authorize file x uid(y) acc(z)
```

### Example: Use Aliases in Context

Aliases are not simply expanded variables; they are only interpreted in a context where a command name or a property name should be specified. For example, define the alias:

```
alias newterm newres terminal
```

Then issue the following command:

```
newterm newterm owner(nobody)
```

The first newterm string is replaced but not the second as the context requires the second instance of the string to be a terminal name. This is the same as entering the following command:

```
newres terminal newterm owner(nobody)
```

## authorize Command Set Access Authorities on a Resource

### Valid in the AC environment

Use the authorize command to change accessors' access authorities to a resource.

This command modifies an access control list associated with a resource. It changes only one entry in an access control list at a time.

When an accessor attempts to access a resource, Privileged Access Manager checks the appropriate access control lists to determine the access authority. These access control lists include those that are in the resource record, and can also include access control lists in resource group records. If an accessor is denied access authority in any NACL that covers the resource, the authority is denied, even if the authority is granted in another ACL.

#### NOTE

The owner of a resource always has all access authorities to the resource. If you want to change the access authority of the user who is the owner, change the resource to have a different owner, for example, the user nobody.

#### NOTE

This command also exists in the Windows environment, but operates differently there.

To use the authorize command, you need sufficient authority, which means that one or more of the following must be true:

- You have the ADMIN attribute.
- You have the GROUP-ADMIN attribute for a resource group of which the resource is a member.
- You are the owner of the resource.
- You have modify access authority in the ADMIN class record that corresponds to the resource.

The authorize command has different forms for different sets of classes. These sets are:

- TCP
- HOST, GHOST, HOSTNET, and HOSTNP
- All other classes

This command has the following format for the TCP class:

```
{authorize|auth} TCP tcpServiceName \
[{access|deniedaccess} {accessType}] \
{[ghost(ghostName [,ghostName]...)] | \
[host(hostName [,hostName]...)] | \
[hostnet(hostNetName [,hostNetName]...)] | \
[hostnp(hostNamePattern [,hostNamePattern]...)]} \
```

```
[[gid|uid|xgid|xuid}{accessor [,accessor]...]] ...
```

This command has the following format for the HOST, GHOST, HOSTNET, and HOSTNP classes:

```
{authorize|auth} {HOST|GHOST|HOSTNET|HOSTNP} stationName
[{access|deniedaccess} (accessType)] \
service({serviceName|serviceNumber|serviceNumberRange})
```

This command has the following format for all other classes:

```
{authorize|auth} classNameresourceName \
[{access|deniedaccess} (accessType)] \
[calendar(calendarName)] \
[{unix|nt}]\
[via (pgm ( program [,program]...))] \
{ gid | uid | xgid | xuid}{accessor [,accessor...]} ...
```

- **access (*accessType*)**  
Defines the access authority entry in the resource ACL access control list. This ACL specifies which access authorities are granted to accessors.
    - **accessType**  
Defines the access type in the resource ACL, for example, read or write.
- NOTE**  
If you omit both the `access(accessType)` and the `deniedaccess(accessType)` options to the `authorize` command, Privileged Access Manager assigns the access that is specified by the implicit access property of the record in the UACC class for the class of resource (for example in the UACC file record if the resource is a file).
- **calendar(*calendarName*)**  
Specifies the calendar to use for determining access authority.
  - **className**  
Defines the class to which *resourceName* belongs.
  - **deniedaccess(*accessType*)**  
Changes the access authority in the resource NACL. The NACL specifies which access types are denied to accessors.
    - **accessType**  
Specifies the access type to be denied, for example, read, or write.
  - **gid (*accessor* [,*accessor*...])**  
Defines one or more internal groups for whom you want to set the access authority.
  - **ghost(*ghostName* [,*ghostName*]...)**  
Defines one or more group hosts for which you want to set access authority to the TCP/IP service.
  - **host(*hostName* [,*hostName*]...)**  
Defines one or more hosts for which you want to set access authority to the TCP/IP service.
  - **hostnet(*hostNetName* [,*hostNetName*]...)**  
Defines one or more HOSTNET records for which you want to set access authority to the TCP/IP service.
  - **hostnp(*hostNamePattern* [,*hostNamePattern*]...)**  
Defines one or more HOSTNP records for which you want to set access authority to the TCP/IP service.
  - **nt**  
Specifies whether to add values to the system ACLs in Windows.  
Valid for the FILE class only.
  - **resourceName**  
Defines the resource record whose access control list is being modified.
  - **service(*serviceName*|*serviceNumber*|*serviceNumberRange*)**  
Defines the services the local host is permitted to provide to the remote host or hosts.  
*serviceNumber* |*serviceNumberRange*

Defines the service number or range.

Specify a range as two integers separated by a -(hyphen), for example, 1-99.

**Limits:** An integer in the range 0 to 65535.

- **stationName**

Specifies the record name within the indicated class, as follows:

- **HOST:** Name of single station.
- **GHOST:** Name of a group of hosts as defined in the database by the ghostcommand.
- **HOSTNET:** Name of a group of hosts as defined by a set of mask and match values for the IP address.
- **HOSTNP:** Name of a group of hosts as defined by a name pattern.

For hosts that cannot be resolved, specify the IP address range in IPv4 or IPv6 format.

- **tcpServiceName**

Specifies the Privileged Access Manager TCP service record whose access authority you are setting.

- **uid (accessor [,accessor...])**

Defines one or more internal users for whom you want to set the access authority.

You can use \* to represent all internal users.

- **unix**

Specifies whether to add values to the system ACLs in UNIX.

Valid only on UNIX environments that support ACLs, and only for records in the FILE class.

- **via(pgm(programName [,programName]...))**

Defines one or more programs for conditional program access. The via parameter specifies an entry in the PACL of the resource. *programName* specifies a program that can access the resource. *programName* can contain wildcard characters. If a program matches several entries in a PACL, the entry with the longest non-wildcard match takes precedence.

If *programName* specifies a program or shell script that is not defined in the PROGRAM class, Privileged Access Manager automatically creates a PROGRAM record to protect it.

- **xgid (accessor [,accessor...])**

Defines one or more enterprise groups for whom you want to set the access authority.

- **xuid (accessor [,accessor...])**

Defines one or more enterprise users for whom you want to set the access authority.

### Example: Authorize Angela to Read a File

The following selang command authorizes enterprise user Angela to read the file protected by the FILE resource /projects/secrets:

```
auth FILE /projects/secrets xuid(Angela) access(read)
```

### Example: Authorize Only Angela to Read a File

The following selang commands authorize enterprise user Angela, but nobody else, to read the file protected by the FILE resource /projects/secrets:

```
auth FILE /projects/secrets xuid(Angela) access(read)
auth FILE /projects/secrets defaccess (none)
chres FILE /projects/secrets owner(nobody)
```

#### NOTE

On UNIX, if you want *read* privileges to control whether users can perform operations that obtain information about the file (such as ls -l), set the STAT\_intercept configuration setting to 1. For more information, see the *Reference Guide*.

### Example: Authorize All Users in a Group to Log in to a Terminal

The following selang command authorizes all members of the enterprise group RESEARCH to log in to the terminal protected by the TERMINAL resource *tty10*:

```
auth TERMINAL tty10 xgid(RESEARCH) access(read)
```

### Example: Authorize Joe to Back up Files

The following selang command authorizes enterprise user Joe to back up the files protected by the GFILE resource `secret_files`:

```
auth GFILE secret_files xuid(Joe) \
via(pgm(/bin/backup)) access(read)
```

For a Windows endpoint, an equivalent command is as follows:

```
auth GFILE secret_files xuid(Joe) \
via(pgm(C:\WINDOWS\system32\ntbackup.exe)) access(read)
```

These commands only have an effect if the Joe's access authority is not determined by the ACL or NACL of the resource.

## authorize- Command Remove Access Authorities from a Resource

### Valid in the AC environment

Use the `authorize-` command to remove accessors from the access control lists (ACLs) of a resource.

#### NOTE

This command also exists in the native Windows environment but operates differently there.

#### NOTE

You need the same access authority to use the `authorize-` command as you do to use the `authorize` command.

The `authorize-` command has different formats for different sets of classes. These sets are:

- TCP
- HOST, GHOST, HOSTNET, and HOSTNP
- All other classes

This command has the following format for the TCP class:

```
{authorize-|auth-} TCP tcpServiceName \
{gid |uid |xgid |xuid } (accessorName [,accessorName]...)\
[host(hostName [,hostName]...)] \
[ghost(ghostName [,ghostname]...)] \
[hostnet(hostNetName [,hostNetName]...)] \
[hostnp(hostNamePattern [,hostNamePattern]...)]
```

This command has the following format for the HOST, GHOST, HOSTNET, and HOSTNP classes:

```
{authorize-|auth-} classNameestationName \
service({serviceName | serviceNumber |serviceNumberRange})
```

This command has the following format for all remaining classes:

```
{authorize-|auth-} classNameresourceName \
[{access-|deniedaccess-}]\
[calendar(calendarName)] \
{gid |uid |xgid |xuid } (accessorName [,accessorName]...)
```

- **access-**  
Specifies that the command should remove accessors from the resource ACL (which grants access authorities), rather than from the NACL.

If neither `access-` or `deniedaccess-` are specified, the command removes the accessors from both ACLs.

- **calendar**(*calendarName*)  
Removes the calendar specified for determining access authority.
- **className**  
Specifies the name of the class to which *resourceName* belongs.
- **deniedaccess-**  
Specifies that the command should remove accessors from the resource NACL (which denies access authority), rather than from the ACL.
- **gid** (*accessor* [,*accessor*]...)  
Defines one or more internal groups whose entries are to be removed. Separate each *accessor* with a comma or space.
- **ghost**(*ghostName*)  
Specifies the name of an object in class GHOST.
- **host**(*hostName*)  
Specifies the name of an object in class HOST.
- **hostnet**(*hostNetName*)  
Specifies the name of an object in class HOSTNET.
- **hostnp**(*hostNamePattern*)  
Specifies a pattern defined in class HOSTNP.
- **nt**  
Specifies whether to remove values from the system ACLs in Windows.  
Valid for the FILE class only.
- **resourceName**  
Specifies the name of the resource record whose access control list is being modified. Specify only one resource record.
- **service**(*serviceName*|*serviceNumber*|*serviceNumberRange*)  
Defines the services you want to remove from an ACL.
  - **stationName**  
Specifies the record name within the indicated class, as follows:
    - **HOSTName** of single station.
    - **GHOSTName** of a group of hosts as defined in the database by the `ghostcommand`.
    - **HOSTNETName** of a group of hosts as defined by a set of mask and match values for the IP address.
    - **HOSTNPName** of a group of hosts as defined by a name pattern.
 For hosts that cannot be resolved, specify the IP address range.
  - serviceNumber** |**serviceNumberRange**  
Defines the service number or range.  
Specify the range as two integers separated by a -(hyphen), for example, 1-99.  
**Limits:** An integer in the range 0 to 65535
- **uid** (*accessor* [,*accessor*]...)  
Defines one or more internal users whose entries are to be removed. Separate each *accessor* with a comma or space.  
You can use `uid(*)` to specify all internal users.
- **unix**  
Specifies whether to remove add from the system ACLs in UNIX.  
Valid only on UNIX environments that support ACLs, and only for records in the FILE class.
- **xgid** (*accessor* [,*accessor*]...)  
Defines one or more enterprise users whose entries are to be removed. Separate each *accessorName* with a comma or space.
- **xuid** (*accessor* [,*accessor*]...)  
Defines one or more enterprise groups whose entries are to be removed. Separate each *accessor* with a comma or space.

### Example: Remove a group authority to access a file

The following command removes the group `research` from both the ACL and NACL of the file covered by the resource `/products/new`:

```
auth- FILE /products/new xgid(research)
```

The `research` group now has the default access to the file.

## check Command Determine a User's Access Authority

### Valid in the AC environment

Use the `check` command to determine if a user has access privileges to a particular resource. The command checks access according to the resource's ACL and default access property. However, it does not support PACLS; that is, it does not indicate whether the user can access a resource using a specific program.

#### NOTE

This command is not available when `seos` is down. For more information about PACLS, see the *Endpoint Administration Guide* for your OS.

To use this command you must have sufficient authority over the resource, as defined by any of the following conditions:

- The process running the command has the `SERVER` attribute.
- You have the `ADMIN` attribute.

This command has the following format:

```
check className resourceName uid(userName) access(authority)
```

- `access(authority)`  
Defines the access authority to be checked for the accessor identified by the `uid` parameter.  
Valid values depend on the resource being checked.
- `className`  
Defines the name of the class to which `resourceName` belongs.
- `resourceName`  
Defines the name of the resource record.
- `uid(userName)`  
Defines the name of the Privileged Access Manager user whose authority to access `resourceName` is to be verified.

### Example: Determine whether a user has access to a resource

To determine whether user `Alain` has write access to the resource `testfile` of class `file`, enter the following command:

```
check FILE /testfile uid(Alain) access(w)
```

The following sample output of this command indicates that user `Alain` has write access to the defined file because `Alain` is the resource's owner:

```
Access to FILE /testfile GRANTED
Stage: Resource OWNER check
```

## checklogin Command Determine Login Information

### Valid in the AC environment

Use the `checklogin` command to determine a user's login privileges, whether a password check is needed, and whether a terminal access check is needed.

**NOTE**

This command is not available when seos is down.

To use this command you must have sufficient authority over the resource, as defined by any of the following conditions:

- The process running the command has the SERVER attribute.
- You have the ADMIN attribute.

This command has the following format:

```
checklogin userName [password(password)] [terminal(terminalName)]
```

- **password(*password*)**  
(Optional) Defines the password that Privileged Access Manager checks against the operating system password and the database, if password checking is enabled.
- **userName**  
Defines the name of the user whose right to login is being verified.
- **terminal(*terminalName*)**  
(Optional) Defines the terminal that Privileged Access Manager checks to determine if a user has login privileges from it.

**Example: Determine whether user has login privileges**

To determine whether user Frank has login privileges to the *localhost* from terminal *mutra*, enter the following command:

```
checklogin Frank terminal(mutra)
```

The following output of the command, indicates that user Frank can login from terminal *mutra* to host *winsome* (localhost):

```
Login by USER frank to host winsome is GRANTED
Stage: Resource class global universal access
```

To verify user Frank's password, enter the following command:

```
checklogin frank password(111) terminal(localhost)
```

To verify user Frank's password against the one in the Privileged Access Manager database, enter the following commands:

```
so class+(PASSWORD) (localhost)
checklogin frank password(moonshine) terminal(tack)
```

The *so* command above enables password checking.

**checkpwd Command Check a Password for Compliance****Valid in the AC environment**

Use the *checkpwd* command to check a user's password for compliance with password rules. This check does not change the password.

To use this command you must be a superuser with the ADMIN attribute.

A new password is accepted or rejected according to Privileged Access Manager password rules:

- If a new password is accepted, the following success message displays:  
Changing *userName*'s password is permitted.
- If a new password is rejected, the following fail message displays:  
Changing *userName*'s password is denied.  
*denied\_reason*

Where *denied\_reason* is the actual password rule that did not pass.

For example:

```
Changing JDoe's password is denied.
Too few lowercase letters in password.
```

Only the first rule that the password fails appears in the *denied\_reason*. If, for example, a password is too short, *and* the password has too few capital letters, only *Password is too short* appears.

#### NOTE

This command is not available when seos is down. For more information about password rules, see the *Endpoint Administration Guide* for your OS.

This command has the following format:

```
checkpwd userName password(newPassword)
```

- *userName*  
Specifies the name of the Privileged Access Manager user whose new password you want to check.
- *password(newPassword)*  
Specifies the password you want to check.

## chfile Command Modify File Records

### Valid in the AC environment

Use the *chfile*, *editfile*, and *newfile* commands to work with records in the FILE class. These commands are identical in structure and only vary in the following way:

- The *chfile* command *modifies* one or more records in the FILE class.
- The *editfile* command *creates or modifies* one or more records in the FILE class.
- The *newfile* command *creates* one or more records in the FILE class.

#### NOTE

This command also exists in the native environment but operates differently.

To add or change a record for a file belonging to the FILE class, you must have sufficient authority over the file. Privileged Access Manager makes the following checks until one of the following conditions is met:

1. You have the ADMIN attribute.
2. The resource record is within the scope of a group in which you have the GROUP-ADMIN attribute.
3. When changing a record, that you are its owner.
4. You have CREATE (for *newfile* or *editfile*) or MODIFY (for *chfile*) access authority in the ACL of the FILE record in the ADMIN class.
5. That you are the owner of the file (when defining a file to Privileged Access Manager that exists in the native OS), if the token *use\_unix\_file\_owner* in the *seos.ini* file is set to yes.

```
{{chfile|cf}}{{editfile|ef}}{{newfile|nf}} filename... \
[audit{none|all|success|failure}] \
[category[-](categoryName)] \
[comment(string)|comment-] \
[defaccess(accessAuthority)] \
[label(labelName)|label-] \
[level(number)|level-] \
[notify(mailAddress)|notify-] \
[gowner(groupName)] \
[owner({userName|groupName})] \
```

```
[restrictions( \[days({anyday|weekdays|{[mon] [tue] [wed] \ [thu] [fri] [sat] [sun]}})] \[time({anytime|
startTime:endTime}) \
|restrictions-] \
[warning|warning-]
```

- **audit{none|all|success|failure}**

Specifies which access events Privileged Access Manager logs:

- **all** - Both authorized accesses and detected unauthorized access attempts.
- **failure** - Detected unauthorized access attempts. This is the default value.
- **none** - Does not write any records in the log file.
- **success** - Authorized accesses to the resource.

**NOTE**

To use the audit parameter, you must have the AUDITOR attribute.

- **category(categoryName)**

Defines a space- or comma-separated list of security category records (defined in the CATEGORY class) to assign to the file.

If you specify the category parameter when the CATEGORY class is not active, Privileged Access Manager updates the definition of the file in the database; however, the updated category assignment has no effect until the CATEGORY class is activated again.

**NOTE**

For more information about security category checking, see the *Endpoint Administration Guide* for your OS.

- **category-(categoryName)**

Deletes one or more security categories from the resource record. When removing more than one security category, separate the security category names with a space or a comma.

The specified security categories are deleted from the resource record, regardless of whether the CATEGORY class is active.

**NOTE**

This parameter is only valid when modifying a record.

- **comment(string)**

Adds an alphanumeric string to the group record. If you previously added a comment string to the group record, the new string specified here replaces the existing string.

**Format:** Up to 255 characters including double bytes and special characters. If the string contains any blanks, enclose the string in quotation marks.

- **comment-**

Deletes the comment string from the file record.

**NOTE**

This parameter is only valid when modifying a record.

- **defaccess(accessAuthority)**

Specifies the default access authority for the file. The default access authority is the authority granted to any accessor that requests access to the file, but that is not in the access control lists of the file. The default access is also applied to users who are not defined in the database.

- **fileName**

Defines the name of the file record. At least one file name must be specified.

If you are adding or changing a record in class FILE using a generic file name, use the wildcard expressions permitted in selang. When defining or changing more than one record, enclose the list of file names in parentheses and separate the file names with a space or a comma.

**NOTE**

If more than one file name is specified, Privileged Access Manager processes each file record independently in accordance with the specified parameters. If an error occurs while processing a file, Privileged Access Manager issues a message and continues processing with the next file in the list.

- **gowner(*groupName*)**  
Assigns a Privileged Access Manager group as the owner of the file record. The group owner of the file record has unrestricted access to the file, provided the group owner's security level, security label, and security category authorities are sufficient to allow access to the file. The group owner of the file is always permitted to update and delete the file record.
- **label(*labelName*)**  
Assigns to the file a security label defined in the SECLABEL class. A security label represents an association between a particular security level and zero or more security categories. If the resource record currently contains a security label, the security label specified here replaces the current security label.

**NOTE**

For more information about security label checking, see the *Endpoint Administration Guide* for your OS.

- **label-**  
Deletes the security label defined in the file record.

**NOTE**

This parameter is only valid when modifying a record.

- **level(*number*)**  
Assigns a security level to the resource record. Enter a positive integer between 1 and 255. If a security level was previously assigned to the resource record, the new value replaces the existing value.

**NOTE**

For more information about security level checking, see the *Endpoint Administration Guide* for your OS.

- **level-**  
Stops Privileged Access Manager from performing security level checking for the resource.

**NOTE**

This parameter is only valid when modifying a record.

- **notify(*mailAddress*)**  
Instructs Privileged Access Manager to send notification messages whenever the file represented by the resource record is successfully accessed. Enter a user name, an email address of a user, or the email address of a mail group if an alias is specified.  
Notification takes place only when the Log Routing System is active. The notification messages are sent either to the screen or to the mailbox of the users, depending on the setup of the Log Routing System.  
Each time a notification message is sent, an audit record is written in the audit log.  
The recipient of notify messages should log in frequently to respond to the unauthorized access attempts described in each message.  
**Limit:** 30 characters.

**NOTE**

For information about filtering and viewing audit records, see the *Endpoint Administration Guide* for your OS.

- **notify-**  
Specifies that no one is notified when Privileged Access Manager grants access to the file represented by the record.

**NOTE**

This parameter is only valid when modifying a record.

- **owner(*Name*)**

Assigns a Privileged Access Manager user or group as the owner of the file record. The owner of the file record has unrestricted access to the file, provided the owner's security level, security label, and security category authorities are sufficient to allow access to the file. The owner of the file is always permitted to update and delete the file record.

- **restrictions(days(*dayData*) time(*timeData*))**  
Specifies the days of the week and the hours in the day when the file is accessible to users.  
If you omit the days argument and specify the time argument, the time restriction applies to any day-of-week restriction already indicated in the record. If you omit time and specify days, the day restriction applies to any time restriction already indicated in the record. If you specify both days and time, the users are allowed to access the system only during the specified time period on the specified days.
  - **days( *dayData* )**  
Specifies the days on which users can access the file. The days argument takes the following sub-arguments:
    - a. **anyday** - Gives access to the file on any day.
    - b. **weekdays** - Gives access to the resource only on weekdays-Monday through Friday.
    - c. **mon tue wed thu fri sat sun** - Gives access to the resource only on the specified days. You can specify the days in any order. If more than one day is specified, separate the days with a space or a comma.
  - **time(*timeData*)**  
Specifies the period during which users can access the file. The time argument takes the following sub-arguments:
    - a. **anytime** - Gives access to the resource at any time of the day.
    - b. **startTime : endTime**-Gives access to the resource only during the specified period. The format of both *startTime* and *endTime* is *hhmm*, where *hh* is the hour in 24-hour notation (00 through 23) and *mm* is the minutes (00 through 59). Note that 2400 is not a valid time value. *StartTime* must be less than *endTime*, and both times must occur on the same day. If the terminal is in a different time zone from the processor, adjust the time values by translating the start and end times for the terminal to the equivalent local times for the processor. For example, if the processor is in New York and the terminal is in Los Angeles, to allow access to the terminal from 8:00 a.m. to 5:00 p.m. in Los Angeles, specify time(1100:2000).
- **restrictions-**  
Deletes any restrictions that limit the ability to access the file.
 

**NOTE**  
This parameter is only valid when modifying a record.
- **warning**

**NOTE**  
Puts the file into Warning mode.
- **warning-**  
Takes the file out of Warning mode.

### Example: Restrict Access to a File to All but the Superuser

To restrict access to the `/etc/passwd` file to READ access to all users except the superuser, enter the following command:

```
chfile /etc/passwd defaccess(read) owner(root)
```

The following must be true:

- You have the ADMIN attribute.
- The record `/etc/passwd` is defined in the database.
- There are no entries in the ACL of the record `/etc/passwd`.

### Example: Restrict Access to a File by Time

To prevent access to the `/home/bob/secrets` file and let the owner access the file only on weekdays between 08:00 and 18:00, enter the following command:

```
newfile /home/bob/secrets defac(none) restrictions(d(weekdays) t(0800:1800))
```

The following must be true:

- You have the ADMIN attribute.
- Bob is a Privileged Access Manager user and is the owner of the /home/ bob/secretsrecord in the FILE class.

### Example: Prevent Access to Your Home Directory

To prevent all other users from accessing any file in your home directory (/home/bob), enter the following command on UNIX:

```
newfile /home/bob/* defaccess(none)
```

You can do the same on Windows using the following command:

```
newfile %userprofile%\* defaccess(none)
```

The following must be true:

- You are defined to Privileged Access Manager.
- You are the native owner of the file.

## ch x grp Command Change Group Properties

### Valid in the AC environment

Use the commands chgrp, chxgrp, editgrp, editxgrp, newgrp, and newxgrp to change the properties of groups, and to create the groups in the Privileged Access Manager database if necessary.

These commands all have synonyms, as follows:

- chgrpcg
- chxgrpcxg
- editgrpeg
- editxgrpexg
- newgrpng
- newxgrpnxg

These commands are identical in structure, and vary only in their scope, in the following ways:

- The chgrp, editgrp, and newgrp commands work with records in the GROUP class. These let you create or modify Privileged Access Manager groups without reference to the enterprise user store. The differences between these commands are as follows:
  - The chgrp command *modifies* one or more records in the GROUP class.
  - The editgrp command *creates or modifies* one or more records in the GROUP class.
  - The newgrp command *creates* one or more records in the GROUP class.

#### NOTE

These commands also exist in the native environment but operate differently there.

- The chxgrp, editxgrp and newxgrp commands work on records in the XGROUP class. These let you create or modify Privileged Access Manager groups that are defined in the enterprise user store. The differences between them are as follows:
  - The chxgrp command *modifies* one or more records in the XGROUP class.
  - The editxgrp command *creates or modifies* one or more records in the XGROUP class.
  - The newxgrp command *creates* one or more records in the XGROUP class.

### Authorization Required

To create a new Privileged Access Manager group, at least one of the following conditions must be true:

- You have the ADMIN attribute.
- You are assigned the CREATE authority in the access control list of the GROUP or XGROUP record in the ADMIN class.

To add or modify a group, at least one of the following conditions must be true:

- You have the ADMIN attribute.
- The group record is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the group.
- You are assigned the MODIFY (for ch[x]grp) or CREATE (for edit[x]grp) authority in the access control list of the GROUP or XGROUP record in the ADMIN class.

```
{ {chgrp|cg} | {chxgrp|cxg} | {editgrp|eg} | {editxgrp|exg} | {newgrp|ng} | {newxgrp|nxg} } groupName ...
[{admin | admin-}] \
[audit(none|all|success|failure|loginsuccess|loginfail|trace|interactive)|audit-] \
[{auditor | auditor-}] \
[comment(string)|comment-] \

[parent(groupName)|parent-] \
[password( \ [history(numberStoredPasswords)|history-] \ [interval(maximumPasswordChangeInterval)|interval-]
 \ [min_life(minimumPasswordChangeInterval)|min_life-] \ [rules( \ [alpha(minimumAlphaCharacters)] \
 [alphanum(minimumAlphanumericCharacters)] \ [bidirectional|bidirectional-] \ [grace(numberOfGraceLogins)] \
 [min_len(minimumPasswordLength)] \ [max_len(maximumPasswordLength)] \ [lowercase(minimumLowercaseCharacters)]
 \ [max_rep(maxRepetitiveCharacters)] \ [namechk|namechk-] \ [numeric(minimumNumericCharacters)] \ [oldpwchk|
oldpwchk-] \ [special(minimumSpecialCharacters)] \ [uppercase(minimumUppercaseCharacters)] \ [use_dbdict|
use_dbdict-] \ )|rules-] \ )] \
[pmdb(PolicyModelName)|pmdb-] \
[{pwmanager | pwmanager-}] \
[restrictions( \ [days({anyday|weekdays|{[mon] [tue] [wed] \ [thu] [fri] [sat] [sun]}})] \ [time(anytime|
startTime:endTime)] \
|restrictions-] \
[resume[(mm/dd/yy[yy] [ @hh:mm]])]|resume-] \
[{server | server-}] \
[shellprog(fullPath)] \
[supgroup(superiorGroup)|supgroup-] \
[suspend[(mm/dd/yy[yy] [ @hh:mm]])]|suspend-] \
[unix[( \ [appl(quotedString)] \ [groupid(groupidNumber)] \ [userlist(userName...)] \
)]] \
```

To remove any record property where the property is defined by a string, type the property followed immediately by either - (minus sign), or () (empty parenthesis).

#### NOTE

Some parameters are relevant only when a group functions as a profile group. A profile group cannot be an enterprise group.

- **admin**  
Assigns the ADMIN attribute to the group. A user who is a member of a group with the ADMIN attribute is allowed to issue all selang commands with all parameters except the audit parameter. You must have the ADMIN attribute to use the admin parameter.
- **admin-**  
Removes the ADMIN attribute from the group. (Privileged Access Manager ensures that at least one user has the ADMIN attribute.)  
You cannot use this parameter with the new[x]grp command.
- **audit(mode)**  
Turns on the trace audit for this command. The audit modes are: none, all, success, failure, loginsuccess, loginfail, trace, interactive.
- **audit-**  
Turns off the trace audit for this command.
- **auditor**  
Assigns the AUDITOR attribute to the group. A user who is a member of a group with the AUDITOR attribute can audit the use of system resources and is able to control the logging of detected accesses to any Privileged Access Manager-protected resource during Privileged Access Manager authorization checking and accesses to the database. See the *Endpoint Administration Guide* for your OS for more information on the authorities granted to a user with the AUDITOR attribute.
- **auditor-**  
Removes the AUDITOR attribute from the group record.  
You cannot use this parameter with the new[x]grp command.
- **comment(string)**  
Adds to the group record a comment string of up to 255 alphanumeric characters (single-byte). If the string contains spaces, enclose the entire string in single quotation marks. The string replaces any existing string that you added previously.

**NOTE**

In German, only 128 characters are recorded.

- **comment-**  
Deletes the comment string, if any, from the group record. Use this parameter only with the chgrp or editgrp command.
- **expire(date)**  
Sets the date on which the accounts of the group members expire. If you do not specify a date, the user accounts expire immediately, provided the users are not currently logged in. If the users are logged in, the accounts expire when the users log out. This parameter applies only to profile groups.  
Specify the expiration date, and optional time, in the following format: *mm/dd/yy [yy][@HH:MM]*. Year can be either 2 or 4 digits.

**NOTE**

You cannot enable expired user records by specifying the resume parameter with a resume date. Use the expire- parameter to enable expired user records.

- **expire-**  
For the newgrp command, defines user accounts that do not have an expiration date. For the chgrp and editgrp commands, removes the expiration date from the user accounts. This parameter applies only to profile groups.
- **gowner(groupName)**  
Assigns a Privileged Access Manager user or group as the owner of the group record. When you specify more than one group name, enclose the names in parentheses and separate the group names with a space or a comma. If you add a group to the database and omit this parameter, you are the owner of the group record.
- **grace(numberOfGraceLogins)**  
Sets the maximum number of logins that are permitted before the users are suspended. The number of grace logins must be between 0 and 255. After the number of grace logins is reached, the users are denied access to the system

and must contact the system administrator to select a new password. If grace is set to zero, the users cannot log in. This parameter applies only to profile groups.

- **grace-**  
Deletes the grace login setting for the group. Use this parameter only with the `chgrp` or `editgrp` command. This parameter applies only to profile groups.
- **groupName**  
Specifies the name of the group you are creating or whose properties you are changing. For the command `new[x]grp`, each group name must be unique and must not currently exist in the database. However, a group and a user can share the same name.
- **history**  
Specifies the number of stored passwords. You can eliminate the history file with `history-`.
- **homedir(*fullPath*|nohomedir)**  
Specifies the full path of the users' home directories. If the path you specify ends with a slash, *groupName* is concatenated to the specified path. If you specify `nohomedir` then a home directory is not automatically set.
- **inactive(*numInactiveDays*)**  
Specifies the number of days that must pass before the system changes users to inactive status. When the number of days is reached, users cannot log in. This parameter applies only to profile groups.  
Enter a positive integer or zero for *numInactiveDays*. If inactive is set to zero, the effect is the same as using the `inactive-` parameter.

#### NOTE

In the user record, inactive users are not marked. To identify inactive users, you must compare the Last Accessed Time value with the Inactive Days value.

- **inactive-**  
Changes the users' status from inactive to active. Use this parameter only with the `chgrp` or `editgrp` command. This parameter applies only to profile groups.
- **interval(*maximumPasswordChangeInterval*)**  
Sets the number of days that must pass after the password was set or changed before the system prompts the user for a new password. Enter a positive integer or zero. An interval of zero disables password interval checking for the group so that the password does not expire. The default set by the `setoptions` command is not used. Set an interval of zero only for users with low security requirements.  
When the specified number of days is reached, Privileged Access Manager informs the user that the current password has expired. The user can immediately renew the password or continue using the old password until the number of grace logins is reached. After the number of grace logins is reached, the user is denied access to the system and must contact the system administrator to select a new password. This parameter applies only to profile groups.
- **interval-**  
Cancels the password interval setting for the group. If canceled, any value in the user record is used. Otherwise, the default set by the `setoptions` command is used. Enter this parameter only with the `chgrp` or `editgrp` command. This parameter applies only to profile groups.
- **maxlogins(*maximumNumberOfLogins*)**  
Sets the maximum number of terminals users can log in to at the same time. A value of 0 (zero) means that users can log in from any number of terminals concurrently. If this parameter is not specified, any value in the user record is used. Otherwise, the global maximum logins setting is used. This parameter applies only to profile groups.

#### NOTE

If `maxlogins` is set to 1, you cannot run `selang`. You must shut down Privileged Access Manager, change the `maxlogins` setting to greater than one, and start Privileged Access Manager again.

- **maxlogins-**  
Deletes the group's maximum login setting. If this parameter is not specified, any value in the user record is used. Otherwise, the global maximum logins setting is used. Use this parameter only with the `chgrp` or `editgrp` command. This parameter applies only to profile groups.
- **mem(*GroupName*) | mem+(*GroupName*)**

Adds members groups (or child groups) to the group in Privileged Access Manager. The member groups (*GroupName*) must already be defined in Privileged Access Manager. If you are adding more than one member group, separate the group names with a comma. If a group name contains a space, enclose it in quotation marks.

**Note:** To add users to a internal group, use the join[x] command.

This option applies to internal groups only.

- **mem-(*GroupName*)**  
Removes member groups from this group. The member groups (*GroupName*) must already be defined in Privileged Access Manager. If you are removing more than one member group, separate the group names with a comma. If a group name contains a space, enclose it in quotation marks.  
**Note:** To remove users from a internal group, use the join[x]- command.  
This option applies to internal groups only.
- **min\_life(*minimumPasswordChangeInterval*)**  
The minimum number of days that must pass before users are allowed to change the password again. This parameter applies only to profile groups.
- **min\_life-**  
Deletes the min\_life setting of a group. If this parameter is not specified and the min\_life parameter is set in a user record, the value in the user record is used. Otherwise, the global min\_life setting is used. Use this parameter only with the chgrp or editgrp command. This parameter applies only to profile groups.
- **name(*fullname*)**  
Specifies the full name of the group. Enter an alphanumeric string of up to 47 characters. If the string contains any blanks, enclose the string in single quotation marks.
- **nt(*nt-group-attributes*)**  
(Windows only) Adds or changes the group definition in the local Windows system.
  - **comment('comment')**  
Adds a comment string to the native record. If you previously added a comment string to the record, the new string specified here replaces the existing string.  
*comment* is an alphanumeric string of up to 255 characters. If the string contains any blanks, enclose the entire string in single quotation marks.
- **operator**  
Assigns the OPERATOR attribute to the group. A user who is a member of a group with the OPERATOR attribute can list all resource records in the database, and has read authority for all Privileged Access Manager defined files. A user who is a member of a group with this attribute can also use all the options of the secons command. See the *Reference Guide* for more information on the secons utility.
- **operator-**  
Removes the OPERATOR attribute from a group record.  
You cannot use this parameter with the new[x]grp command.
- **owner(*Name*)**  
Assigns a Privileged Access Manager user or group as the owner of the group record. If you are adding a group to the database and you omit this parameter, you are the owner. See the *Endpoint Administration Guide* for your OS for more information.
- **parent(*groupName*)**  
Assigns an existing Privileged Access Manager group as the parent group of the group record. See the *Endpoint Administration Guide* for your OS for more information on parent and child relationships.
- **parent-**  
Deletes the link between a group and its parent group. Use this parameter only with the chgrp or editgrp command.
- **password**  
Assigns a password to this group.
- **password-**  
Deletes the need for a password for this group.
- **pmdb(*PolicyModelName*)**

Specifies that when a user in the group changes a password with the utility `sepass`, the new password is propagated to the specified Policy Model. Enter the fully qualified name of the PMDB.

The password is not sent to the Policy Model defined in the `parent_pmd` or `passwd_pmd` token in the `[seos]` section of `seos.ini`. This parameter applies only to profile groups.

- **pmdb-**  
Removes the PMDB attribute from the group record. Use this parameter only with the `chgrp` or `editgrp` command. This parameter applies only to profile groups.
- **pwmanager**  
Assigns the PWMANAGER attribute to the group. A user who is a member of a group with this attribute can change the passwords of users in the database. See the *Endpoint Administration Guide* for your OS for more information.
- **pwmanager-**  
Removes the PWMANAGER attribute from the group record.  
You cannot use this parameter with the `new[x]grp` command.
- **restrictions(days(*dayData*) time(*timeData*))**  
Specifies the days of the week and the hours in the day when members of the group are allowed to log in to the system.  
Privileged Access Manager does not force a user off the system if the login period expires while the user is logged in. Also, the login restrictions do not apply to batch jobs; a user can run a background process at any time. This parameter applies only to profile groups.  
If you omit the `days` argument and specify the `time` argument, the time restriction applies to any day-of-week restriction already indicated in the record. If you omit `time` and specify `days`, the day restriction applies to any time restriction already indicated in the record. If you specify both `days` and `time`, the members of the group are allowed to access the system only during the specified time period on the specified days.
  - **days( *dayData* )**  
Specifies the days on which users can log in to the system. The `days` argument takes the following sub-arguments:
    - a. **anyday**-Lets users log in on any day.
    - b. **weekdays**-Lets users log in only on weekdays-Monday through Friday.
    - c. **mon tue wed thu fri sat sun**-Lets users log in only on the specified days. You can specify the days in any order. If more than one day is specified, separate the days with a space or a comma.
  - **time( *timeData* )**  
Specifies the period during which users can log in to the system. The `time` argument takes the following sub-arguments:
    - a. **anytime**-Lets users log in at any time of the day.
    - b. **startTime : endTime**-Lets users log in only during the specified period. The format of both *startTime* and *endTime* is *hhmm*, where *hh* is the hour in 24-hour notation (00 through 23) and *mm* is the minutes (00 through 59). Note that 2400 is not a valid time value. If *endTime* is a smaller number than *endTime*, the period is considered to extend across midnight. Otherwise, it is considered to take place on a single day.  
**Note:** Privileged Access Manager uses the time zone of the processor. If the user logs in at a terminal in a different time zone from the processor, you must take this into account.
- **restrictions-**  
Deletes any restrictions that limit the users' ability to log in to the system from the group record. If this parameter is not specified and the `restrictions` parameter is set in a user record, the value in the user record is used. Use this parameter only with the `chgrp` or `editgrp` command. This parameter applies only to profile groups.
- **resume(*date*)**  
Enables user records that were disabled by specifying the `suspend` parameter. Enter a date, and optional time, in the following format: *mm/dd/yy[@HH:MM]*.  
If you specify both the `suspend` parameter and the `resume` parameter, the resume date must fall after the suspend date. If you omit *date*, the user is enabled immediately on execution of the `chgrp` command. See the *Endpoint Administration Guide* for your OS for more information. This parameter applies only to profile groups.
- **resume-**

Erases the resume date, and time if used, from the group record. Consequently, the status of the users is changed from active (enabled) to suspended. Use this parameter only with the `chgrp` or `editgrp` command. This parameter applies only to profile groups.

- **rules**

Specifies rules for the password:

- `alpha(minimumAlphaCharacters)`  
Minimum number of alphabetic characters.
- `alphanum(minimumAlphanumericCharacters)`  
Minimum number of characters.
- **bidirectional|bidirectional-**  
Specifies whether to use bidirectional password encryption. If bidirectional password encryption is enabled, each new password is encrypted and can be decrypted back to clear text. This encryption gives a wider comparison between new passwords and old passwords (password history). When bidirectional encryption is disabled, one-way password history encryption is activated, and you cannot decrypt old passwords.

**NOTE**

You must set history to a value greater than 1 to use this feature.

**WARNING**

If you set the `seos.ini` file token "passwd\_format" ([passwd] section) to "NT", you must use the "native" option (rather than `unix`) when you create a user in `selang`. For example:

```
nu uSr_1026 native password(uSr_1026)
```

**WARNING**

Alternatively, make sure that you work in the native environment (rather than the `unix` one), as follows:

```
env native
chusr usr_1 password(mypassword)
```

- `min_len(minimumPasswordLength)`  
Minimum password length.
- `max_len(maximumPasswordLength)`  
Maximum password length.
- `lowercase(minimumLowercaseCharacters)`  
Minimum number of lowercase characters.
- `max_rep(maximumRepetitiveCharacters)`  
Maximum number of repeated characters.
- **namechk|namechk-**  
Check password against name.
- `numeric(minimumNumericCharacters)`  
Minimum number of numeric characters.
- **oldpwchk|oldpwchk-**  
Check password against old password.

**NOTE**

Valid only on Unix and Linux operating systems.

`special(minimumSpecialCharacters)`

Minimum number of special characters.

- `uppercase(minimumUppercaseCharacters)`  
Minimum number of uppercase characters.
- **use\_dbdict|use\_dbdict-**

Sets the password dictionary. `use_dbdict` sets the token to **db** and compares passwords against words in the Privileged Access Manager database. `use_dbdict-` sets the token to **file** and checks passwords against a file specified in the `seos.ini` file for UNIX or Windows registry for Windows.

## server

Sets the SERVER attribute on. If the current user is a member of a group with the SERVER attribute on, it allows a process running on behalf of the current user to ask for authorization for other users. See the *Endpoint Administration Guide* for your OS for more information.

## server-

Sets the SERVER attribute off.

You cannot use this parameter with the `new[x]grp` command.

## shellprog(fullPath)

Specifies the full path of the initial program or shell that is executed after the user invokes the login or su command. *FullPath* is a character string.

`supgroup(Group'sSuperiorGroup)`

Specifies a supergroup (or parent group).

`suspend(date)`

Disables user records, but leaves them defined in the database. Enter a date, and optional time, in the following format: *mm/dd/yy[@HH:MM]*.

A user cannot use a suspended user account to log in to the system. If *date* is specified, the user records are suspended on the specified date. If *date* is omitted, the user records are suspended immediately upon execution of the `chgrp` command. This parameter applies only to profile groups.

`suspend-`

Erases the suspend date from the user records, changing the status of the users from disabled to active (enabled). Use this parameter only with the `chgrp` or `editgrp` command. This parameter applies only to profile groups.

`unix(groupidNumber)`

(UNIX only) Sets group attributes on UNIX or creates the group if it does not already exist.

The *groupidNumber* is a decimal number. You cannot specify a group ID of zero. If you omit the number, Privileged Access Manager finds the largest current group ID and sets the ID of the group to this number. Privileged Access Manager creates group ID numbers in the same way when adding or modifying more than one group at a time. The token `AllowedGidRange` in the `seos.ini` file may define certain unavailable numbers.

`userlist(userName)`

Assigns members to the group. *UserName* is the user name of one or more UNIX users. When assigning more than one user, separate the user names with a comma or a space. For the `chgrp` and `editgrp` commands, the member list specified here replaces any member list that is currently defined for the group.

## Examples

- The user Bob wants to change the parent group and owning group for the enterprise group Sales from ACCOUNTS to PAYROLL.  
`chxgrp Sales parent(PAYROLL) owner(PAYROLL)`
- The user Admin1 wants to change the parent of group projectB from divisionA to divisionB and assign the group RESEARCH as the new owner.  
Admin1 has the ADMIN attribute.

```
chxgrp projectB parent (divisionB) owner (RESEARCH)
```

- The admin user Sally wants to remove the home directory and the shell program specifications for the group profile NewEmployee.  
Sally is the owner of NewEmployee.

```
editgrp NewEmployee homedir() shellprog()
```

- The user Admin1 wants to add the group ProjectA as a child group of the group RESEARCH. The user Admin1 is to be the owner of the ProjectA group.  
Admin1 has the ADMIN attribute.  
The default is owner(Admin1).

```
newgrp ProjectA parent (RESEARCH)
```

## chres Command Modify Resource Records

### Valid in the AC environment

Use the chres, editres, and newres commands to work with resource records that belong to a Privileged Access Manager class. These commands are identical in structure and only vary in the following way:

- The chres command *modifies* one or more resources.
- The editres command *creates or modifies* one or more resources.
- The newres command *creates* one or more resources.

#### NOTE

This command also exists in the native Windows environment but operates differently there.

To add a resource using the newres command, at least one of the following conditions must be true:

- You have the ADMIN attribute.
- You have CREATE access authority in the ACL of the record of the resource class in the ADMIN class.
- If the token use\_unix\_file\_owner in the seos.ini file is set to yes, an owner of a file in UNIX can define it as a new resource to Privileged Access Manager.

To add or change a resource using the chres or editres commands, you must have sufficient authority over the resource. Privileged Access Manager checks in the following order for any *one* of these conditions:

1. You have the ADMIN attribute.
2. The resource record is within the scope of a group in which you have the GROUP-ADMIN attribute.
3. You are the owner of the record.
4. You are assigned MODIFY (for chres) or CREATE (for editres) access authority in the access control list of the resource class's record in the ADMIN class.

#### NOTE

The maximum length of a resource name is 255 single-byte characters.

The following content lists command parameters that apply for each class that can be administered using the chres, editres, and newres commands.

```

- **audit**  
Indicates which access events Privileged Access Manager logs:
  - **all** - Both authorized and unauthorized access attempts.
  - **failure** - Unauthorized access attempts. This value is the default.
  - **none** - Does not write any records in the log file.
  - **success** - Authorized access attempts.
- **category(categoryName [,categoryName...])**  
Assigns one or more security categories to the resource record.  
If you specify the category parameter when the CATEGORY class is not active, Privileged Access Manager updates the resource definition in the database. However, the updated category assignment has no effect until the CATEGORY class is activated again.
- **category-(categoryName [,categoryName...])**  
Deletes one or more security categories from the resource record.  
The specified security categories are deleted from the resource record, regardless of whether the CATEGORY class is active. Use this parameter only with the chres or editres command.
- **className**  
Specifies the name of the class to which the resource belongs. To list the resource classes that are defined to Privileged Access Manager, use the find command.
- **cmd+(selang\_command\_string)**  
Specifies a list of selang commands that define the policy. These commands are used to deploy the policy. For example,  

```
editres RULESET IIS5#02 cmd+("nr FILE /inetpub/* defaccess(none) owner(nobody)")
```
- **cmd-**  
Removes policy deployment command list from the RULESET object.
- **comment(string)**  
Adds an alphanumeric string of up to 255 characters to the resource record. If the string contains any blanks, enclose the entire string in single quotation marks. The string replaces any existing string defined previously.

**NOTE**

For the SUDO class, this string has a special meaning. For more information about defining SUDO records, see the *Endpoint Administration Guide for UNIX*.

- **comment-**  
Deletes the comment from the resource record. Use this parameter only with the chres or editres command.
- **container(containerName)**

Represents CONTAINER objects, a generic grouping class.

*containerName* is the name of one or more CONTAINER records defined in the CONTAINER class. When assigning more than one CONTAINER, separate the names with a space or a comma.

- **container-(containerName)**  
Deletes one or more CONTAINER records from the resource record. Use this parameter with the `chres` or `editres` command only.
- **dates(time-period)**  
Defines one or more periods when users cannot log in, such as holidays. If more than one time period is specified, separate the periods with a space. Use the following format:  
`mm/dd[/yy[yy]] [@hh:mm] [-mm/dd]/[/yy[yy]] [@hh:mm]`  
If you do not specify a year (or you specify a year before 1990), it means that the period or holiday is annual. You can specify the year with two digits or four digits. Example: 98 or 1998.  
If you do not specify a start time, then the start of the day (midnight) is used; if you do not specify an end time then the end of the day (midnight) is used. The format of the hours and the minutes is *hh:mm*, where *hh* is the hour in 24-hour notation (00 through 23) and *mm* is the minutes (00 through 59).  
If you do not specify an interval of time (for example, 12/25@14:00-12/25@17:00), but only a day and a month (12/25), then the holiday lasts for one whole day.  
If you are issuing the command in a different time zone from where the holiday occurs, translate the period to your local time. For example, if you are in New York and Los Angeles has a half-day holiday, you must enter 09/14/98@18:00-09/14/98@20:00. This prevents the users from logging in from 3:00 pm to 5:00 pm in Los Angeles.
- **defaccess([accessAuthority])**  
Defines the default access authority for the resource. The default access authority is the authority that is granted to any accessor not in the access control list of the resource that requests access to the resource. The default access is also applied to users who are not defined in the database. Valid access authority values vary by class.  
If you omit *accessAuthority*, Privileged Access Manager assigns the implicit access that is specified in the UACC property of the record that represents the class of the resource in the UACC.
- **dh\_dr{+|-}(dh\_dr)**  
Defines Distribution Hosts this endpoint uses for disaster recovery.
- **filepath(filePaths)**  
Defines one or more absolute file paths, each of which constitutes a valid kernel module. Multiple file paths are separated by a colon (:).
- **flags(flagName)**  
Defines how the resource is to be trusted and how to check it for trusted status. Available flags are Ctime, Mtime, Mode, Size, Device, Inode, Crc, and Own/All/None.
- **gacc(access-value)**  
Lets a program access protected, frequently opened files at a much faster rate than otherwise possible.
- **gowner(groupName)**  
Assigns a Privileged Access Manager group as the owner of the resource record. The group owner of the resource record has unrestricted access to the resource, as long as the following criteria are true: the security level of the group owner, security label, and security category authorities are sufficient to allow access to the resource. The group owner of the resource is always permitted to update and delete the resource record. See the *Endpoint Administration Guide for UNIX* for more information.
- **label(labelName)**  
Assigns a security label to the resource record.
- **label-**  
Deletes the security label from the resource record. Use this parameter only with the `chres` or `editres` command.
- **level(number)**  
Assigns a security level to the resource record. Enter a positive integer from 1 through 255.
- **level-**  
Removes any security level from the resource. Use this parameter only with the `chres` or `editres` command.
- **mask (IPv4-address)** and **match (IPv4-address)**

The *mask* and *match* parameters are applicable only to HOSTNET records. They are required when creating a HOSTNET record and are optional when modifying a record.

Use mask and match together to define the group of hosts defined by a HOSTNET record. A host is a member of a HOSTNET record group if an AND of the host IP address with the mask address produces the match address. For example, specifying mask(255.255.255.0) and match(192.16.133.0) means that a host is a member of the group if it has an IP address in the range 192.16.133.0 to 192.16.133.255.

The mask and match parameters require IPv4 addresses.

- **mem(resourceName)**

Adds a member resource to a resource group. If you are adding more than one member resource, separate each name with a comma.

You can use the mem parameter only with resource records of the following classes:

- CONTAINER - This class defines a group of objects from other resource classes.
- GFILE - This class contains resource records that define groups of files.
- GHOST - This class contains resource records that define groups of hosts.
- GSUDO - This class contains resource records that define groups of commands.
- GTERMINAL - This class contains resource records that define groups of terminals.
- GPOLICY - This class contains resource records that define a logical policy.
- GHNODE - This class contains resource records that define a host group.
- GDEPLOYMENT - This class contains resource records that define the policy deployment.

Use the mem parameter to add a record of the appropriate type to a resource group, for example, to add a FILE record to a resource group of class GFILE.

**NOTE**

If you are using the mem parameter for CONTAINER resources, you must also include the of\_class parameter.

Both the member resource and the resource group must already be defined in Privileged Access Manager. To create a resource group, create a resource of the class you want. For example, the following command creates a GFILE resource group:

```
newres GFILE myfiles
```

- **mem-(resourceName)**

Removes member resources from a resource group. If you are removing more than one member resource, separate the resource names with a space or a comma. Use this parameter only with the chres or editres command.

- **node\_alias{-|+}(alias)**

Defines an endpoint alias.

Defining aliases for the endpoint aliases lets Privileged Access Manager send advanced policy management commands to the actual endpoint based on the alias.

- **node\_ip{-|+}(ip)**

Defines the IP address of the host. Advanced policy management uses the IP address, with the name of the endpoint, to locate the required endpoint.

- **notify(mailAddress)**

**NOTE**

Instructs Privileged Access Manager to send notification messages whenever the resource that is represented by the resource record is accessed. Enter a user name, an email address of a user, or the email address of a mail group if an alias is specified.

Notification takes place only when the Log Routing System is active. The notification messages are sent either to the screen or to the mailbox of the users, depending on the setup of the Log Routing System.

Each time a notification message is sent, an audit record is written in the audit log. For information about filtering and viewing audit records, see the *Endpoint Administration Guide for UNIX*.

The recipient of notify messages should log in frequently to respond to the unauthorized access attempts described in each message.

**Limit:** 30 characters.

- **notify-**  
Specifies that no one is notified when the resource that is represented by the resource record is successfully accessed. Use this parameter only with the `chres` or `editres` command.
- **of\_class(className)**  
Specifies the resource type for the record you are adding to the CONTAINER class with the `mem` parameter.
- **owner(Name)**  
Assigns a Privileged Access Manager user or group as the owner of the resource record. The owner of the resource record has unrestricted access to the resource, provided the security level of the owner, security label, and security category authorities are sufficient to allow access to the resource. The owner of the resource is always permitted to update and delete the resource record. See the *Endpoint Administration Guide for UNIX* for more information.
- **password**  
Specifies, for the SUDO class, that the `sesudo` command requires the original password of the user.
- **password-**  
Cancels the `password` parameter, so that the `sesudo` command no longer requires the original password of the user. Use this parameter with the `chres` or `editres` command only. If the `password` parameter was not used previously, then this parameter is unnecessary.
- **policy(name(name#xx) status(status) updated\_by(name)) | policy(name(name#xx) deviation{+|-})**  
Adds a subscriber of the node in the propagation tree and specifies its status. Alternatively, updates an existing policy version to specify whether a policy deviation exists or not. The `updated_by` property must be updated when updating policy status. It is a string representing the name of the user that changed the policy status.  
Policy status can be one of Transferred, Deployed, Undeployed, Failed, SigFailed, Queued, UndeployFailed, or TransferFailed.
- **policy-[(name(name#xx))]**  
Removes the named policy version from the node. If no policy is specified, all policies that are deployed to this node are removed.
- **resourceName**  
Defines the name of the resource record to modify or add. When changing or adding more than one resource, enclose the list of resource names in parentheses. Separate the resource names with a space or a comma. At least one resource name must be specified.  
Privileged Access Manager processes each resource record independently in accordance with the specified parameters. If an error occurs while processing a resource, Privileged Access Manager issues a message and continues processing with the next resource in the list.  
**Note:** If you use a variable in a resource name, use the following syntax to refer to the variable: `<!variable>`, for example, `<!AC_ROOT_PATH>\bin`. You can only use variables in `selang` rules in policies.
- **restrictions([days] [time])**  
Specifies the days of the week and the hours in the day when users can access the file.  
If you omit the `days` argument and specify the `time` argument, the time restriction applies to any day-of-week restriction already indicated in the record. If you omit `time` and specify `days`, the day restriction applies to any time restriction already indicated in the record. If you specify both `days` and `time`, the users may access the system only during the specified time period on the specified days.
  - [Days] specifies the days on which users may access the file. The `days` argument takes the following subarguments:
    - a. **anyday**-Allow users access to the file on any day.
    - b. **weekdays**-Allow users access to the resource only on weekdays-Monday through Friday.
    - c. **Mon, Tue, Wed, Thu, Fri, Sat, Sun**-Allow users access to the resource only on the specified days. You can specify the days in any order. If you specify more than one day, separate the days with a space or a comma.
  - [Time] specifies the period during which users may access the resource. The `time` argument takes the following subarguments:
    - a. **anytime**-Allow users access to the resource at any time of the day.

- b. **startTime:endTime**-Allow access to the resource only during the specified period. The format of both **startTime** and **endTime** is *hhmm*, where *hh* is the hour in 24-hour notation (00 through 23) and *mm* is the minutes (00 through 59). Note that 2400 is not a valid time value. **startTime** must be less than **endTime**, and both times must occur on the same day. If the terminal is in a different time zone from the processor, adjust the time values by translating the start and end times for the terminal to the equivalent local times for the processor. For example, if the processor is in New York and the terminal is in Los Angeles, to allow access to the terminal from 8:00 am to 5:00 pm in Los Angeles, specify time (1100:2000).
  - **restrictions-([days] [time])**  
Deletes any restrictions that limit the ability of the user to access the file.
  - **ruleset+(name)**  
Specifies a rule set to associate with the policy.
  - **ruleset-(name)**  
Deletes a rule set from the policy. If no ruleset is specified, removes all rulesets from the policy.
  - **signature(hash\_value)**  
Specifies a hash value. For a policy, this is based on signatures of RULESET objects associated with the policy. For a ruleset, this is based on the policy deployment command list and policy undeployment (removal) command list.
  - **subscriber(name(sub\_name) status(status))**  
Adds a subscriber of the node in the propagation tree and specifies its status. Status can be one of **unknown**, **available**, **unavailable**, or **sync**.
  - **subscriber-(name(sub\_name)) | sub-**  
Removes a subscriber database from the node. If no subscriber is specified, all subscribers are removed.
  - **targuid(userName)**  
Specifies, for the SUDO class, the name of the user whose authority is borrowed for executing the command. Default is root.
  - **trust**  
Specifies that the resource is trusted. The trust parameter applies only to resources of the PROGRAM and SECFILE classes. Users can execute the program as long as the program remains trusted. See the *Endpoint Administration Guide for UNIX* for more information. Use this parameter only with the **chres** or **editres** command.
  - **trust-**  
Specifies that the resource is untrusted. The trust- parameter applies only to resources of the PROGRAM and SECFILE classes. Users cannot execute an untrusted program. See the *Endpoint Administration Guide for UNIX* for more information. Use this parameter only with the **chres** or **editres** command.
  - **undocmd+(selang\_command\_string)**  
Specifies a list of selang commands that define policy undeployment. The commands in this list are used to remove the deployed policy (undeploy). For example:  

```
editres RULESET IIS5#02 undocmd+("rr FILE /inetpub/*")
```
  - **undocmd-**  
Removes policy removal command list from the RULESET object.
  - **value+(value)**  
Adds the specified value to the specified variable (ACVAR object).
  - **value-(value)**  
Removes the specified value from the specified variable (ACVAR object).
  - **warning**  
Specifies that Privileged Access Manager allows access to the resource even if the authority of the accessor is insufficient to access the resource. However, Privileged Access Manager writes a warning message in the audit log.
- NOTE**  
In Warning Mode, Privileged Access Manager does not create warning messages for the resource groups.
- **warning-**

Specifies that Privileged Access Manager is to deny the user access to the resource. Does not write a warning message if the authority of an accessor is insufficient to access the resource. Use this parameter only with the `chres` or `editres` command.

## Examples

- The user (`admin1`) wants to change the owner and default access for the terminal (`tty30`) and restrict the use of the terminal to weekdays during regular business hours (8:00 am to 6:00 pm).
  - The user `admin1` has the `ADMIN` attribute.

```
chres TERMINAL tty30 owner(admin1) defaccess(read) restrictions \(days(weekdays)time(0800:1800))
```
- The admin user Sally wants to remove the group and owner property stored in a `FILE` class record for file `account.txt`.
  - The user Sally is the owner of the user record of Jared.

```
chres FILE /account.txt group() owner()
```

To remove any record property, if a string defines the property, type the property with either the `-` sign or empty parenthesis `()`.
- The user Bob wants to delete the comment field of the terminal `tty190` and be notified whenever access to the terminal is granted.
  - The user Bob is a Privileged Access Manager user and is the owner of the terminal `tty190`.

```
chres TERMINAL tty190 comment- notify(Bob@athena)
```
- The user `Admin1` wants to add the `OPERATOR` category to the list of security categories of the resource `USER.root`, which is in the `SURROGATE` class.
  - The user `Admin1` has the `ADMIN` attribute.
  - The `OPERATOR` category is defined in the database.

```
chres SURROGATE USER.root category(OPERATOR)
```
- The user `admin1` wants to define `/bin/su` as a trusted program with a global access of `EXECUTE`.
  - The user `admin1` has the `ADMIN` attribute.
  - The following defaults apply:
    - `restrictions(days(anyday) time(anytime))`
    - `owner(admin1)`
    - `audit(failure)`

```
newres PROGRAM /bin/su defaccess(x) trust
```
- The user `admin1` wants to define the substitution of group ID to the group system as a protected resource to which no user, including `admin1`, has access.
  - The user `admin1` has the `ADMIN` attribute. The user `nobody` is defined to Privileged Access Manager.
  - The following defaults apply:
    - `restrictions(days(anyday) time(anytime))`
    - `audit(failure)`

```
newres SURROGATE GROUP.system defaccess(n) owner(nobody)
```
- The user `SecAdmin` wants to define `ProjATerms`, a group of terminals containing the terminals `T1`, `T8`, and `T11`. The terminal group is to be used only by the group `PROJECTA` and only on weekdays during regular business hours (8:00 am to 6:00 pm).
  - The user `SecAdmin` has the `ADMIN` attribute.
  - The terminals `T1`, `T8`, and `T11` are defined to Privileged Access Manager.
  - The group `PROJECTA` is defined to Privileged Access Manager.
  - `audit(failure)`

```
newres GTERMINAL ProjATerms mem(T1,T8,T11) owner(PROJECTA) \restrictions(days(weekdays) time(0800:1800))
defaccess(n)
```

## ch x usr Command Change User Properties

### Valid in the AC environment

Use the commands `chusr`, `chxusr`, `editusr`, `editxusr`, `newusr`, and `newxusr` to change the properties of users, and to define the user records in the Privileged Access Manager database if necessary.

These commands all have synonyms, as follows:

- `chusrcu`
- `chxusrcxu`
- `editusreu`
- `editxusrexu`
- `newusrnu`
- `newxusrnxu`

This means, for example, that the command `cu` is identical to the command `chusr`.

All these commands are identical in structure, and vary only in their scope. Use these commands as follows:

- Use the `chusr`, `editusr`, and `newusr` commands for internal users. The differences between these commands are as follows:
  - The `chusr` command *modifies* one or more USER records.
  - The `editusr` command *creates or modifies* one or more USER records.
  - The `newusr` command *creates* one or more USER records.

#### NOTE

These commands also exist in the native environment but operate differently there.

- Use the `chxusr`, `editxusr` and `newxusr` commands for enterprise users. The differences between these commands are as follows:
  - The `chxusr` command *modifies* one or more XUSER records.
  - The `editxusr` command *creates or modifies* one or more XUSER records.
  - The `newxusr` command *creates* one or more XUSER records.

#### NOTE

The USER and XUSER class records are identical for all properties, except that where properties are defined in the enterprise user stores, the XUSER records do not redefine them.

#### NOTE

When you execute these commands, the changes that you make modify the user record immediately, even if the user is currently logged in to the system.

### Authorization Required

To create a Privileged Access Manager user, at least one of the following conditions must be true:

- You have the ADMIN attribute.
- You are assigned the CREATE authority in the access control list of the USER or XUSER record in the ADMIN class.

To add or modify a user, at least one of the following conditions must be true:

- You have the ADMIN attribute.
- The user record is within the scope of a group in which you have the GROUP-ADMIN attribute and you have the same authority as the owner of the record.
- The user record is within the scope of a group in which you have the GROUP-AUDITOR attribute, and you want to specify the audit parameter.
- You are the owner of the group.
- You are assigned the MODIFY (for ch[x]usr) or CREATE (for edit[x]usr) authority in the access control list of the USER or XUSER record in the ADMIN class.

```

path)] \[workstations(workstations-list)] ]] \
[unix({ [gecos(string)] \[homedir(path)] \[pgroup(groupName)] \[shellprog(fileName)] \[userid(number)]}]

```

- **admin**  
Assigns the ADMIN attribute to the user. A user with the ADMIN attribute is allowed to issue all selang commands with all parameters except the audit parameter. You must have the ADMIN attribute to use the admin parameter.
- **admin-**  
Removes the ADMIN attribute from the user. (Privileged Access Manager verifies that at least one user has the ADMIN attribute.)  
You cannot use this parameter with the new[x]usr command.
- **audit**  
Specifies which user activities on resources protected by Privileged Access Manager are logged to the audit log. To specify more than one event type, separate the event type names with a space or a comma. Privileged Access Manager logs activities based on these attributes:
  - **all** - All user activities. The monitored activities are: failure, loginfail, loginsuccess, success, interactive and trace.
  - **failure** - Failed access attempts.
  - **loginfail** - Failed login attempts.
  - **loginsuccess** - Successful logins.
  - **none** - No user activities.
  - **success** - Successful accesses.
  - **interactive** - Interactive sessions.
  - **trace** - Every message that appears in the trace file because of this user's actions.
- **auditor**  
Assigns the AUDITOR attribute to the user. A user with the AUDITOR attribute can audit the use of system resources and is able to control the logging of detected accesses to any Privileged Access Manager-protected resource during Privileged Access Manager authorization checking and accesses to the database. See the *Endpoint Administration Guide* for your OS for more information about the authorities granted to a user with the AUDITOR attribute.
- **auditor-**  
Removes the AUDITOR attribute from the user record.  
You cannot use this parameter with the new[x]usr command.
- **auth\_type**  
Specifies the authentication method.  
Used only by SSO.  
You cannot use this parameter for enterprise users.
- **category(categoryName[, categoryName...])**  
Assigns one or more security categories to the user.
- **category-(categoryName[, categoryName...])**  
Removes one or more security categories from the user record.  
You cannot use this parameter with the new[x]usr command.
- **comment(commentString )**  
Assigns a comment to the user record.
  - *commentString*  
Specifies the comment. *commentString* is an alphanumeric string of up to 255 characters. If *commentString* contains blanks, enclose it in single quotation marks.
- **comment-**  
Deletes the comment from the user record.  
You cannot use this parameter with the new[x]usr command.
- **country(countryName)**

Specifies the country where the user is located. The country is not used during the authorization process.

- *countryName*  
Defines the country. This parameter is an alphanumeric string of up to 19 characters. If the string contains blanks, enclose the entire string in single quotation marks.
- *email(emailAddress)*  
Defines the email address of the user.
  - *emailAddress*  
Defines the email address of the user.  
**Limits:** Up to 128 characters
- **enable**  
Enables the login of a user that has for any reason been disabled.  
You cannot use this parameter with the `new[x]usr` command.
- *epwasown(password)*  
Changes the user password as if the user changes their own password. This password change is not an administrative change and so does not automatically expire the password.  
**Note:** This command is for internal use only. This command sets password in plain text as specified as an argument to `/etc/shadow` or the `passwd` file.
- *expire(dateTime)*  
Sets the date when the user account expires. If a date is not specified, the account expires immediately, or if the user is logged in, when the user logs out.  
If the user record has a value for this property, that value overrides the value in the GROUP record.

#### NOTE

Use the `expire-` parameter to enable expired user records; you do not use the `resume` parameter to do this.

- *dateTime*  
Defines the date, and optionally the time. It has the following format: `mm/dd/[yy]yy[ @HH:MM]`  
You can use either two digits or four digits to specify the year.
- **expire-**  
For the `new[x]usr` command, defines a user account that does not have an expiration date.  
For the `ch[x]usr` and `edit[x]usr` commands, removes an expiration date from a user account.
- *flags(accountFlags|-accountFlags)*  
Specifies particular attributes of a user's account. See the appendix Windows Values for a list of valid flag values.  
To remove flags from the user record, precede *accountFlags* with a minus (-).
- *fullName(fullName)*  
Specifies the full name of the user.
  - *fullName*  
Defines the full name. It is an alphanumeric string of up to 255 characters. If *fullName* contains blanks, enclose the entire string in single quotation marks.
- *gecos(string)*  
Specifies a comment string for the user. Enclose the string in single quotation marks.
- *gowner(groupName)*  
Assigns a Privileged Access Manager group as the owner of the user record. The group owner of the user record has unrestricted access to it, provided the group owner's security level and security category authorities are sufficient. The group owner of the user record is always permitted to update and delete the user record.
- *grace(nLogins)*  
Defines the number of grace logins the user is allowed.  
After the number of grace logins is reached, the user cannot access the system and must contact the system administrator to select a new password. If `grace` is set to zero, the user cannot log in.  
If the user record has a value for this parameter, that value overrides the value in the GROUP record.

If this parameter is not specified and the user has a profile group that contains a value for this parameter, the value in the GROUP record is used. If neither the USER nor GROUP record contains a value, the Privileged Access Manager global grace login setting is used.

– *nLogins*

Defines the number of grace logins. Enter an integer between 0 and 255.

**NOTE**

The user should change the password before the grace value reaches 0. Contact the system administrator to select a new password if the grace login value is reached.

- **grace-**

Deletes the user's grace login setting. The Privileged Access Manager global grace login setting is used instead. You cannot use this parameter with the `newusr` command.

- **homedir(*path*)**

Specifies the full path of the user's home directory. If *path* ends with a slash, Privileged Access Manager concatenates *userName* to the path.

- **homedrive(*drive*)**

Specifies the drive of the user's home directory.

- **ign\_hol**

Assigns the IGN\_HOL attribute to the user. A user with the IGN\_HOL attribute can log in during any period defined in a holiday record.

- **ign\_hol-**

Removes IGN\_HOL attribute from the user.

- **inactive(*nDays*)**

Specifies the number of days that must pass before the system changes the user to inactive. When the number of days is reached, the user cannot log in.

**NOTE**

Inactive users are not marked in the user record. To identify inactive users, you must compare the Last Accessed Time value with the Inactive Days value.

– *nDays*

Defines the number of days. *nDays* is zero or a positive integer. If *nDays* is zero, the effect is the same as using the `inactive-` parameter.

- **inactive-**

Changes the user's status from inactive to active. You cannot use this parameter with the `newusr` command.

- **interval(*nDays*)**

Defines the number of days that must pass after the password was set or changed before the system prompts the user for a new password. Enter zero or a positive integer. If *nDays* is zero Privileged Access Manager disables password interval checking and the password does not expire. This means the default set by the `setoptions` command is not used. Set *nDays* to zero only for users with low security requirements.

When *nDays* is reached, Privileged Access Manager informs the user that the password has expired. The user can continue to use the password until the number of grace logins is reached. After the number of grace logins is reached, the user is denied access to the system and must contact the system administrator to be given a new password.

- **interval-**

Cancels a user's password interval setting. If the user has a profile group with a value for this parameter, that value is used. Otherwise, the default set by the `setoptions` command is used. You cannot use this parameter with the `new[x]usr` command.

- **label(*labelName*)**

Assigns a security label to the user.

- **label-**

Deletes the security label from the user record.

You cannot use this parameter with the `new[x]usr` command.

- **level(*levelNumber*)**  
Assigns a security level to the user record.  
*levelNumber* is an integer between 0 and 255.
- **level-**  
Deletes the security level from the user record,  
You cannot use this parameter with the `newusr` command.
- **localapps**  
Used by CA SSO.
- **location(*locationString*)**  
Specifies the user's location. The location is not used during the authorization process.
  - *locationString*  
Defines the location. *locationString* is an alphanumeric string of up to 47 characters. If *locationString* contains blanks, enclose it in single quotation marks.
- **logical**  
Assigns the LOGICAL attribute to the user. A user with the LOGICAL attribute cannot log in and is used for internal Privileged Access Manager purposes only.  
For example, the user `nobody` that you can use as the owner of resources to prevent even the resource owner from accessing the resource is a logical user by default. This means that no user can log in using this account.
- **logical-**  
Removes the LOGICAL attribute from the user.
- **logonserver(*server-name*)**  
Specifies the server that verifies the login information for the user. When the user logs in to the domain workstation, Privileged Access Manager transfers the login information to the server, which gives the workstation permission for the user to work.
- **maxlogins(*nLogins*)**  
Sets the maximum number of concurrent logins for the user. A value of 0 (zero) means that the user can log in from any number of terminals concurrently. If this parameter is not specified, the global maximum logins setting is used.

#### NOTE

If `maxlogins` is set to 1, you cannot run `selang`. You must shut down Privileged Access Manager, change the `maxlogins` setting to greater than one, for example by using `setpropadm` utility, and start Privileged Access Manager again.

- **maxlogins-**  
Deletes the user's maximum login setting. The global setting is used instead.  
You cannot use this parameter with the `new[x]usr` command.
- **min\_life(*nDays*)**  
The minimum number of days that must pass before the user is allowed to change the password again. Enter a positive integer.
- **min\_life-**  
Deletes the user's `min_life` setting. If the user has a profile group with a value for this parameter, that value is used. Otherwise, the default set by the `setoptions` command is used.  
You cannot use this parameter with the `new[x]usr` command.
- **nochngpass**  
Specifies that the user is not allowed to change passwords for another user.
- **notify(*notifyAddress*)**  
Sends an email to *notifyAddress* every time the user logs in. The recipient of the notify messages should log in frequently to respond to the unauthorized access attempts described in each message.  
When Privileged Access Manager sends a notification message, it writes an audit record in the audit log.
  - *notifyAddress*  
Defines a user name or an email address.

**Limit:** 30 characters.

- **notify-**  
Specifies that no one is notified when the user logs in.  
You cannot use this parameter with the new[x]usr command.
- **nt**  
For the chusr and editusr commands, this parameter changes the user's definition in the local Windows system.  
For the newusr command, this parameter adds the user to the local Windows system.  
If more than one argument is specified, separate the arguments with a space.  
See the environment command, for more information about how to operate on the local Windows system from within Privileged Access Manager.  
The nt option, and sub-options under the nt option, are not valid for enterprise users.
- **operator**  
Assigns the OPERATOR attribute to the user. A user with the OPERATOR attribute can list all resource records in the database, and has read authority for all Privileged Access Manager defined files.  
A user with this attribute can also use all the options of the secons command. See the *Reference Guide* for more information about the secons utility.
- **operator-**  
Removes the OPERATOR attribute from a user record.  
You cannot use this parameter with the newusr command.
- **organization(*organizationString*)**  
Specifies the user's organization. The organization is not used during the authorization process.
  - *organizationString*  
Defines the organization. *organizationString* is an alphanumeric string of up to 255 characters. If *organizationString* contains blanks, enclose it in single quotation marks.
- **org\_unit(*org\_unitString*)**  
Specifies the user's organization unit. The organization unit is not used during the authorization process.
  - *org\_unitString*  
Defines the organization unit. *org\_unitString* is an alphanumeric string of up to 255 characters. If *organizationString* contains blanks, enclose it in single quotation marks.
- **owner(*Name*)**  
Assigns a Privileged Access Manager user or group as the owner of the user record. See the *Endpoint Administration Guide* for your OS for more information.
- **password(*string*)**  
Assigns a password to a user. Specify any character except a space or a comma. If password checking is enabled, the password is valid for one login only. When the user next logs in to the system, a new password must be set.  
To change your own password, you need to set selang options using *setoptions cng\_ownpwd* or use sepass.
- **pgroup(*groupName*)**  
Sets the user's primary group ID. *groupName* is the name of a UNIX group.
- **phone(*phoneString*)**  
Defines the user's telephone number. The telephone number is not used during the authorization process.
  - *phoneString*  
Defines the telephone number. *phoneString* is an alphanumeric string of up to 19 characters. If *phoneString* contains blanks, enclose it in single quotation marks.
- **pmdb(*pmdbName*)**  
Specifies that when a user changes a password with the sepass utility, the new password is propagated to the specified PMDB. Enter the fully qualified name of the PMDB. The password is not sent to the Policy Model defined in the parent\_pmd or passwd\_pmd tokens in the [seos] section of seos.ini.  
This option cannot be used for enterprise users.
- **pmdb-**  
Removes the PMDB attribute from the user record.

You cannot use this parameter with the new[x]usr command.

- **privileges(*privilege-list*)**  
Adds specific rights to the Windows user record or, when privList is preceded by a minus sign (-), removes the specified rights.  
You cannot use this parameter with the newusr command.
- **profile(*groupName*)**  
Assigns a user to a profile group. The following values can be taken from the profile group:
  - audit
  - auth\_type
  - expire
  - grace
  - inactive
  - interval
  - maxlogins
  - min\_life
  - password rules
  - pmdb
  - pwd\_autogen
  - pwd\_policy
  - pwd\_sync
  - restrictions (days, time)
  - resume
  - suspend
  - unix (homedir, shellprog)
- **profile-**  
Removes a user from the profile group.  
You cannot use this parameter with the new[x]usr command.
- **pwmanager**  
Assigns the PWMANAGER attribute to the user. A user with this attribute can change the passwords of users in the database. See the *Endpoint Administration Guide* for your OS for more information.
- **pwmanager-**  
Removes the PWMANAGER attribute from the user record.  
You cannot use this parameter with the new[x]usr command.
- **pwasown(*string*)**  
Replaces a password as if changed by the user. Specifying this parameter updates the time and date of the last change in the database. Grace logins are terminated.
- **regular**  
Resets the OBJ\_TYPE property of the record, and so removes authority attributes from the user.
- **restrictions([*Days*] [*Time*])**  
Specifies the days of the week and the times in the day when users can be logged in. The restrictions are stored in the DAYTIME property of the [X]USER record.  
If you omit *Days* and specify *Time*, the time restriction applies to any day-of-week restriction that is already defined in the record.  
If you omit *Time* and specify *Days*, the *Days* restriction applies to any time restriction already defined in the record.  
If you specify both *Days* and *Time*, the users can access the system only during the specified time period on the specified days.
  - *Days*  
Specifies the days on which users can be logged in. You can use the following keywords when you specify *Days*:
    - a. **anyday** Allow users access to the file on any day.

- b. **weekdays** Allow users access to the resource only on weekdays-Monday through Friday.
- c. **Mon, Tue, Wed, Thu, Fri, Sat, Sun** Allow users access to the resource only on the specified days. You can specify the days in any order. If you specify more than one day, separate the days with a space or a comma.
- **Time**  
Specifies the period during which users can be logged in. The time argument takes the following sub-arguments:
  - a. **anytime** Allow users access to the resource at any time of the day.
  - b. **startTime : endTime** Allow access to the resource only during the specified period.  
The format of *startTime* and *endTime* is *hhmm*, where *hh* is the hour (00 through 23) and *mm* is the minutes (00 through 59). Note that 2400 is not a valid time value; use 0000 instead.  
*startTime* must be less than *endTime*.  
**Note:** Privileged Access Manager uses the time zone of the processor. If the user logs in at a terminal in a different time zone from the processor, you must take this into account.
- **restrictions-([days] [time])**  
Deletes any restrictions that limit the users' ability to be logged in.
- **resume([dateTime])**  
Enables a user record that was disabled by specifying the suspend parameter. If you specify both the suspend parameter and the resume parameter, the resume date must fall after the suspend date. If you omit *dateTime*, the user record is resumed immediately upon execution of the *chusr* command. See the *Endpoint Administration Guide* for your OS for more information.  
Enter *dateTime* in the format *[m]m/[d]d/yy[@HH:MM]*.
- **resume-**  
Erases the resume date, and time if used, from the user record. Consequently, the status of the user is changed from active (enabled) to suspended.  
You cannot use this parameter with the *new[x]usr* command.
- **script(logon-script-path)**  
Specifies the location of a file that runs automatically when the user logs in. This parameter is optional. Typically, this login script configures the working environment. You can also use the profile parameter to set up the user's working environment.
- **server**  
Sets the SERVER attribute on. This attribute allows a process running on behalf of the current user to ask for authorization for other users. See the *Endpoint Administration Guide* for your OS for more information.
- **server-**  
Sets the SERVER attribute off.  
You cannot use this parameter with the *new[x]usr* command.
- **shellprog(fileName)**  
Specifies the full path of the initial program or shell that is executed after the user invokes the login or su command.  
*fileName* is a character string.  
This option cannot be used for enterprise users.
- **suspend([dateTime])**  
Disables a user record, but leaves it defined in the database. A user cannot use a disabled user account to log in to the system.  
If *dateTime* is specified, the user record is disabled on the specified date. If *dateTime* is omitted, the user record is disabled immediately upon execution of the *ch[x]usr* command.  
Enter *dateTime* in the format *mm/dd/yy[@HH:MM]*.
- **suspend-**  
Erases the suspend date from the user record, changing the status of the user from disabled to enabled (active).  
You cannot use this parameter with the *new[x]usr* command.
- **unix**  
For the *chusr* and *editusr* commands, this parameter changes the user's definition in the local UNIX system.  
For the *newusr* command, this parameter adds the user to the local UNIX system.  
If more than one argument is specified, separate the arguments with a space.

See the environment command in this chapter for more information about how to operate on the local UNIX system from within Privileged Access Manager.

The unix option, and sub-options under the unix option are not valid for enterprise users.

- **userid(*number*)**  
Sets the user's unique numeric ID (UID), used for unique discretionary access control. *number* is a decimal number. By default, numbers less than 100 are not accepted. See the AllowedGidRange token in the appendix *Reference Guide* for more information about excluded numbers.
- **userName|(userName [,userName...])**  
Defines the name or names of the user or users. Each user name must be unique.  
When using the newusr command, *userName* identifies a new user to Privileged Access Manager. If you are using the newusr command and the user is already defined to the native environment, this username will be used by Privileged Access Manager as the USER record that corresponds to that user. Typically, however, you should take advantage of the Privileged Access Manager ability to use enterprise users, and not use newusr to create a USER record for a username that already exists in the native environment. Instead, use the chgxusr command to change the Privileged Access Manager properties of that user.  
Sometimes you may want a Privileged Access Manager user name that is not a native login name. In that case, the login command could not put that user to work, but another command such as sesu could.

#### NOTE

ON UNIX, where a user name includes a backslash, use two backslashes when specifying *userName*.

#### Examples

- The user Bob wants to add the FINANCIAL category to Jim's record, change Jim's security level to 155, and restrict Jim's access to the system to weekdays between 8:00 a.m. and 8:00 p.m.
  - The user Bob has the ADMIN attribute.
  - The user Jim is defined to Privileged Access Manager.
  - The FINANCIAL category is defined to Privileged Access Manager.

```
chuxsr Jim category(FINANCIAL) level(155) restrictions \
(days(weekdays)time(0800:2000))
```
- The user admin wants to suspend the user Joel, who will be on vacation for three weeks, starting on August 5, 1995.
  - The user admin has the ADMIN attribute.
  - The user Joel is defined to Privileged Access Manager.
  - Today's date is August 3, 1994.

```
chxusr Joel suspend(8/5/95) resume(8/26/95)
```
- The user Security2 wants to remove the AUDITOR attribute from the user Bill and wants to audit all activity by Bill.
  - The user Security2 has the ADMIN and AUDITOR attributes.
  - The user Bill is defined to Privileged Access Manager.

```
chxusr Bill auditor audit(all)
```
- The user Rob wants to change the comment stored in the record of the user Mary.
  - The user Rob is the owner of Mary's user record.

```
chxusr Mary comment ('Administrator of the SALES group')
```
- The admin user Sally wants to remove the country name and the location properties stored in the record of the user Jared.
  - The user Sally is the owner of Jared's user record.

```
chxusr Jared country() location()
```
- The user Bob wants to define the users Peter and Joe to Privileged Access Manager.
  - The user Bob has the ADMIN attribute.
  - The users Peter and Joe are not defined to Privileged Access Manager.
  - The following defaults apply:

- owner(Bob)
- audit(failure,loginfailure)

```
newusr (Peter Joe)
```

- The user Bob wants to define the user Jane to Privileged Access Manager and assign payroll as the owning group.
  - The user Bob has the ADMIN attribute.
  - The user Jane is not defined to Privileged Access Manager.
  - The full name of the user Jane is JG Harris.
  - audit(failure,loginfailure)

```
newusr Jane owner(payroll) name('J.G. Harris')
```

- The user Bob wants to define the user *JohnD* to Privileged Access Manager with the security category NewEmployee and a security level of three. JohnD is to be allowed to use the system only on weekdays between the hours of 8:00 a.m. and 6:00 p.m.
  - The user Bob has the ADMIN attribute.
  - The NewEmployee category is defined to Privileged Access Manager.
  - The new user's full name is John Doe.
  - The following defaults apply:
    - owner(Bob)
    - audit(failure)

```
newusr JohnD name('John Doe') category(NewEmployee) level(3) \
restrictions(days(weekdays) time(0800:1800))
```

## deploy Command Initiate Policy Deployment

### Valid in the AC environment

Use the deploy command to initiate policy deployment. The command executes selang commands stored with the RULESET object that is associated with the POLICY object you are deploying. These are policy deployment commands.

#### **WARNING**

We strongly recommend that you use the policydeploy utility to deploy a stored policy. The deploy command only executes part of the policy deployment and does not update the DMS when deploying a policy to an endpoint.

To run the deploy command, you need to have:

- Sub-administration rights for the POLICY, HNODE, and RULESET classes on each database in the hierarchy below the database where you deploy the policy.
- Appropriate sub-administration rights on each database in the hierarchy below the database where you deploy the policy.

These are the permissions necessary to execute the selang commands that form the policy on each of these computers.

For example, you'll need sub-administration rights for the FILE class if you are creating a new file resource:

```
nr FILE /inetpub/* defaccess(none)
```

#### **NOTE**

For more information about policy deployment, see the *Enterprise Administration Guide*.

This command has the following format:

```
deploy POLICY name#xx
```

- *name#xx*  
The name of the POLICY object (policy name and version number) for the policy you want to deploy.

## deploy- Command Initiate Policy Removal

### Valid in the AC environment

Use the deploy- (or undeploy) command to initiate policy undeployment. The command executes selang commands stored with the RULESET object that is associated with the POLICY object you are deploying. These are policy undeployment commands.

#### **WARNING**

We strongly recommend that you use the policydeploy utility to undeploy a policy. The deploy- command only executes part of the policy undeployment and does not update the DMS when undeploying a policy from an endpoint.

To run this command, you need to have:

- Sub-administration rights for the POLICY, HNODE, and RULESET classes on each database in the hierarchy below the database where you undeploy the policy.
- Appropriate sub-administration rights on each database in the hierarchy below the database where you undeploy the policy.

These are the permissions necessary to execute the selang commands that form the policy undeployment script on each of these computers.

#### **NOTE**

For more information about deploying a policy, see the *Enterprise Administration Guide*.

This command has the following format:

```
{deploy-|undeploy} POLICY name#xx
```

- *name#xx*  
The name of the POLICY object (policy name and version number) for the policy you want to undeploy.

## editfile Command Create and Modify File Records

### Valid in the AC environment

This command is documented with the chfile command.

## edit x grp Command Create and Modify Group Records

### Valid in the AC environment

This command is documented with the ch[x]grp command.

## editres Command Modify Resource Records

### Valid in the AC environment

This command is documented with the chres command.

## edit x usr Command Modify User Records

### Valid in the AC environment

This command is documented with the chxusr command.

## end\_transaction Command Complete Recording Dual Control Transactions

### Valid on UNIX hosts in the AC environment

The end\_transaction command completes the start\_transaction command for Dual Control PMDB processes.

## environment Command Set the Security Environment

### Valid in all environments

The environment command sets the security environment. Privileged Access Manager supports the Privileged Access Manager and UNIX security environments. When the selang command shell is invoked, the AC environment is selected by default.

This command has the following format:

```
environment {ac|config|etrust|native|nt|pmd|seos|unix}
```

- **ac**  
Specifies the Privileged Access Manager security environment. The selang commands affect the local Privileged Access Manager database. Some commands support simultaneous updates to the native OS security settings of the host you are connected to. In the Privileged Access Manager environment, the selang prompt is as follows:

```
PAMSC>
```

- **config**  
Specifies the remote configuration environment, which lets you change endpoint configuration settings.
- **etrust**  
Specifies the Privileged Access Manager security environment.

#### NOTE

This is the same as specifying AC and is maintained for compatibility with older versions.

- **native**  
Specifies the native operating system security environment (either Windows or UNIX) of the host you are connected to, whether local or remote. The selang commands affect the native OS database. In the native environment, the selang prompt is:

```
PAMSC (native)>
```

- **nt**  
Specifies the Windows security environment. The selang commands affect the Windows database. Some commands support simultaneous updates to the Privileged Access Manager security settings. In the Windows environment, the selang prompt is:

```
PAMSC (nt)>
```

- **pmd**  
Specifies the selang commands in the remote management environment. When the selang command shell is set to the pmd environment, the commands operate on the PMDB of the selected host. In the pmd environment, the selang prompt is as follows:

PAMSC (pmd) >

- **seos**  
Specifies the Privileged Access Manager security environment.

**NOTE**

This is the same as specifying *AC* and is maintained for compatibility with older versions.

- **unix**  
Specifies the UNIX security environment. The *selang* commands operate on the UNIX security system. In the UNIX environment, the *selang* prompt is as follows:

PAMSC (unix) >

## find Command List Database Records

### Valid in AC and native environments

The *find* command displays the names of records in a specified class. If you do not specify any parameters, it displays the names of all classes.

**NOTE**

The *find* command is identical to the commands *list* and *search*.

To use this command you must have sufficient authority, as defined by the following conditions:

- If you have the ADMIN, AUDITOR, or OPERATOR attribute, you can use the *find* command with all parameters.
- If you have READ authority for a record in the ADMIN class, you can specify the class parameter for the class represented by the record.

This command has the following format:

```
{find|f|list|search} [{className|class(className)}] [objName]
```

- *className*  
Specifies the class within which *find* searches for records. If *className* is not provided, *find* lists all classes.
- *objName*  
Specifies the records that Privileged Access Manager searches for. *objName* can include wildcard characters.

### Example: Display all Records in the TERMINAL Class

To display all the members in the TERMINAL class, enter the following command:

```
find terminal
```

## get dbexport Command Retrieve Exported Database Rules

### Valid in the AC environment

The *get dbexport* command retrieves the rules that were exported from the Privileged Access Manager database or PMD database on the host you are connected to. For the exported database to exist, you must issue the *start dbexport* command before you issue the *get dbexport* command.

This command has the following format:

```
get dbexport [pmdname(name)] [params(OFFSET=number)]
```

- `pmdname(name)`  
(Optional) Defines the name of the PMD database that you exported.
- `params(OFFSET=number)`  
(Optional) Defines the offset for retrieving more lines from the database output. The `get dbexport` command can only return 200 lines from the exported database per request. If there is more information in the output, the command returns offset data that specifies the last line returned.

### Example: Retrieve rules from an exported database

The following example shows how the `get dbexport` command is used to retrieve information from the exported Privileged Access Manager database on the host you are connected to. The first command retrieves the first 200 lines and the second command retrieves the following 200 lines of the output:

```
PAMSC> get dbexport

(localhost)

Data for DBEXPORT 'seosdb'

-----

setoptions class+(CLASS)setoptions class+(CLASS)

setoptions class+(CLASS)

...

chres CLASS ("resource") defaccess(none)

OFFSET:      201
```

```
PAMSC> get dbexport params("offset=201")

(localhost)

Data for DBEXPORT 'seosdb'

-----

chres CLASS ("resource") defaccess(none)

chres CLASS ("resource") defaccess(none)

chres CLASS ("resource") defaccess(none)

...
```

```
chres CLASS ("resource") defaccess(none)

OFFSET:      401
```

## get devcalc Command Retrieve Policy Deviation Data

### Valid in the AC environment

The get devcalc command retrieves information from the policy deviation data file (deviation.dat) that contains policy deviation calculation results and sends it to one or more set DMS databases. For the data file to exist, the start devcalc command must have been issued before.

When you create a policy or host report, you can also specify to include deviation calculation results. The reporting utility then issues this command.

#### WARNING

The deviation calculation does not check whether native rules are applied. It also ignores rules that remove objects (user or object attributes, user or resource authorization, or actual users or resources) from the database. For example, the calculation cannot verify whether the following rule is applied:rr SUDO admCommand

#### NOTE

For more information about the policy deviation data file and advanced policy reporting, see the *Enterprise Administration Guide*.

To run the get devcalc command you must have terminal access rights to the computer and read access to DEVCALC sub-administration class.

This command has the following format:

```
get devcalc [params("offset=number")]
```

- **offset=number**  
(Optional) Defines the offset for retrieving more lines from the policy deviation data file. The get devcalc command can only return a maximum number of lines (set by the max\_lines\_request configuration setting) from the policy deviation data file per request. If there is more information in the file, the command returns offset data that specifies the last line returned.

### Example: Get policy deviation data

The following example shows how the get devcalc command is used to retrieve information from the policy deviation data file when the max\_lines\_request setting is set to 10. The first command retrieves the first ten lines and the second command then retrieves the following ten lines of the output:

```
PAMSC> get devcalc

(localhost)

Data for DEVCALC 'deviation'

-----
```

## help Command Get selang Help

### Valid in all environments

The help command displays selang syntax in several ways:

- Used without parameters, it displays a list of the selang commands, with a brief explanation of each.
- Used with a selang command name, it displays the syntax of the given command.
- Used with the access parameter, it displays a list of values for the access parameter of the authorize command and the defaccess parameter of the new\*, ch\*, and edit\* commands.
- Used with the lineedit parameter, it displays a list of special characters for selang command line manipulations.

#### NOTE

To display the help text for a command typed in the command line without deleting the text in the command line, type Ctrl+2.

```
{help|h} [commandName|access|lineedit|className|properties|privilege]
```

- **access**  
Requests a class-by-class list of the access types that the access and defaccess parameters can specify.
- **className**  
Requests a short description of the specified class.
- **command-name**  
Requests the syntax for the specified command.
- **lineedit**  
Requests a list of special characters for selang command line manipulations.
- **properties**  
(AC environment) Requests information on how to update user-defined properties.
- **privilege**  
(Windows environment) Requests a list of possible Windows privileges for the ch[x]grp, ch[x]usr, edit[x]grp, and edit[x]usr commands.

## history Command Show Previously Issued Commands

### Valid in all environments

The history command lists all the commands that were entered during the current selang command shell session. The commands are ordered chronologically. Each command is preceded by the number of the command. For example, the third command entered is preceded by the number three.

The history command does not display a password even if one was entered as part of a ch[x]usr, new[x]usr, or edit[x]usr commands. The history command displays a series of asterisks (\*\*\*) instead of the clear text password.

This command has the following format:

```
history
```

## hosts Command Connect to a Remote Terminal

### Valid in all environments

The hosts command specifies the hosts or Policy Models to which the selang commands are sent. It lets you connect to a remote Privileged Access Manager computer with a different name, so you can remotely manage the computer while local Privileged Access Manager services are running. By default, all selang commands are directed to the database on the local host.

The hosts command must be executed before executing the commands that are to be directed to the hosts.

To administer (update) a remote host database from the local host, you must meet *one* of the following criteria:

- Be explicitly authorized to update the remote host database from the local database
- Be a member of a group that is allowed to update the remote host database from the local database
- Be the owner of the local host as defined in the remote host

To list all the hosts and PMDBs that are currently available, specify the hosts command without any parameters.

#### NOTE

Privileged Access Manager protects hosts through their canonical host names and not through aliases. To avoid the confusion caused by alias names, Privileged Access Manager issues a warning when a HOST rule is defined for an alias name. Similarly, Privileged Access Manager gives a warning if a HOST is defined with less than a fully qualified name, because Privileged Access Manager uses fully qualified names (for example, mymachine.yourcompany.com) for hosts.

This command has the following format:

```
hosts [{systemIds|policyModel@[hostname]]} [uid(username) password(pw)]
```

- **systemIds**  
Specifies the system IDs of the hosts on which the selang commands are to be executed. When specifying more than one host, enclose the list of systems IDs in parentheses and separate the system IDs with a space or a comma.
- **policyModel@[hostname]**  
Specifies the addresses of the Policy Models on which the selang commands are to be executed. When specifying more than one Policy Model, enclose the list of Policy Model addresses in parentheses and separate the Policy Model addresses with a space or a comma.  
**Default:** If you do not specify *hostname*, Privileged Access Manager tries to connect to the PMDB on the local host.

#### NOTE

The advantage of using a Policy Model over explicitly specifying the hosts is that the system where the Policy Model resides keeps on trying to update all the systems defined to the Policy Model, even if they are currently unavailable. For more information about Policy Models, see the *Endpoint Administration Guide* for your OS.

- **uid(username)**  
(Optional) Specifies the name of an alternate Privileged Access Manager admin that may be used to log into the target database.
  - **password(pw)**  
Specifies the password of the user ID in the uid token.

#### Example: Connect to the Local Host

To connect to the local seosdb database, use the following command:

```
hosts @
```

To connect to a local PMDB, use the following command:

```
hosts PMDB@
```

**Example: Let a User or Group Update Remote Hosts**

To give a user authorization to update the remote host database from the local database, on the remote host enter the command:

```
authorize TERMINAL local_host uid user_name access(write)
```

To give a group authorization to update the remote host database from the local database, on the remote host enter the command:

```
authorize TERMINAL local_host gid(group_name) access(write)
```

**Example: Apply selang Commands to a Remote Policy Model**

To apply all subsequent commands to the Policy Model on the station h1, type the command:

```
hosts Policy@h1
```

If the connection to *Policy@h1* is successful, the following message appears.

```
Successfully connected to h1
```

All commands entered from now on are directed to *Policy@h1* and not to the local host. The selang prompt changes to the following:

```
Remote_PAMSC>
```

**Example: Apply selang Commands to a Remote Host**

To apply all future commands to the station athena, type the command:

```
hosts athena
```

If successful connections are made to athena, the following messages appear on the screen.

```
(athena)
```

```
Successfully connected
```

```
INFO: Target version is 2.50
```

Any command you enter is applied to athena and is not sent to the local host. If you add a new user, the user is only added to athena, as shown in this example:

```
Remote_PAMSC>newusr steve

(athena) USER steve successfully added.
```

### Example: Connect as a Different User

You can use the uid and password parameters to log into the database (seosdb or PMDB) as a different user. This is useful when connecting to the local or remote host as administrator (root).

```
hosts @ uid(root) password(P@ssword01)
```

## join x Command Add Users to Internal Groups

### Valid in the AC environment

The join[x] command adds users to one or more internal groups, or changes the users' properties with respect to the groups. The specified users and groups must already be defined to Privileged Access Manager.

Use join to add internal users to groups.

Use joinx to add enterprise users to groups.

#### NOTE

This command also exists in the native environment but operates differently there.

The set of properties from the join command *completely replaces* any previous set of properties for the specified users in the specified groups. If any such properties were defined earlier, they are not retained unless the new join command specifies them again.

#### NOTE

For more information about group properties, see the *Endpoint Administration Guide* for your OS.

You can use the join command if at least one of the following conditions is true:

- You have the ADMIN attribute.

#### NOTE

If you want to modify Privileged Access Manager GROUP records *and* enterprise groups you need both the MODIFY and JOIN access authority.

- The group record is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the group.
- You are assigned CONNECT authority in the access control list of the GROUP record in the ADMIN class.

This command has the following format:

```
{join[x]|j[x]} {userName|(userName [,userName...])} \
group(groupName [,groupName...]) \
[admin|admin-] \
[auditor|auditor-] \
[gowner(group-name)] \
[operator|operator-] \
```

```
[owner(userName|groupName)] \
[pwmanager | pwmanager-] \
[regular] \
[nt | unix]
```

- **admin**  
Assigns the GROUP-ADMIN attribute to the user specified by *userName*.
- **admin-**  
Removes the GROUP-ADMIN attribute from the user.
- **auditor**  
Assigns the GROUP-AUDIT attribute to the user specified by *userName*.
- **auditor-**  
Removes the GROUP-AUDIT attribute from the user.
- **gowner(groupName)**  
Specifies that the user is being added to the group *groupName*.
- **group(groupName [,groupName...])**  
Specifies the group or groups to which the that the user is being added as a member.
- **nt**  
Connects *userName* to a group in the Windows database.
- **operator**  
Assigns the GROUP-OPERATOR attribute to the user specified by *userName*.
- **operator-**  
Removes the GROUP-OPERATOR attribute from the user.
- **owner(Name)**  
Specifies a Privileged Access Manager user or group as the owner of the join record. If you are creating a connection and you do not specify an owner, you are the owner of the connection.
- **pwmanager**  
Assigns the GROUP-PWMANAGER attribute to the user specified by *userName*.
- **regular**  
Resets the administrative flags for the user.
- **unix**  
Connects *userName* to the group in the UNIX security system.
- **userName**  
Specifies a user who is to be connected (or reconnected with a new set of properties) to the group or groups specified by the group parameter.  
If the command is join, *userName* is the name of a USER record. If the command is joinx, *userName* is the name of an enterprise user.

## Examples

- The user Rorri wants to join the user Bob to the internal group staff.
  - Rorri has the ADMIN attribute.
  - The following defaults apply:
    - admin
    - auditor
    - owner(Rorri)
    - pwmanager

```
join Bob group(staff)
```
- The user Rorri wants to change the definition of Sue in the group staff. She currently is a GROUP-AUDITOR; Rorri wants to add the GROUP-PWMANAGER attribute.

- Rorri has the ADMIN attribute.
- The following defaults apply:
  - admin
  - owner(Rorri)

```
join Sue group(staff) auditor pwmanager
```

When selang executes this command, it deletes the previous record. No record is kept of Sue's previous attributes. Therefore, Rorri must specify the two attributes Sue should have now.

## join x - Command Remove Users from Groups

### Valid in the AC environment

The join[x]- command removes users from internal groups.

join- removes internal users from internal groups.

joinx- removes enterprise users from internal groups.

#### NOTE

The join[-] command also exists in the native environment but operates differently there.

To use the join[x]- command, one of the following conditions must be true:

- You have the ADMIN attribute.

#### NOTE

If you want to modify Privileged Access Manager GROUP records *and* native groups you need both the MODIFY and JOIN access authority.

- The group record is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the group.
- You are assigned CONNECT authority in the access control list of the GROUP record in the ADMIN class.

This command has the following format:

```
{join[x]-|j[x]-} {userName| (userName [,userName...])} \
group(groupName [,groupName...])
```

- **group(groupName [,groupName...])**  
Specifies the group or groups from which to remove the user.
- **userName**  
Specifies the user you want to remove from the group.  
If the command is join, *userName* is the name of a USER record.  
If the command is joinx, *userName* is the name of an enterprise user.

### Example

The user Bill wants to remove the users sales25 and sales43 from the group PAYROLL.

The user Bill has the ADMIN attribute.

```
joinx- (sales25 sales43) group(PAYROLL)
```

## newfile Command Create File Records

### Valid in the AC environment

This command is documented with the chfile command.

## new x grp Command Create Group Records

### Valid in the AC environment

This command is documented with the chgrp command.

## newres Command Create Resource Records

### Valid in the AC environment

This command is documented with the chres command.

## new x usr Command Create User Records

### Valid in the AC environment

This command is documented with the ch[x]usr command.

## rename Command Rename a Database Record

### Valid in the AC environment

Renames a record name in the database. The record is now known by its new name only.

#### NOTE

You cannot rename records in the SEOS, UACC, and ADMIN classes.

To use the rename command, you must have sufficient authority over the record. Privileged Access Manager makes the following checks until one of the conditions is met:

- You have the ADMIN attribute.
- The resource record is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the record.
- You are assigned CREATE (for editres) access authority in the access control list of the resource class's record in the ADMIN class.

This command has the following format:

```
rename classNameoldresourceNamenewresourceName
```

- *className*  
Defines the class to which the record you want to rename belongs.
- *oldresourceName*  
Defines the current name of the record in Privileged Access Manager.
- *newresourceName*  
Defines the new name you want to assign to the record.

### Example

The user ADMIN 1 wants to rename the record *spree3* in class Host to *spree4*.

- The security administrator has the ADMIN attribute.

```
rename host spree3 spree4
```

## rmfile Command Delete File Records

### Valid in the AC environment

The rmfile command deletes records belonging to the FILE class from the database.

You can delete a file record if one of the following conditions is met:

- You have the ADMIN attribute.
- The record is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the file.
- You have the DELETE access authority assigned in the ACL of the FILE record in the ADMIN class.

This command has the following format:

```
{rmfile|rf} {fileName | (filename [,filename...])}
```

- *fileName*  
Defines the file you are removing.  
Privileged Access Manager processes each file record independently. If an error occurs while processing a file, Privileged Access Manager issues a message and continues processing with the next file in the list.

### Example: Remove File Protection

The security administrator (which has the ADMIN attribute) wants to remove Privileged Access Manager protection for a file. On UNIX, this can look like this:

```
rmfile /etc/passwd
```

The same command on Windows can look like this:

```
rmfile C:\temp\passwords.txt
```

## rm x grp Command Delete Group Records

### Valid in the AC environment

The rmgrp and rmxgrp commands remove one or more groups from Privileged Access Manager and, optionally, from the native environment.

#### NOTE

There may be occurrences in the database of the group's group ID that the rmgrp command does not delete. For example, the group could be the owner of another group, the owner of other records, or in an access control list for a resource. Use the chgrp, chusr, chres, and authorize commands, as required, to manually change ownership and remove access authorities relating to the group record you want to delete. Alternatively, use the sepurgedb utility to clean up inconsistencies in the database automatically.

#### NOTE

The rmgrp command also exists in the native environment but operates differently there.

To use the rmgrp command, at least one of the following is required:

- You have the ADMIN attribute.
- The group to be deleted is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the group to be deleted.
- You are assigned DELETE authority in the GROUP record of the AUDIT class.

This command has the following format:

```
{rmgrp|rg | rmxgrp|rxg} { groupName | (groupName [,groupName...]) } [unix|nt]
```

- *groupName*  
Specifies the Privileged Access Manager group to be deleted.
- **nt**  
(Optional) Deletes a group from the local Windows database in addition to deleting the group from the Privileged Access Manager database.
- **unix**  
(Optional) Deletes a group from the local UNIX system in addition to deleting the group from the Privileged Access Manager database.

### Example

The user Joe wants to delete the groups DEPT1 and DEPT2 from the database.

- The user Joe has GROUP-ADMIN authority to the SALES group.
- The groups DEPT1 and DEPT2 are owned by the SALES group.

```
rmxgrp (DEPT1, DEPT2)
```

## rmres Command Delete a Resource

### Valid in the AC environment

The `rmres` command removes resources from the database. Records belonging to the following classes can be deleted using the `rmres` command: ACVAR, ADMIN, APPL, CATEGORY, CONNECT, FILE, GAPPL, GHOST, GSUDO, GTERMINAL, HNODE, HOST, HOSTNET, HOSTNP, LOGINAPPL, MFTERMINAL, POLICY, PWPOLICY, SECFILE, SECLABEL, SPECIALPGM, SUDO, SURROGATE, TERMINAL, PROGRAM, PROCESS, RULESET, TCP, UACC, and any user defined class.

#### NOTE

This command also exists in the native Windows environment but operates differently.

To remove a record from the database, you must meet one of the following conditions:

- You have the ADMIN attribute.
- The resource record is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the resource record.
- You are assigned the DELETE authority in the access control list of the resource class's record in the ADMIN class.

This command has the following format:

```
{rmres|rr} classNameresourceName
```

- *className*  
Specifies the name of the class to which the resource belongs. To list the resource classes defined to Privileged Access Manager, use the `find` command. See the `find` command in this chapter for more information.
- *resourceName*  
Specifies the name of the resource record you are deleting. When removing more than one resource, enclose the list of resource names in parentheses and separate the resource names with a space or a comma.  
Privileged Access Manager processes each resource record independently. If an error occurs while processing a resource, Privileged Access Manager issues a message and continues processing with the next resource in the list.

### Example

The user Admin1 wants to remove the record TERMS from the TERMINAL class in the database.

- The user Admin1 has the ADMIN attribute.

```
rmres TERMINAL TERMS
```

## rm x usr Command Delete User Records

### Valid in the AC environment

The `rmusr` and `rmxusr` commands remove users from the Privileged Access Manager database, and also remove references to the user's record that exist in Privileged Access Manager group records.

`rmxusr` removes an enterprise user from the Privileged Access Manager database. `rmusr` removes an internal user from the database. The `rmusr` command can, optionally, remove the user from the native environment as well.

#### NOTE

There may be occurrences in the database of the user that `rm[x]usr` does not delete. For example, the user could be the owner of a group, the owner of other records, or in an access control list for a resource. Use the `ch[x]grp`, `ch[x]usr`, `ch[x]res`, and `authorize` commands, as required, to manually change ownership and remove access authorities relating to the user record you want to delete. Alternatively, use the `sepurgedb` utility to clean up inconsistencies in the database automatically.

#### NOTE

The `rmusr` command also exists in the native environment but operates differently there.

To execute the `rm[x]usr` command you need to meet at least one of the following requirements:

- You have the ADMIN attribute.
- The user record to be deleted is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are assigned the DELETE authority in the access control list of the USER record in the ADMIN class.
- You are the owner of the user record.

`ru` is a synonym of `rmusr`.

`rxu` is a synonym of `rmxusr`.

This command has the following format:

```
{rmusr|ru | rmxusr | rxu} { userName | (userName [,userName...]) } \
[unix|nt] [appl(homedir=yes)]
```

- **appl(homedir=yes)**  
(UNIX only). Deletes the user's home directory  
This argument checks for the existence of the user's home directory in `/home`, `/tmp` or `/users`. If the home directory located in another directory, edit the `S99DELETE_postrmusrdir.sh` script to incorporate it.

#### NOTE

You must specify the `unix` option before you specify this option.

- **nt**  
Deletes the user from the Windows environment, in addition to deleting the user from Privileged Access Manager.  
Valid only for `rmusr`.
- **userName**  
Defines a user record.
- **unix**  
Deletes the user from the UNIX environment, in addition to deleting the user from Privileged Access Manager.  
Valid only for `rmusr`.

### Example

The following command deletes enterprise users Terry and Jane from Privileged Access Manager:

```
rxu (Terry, Jane)
```

## ruler Command Select Properties to Display

### Valid in AC and native environments

The ruler command defines the ruler for a class, and so lets you define the set of properties of a class that Privileged Access Manager displays.

The ruler command only applies to the hosts of the current session. The properties of each host are displayed in a separate list. If you change hosts, the ruler command does not change the display of properties in the new hosts.

The following users can issue this command:

- Users with the ADMIN, AUDITOR, or OPERATOR attribute.
- Users who have access read in class ADMIN for the class whose ruler they are trying to set. For example, if you have access read in class ADMIN for the record representing class TERMINAL, you can set the ruler for class TERMINAL.

This command has the following format:

```
ruler className [props( all | propertyName [,propertyName...])]
```

- *className*  
The name of the class whose display you want to change.
- [props(all | *propertyName* [,*propertyName*...])]  
Specifies the properties to be displayed.  
If you omit the props parameter, Privileged Access Manager displays the names of the properties that are in the current ruler.
  - **all**  
Specifies that all the properties of the class to be displayed.
  - *propName*  
Specifies a Privileged Access Manager property to be displayed. You can specify up to 40 properties, separated by spaces or commas.

### Examples

- The user admin wants Privileged Access Manager to display only two properties for each user: the owner and the user who is notified about changes.

```
ruler USER props(NOTIFY, OWNER)
```

- The user admin wants to display the properties in the current ruler for class USER.

```
ruler USER
```

- The user admin wants Privileged Access Manager to revert to the default ruler, which is to display all the properties in the class USER.

```
ruler USER props(all)
```

## setoptions Command Set Options

### Valid in the AC environment

The setoptions command sets system-wide Privileged Access Manager options in the running system. For example, you can use setoptions to:

- Enable or disable security checking for each class, or for all classes
- Set the password policies
- List the current settings of the Privileged Access Manager options

#### NOTE

This command also exists in the Windows environment, but operates differently there.

You need the ADMIN attribute to use the setoptions command. However, you only need the AUDITOR or OPERATOR attribute to use the command setoptions list.

This command has the following format:

```
{setoptions|so} \
[accgrr|accgrr-] \
[accpacl|accpacl-] \
[ac_id(id)] \
[class+ (className)] \
[class- (className)] \
[class (className)] \
[flags{+|-} (I|W)] \
[cng_adminpwd|cng_adminpwd-] \
[cng_ownpwd|cng_ownpwd-] \
[cwarnlist] \
[dms{+|-} (dms@hostname)] \
[inactive(nDays)|inactive-] \
[is_dms{+|-}] \
[list] \
[maxlogins (nLogins)|maxlogins-] \
[password( \[{history(nStoredPasswords) | history-}] \[(interval(nDays) | interval-)] \[(min_life(nDays) |
min_life-)] \[{rules( \ [alpha(nCharacters)] \ [alphanum(nCharacters)] \ [(bidirectional) | (bidirectional-)]
\ [grace(nLogins)] \ [lowercase(nCharacters)] \ [min_len(nCharacters)] [max_len(nCharacters)]
\ [max_rep(nCharacters)] \ [{namechk|namechk-}] [numeric(nCharacters)] \ [{oldpwchk|oldpwchk-}]
[prohibited(prohibitedCharacters)] \ [special(nCharacters)] \ [sub_str_len(nCharacters)] \
[uppercase(nCharacters)] \ [use_dbdict|use_dbdict-] \)|rules-}] \
)] \
```

- **accgrr**  
Enables the accumulative group rights (ACCGRR) option.  
The default value is enabled.
- **accgrr-**  
Disables the accumulative group rights (ACCGRR) option.
- **accpacl**  
Enables the use of PACLs in all resources.
- **accpacl-**  
Disables the use of PACLs.
- **ac\_id(id)**  
Defines a unique ID for the endpoint (HNODE object) that is saved in the local Privileged Access Manager database and on the DMS. Privileged Access Manager uses this ID to identify the HNODE, so that changes to the endpoint's IP address or name do not affect advanced policy management functionality; Privileged Access Manager can still trace the endpoint.
- **class (className)**  
Sets or clears a setting for a Privileged Access Manager class.
- **class+(className)**  
Enables one or more Privileged Access Manager classes. A class must be enabled for Privileged Access Manager to protect resources of that class. A class should be activated only after you have defined the necessary records to allow access to the resources that belong to the class. See the *Endpoint Administration Guide for UNIX* for more information about the resource classes supplied with Privileged Access Manager.  
Use one of the following values:

- The name of a Privileged Access Manager class
- SECLEVEL. This enables security level checking.
- PASSWORD. This activates the password rules. On Windows, it also enables arbitrarily long passwords.
- **class-(className)**  
Disables one or more Privileged Access Manager classes. Resources that belong to a disabled class are not protected by Privileged Access Manager. Use one of the following values:
  - The name of a class
  - SECLEVEL. This disables security level checking.
  - PASSWORD. This disables the password rules. On Windows, this also disables the long passwords.
 You cannot disable the classes GROUP, SECFILE, SEOS, UACC, and USER.
- **cng\_adminpwd**  
Enables users with the PWMANAGER attribute to change the ADMIN user's password.
- **cng\_adminpwd-**  
Disables users with the PWMANAGER attribute from changing the ADMIN user's password. This is the default setting.
- **cng\_ownpwd**  
Enables users to change their own passwords through selang.
- **cng\_ownpwd-**  
Disables users from changing their own passwords through selang. This is the default setting.
- **cwarnlist**  
Displays a table with data about which classes are in Warning mode.
- **dms{+|-}(dms@hostname)**  
Adds or removes DMS databases from the list of DMS databases for this database.
- **flags{+|-} (I|W)**  
Sets or clears functionality that is associated with a class. Valid values are:
  - **I**  
Case-sensitivity for objects in the specified class.
 

**NOTE**  
Verify that there is a resource with the same name before setting I flag. Privileged Access Manager shows a database error on restarting, if there are multiple upper or lower case resources. Restart Privileged Access Manager for the I flag change to take effect.
  - **W**  
Warning mode for the specified class.
 

**NOTE**  
Flags are case-sensitive; use uppercase letters.
- **history(NStoredPasswords)**  
Specifies the number of previous passwords that are stored in a history list. When a password is changed, the previous password is added to the list, and the oldest password is dropped from the list if necessary. Privileged Access Manager prevents a user from changing their password to one that is in the list.  
Enter an integer from 1 through 24. If you specify zero, no passwords are saved.  
On Windows, the history option enables the use of passwords longer than eight characters. The setoptions bidirectional or bidirectional- option determines the form of encryption used when storing the password.  
On UNIX, the history option does *not* affect whether long passwords are enabled. Use the passwd\_local\_encryption\_method configuration setting to determine whether long passwords are enabled.
- **history-**  
Disables password history checking.  
On Windows, this option disables the use of long passwords.
- **inactive(nDays)**

Specifies the number of inactive days after which a user's login is suspended. An inactive day is a day when the user does not log in. Enter a positive integer. If inactive is set to zero, the effect is the same as using the inactive-parameter.

- **inactive-**  
Disables the inactive login check.
- **interval(*nDays*)**  
Sets the number of days that must pass after passwords are set or changed before the system prompts users for a new password. Enter a positive integer or zero. An interval of zero disables password interval checking for users. Set the interval to zero if you do not want passwords to expire.  
If the utility `segrace` is part of the user's login script, Privileged Access Manager informs the users that the current password has expired when the specified number of days is reached. The users can immediately renew the password or continue using the old password until the number of grace logins is reached. After the number of grace logins is reached, the users are denied access to the system and must contact the system administrator to select a new password.
- **interval-**  
Cancels the password interval setting.
- **is\_dms+**  
Designates the current database as a DMS.
- **is\_dms-**  
Removes the designation of the current database as a DMS.
- **list**  
Displays the current settings on the screen.
- **maxlogins(*nLogins*)**  
Sets the maximum number of terminals the user can log in to at the same time. A value of 0 (zero) means that the user can log in from any number of terminals concurrently. This value can be overridden by assigning a value in the user's user record.

**NOTE**

If maxlogins is set to 1, you cannot run `selang`. You must shut down Privileged Access Manager, change the maxlogins setting to greater than one, and restart Privileged Access Manager.

**NOTE**

Valid only on Unix and Linux operating systems.

- **maxlogins-**  
Disables the global maximum logins check. The number of terminals a user can log in is from unlimited, unless the user's login is restricted in the user record of the user.
- **min\_life(*NDays*)**  
Sets the minimum number of days between password changes. Enter a positive integer.
- **password**  
Sets the password options.
- **rules**  
Sets one or more password rules that Privileged Access Manager uses to check the quality of new passwords. The rules are:
  - **alpha(*nCharacters*)**  
Sets the minimum number of alphabetic characters the new password must contain. Enter an integer.
  - **alphanum(*nCharacters*)**  
Sets the minimum number of alphanumeric characters the new password must contain. Enter an integer.
  - **bidirectional**  
Specifies that when passwords are sent to other systems as part of PMDB, they are distributed in clear text (within encrypted messages).  
On UNIX, this option is equivalent to setting the following passwd section setting value:

```
Passwd_distribution_encryption_mode=bidirectional
```

#### NOTE

We recommend that you set the configuration setting rather than use the `setoptions` command.

On Windows, the passwords are stored in the history list with the encryption specified in the registry value:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Encryption Package
```

#### – **bidirectional-**

Specifies that passwords are sent in their hash encrypted form.

On Windows the hash function used is SHA-1.

On UNIX, this option is equivalent to setting the following `passwd` section setting value:

```
Passwd_distribution_encryption_mode=compatibility
```

#### NOTE

We recommend that you set the configuration setting rather than use the `setoptions` command.

If this option is specified, long passwords cannot be distributed between heterogeneous operating systems.

#### – **grace(*nLogins*)**

Sets the maximum number of grace logins that are permitted before the user is suspended. The number of grace logins must be from 0 through 255 inclusive.

#### – **lowercase(*nCharacters*)**

Sets the minimum number of lowercase characters the new password must contain. Enter an integer.

#### – **min\_len(*nCharacters*)**

Sets the minimum password length. Enter the minimum total number of characters that the new password must contain.

#### – **max\_len(*nCharacters*)**

Sets the maximum password length. Enter the maximum total number of characters that the new password must contain.

#### – **max\_rep(*nCharacters*)**

Sets the maximum number of repetitive characters the new password must contain. Enter an integer.

#### – **namechk**

Checks whether the password contains or is contained by the user's name. By default, Privileged Access Manager performs this check.

#### – **namechk-**

Turns off the `namechk` check.

#### – **numeric(*nCharacters*)**

Sets the minimum number of numeric characters the new password must contain. Enter an integer.

#### – **oldpwchk**

Checks whether the new password contains or is contained by the password being replaced. By default, Privileged Access Manager performs this check.

#### NOTE

Valid only on Unix and Linux operating systems.

#### – **oldpwchk-**

Turns off the `oldpwchk`.

#### – **prohibited(*prohibitedCharacters*)**

Specifies characters a user cannot use in a password. Enter the prohibited characters.

#### NOTE

We recommend you to verify that control characters '\ ' and 't' are both specified in the `prohibitedCharacters` list, to block the use of the tab key.

#### – **special(*nCharacters*)**

Sets the minimum number of special characters the new password must contain. Enter an integer.

#### – **sub\_str\_len(*nCharacters*)**

- Sets the maximum number of characters the new password can share with the previous password. Enter an integer.
- **uppercase(*nCharacters*)**  
Sets the minimum number of uppercase characters the new password must contain. Enter an integer.
- **use\_dbdict | use\_dbdict-**  
Sets the password dictionary. use\_dbdict sets the token to db and compares passwords against words in the Privileged Access Manager database. use\_dbdict- sets the token to file and checks passwords against a file specified in the seos.ini file for UNIX or Windows registry for Windows.
- **rules-**  
Disables password quality checking. None of the rules specified by the rules argument are used for password quality checking.

### Examples: Set Privileged Access Manager Options

- The user John wants to activate the OpsAct class, an installation-defined class used to protect operator actions. The user John has the ADMIN attribute.  

```
setoptions class+(OpsAct)
```
- The user Mike wants to set a password policy that forces users to supply passwords of length at least 6 characters. Mike also wants to activate password policy enforcement. The user Mike has the ADMIN attribute.  

```
setoptions class+(PASSWORD)
setoptions password(rules(min_len(6)))
```
- The user SecAdmin wants to enable security level checking. The user SecAdmin has the ADMIN attribute.  

```
setoptions class+(SECLEVEL)
```
- The user Janani wants to set a DMS for this database to send notification to. The user Janani has the ADMIN attribute.  

```
setoptions dms+(apache@myHost)
```

### Example: Put a Class into Warning Mode

Put a class into Warning mode by setting the Warning property on the class. You can use the setoptions selang command to do this, as follows:

```
setoptions class(classname) flags+ (W)
```

- **classname**  
Defines the name of the class you want to put into Warning mode.

#### NOTE

The W flag is case-sensitive and must be in uppercase.

To clear Warning mode for the class, you can also use the setoptions command, as follows:

```
setoptions class(classname) flags- (W)
```

### search Command List Database Records

#### Valid in AC and native environments

This is identical to the find command.

### showfile Command Display File Properties

#### Valid in the AC environment

The showfile command lists the properties of a file record. The properties are listed in alphabetical order. Privileged Access Manager processes each record independently and displays information only for those resources for which you have sufficient authority.

### NOTE

This command also exists in the native environment but operates differently there.

To execute a showfile command, at least one of the following conditions is required:

- You have at least one of the following attributes: ADMIN, AUDITOR, and OPERATOR.
- You are the owner of the file.
- You are assigned read authority in the access control list of the object representing the FILE class record in the ADMIN class.
- You have the GROUP-ADMIN or GROUP-AUDITOR attribute in the group that owns the file or that is a parent of the group that owns the file.

This command has the following format:

```
{showfile|sf} {fileName |(fileName [,fileName...])} \
[addprops(propName [,propName ...])] \
[next] \
[props(all | propName [,propName ...])] \
[useprops(propName [,propName ...])] \
[nt|unix]
```

- **addprops(propName [,propName ...])**  
Defines properties to be added to the class ruler for this query only.
- **fileName**  
Specifies the name of the file record whose properties are to be listed.  
Privileged Access Manager processes each file record independently. If an error occurs while processing a file, Privileged Access Manager issues a message and continues processing with the next file in the list.  
*fileName* can contain wildcard characters, and so match multiple file names.  
On UNIX, to display the properties of a file whose name contains a special character or space, type an extra slash (/) before the file name.
- **next**  
Displays parts of the requested data. This option is useful when the query data is larger than the set query size.  
The maximum query size is determined by the query\_size configuration setting. The default query\_size setting is 100.
- **nt**  
Displays the Windows file attributes as well as the Privileged Access Manager properties.
- **props(all|propName [,propName ...])**  
Defines a new ruler for this class for this query and future queries.
- **unix**  
Displays the UNIX file attributes as well as the Privileged Access Manager properties.
- **useprops(propName [,propName ...])**  
Defines a ruler for this query only. The class ruler is unaffected.

### Example

The user root wants to list the properties of the file record /etc/passwd.

- User root has the ADMIN attribute.

```
showfile /etc/passwd
```

## show x grp Command Display Group Properties

### Valid in the AC environment

The show[x]grp command displays the settings of all the Privileged Access Manager properties of a group record. Optionally, the native environment properties are also shown.

#### NOTE

The showgrp command also exists in the native environment but operates differently there.

You can execute a show[x]grp command if at least one of the following conditions are true:

- You have at least one of the following attributes: ADMIN, AUDITOR, and OPERATOR.
- You have the GROUP-ADMIN or GROUP-AUDITOR attribute in each group to be listed, or each group to be listed is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the group.
- You are assigned read authority in the access control list of the GROUP record in the ADMIN class.

This command has the following format:

```
{showgrp|sg} {groupName |groupName [,groupName...] } \
[addprops(propName[,propName ...])] \
[next] \
[props(all | propName[,propName ...])] \
[useprops(propName[,propName ...])] \
[nt|unix]
```

- **addprops(propName [,propName ...])**  
Defines properties to be added to the ruler for this query only.
- **groupName**  
Specifies the group whose properties you want to list.  
groupName can contain wildcard characters.  
On UNIX, to display the properties of a group whose name contains a special character or space, type an extra slash (/) before the group name.
- **next**  
Display parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the query\_size configuration setting. The default query\_size is 100.
- **nt**  
Shows the group's details from the local Windows system in addition to the properties in the database.
- **props(all|propName [,propName ...])**  
Defines the ruler for this class for this query and future queries.
- **useprops(propName [,propName ...])**  
Defines a ruler for this query only. The class ruler is unaffected.
- **unix**  
Shows the group's details from the local UNIX system in addition to the properties in the database.

### Examples

- The user root wants to display the properties of the security group.
  - The user root has the GROUP-ADMIN attribute in the security group.
- The user admin wants to display the properties of all enterprise groups.
  - The user admin has the ADMIN and AUDITOR attributes.

```
showgrp security
```

```
showxgrp *
```

The properties of all enterprise groups defined to Privileged Access Manager are listed.

## showres Command Display Resource Properties

### Valid in the AC environment

The showres command displays the properties of resources belonging to classes in the database. The properties are listed in alphabetical order. The following classes can be listed using the showres command: ACVAR, ADMIN, CATEGORY, CONNECT, FILE, GHOST, GSUDO, GTERMINAL, HOST, HOSTNET, HOSTNP, SECFILE, SECLABEL, SUDO, SURROGATE, TERMINAL, PROGRAM, PROCESS, TCP, UACC, and any user defined class. Privileged Access Manager processes each resource independently and displays information only for those resources for which you have sufficient authority.

#### NOTE

This command also exists in the native Windows environment but operates differently there.

showres also displays information about any programs that have become untrusted. The information includes:

- The reason that the program became untrusted.
- The UID of the last user to access the program (not necessarily the user who caused the program to become untrusted).
- The date and time that this user accessed the program.

You can execute a showres command if at least one of the following conditions is true:

- You have at least one of the following attributes: ADMIN, AUDITOR, and OPERATOR.
- You are the owner of the resource.
- You are assigned read authority in the access control list of the object representing the resource class record in the ADMIN class.

This command has the following format:

```
{showres|sr} classNameresourceName \

[addprops(propName [,propName...])] \

[next] \

[props(all | propName [,propName...])] \

[useprops(propName [,propName...])]
```

- **addprops(propName [,propName...])**  
Defines properties to be added to the current ruler for this query only.
- **className**  
Specifies the name of the class to which the resource belongs. To list the resource classes defined to Privileged Access Manager, use the find command.
- **next**  
Displays parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the query\_size configuration setting. The query size default is set at 100.
- **props(all|propName [,propName ...])**  
Defines a new ruler for this class for this query and future queries.
- **resourceName**

Specifies the name of the resource record whose properties are to be listed. When listing the properties of more than one resource, enclose the list of resource names in parentheses and separate the resource names with a space or a comma.

Privileged Access Manager processes each resource record independently. If an error occurs while processing a resource, Privileged Access Manager issues a message and continues processing with the next resource in the list.

*resourceName* can contain wildcard characters.

On UNIX, to display the properties of a single resource record whose name contains a special character or space, type an extra slash (/) before the resource name.

- `useprops(propName [,propName ...])`  
Defines a ruler for this query only. The class ruler is unaffected.

### Example: List record properties

In this example the user Admin1 wants to list the properties of the records whose names match the mask `ath*` in the `TERMINAL` class.

User Admin1 has the `ADMIN` and `AUDITOR` attributes.

```
showres TERMINAL ath*
```

### Example: List host attributes

In this example the user Admin1 lists the attributes of the local host in the `HNODE` class.

```
PAMSC> showres HNODE '__local__'
```

```
(localhost)
```

```
Data for HNODE '__local__'
```

```
-----
```

```
Owner           : LOCALHOST\Administrator (USER)
```

```
Create time     : 13-Oct-2010 11:12
```

```
Update time     : 13-Oct-2010 11:13
```

```
Updated by      : LOCALHOST\Administrator (USER)
```

```
Attributes      :
```

```
REGISTERED_NAME=localhost.domain.com
```

```
MAC_ADDRESS=00-50-56-B5-6B-XD
```

In this example, the command returns the following attributes:

- `REGISTERED_NAME=localhost.domain.com`
- `MAC_ADDRESS=00-50-56-B5-6B-XD`

## show x usr Command Display User Properties

### Valid in the AC environment

The show[x]usr command displays the values of all the properties of one or more users defined to Privileged Access Manager.

Use showusr to display the properties of internal users. Use showxusr to display the properties of enterprise users.

#### NOTE

The showusr command also exists in the native environment but operates differently there.

You can always list the properties of your own user record. To list properties of another user's record, one of the following conditions must be true:

- You are the owner of the user record.
- You have at least one of the following attributes: ADMIN, AUDITOR, and OPERATOR.
- The user record is within the scope of a group in which you have at least one of the following group attributes: ADMIN, AUDITOR, OPERATOR.
- You are assigned read authority in the access control list of the USER record in the ADMIN class.

This command has the following format:

```
{showusr|su |showxusr |sxu } [ {userName |(userName [,userName...]) } ] \
[addprops(propName [,propName...])] \
[next] \
[props( all | propName [,propName...])] \
[useprops(propName[,propName...])] \
[nt|unix]
```

- **addprops(propName [,propName...])**  
Defines properties to be added to the current ruler for this query only.
- **next**  
Displays parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the query\_size configuration setting. The query size default is set at 100.
- **nt**  
Displays the user Windows' properties in addition to the properties in the database.
- **props(all|propName [,propName ...])**  
Defines a new ruler for this class for this query and future queries.
- **unix**  
Displays the user's UNIX properties in addition to the properties in the database.
- **userName**  
Defines the name of a user. It can include wildcard characters.  
On UNIX, to display the properties of a single user record whose name contains a special character or space, type an extra slash (/) before the group name.  
If you do not specify *userName*, the command displays the properties of your own user record.
- **useprops(propName [,propName ...])**  
Defines a ruler for this query only. The class ruler is unaffected.

### Examples

- The user root wants to list the properties of enterprise user Robin. The root has ADMIN and AUDITOR attributes.  
`showxusr Robin`
- The user root wants to list the user properties of enterprise users Robin and Leslie. The root has ADMIN and AUDITOR attributes.  
`showxusr (Robin,Leslie)`

## source Command Execute Commands from a File

### Valid in all environments

The source command allows you to execute one or more selang commands that have been placed in a file. Privileged Access Manager reads the specified file, executes the commands, and returns a selang prompt. Any user defined in the database can use this command.

This command is like the source command in csh and tcsh in UNIX.

This command has the following format:

```
source fileName
```

- **fileName**  
Specifies the name of the file that contains the selang commands.

### Example

The user admin wants to execute the commands in the file called initf1. The user enters the following command:

```
source initf1
```

## start dbexport Command Initiate Database Export

### Valid in the AC environment

The start dbexport command exports the Privileged Access Manager database of the host you are connected to, and copies the output to a buffer. If you are connected to a PMDB, you can also use this command to export the PMD database.

#### NOTE

Use the get dbexport command to view the output.

This command has the following format:

```
start dbexport [pmdname(name)] [filter("CLASS, CLASS...")] [param("depend=yes")] [param("edit=yes")]
```

- **filter("CLASS, CLASS...")**  
(Optional) Defines the classes to export from the database. If you do not specify a class, all rules in the database are exported.
- **param("depend=yes")**  
(Optional) Specifies to export dependent classes along with the class that you specify in the filter parameter. When you specify this parameter, Privileged Access Manager exports the specified class and the following dependent classes:

If you export rules that modify resources in a particular class, and the class has a corresponding resource group, Privileged Access Manager also exports the rules that modify resources in that resource group.

If you export rules that modify resources in a particular resource group, Privileged Access Manager also exports the rules that modify the member resource of the resource group.

If you export rules that modify resources in a particular class and that class has a PACL, Privileged Access Manager also exports the rules that modify resources in the PROGRAM class.

If you export rules that modify resources in a particular class and that class has a CALACL, Privileged Access Manager also exports the rules that modify resources in the CALENDAR class.

If you export rules that modify resources in a particular class, and one of the resources in that class is a member of a CONTAINER resource group, Privileged Access Manager exports the rules that modify resources in the CONTAINER class and the rules that modify the resources that are members of each CONTAINER resource group.

- **param("edit=yes")**  
(Optional) Specifies that Privileged Access Manager changes each rule that creates a new resource or accessor to a rule that modifies the resource or accessor.  
**Example:** If you specify this parameter Privileged Access Manager changes all newres rules to editres rules.
- **pmdname(*name*)**  
(Optional) Defines the name of the PMD database to export.

### Example: Initiate Database Export

The following example initiates the export of rules that modify FILE and GFILE class resources. The rules are exported from seosdb, the Privileged Access Manager database on the host you are connected to.

```
start dbexport filter("FILE, GFILE")
```

### Example: Initiate Database Export with Dependent Classes

The following example initiates the export of rules that modify FILE class resources and any classes that are dependent on FILE class resources, and changes each rule that creates a new resource or accessor to a rule that modifies the resource or accessor:

```
start dbexport filter("FILE") param("depend=yes edit=yes")
```

## start devcalc Command Initiate Policy Deviation Calculation

### Valid in the AC environment

The start devcalc command initiates policy deviation calculation and sends deviation status. The deviation data is stored in a local policy deviation data file (deviation.dat) and policy deviation status is sent to a DMS through one or more set DHs. To retrieve the actual deviation data, you need to run the get devcalc command.

#### NOTE

You do not need to run the deviation calculator manually. If you use advanced policy management, the policyfetcher does this for you regularly. If you have enterprise reporting enabled, the Report Agent also does this regularly. For more information about policy deviation calculation, see the *Enterprise Administration Guide*.

To run the start devcalc command you must have terminal access rights to the computer and execute access to DEVCALC sub-administration class.

This command has the following format:

```
start devcalc [params("-pn name#xx -strict -nonotify -precise")]
```

- **-nonotify**  
(Optional) Specifies that devcalc does *not* send deviation status to the DMS through the DH.

#### NOTE

The deviation calculation command policyfetcher runs is defined in the devcalc\_command configuration setting and, by default, uses this option to avoid sending deviation status twice.

- **-pn *name#xx***  
(Optional) Defines a comma-separated list of POLICY objects (policy version) the deviation calculator should calculate differences for. If no policy is specified, the deviation calculator calculates differences for all policies deployed on the local host.
- **-strict**  
(Optional) Compares between the policies associated with the local HNODE object and the ones associated with the HNODE object on the first available DMS.

Normally, the deviation calculator checks for deviations only on the local host. If this option is specified, the deviation calculator also compares the local policies to the policies on the first available DMS in the list. It compares the:

- a. List of policies associated with the HNODE object representing the local host.
- b. Policy state of each POLICY object associated with the HNODE object.
- c. Policy signature of each POLICY object associated with the HNODE object.

Use this option when you need to validate the result of the deviation calculation.

#### NOTE

If you have a large number of endpoints running the deviation calculation simultaneously, the DMS will be heavily loaded. We recommend that you configure your endpoints to use a DMS list or divide your hierarchy into smaller hierarchies and use this option within those smaller hierarchies.

- **-precise**

(Optional) Specifies that the deviation report also displays added objects, properties, and values that exist in the endpoint database and are not found in the policy. By default, the report only displays missing and mismatched items. Use this option when you would like to view the contents on the endpoint database and compare it to the deployed policy.

#### Example: Start a Policy Deviation Calculation for a Specific Policy

The following example shows how you can use the start devcalc command to calculate policy deviations for the second version of a policy called myPolicy and send the deviation status to the DMS list specified in the local Privileged Access Manager database:

```
PAMSC> start devcalc params("-pn myPolicy#02")
```

## start\_transaction Command Start Recording Dual Control Transactions

### Valid on UNIX hosts in the AC environment

The start\_transaction and end\_transaction commands create a file that contains an unprocessed transaction for Dual Control PMDB processes, with one or more commands. The administrator (any user with the ADMIN attribute) who entered the commands in the transaction is called a Maker. The commands must be authorized by a Checker (any administrator who is *not* the Maker) before they are executed in the PMDB.

The Checker must lock transactions before they can be processed. Until the transaction is locked by the Checker, the Maker can retrieve it, change the commands, or delete it. (See the sepmdb utility in the *Reference Guide* for details.) When the Maker enters the end\_transaction command, the transaction receives a unique id number. If the Maker wants to edit or retrieve the transaction later, this identifying number must be added after the transaction's name in the start\_transaction command. When the Maker retrieves the transaction, the name of the Maker, the id number of the transaction, and a short description are displayed (if the Maker entered a description in the *transactionName* parameter).

A Maker cannot change the transactions of other Makers. The objects used in a transaction cannot be used by other Makers in different transactions until the commands have been processed.

Each unprocessed transaction stays in a separate file until a Checker processes it. The Checker can authorize or reject a transaction. If the transaction is authorized, the commands are executed and the PMDB is changed accordingly. If the Checker rejects the transaction, the commands are deleted and the PMDB is not changed.

When the end\_transaction command is entered at the end of the Maker's work, the numeric id of the transaction appears. The commands can fail for the following reasons:

- if a command refers to an object that has been used in a different transaction which has not been processed yet
- if a command pertains to the Maker-you cannot change yourself
- if a command contains invalid syntax
- if a command refers to objects that do not exist (in this case a warning message appears)
- You can execute the start\_transaction and end\_transaction commands if you have the ADMIN attribute.
- Since the hosts command must be executed before invoking the start\_transaction and end\_transaction commands, you must be authorized to use the hosts command.

**Note:** For more information on Dual Control, see the *Endpoint Administration Guide for UNIX*.

#### Usage notes:

- The hosts command must be executed before invoking the start\_transaction and end\_transaction commands, and the name of the PMDB must be maker.
- In order for the start\_transaction and end\_transaction commands to function, the value for the is\_maker\_checker token in the pmd.ini file and in the [pmd] section of the seos.ini file must be set to yes.

This command has the following format:

```
start_transaction transactionName [transactionId]
.
.
.
end_transaction
```

- **transactionName**  
Specifies the name or a description of the transaction. You can enter a string of up to 256 alphanumeric characters.
- **transactionId**  
Specifies the unique number given to the transaction when it is created. This numeric id appears automatically when you create a transaction. You must specify this id number when you update the same transaction.

#### Examples

- The Maker Sally wants to add user Anne to the PMDB, and restrict their access to the system to weekdays between 8:00 a.m. and 8:00 p.m. Then Sally wants to change the default access to the tty30 terminal to read only. Sally wants to call this transaction general.

– The Maker has the ADMIN attribute.

```
hosts maker@
start_transaction general
newusr anne
(days (weekdays) time (0800:2000))
chres TERMINAL tty30
defaccess(read)
end_transaction
```

When Sally enters the end\_transaction command, the transaction is assigned an ID number, such as seven.

- The Maker Sally wants to add the FINANCIAL category to the user Anne. Sally added the user Anne record earlier the same day, and the command has not yet been processed or implemented on the PMDB.

– The Maker has the ADMIN attribute.

```
hosts maker@
start_transaction general 7
chusr anne category(FINANCIAL)
end_transaction
```

## unalias Command Remove selang Aliases

### Valid on UNIX hosts

The unalias command removes an alias defined by the alias command.

**Note:** You can list all defined aliases and their values using the alias command.

This command has the following format:

```
unalias aliasName
```

- *aliasName*  
Specifies the name of the alias you want to delete from the database.

## undeploy Command Initiate Policy Removal

### Valid in the AC environment

This command is a synonym of the deploy- command.

## selang Commands in the Remote Configuration Environment

This section contains a complete alphabetic reference to all the selang commands that operate on the Privileged Access Manager configuration resources (commands in the config environment).

## editres config Modify Configuration Settings

### Valid in the config environment

Use the editres config command to modify Privileged Access Manager configuration settings.

The editres config command has different formats for different sets of files. These sets are:

- Audit configuration files (audit.cfg and auditrouteflt.cfg) and PMDB filter files
- All other files

This command has the following syntax for audit configuration files and PMDB filter files:

```
editres config name [line+|- (value)] [clear]
```

This command has the following syntax for all other files:

```
editres config name section(path) token[-] (name) value[+|-] (value) data_type(type)
```

- *name*  
Specifies the configuration resource you want to modify. To modify a PMDB filter file, specify the file name in the format *pmdname@filter*, for example, *master\_pmdb@filter.flt*  
**Note:** For a list of configuration resources for the host you are managing, use the *find config* command.
- *clear*  
Deletes all values from the audit configuration file or PMDB filter file.

### NOTE

This option does not delete comments from the file.

- *data\_type(type)*  
Specifies the data type of the configuration entry.  
**Values:** str, numeric, multi\_str  
**Default:** str

**NOTE**

For UNIX, `data_type` can only be `str`. Other data types are not applicable to UNIX, as it stores configuration settings in files (text strings).

- `line+(value)`  
Defines the value you want to add to the audit configuration file or PMDB filter file.

**NOTE**

The *value* can be a value or a comment.

- `line-(value)`  
Defines the value you want to remove from the audit configuration file or PMDB filter file.

**NOTE**

The *value* can be a value or a comment.

- `section(path)`  
Defines the section of the configuration resource that you want to modify.

**NOTE**

For Windows registry settings, if you do not specify this option, the command modifies the registry key *name* defines.

- `token(name)`  
Defines the name of the configuration entry that you want to modify.
- `token-(name)`  
Defines the name of the configuration entry that you want to remove.
- `value(value)`  
Defines the value that you want to assign to a configuration entry. If a value for the configuration entry already exists, Privileged Access Manager replaces the value with *value*.  
If you do not specify a *value*, the command resets the configuration entry value.
- `value+(value)`  
(Windows REG\_MULTI\_SZ registry entries only) Defines the value that you want to append to a configuration entry.  
(All other configuration values) Defines the value that you want to assign to a configuration entry. If a value for the configuration entry already exists, Privileged Access Manager replaces the value with *value*.

**NOTE**

To ensure `selang` correctly translates the assigned value, enclose the value in quotes (" ").

- `value-(value)`  
(Windows REG\_MULTI\_SZ registry entries only) Defines the value that you want to remove from a configuration entry.  
(All other configuration values) Specifies to remove any value from the configuration entry.

**Examples: Modify ACROOT Configuration Settings on Windows**

The following examples show how to modify Privileged Access Manager for Windows configuration settings.

- This example configures Privileged Access Manager to use Audit Only mode:  

```
er CONFIG ACROOT section(SeOSD) token(GeneralInterceptionMode) value(1)
```
- This example adds a domain name to the list of domain names Privileged Access Manager maintains for host name resolution. The `domain_names` registry entry is a REG\_MULTI\_SZ registry entry:  

```
er CONFIG ACROOT section(SeOSD) token(domain_names) value+(company.com)
```
- This example removes a domain name from the list of domain names Privileged Access Manager maintains for host name resolution. The `domain_names` registry entry is a REG\_MULTI\_SZ registry entry:  

```
er CONFIG ACROOT section(SeOSD) token(domain_names) value-(company.com)
```
- This example removes a configuration setting:  

```
er CONFIG ACROOT section(AccessControl) token-(Emulate)
```
- This example configures the parent Policy Model of a Policy Model on the managed host:

```
er config myPMDb@PMDROOT token(Parent_Pmd) value(topPMDb@host1.comp.ca)
```

### Examples: Modify seos.ini Configuration Settings on UNIX

The following examples show how to modify Privileged Access Manager for UNIX configuration settings.

- This example configures Privileged Access Manager to enable PAM authentication:  

```
er CONFIG seos.ini section(seos) token(pam_enabled) value(yes)
```
- This example configures the domain name that Privileged Access Manager maintains for host name resolution:  

```
er CONFIG seos.ini section(seosd) token(domain_names) value+(company.com)
```
- This example removes the domain name that Privileged Access Manager maintains for host name resolution:  

```
er CONFIG seos.ini section(seosd) token(domain_names) value-(company.com)
```
- This example removes a configuration setting:  

```
er CONFIG seos.ini section(serevu) token-(admin_user)
```

### Example: Modify Audit Configuration File

The following example adds a line to the audit configuration file:

```
er CONFIG audit.cfg line+("FILE;*;Administrator;*;R;P")
```

### Example: Modify PMD Filter File

The following example adds a line to the PMD filter file:

```
er config pmdb@filter line+("*;*;USER;*;OLD_PASSWD;PASS")
```

## find config List Configuration Resources

### Valid in the config environment

The find config command lists the Privileged Access Manager configuration resources for the host you are managing. These resources can be registry keys or configuration files.

Possible resources vary by host type:

UNIX	Windows
seos.ini	ACROOT
pmd.ini@ <i>pmd_name</i>	pmd_name@PMDROOT
	SEOSDRV

This command has the following format:

```
find config
```

### NOTE

This command does not return a list of audit.cfg or auditrouteflt.cfg configuration files.

### Example: List Configuration Resources for a Windows Host

The following example shows the output of the find config command on a Windows host that has a Policy Model named pmdb:

```
PAMSC(config)> find config
```

```
(localhost)
```

```
pmdb@PMDROOT
```

```
ACROOT
```

```
SEOSDRV
```

## showres config Display Configuration Information

### Valid in the config environment

Use the showres config command to display Privileged Access Manager configuration information.

The showres config command has different formats for different sets of files. These sets are:

- Audit configuration files (audit.cfg and auditrouteflt.cfg) and PMDB filter files
- All other files

This command has the following syntax for audit configuration files and PMDB filter files:

```
showres config name
```

This command has the following syntax for all other files:

```
showres config name [section(path)] [token(name)] [recursive] [section_only]
```

- **name**  
Specifies the configuration resource you want to view information about. To view information about a PMDB filter file, specify the file name in the format *pmdbname@filter*, for example, master\_pmdb@filter.flit

#### NOTE

For a list of configuration resources for the host you are managing, use the *find config* command.

- **section(path)**  
(Optional) Defines the section of the configuration resource that you want to view information about. If you do not specify this option, the command lists all of the configuration entries and sections in the *name* configuration resource.
- **token(name)**  
(Optional) Defines the name of the configuration entry that you want to view information about. If you do not specify this option, the command lists all configuration entries and sections in the section(*path*) you defined.
- **recursive**  
Specifies to display information about all configuration entries and sections in all sub sections.
- **section\_only**  
Specifies to display information about sections only (no configuration entries will be listed).

## selang Commands in the Native UNIX Environment

This section contains a complete alphabetic reference to all the selang commands that operate on the UNIX system files (commands in the native UNIX environment).

**Use the table of contents to access the topics in this section.**

## chfile Command Modify UNIX File Settings

### Valid in the native UNIX environment

The chfile and editfile commands change the settings of one or more UNIX files.

#### NOTE

This command also exists in the AC environment but operates differently.

This command has the following format:

```
{{chfile|cf}}{{editfile|ef}} fileName \
[owner(userName)] \
[group(groupName)] \
[mode( \[fowner(string)] \[fgroup(string)] \[fother(string)] \
)]
```

- **fileName**  
Specifies the name of the file whose settings are to be changed. Enter at least one UNIX file name. When changing more than one file, enclose the list of file names in parentheses and separate the file names with a space or a comma.
- **group(groupName)**  
Changes the group to which the file belongs. Specify a valid group name.
- **mode**  
Updates the access modes of the file.
- **fowner(string)**  
Specifies the access modes for the owner of the file. Use the letters r, w, and x in *string* to assign read, write, and execute permissions, respectively. Use the letter s to make a file setuid.  
Specify a plus sign (+) at the beginning of *string* to add permissions to the existing permissions. Specify a minus sign (-) at the beginning of *string* to remove the permissions. If you do not specify a prefix, the previous permissions are reset to *string*.
- **fgroup(string)**  
Specifies the access modes for the file's group. Use the letters r, w, and x in *string* to assign read, write, and execute permissions, respectively. Use the letter s to make a file setgid.  
Specify a plus sign (+) at the beginning of *string* to add permissions to the existing permissions. Specify a minus sign (-) at the beginning of *string* to remove the permissions. If you do not specify a prefix, the previous permissions are reset to *string*.
- **fother(string)**  
Specifies the access modes that apply to other accessors. Use the letters r, w, and x in *string* to assign read, write, and execute permissions, respectively. Specify a plus sign (+) at the beginning of *string* to add permissions to the existing permissions. Specify a minus sign (-) at the beginning of *string* to remove the permissions. If no prefix is specified, the previous permissions are reset to *string*.
- **owner(userName)**  
Changes the owner of the file. Specify the user name of a valid UNIX user.

## chgrp Command Modify UNIX Groups

### Valid in the native UNIX environment

Use the chgrp, editgrp, and newgrp commands to work with UNIX groups. These commands are identical in structure and only vary in the following way:

- The chgrp command *modifies* one or more UNIX groups.
- The editgrp command *creates or modifies* one or more UNIX groups.
- The newgrp command *creates* one or more UNIX groups.

**NOTE**

Groups are read, added, updated, and deleted from the file specified in the configuration settings (seos.ini); by default, this file is /etc/group. For more information, see the *Endpoint Administration Guide for UNIX*.

**NOTE**

This command also exists in the AC environment but operates differently.

This command has the following format:

```
{{chgrp|cg}}|{{editgrp|eg}}|{{newgrp|ng}} groupName \
[groupid(integer)] \
[userlist(userNames)]
```

- **groupid(integer)**  
Sets the group ID of the group. Enter a positive integer representing the group's unique numeric ID. Privileged Access Manager does not allow a group ID of zero.
- **groupName**  
Specifies the name of the group to be modified. Specify the name of an existing UNIX group. When altering more than one group, enclose the list of group names in parentheses and separate group names with a space or a comma.
- **userlist(userNames)**  
Specifies a new member list. Each user name must already be defined to UNIX. When more than one user is in the list, separate the user names with a space or comma. The user list specified here replaces any previous user list defined to the group.

## chusr Command Modify UNIX Users

### Valid in the native UNIX environment

Use the chusr, editusr, and newusr commands to work with UNIX users. These commands are identical in structure and vary only in the following ways:

- The chusr command *modifies* one or more UNIX users.
- The editusr command *creates or modifies* one or more UNIX users.
- The newusr command *creates* one or more UNIX users.

**NOTE**

Users are read, added, updated, and deleted from the file specified in the configuration settings (seos.ini); by default, this file is /etc/passwd. For more information, see the *Endpoint Administration Guide for UNIX*.

**NOTE**

This command also exists in the Privileged Access Manager environment but operates differently there.

This command has the following format:

```
{{chusr|cu}}|{{editusr|eu}}|{{newusr|nu}} userName \
[enable] \
[gecos(string)] \
[homedir({path|nohomedir})] \
[password(string)] \
[pgroup(groupName)] \
[shellprog(path)] \
[userid(number)]
```

- **enable**  
Enables the login of a user account that was disabled for any reason. This is a chusr and editusr parameter.
- **gecos(string)**

Specifies a string containing general comments about the user, such as the user's full name. Enclose the string in single quotation marks.

- **homedir(*path*|nohomedir)**  
Specifies the full path of the user's home directory. Privileged Access Manager attempts to create the directory. If the path you specify ends with a slash, *groupname* is concatenated to the specific path. The UNIX file is updated, regardless of whether Privileged Access Manager successfully creates the home directory.  
If you specify nohomedir, UNIX does not create a homedir for the user.
- **password(*string*)**  
Assigns a password to the user. Specify any character except a blank space. The password is valid for one login only. When the user next logs in to the system, a new password must be set.
- **pgroup(*groupName*)**  
Specifies the user's primary group name.
- **shellprog(*path*)**  
Specifies the full path of the initial program or shell that is executed after the user invokes the login command or the su command.
- **userid(*number*)**  
Specifies the user's unique numeric ID, used for unique discretionary access control. Enter a decimal number greater than 100; values less than 100 are not accepted.
- **userName**  
The name of an existing UNIX user. When changing more than one user, enclose the list of user names in parentheses and separate the names with a space or a comma.

## editfile Command Modify UNIX File Settings

### Valid in the native UNIX environment

This command is documented with the chfile command.

## editgrp Command Create and Modify UNIX Groups

### Valid in the native UNIX environment

This command is documented with the chgrp command.

## editusr Command Create and Modify UNIX Users

### Valid in the native UNIX environment

This command is documented with the chusr command.

## find file Command List Native Files

### Valid in the native environment

Use the find file command to list all the system files that match the mask, which is a string. The files are ordered chronologically in one column.

This command has the following format:

```
find file [directory] [/mask]
```

- *directory*  
Lists all the files in the directory *directory*.
- *mask*  
Lists all the files in the directory *directory* that match the *mask* variable. The *mask* may include wildcard characters.

### Example: Find Executable Program Files in a Specific Path on Windows

The following command lists all executable files in the Privileged Access Manager bin directory:

```
find file C:\Program\Files\CA\PAMSC\bin\*.exe
```

### Example: Find Files Matching a Pattern on UNIX

The following command lists all files in the Privileged Access Manager bin directory that begin with the letter se:

```
find file <installpath2>/bin/se*
```

## join Command Add Users to Native Groups

### Valid in the native environments

The join command adds users to a group. The specified users and group must already be defined to native OS.

#### NOTE

This command also exists in the AC environment but operates differently.

To use the join command, at least one of the following must be true:

- You have the ADMIN attribute in your Privileged Access Manager user record.
- The group record is within the scope of a group in which you have the GROUPADMIN attribute.
- You are the owner of the group record in the database.
- You have JOIN or MODIFY access authority in the access control list of the GROUP record in the ADMIN class.

#### NOTE

Both the MODIFY and JOIN properties are required if an ADMIN is to have the authority to modify Privileged Access Manager GROUP records and native groups.

This command has the following format:

```
{join|j} userName group(groupName)
```

- *group(groupName)*  
Specifies the native group to which the users are being added.
- *userName*  
Specifies the user name of the native user who is being connected to the group specified by the group parameter. When specifying more than one user, enclose the user names in parentheses and separate the user names with a space or a comma.

### Example

The user Eli wants to join the user Bob to the group staff.

- Eli has the ADMIN attribute and the current environment is *native*.

```
join Bob group(staff)
```

## join- Command Remove Users from Native Groups

### Valid in the native environments

The join command removes users from a group.

#### NOTE

This command also exists in the AC environment but operates differently.

To use the join command, one of the following conditions must be true:

- You have the ADMIN attribute.
- The group record is within the scope of a group in which you have the GROUPADMIN attribute.
- You are the owner of the group record in the database.
- You have JOIN or MODIFY access authority in the access control list of the GROUP record in the ADMIN class.

If you only have ownership of the user's profile, you do not have sufficient authority to remove the user from a group. Both the MODIFY and JOIN properties are required if an ADMIN is to have the authority to modify Privileged Access Manager records and native groups

This command has the following format:

```
{join
  |j
} userName group(groupName)
```

- **group(groupName)**  
Specifies the native group from which to remove the user.
- **userName**  
Specifies the user name of the user you want to remove from the group. When removing more than one user from the group, enclose the list of user names in parentheses and separate the user names with a space or a comma.

### Example

The user Bill wants to remove the users sales25 and sales43 from the PAYROLL group.

- The user Bill has the ADMIN attribute and the current environment is *native*.

```
join
(sales25 sales43) group(PAYROLL)
```

## newgrp Command Create UNIX Groups

### Valid in the native UNIX environment

This command is documented with the chgrp command.

## newusr Command Create UNIX Users

### Valid in the native UNIX environment

This command is documented with the chusr command.

## rmgrp Command Delete UNIX Groups

### Valid in the native UNIX environment

The rmgrp command deletes one or more groups from the UNIX system.

**NOTE**

This command also exists in the AC environment but operates differently.

**NOTE**

Groups are read, added, updated, and deleted from the file specified in the configuration settings (seos.ini); by default, this file is /etc/group. For more information, see the *Endpoint Administration Guide for UNIX*.

This command has the following format:

```
{rmgrp|rg} groupName
```

- **groupName**  
Specifies the name of the group to be deleted. The group name must be an existing UNIX group name. Specify one or more group names. When removing more than one group, enclose the list of group names in parentheses and separate the group names with a space or a comma.

## rmusr Command Delete UNIX User

### Valid in the native UNIX environment

The rmusr command removes one or more users from the UNIX system.

**NOTE**

This command also exists in the AC environment but operates differently.

**NOTE**

Users are read, added, updated, and deleted from the file specified in the configuration settings (seos.ini); by default, this file is /etc/passwd. For more information, see the *Endpoint Administration Guide for UNIX*.

This command has the following format:

```
{rmusr|ru} userName
```

- **userName**  
Specifies the user name of an existing UNIX user. When removing more than one user, enclose the list of user names in parentheses and separate the user names with a space or a comma.

## showfile Command Display Native File Properties

### Valid in the native environments

The showfile command lists the native details of one or more system files.

**NOTE**

This command also exists in the AC environment but operates differently.

This command has the following format:

```
{showfile|sf} fileName [next] \
[{{props|addprops} (propNames)}]
```

- **addprops(propName)**  
Sets the properties (ruler) to be displayed. The list of properties is added to the current ruler. The ruler is set for this query only, and reverts to the previously set ruler.
- **fileName**  
Specifies the name of the file whose details are to be listed. Enter one or more UNIX file names. When specifying more than one file, enclose the list of file names in parentheses and separate the individual names with a space or a comma.
- **next**

Displays parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the `query_size` configuration setting. The query size default is set at 100.

- `props(all|propName)`  
Sets the properties (ruler) to be displayed.  
The ruler remains set for future queries.

### Example: Show the Details of a UNIX File

You want to list the details of the UNIX file `/tmp/foo`.

```
showfile /tmp/foo
```

### Example: Show the Owner of a Windows File

You want to know who the owner of the Windows file `C:\tmp\foo.exe` is.

```
showfile C:\tmp\foo.exe props (Owner)
```

## showgrp Command Display Native Group Properties

### Valid in the native environments

The `showgrp` command displays the details of one or more groups in the native operating system.

#### NOTE

This command also exists in the AC environment but operates differently.

#### NOTE

On UNIX, groups are read, added, updated, and deleted from the file specified in the configuration settings (`seos.ini`); by default, this file is `/etc/group`. For more information, see the *Endpoint Administration Guide for UNIX*.

This command has the following format:

```
{showgrp|sg} groupName [next] \
[ {props|addprops} (propNames) ]
```

- `addprops(propName)`  
Sets the properties (ruler) to be displayed. The list of properties is added to the current ruler. The ruler is set for this query only, and reverts to the previously set ruler.
- `groupName`  
Specifies the name of the group whose details are to be displayed. The group name must be an existing native group name. Specify one or more group names. When listing more than one group, enclose the list of group names in parentheses and separate the group names with a space or a comma.
- **next**  
Displays parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the `query_size` configuration setting. The query size default is set at 100.
- `props(all|propName)`  
Sets the properties (ruler) to be displayed.  
The ruler remains set for future queries.

### Example

To list details of the UNIX group *security* when you are in the *unix* environment, enter the following command:

```
showgrp security
```

## showusr Command Display Native User Properties

### Valid in the native UNIX environment

The showusr command displays the properties of one or more users defined in the native operating system.

#### NOTE

This command also exists in the AC environment but operates differently.

#### NOTE

On UNIX, users are read, added, updated, and deleted from the file specified in the configuration settings (seos.ini); by default, this file is /etc/passwd. For more information, see the *Endpoint Administration Guide for UNIX*.

This command has the following format:

```
{showusr|su} userName [next] \
[{props|addprops} (propNames) ]
```

- **addprops(propName)**  
Sets the properties (ruler) to be displayed. The list of properties is added to the current ruler. The ruler is set for this query only, and reverts to the previously set ruler.
- **userName**  
Specifies the name of the user whose native properties are to be displayed. Specify an existing native user name. When listing the properties of more than one user, enclose the list of user names in parentheses and separate the names with a space or a comma.
- **next**  
Displays parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the query\_size configuration setting. The query size default is set at 100.
- **props(all|propName)**  
Sets the properties (ruler) to be displayed. The ruler remains set for future queries.

### Example

To list details of the UNIX user *leslie* when you are in the *unix* environment, enter the following command:

```
showusr leslie
```

## selang Commands in the Native Windows Environment

This section contains a complete alphabetic reference to all the selang commands that operate on the native Windows environment.

**Use the table of contents to access the topics in this section.**

## authorize Command Set Accessors Authority to Access Windows Resources

### Valid in the native Windows environment

The authorize command maintains the lists of users and groups authorized to access a particular resource. Using authorize, you can change a list to:

- Permit access to a resource for specific Privileged Access Manager users or groups.
- Block access to a resource for specific Privileged Access Manager users or groups.
- Change the level of access authority to a resource for specific users or groups.

**NOTE**

This command also exists in the AC environment but operates differently.

The following Windows environment classes support ACLs, and can be controlled by the authorize command.

- COM
- DISK
- FILE
- PRINTER
- REGKEY
- SHARE

Classes that do not appear in the list have no access control lists and cannot be controlled by the authorize command.

This command has the following format:

```
{authorize|auth} classNameresourceName \
[access(accessValue)|deniedaccess(accessvalue)] \
[gid(groupName, ...)] \
[uid(userName, ...)]
```

- **access(*accessValue*)**  
Specifies the access authority you want the accessors you identify in the uid or gid parameters to have to the resource.
- **className**  
Specifies the name of the class to which *resourceName* belongs.
- **deniedaccess(*accessvalue*)**  
Specifies the negative access authority that you want accessors, who you identify in the uid or gid parameters, to have to the resource.  
The denied *accessvalue* can be: all, create, delete, join, modify, none, password, or read.

**NOTE**

You can only use *accessValue* with the authorize command, not with authorize-.

- **gid(*groupName*)**  
Specifies the Windows group or groups whose access authority to the resource you are setting. The value *groupName* represents the name of one or more Windows groups. When specifying more than one group, separate the group names with a space or a comma.
- **resourceName**  
The name of the resource record to modify or add. When changing or adding more than one resource, enclose the list of resource names in parentheses and separate the resource names with a space or a comma. At least one resource name must be specified.  
Privileged Access Manager processes each resource record independently in accordance with the specified parameters. If an error occurs while processing a resource, Privileged Access Manager issues a message and continues processing with the next resource in the list.
- **uid(*userName*)**  
Specifies the Windows users whose access authority to the resource you are setting. *userName* is the user name of one or more Windows users. When specifying more than one user, separate the user names with a space or a comma. To specify all users who are defined in Windows, specify an asterisk (\*) for *userName*.

## authorize- Command Remove Accessors' Authority to Access Windows Resources

### Valid in the native Windows environment

The authorize- command removes the access authority to a resource by deleting the accessors from the standard access control list. This leaves the default access to determine accessors' ability to access a particular resource.

**NOTE**

This command also exists in the AC environment but operates differently.

This command has the following format:

```
{authorize|auth-} classNameresourceName \
[gid(groupName, ...)] \
[uid(userName, ...)]
```

- **className**  
Specifies the name of the class to which *resourceName* belongs.
- **gid(groupName)**  
Specifies the Windows group or groups whose access authority to the resource you are setting. The value *groupName* represents the name of one or more Windows groups. When specifying more than one group, separate the group names with a space or a comma.
- **resourceName**  
Specifies the name of the resource record to modify or add. When changing or adding more than one resource, enclose the list of resource names in parentheses and separate the resource names with a space or a comma. At least one resource name must be specified.  
Privileged Access Manager processes each resource record independently in accordance with the specified parameters. If an error occurs while processing a resource, Privileged Access Manager issues a message and continues processing with the next resource in the list.
- **uid(userName)**  
Specifies the Windows users whose access authority to the resource you are setting. *userName* is the user name of one or more Windows users. When specifying more than one user, separate the user names with a space or a comma. To specify all users who are defined in Windows, specify an asterisk (\*) for *userName*.

## chfile Command Modify Windows File Settings

### Valid in the native Windows environment

The chfile and editfile commands are identical. They modify one or more Windows files.

**NOTE**

This command also exists in the AC environment but operates differently.

This command has the following format for NTFS file systems:

```
{{chfile|cf}}{{editfile|ef}} fileName \
[attrib(attributeValue)] \
[attrib(-attributeValue)] \
[defaccess(accessValue)] \
[owner(userName|groupName)]
```

This command has the following format for FAT file systems:

```
{{chfile|cf}}{{editfile|ef}} fileName \
[attrib([-]attributeValue)]
```

- **attrib([-]attributeValue)**  
Specifies a set of attributes that determine the character of the file. When a minus sign (-) precedes the argument *value*, this parameter removes the attribute.
- **defaccess(accessValue)**  
Specifies the access authority for the Native security built-in group Everyone. All the system users are members of the Everyone group. Providing access to the Everyone group covers all the potential anonymous users in addition to all authenticated users.

**NOTE**

Default access for an object defined in the Privileged Access Manager environment has a different meaning; the default access authority is the authority granted to any accessor who is not in the resource's Privileged Access Manager list who requests access to the resource. The default access also applies to users not defined in Privileged Access Manager.

The defaccess parameter applies only to NTFS file systems.

- **owner(*userName|groupName*)**  
Assigns a user or group as the owner of the file record. The owner of the file record has unrestricted access to the file. The owner of the file may always update or delete the file record.

## chgrp Command Modify Windows Groups

### Valid in the native Windows environment

Use the chgrp, editgrp, and newgrp commands to work with Windows groups. These commands are identical in structure and only vary in the following way:

- The chgrp command *modifies* one or more Windows groups.
- The editgrp command *creates or modifies* one or more Windows groups.
- The newgrp command *creates* one or more Windows groups.

**NOTE**

This command also exists in the AC environment but operates differently.

When defining more than one group or changing the properties of more than one group, enclose the list of group names in parentheses and separate the group names with a space or a comma.

**NOTE**

To add or remove members from a group use the join or join- command.

This command has the following format:

```
{{chgrp|cg}}{{editgrp|eg}}{{newgrp|ng}} groupName \
[global] \
[comment(string)|comment-] \
[privileges(privList)] \
[privileges(-privList)] \
[rename_group]
```

- **comment(*string*)**  
Adds an alphanumeric comment string of up to 255 characters to the group record. If you previously added a comment string to the group record, the new string specified here replaces the existing string. If the string contains any blanks, enclose the entire string in single quotation marks.  
Standard Windows groups have a descriptive comment added on system installation. If you create a new group in both the Windows and AC environments, Privileged Access Manager inserts the comment Privileged Access Manager Group.
- **global**  
Indicates a global group. Each group name must be unique and cannot currently exist in the Windows database. Windows does not allow groups and users to share the same name.

**NOTE**

Use *~groupName* when you create global groups and use the services of Privileged Access Manager version 4.1. Version 4.1 and above support this format for backward compatibility.

- *groupName*

**NOTE**

For the command `newgrp`, specifies the name of the group record added to the database. Each group name must be unique and must not currently exist in the Windows database. Unlike the Privileged Access Manager database, Windows does not allow groups and users to share the same name.

For the command `chgrp`, specifies the name of the group whose properties you are changing.

When defining more than one group or changing the properties of more than one group, enclose the list of group names in parentheses and separate the group names with a space or a comma.

- `privileges(privList[-privList])`

Adds specific rights to the Windows group record or, when `privList` is preceded by a minus sign (-), removes the specified rights. Valid values are any of the privileges available in native Windows.

You can specify this parameter only with the `chgrp` or `editgrp` command, and only when you are changing an existing group record. You cannot use it to assign privileges when you are creating a new group record.

- `rename_group`

Renames the group account in the Windows database. All the properties of the old group name apply to the renamed group account. Each group name must be unique and must exist in the Windows database. Unlike the Privileged Access Manager database, Windows does not allow groups and users to share the same name.

**NOTE**

When Privileged Access Manager is installed on Windows 2000 with Active Directory, it renames the pre-Windows 2000 group name.

## chres Command Modify Windows Resources

### Valid in the native Windows environment

Use the `chres`, `editres`, and `newres` commands to work with resource records that belong to a Privileged Access Manager class in the Windows environment. These commands are identical in structure and only vary in the following way:

- The `chres` command *modifies* one or more resources.
- The `editres` command *creates or modifies* one or more resources.
- The `newres` command *creates* one or more resources.

**NOTE**

This command also exists in the AC environment but operates differently.

This command has the following formats:

```
{{chres|cr}}{{editres|er}}{{newres|nr}} classNameresourceName \
[comment(string)|comment-] \
[defaccess(accessValue)] \
[dword(integer)|string(string)|binary(hexastring)|multistring(string)] \
[location(string)|location()] \
[maxusers(integer)] \
[owner(userName|groupName)] \
[share_name(string)|sharename-]
```

or

```
{{chres|cr}}{{editres|er}}{{newres|nr}} \
DOMAIN resourceName \
[computer(workstationName)|computer-(workstationName)] \
[domainpwd(connectPassword)] \
[trusted(domainName)|trusted-(domainName)]
```

- `binary(hexastring)`

Specifies the value of a registry key when it is a hexadecimal.

- *className*  
Specifies the name of the class to which *resourceName* belongs.  
For the newres command, valid values are: REGKEY, REGVAL, OU, and SHARE. For the chres and editres commands, valid values are: COM, DISK, DOMAIN, FILE, PRINTER, REGKEY, REGVAL, SERVICE, DEVICE, SESSION, OU, and SHARE.
- *comment(string)*  
Adds a comment string to the resource record. If you previously added a comment string to the resource record, the new string specified here replaces the existing string. This parameter is valid for SHARE and PRINTER resources only.
- *computer(workstationName)|computer-(workstationName)*  
Specifies the name of the workstation you are adding to the domain, or, when a minus sign precedes the argument, the name of the workstation you are removing from the domain. This parameter can only be used with DOMAIN resources. You can specify this parameter only with the chres or editres command.
- *defaccess(accessValue)*  
Specifies the access authority for the Native security built-in group Everyone. All the system users are members of the Everyone group. Providing access to the Everyone group covers all the potential anonymous users in addition to all authenticated users.

#### NOTE

Defaccess for an object defined in the Privileged Access Manager environment has a different meaning; the default access authority is the authority granted to any accessor who is not in the resource's Privileged Access Manager list who requests access to the resource. The default access also applies to users not defined in Privileged Access Manager.

The defaccess parameter applies only to NTFS file systems.

- *domainpwd(connectPassword)*  
Specifies the password an administrator must enter when changing trust relationships.  
This parameter can only be used with DOMAIN resources. You can specify this parameter only with the chres or editres command.
- *dword(integer)*  
Specifies the value of a registry key when it is an integer.
- *gen\_prop(propertyName)*  
Specifies the property for the OU class.  
This parameter is valid for the OU class only.
- *gen\_value(valueName)*  
Specifies the property value for the OU class.  
This parameter is valid for the OU class only.
- *location(string)*  
Indicates the location of a printer. Use ( ) with blanks to remove this property.  
This parameter is valid for PRINTER resources only.
- *maxusers(integer)*  
Specifies the maximum number (*integer*) of users that can connect to a shared directory at one time.  
This parameter is valid for SHARE resources only.
- *multistring(string)*  
Specifies the value of a registry key when it is a multistring.
- *owner(userName|groupName)*  
Assigns a user or group as the owner of the resource record. The owner of the resource record has unrestricted access to the resource. The owner of the resource is always permitted to update and delete the resource record. For more information, see the *Endpoint Administration Guide for Windows*.  
For FILE or SHARE records on a FAT file system, you may not specify the owner parameter. This parameter is also not valid for DEVICE, DOMAIN, OU, PROCESS, REGVAL, SERVICE, and SESSION resources.
- *resourceName*

The name of the resource record to modify or add. When changing or adding more than one resource, enclose the list of resource names in parentheses and separate the resource names with a space or a comma. At least one resource name must be specified.

Privileged Access Manager processes each resource record independently in accordance with the specified parameters. If an error occurs while processing a resource, Privileged Access Manager issues a message and continues processing with the next resource in the list.

- `share_name(shareName)|share_name-`  
Identifies the share point for a printer.  
This parameter is valid for PRINTER resources only.
- `string(string)`  
Specifies the value of a registry key when it is a string.
- `trusted(domainName) | trusted-(domainName)`  
Specifies the name of the domain you are adding to trusted domains, or, when a minus sign precedes the argument, the name of the domain you are untrusting. This parameter can only be used with DOMAIN resources. You can specify this parameter only with the `chres` or `editres` command.

## chusr Command Modify Windows Users

### Valid in the native Windows environment

Use the `chusr`, `editusr`, and `newusr` commands to work with Windows users. These commands are identical in structure and only vary in the following way:

- The `chusr` command *modifies* one or more Windows users.
- The `editusr` command *creates or modifies* one or more Windows users.
- The `newusr` command *creates* one or more Windows users.

### NOTE

This command also exists in the AC environment but operates differently.

This command has the following format:

```
{ {chusr|cu} | {editusr|eu} | {newusr|nu} } userName \
[comment(string)|comment-] \
[country(string)] \
[expire|expire(mm/dd/yy[@hh:mm])|expire-] \
[flags( (accountFlags) |-(accountFlags) )] \
[full_name(fullName)] \
[homedir(homeDir)] \
[homedrive(homeDrive)] \
[location(string)] \
[logonserver(serverName)] \
[organization(name)] \
[org_unit(name)] \
[password(password)] \
[pgroup(primaryGroup)] \
[phone(string)] \
[privileges(privList)] \
[profile(path)] \
[restrictions( \days({[mon] [tue] [wed] [thu] [fri] [sat] [sun] }|anyday|weekdays) \time(startTime:endTime|
anytime))]\
[restrictions-] \
[resume[(date)]|resume-] \
[script(logonScriptPath)] \
```

```
[suspend[(date)] | suspend-] \
[terminals (terminalList) | terminals- (terminalList)] \
[workstations (workstationList) | workstations- (workstationList) | workstations-]
```

- **comment(*string*)|comment-**  
Assigns a comment string to the user record.  
The argument is an alphanumeric string of up to 255 characters. If the string contains any blanks, enclose the entire string in single quotation marks.
- **country(*string*)**  
Specifies the country where the user is located. This string is not used during the authorization process.  
The argument is an alphanumeric string of up to 19 characters. If the string contains any blanks, enclose the entire string in single quotation marks.
- **expire|expire(*mm/dd/yy*[@*hh:mm*]) | expire-**  
Sets the date on which the user's account expires. If a date is not specified, the user account expires immediately, provided the user is not currently logged in. If the user is logged in, the account expires when the user logs out.  
expire- with the newusr command defines a user account that does not have an expiration date. For the chusr and editusr commands, it removes an expiration date from the specified user account.  
The date argument takes the format: *mm/dd/yy* [@*hh:mm*].
- **flags(*accountFlags*)|- *accountFlags*)**  
Specifies particular attributes of a user's account. See the appendix Windows Values for a list of valid flag values.  
To remove flags from the user record, precede *accountFlags* with a minus (-).
- **full\_name(*fullName*)**  
Specifies the full name of the user associated with the user record.  
The argument is an alphanumeric string of up to 256 characters. If the string contains any blanks, enclose the entire string in single quotation marks.
- **gecos(*string*)**  
Specifies a comment string for the user, such as the user's full name. Enclose the string in single quotation marks.
- **homedir(*homeDir*)**  
Specifies the user's home directory. Users log in automatically to their own home drives and home directories.
- **homedrive(*homeDrive*)**  
Specifies the drive of the user's home directory. Users log in automatically to their own home drives and home directories.
- **location(*string*)**  
Specifies the user's location. This string is not used during the authorization process.  
The argument is an alphanumeric string of up to 19 characters. If the string contains any blanks, enclose the entire string in single quotation marks.
- **logonserver(*serverName*)**  
Specifies the server that verifies the login information for the user. When the user logs in to the domain workstation, Privileged Access Manager transfers the login information to the server, which gives the workstation permission for the user to work.
- **organization(*name*)**  
Specifies the organization in which the user works. This information is not used during the authorization process.  
The argument is an alphanumeric string of up to 256 characters. If the string contains any blanks, enclose the entire string in single quotation marks.
- **org\_unit(*name*)**  
Specifies the organizational unit in which the user works. This information is not used during the authorization process.  
The argument is an alphanumeric string of up to 256 characters. If the string contains any blanks, enclose the entire string in single quotation marks.
- **password(*password*)**  
Assigns a password to a user. If password checking is enabled, the password is valid for one login only. When the user next logs in to the system, a new password must be set.

The argument is a string of up to 14 characters, and cannot include either a space or a comma. If password checking is enabled, the password is valid for one login only. When the user next logs in to the system, the user must set a new password, unless you set the flag for Password Never Expires.

To change your own password, you need to set `selang` options using `setoptions cng_ownpwd` or use `sepass`.

If you are setting passwords for users on Windows NT systems, the following message may appear:

The password is shorter than required.

This error means that the password does not meet the policy requirements. This is caused by any of the following:

- The password is shorter or longer than the required length.
- The password has been used recently and exists in the Windows NT Change History field.
- The password does not have enough unique characters.
- The password does not meet other password policy requirements (such as those set with Privileged Access Manager password policies).

To avoid this error, make sure you set a password which meets all applicable requirements.

- `pgroup(primaryGroup)`  
Sets the user's primary group ID. A primary group is one of the groups in which a user is defined and must be a Global group.  
The argument is a string of up to 14 characters, and cannot include either a space or a comma.
- `phone(string)`  
Specifies the user's phone number. This information is not used during the authorization process.
- `privileges(privList)`  
Adds specific rights to the Windows user record or, when `privList` is preceded by a minus sign (-), removes the specified rights. You can specify this parameter only with the `chusr` or `editusr` command, and only when you are changing an existing user record. You cannot use it to assign privileges when you are creating a new user record.
- `profile(path)`  
Specifies the full path location of the file that contains a user's profile for the Desktop environment (program groups, network connections). Every time the user logs in to any workstation, the same environment appears on the screen.
- `restrictions([days] [time])|restrictions-([days] [time])`  
Specifies the days of the week and the hours in the day when users may access the file.  
If you omit the days argument and specify the time argument, the time restriction applies to any day-of-week restriction already indicated in the record. If you omit time and specify days, the day restriction applies to any time restriction already indicated in the record. If you specify both days and time, the users may access the system only during the specified time period on the specified days.
  - [Days] specifies the days on which users may access the file. The days argument takes the following sub-arguments:
    - a. **anyday**-Allow users access to the file on any day.
  - **weekdays**-Allow users access to the resource only on weekdays-Monday through Friday.
    - a. **Mon, Tue, Wed, Thu, Fri, Sat, Sun**-Allow users access to the resource only on the specified days. You can specify the days in any order. If you specify more than one day, separate the days with a space or a comma.
  - [Time] specifies the period during which users may access the resource. The time argument takes the following sub-arguments:
    - a. **anytime**-Allow users access to the resource at any time of the day.
    - b. **startTime:endTime**-Allow access to the resource only during the specified period. The format of both `startTime` and `endTime` is `hhmm`, where `hh` is the hour in 24-hour notation (00 through 23) and `mm` is the minutes (00 through 59). Note that 2400 is not a valid time value. `startTime` must be less than `endTime`, and both times must occur on the same day. If the terminal is in a different time zone from the processor, adjust the time values by translating the start and end times for the terminal to the equivalent local times for the processor. For example, if the processor is in New York and the terminal is in Los Angeles, to allow access to the terminal from 8:00 a.m. to 5:00 p.m. in Los Angeles, specify time (1100:2000).
- `resume(date)|resume-`

The date, and optionally time, at which Windows will reinstate the user account. If you specify both the suspend parameter and the resume parameter, make sure the resume date falls after the suspend date or the user will stay suspended indefinitely.

Enter a date, and optional time, in the following format:

```
mm/dd/yy[@HH:MM]
```

Use resume- parameter to change the status of the user account from active (enabled) to suspended. Use this parameter with the chusr or editusr commands only.

- **script(*loginScriptPath*)**  
Specifies the location of a file that runs automatically when the user logs in. This login script configures the working environment. This parameter is optional, since the profile parameter also sets up the user's working environment.
- **suspend(*date*)|suspend-**  
Disables a user account. A user cannot use a suspended user account to log in to the system. If you specify date, Windows suspends the user account on the specified date. If you omit a date, Windows suspends the user account immediately upon execution of the chusr command.  
Enter a date, and optional time, in the following format: *mm/dd/yy[@HH:MM]*.  
Use the suspend- parameter to change the status of the user account from disabled to active (enabled). Use this parameter with the chusr or editusr commands only.
- **terminals(*terminalList*)|terminals-(*terminalList*)**  
Specifies up to eight terminals from which the user can log in. Surround the list with quotation marks, and separate the names with commas. For example:  

```
"terminal1,terminal2"
```
- **workstations(*workstationList*)|workstations-(*workstationList*)|workstations-**  
Specifies up to eight workstations from which the user can log in. Surround the list with quotation marks, and separate the names with commas. For example:  

```
"workstation1,workstation2"
```

## editfile Command Modify Windows File Settings

### Valid in the native Windows environment

This command is documented with the chfile command.

## editgrp Command Create and Modify Windows Groups

### Valid in the native Windows environment

This command is documented with the chgrp command.

## editusr Command Create and Modify Windows Users

### Valid in the native Windows environment

This command is documented with the chusr command.

## editres Command Create and Modify Windows Resources

### Valid in the native Windows environment

This command is documented with the chres command.

## find file Command List Native Files (Windows)

### Valid in the native environment

Use the find file command to list all the system files that match the mask, which is a string. The files are ordered chronologically in one column.

This command has the following format:

```
find file [directory] [/mask]
```

- **directory**  
Lists all the files in the directory *directory*.
- **mask**  
Lists all the files in the directory *directory* that match the *mask* variable. The *mask* may include wildcard characters.

### Example: Find Executable Program Files in a Specific Path on Windows

The following command lists all executable files in the Privileged Access Manager bin directory:

```
find file C:\Program\Files\CA\PAMSC\bin\*.exe
```

### Example: Find Files Matching a Pattern on UNIX

The following command lists all files in the Privileged Access Manager bin directory that begin with the letter *se*:

```
find file /opt/CA/PAMSC/bin/se*
```

## find xuser xgroup Command List Enterprise Users or Groups

### Valid in the native Windows environment

The find {xuser|xgroup} command lists the names of enterprise users or groups in the current or *trusted* domains.

#### NOTE

This command is supported only on supported Windows 2000 operating systems with Directory Services.

This command has the following format:

```
find {xuser|xgroup} mask [domain(domainName)] [next]
```

- **xgroup**  
Specifies for the command to return enterprise groups.
- **xuser**  
Specifies for the command to return enterprise users.
- **domain(domainName)**  
Defines the trusted domain to restrict the search to.  
If you do not specify this option, the command returns users from the current domain.
- **mask**  
Defines a mask for the enterprise users.
- **next**

Specifies that selang output should continue the listing of enterprise users or groups that was started by a previous find xuser or find xgroup command.

Use this option if there are more than 100 items in the list.

### Example: Display Enterprise Users

The following command lists the first 100 enterprise users in the current domain that begin with abc:

```
find xuser abc*
```

## join Command Add Users to Native Groups (Windows)

### Valid in the native environments

The join command adds users to a group. The specified users and group must already be defined to native OS.

#### NOTE

This command also exists in the AC environment but operates differently.

To use the join command, at least one of the following must be true:

- You have the ADMIN attribute in your Privileged Access Manager user record.
- The group record is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the group record in the database.
- You have JOIN or MODIFY access authority in the access control list of the GROUP record in the ADMIN class.

#### NOTE

Both the MODIFY and JOIN properties are required if an ADMIN is to have the authority to modify Privileged Access Manager GROUP records and native groups.

This command has the following format:

```
{join|j} userName group(groupName)
```

- **group(groupName)**  
Specifies the native group to which the users are being added.
- **userName**  
Specifies the user name of the native user who is being connected to the group specified by the group parameter. When specifying more than one user, enclose the user names in parentheses and separate the user names with a space or a comma.

### Example

The user Eli wants to join the user Bob to the group staff.

- Eli has the ADMIN attribute and the current environment is *native*.

```
join Bob group(staff)
```

## join- Command Remove Users from Native Groups (Windows)

### Valid in the native environments

The join- command removes users from a group.

#### NOTE

This command also exists in the AC environment but operates differently.

To use the join- command, one of the following conditions must be true:

- You have the ADMIN attribute.
- The group record is within the scope of a group in which you have the GROUP-ADMIN attribute.
- You are the owner of the group record in the database.
- You have JOIN or MODIFY access authority in the access control list of the GROUP record in the ADMIN class.

If you only have ownership of the user's profile, you do not have sufficient authority to remove the user from a group. Both the MODIFY and JOIN properties are required if an ADMIN is to have the authority to modify Privileged Access Manager records and native groups

This command has the following format:

```
{join-|j-} userName group(groupName)
```

- **group(*groupName*)**  
Specifies the native group from which to remove the user.
- **userName**  
Specifies the user name of the user you want to remove from the group. When removing more than one user from the group, enclose the list of user names in parentheses and separate the user names with a space or a comma.

### Example

The user Bill wants to remove the users sales25 and sales43 from the PAYROLL group.

- The user Bill has the ADMIN attribute and the current environment is *native*.

```
join- (sales25 sales43) group(PAYROLL)
```

## newgrp Command Create Windows Groups

### Valid in the native Windows environment

This command is documented with the chgrp command.

## newres Command Create Windows Resources

### Valid in the native Windows environment

This command is documented with the chres command.

## newusr Command Create Windows Users

### Valid in the native Windows environment

This command is documented with the chusr command.

## rmgrp Command Delete Windows Groups

### Valid in the native Windows environment

The rmgrp command deletes one or more groups from the Windows database.

#### NOTE

This command also exists in the AC environment but operates differently.

This command has the following format:

```
{rmgrp|rg} groupName
```

- *groupName*  
Specifies the name of the group to be deleted. The group name must be an existing Windows group name. Specify one or more group names. When removing more than one group, enclose the list of group names in parentheses and separate the group names with a space or a comma.

## rmres Command Delete a Windows Resource

The rmres command removes one or more resources from the Windows system database.

### NOTE

This command also exists in the AC environment but operates differently.

This command has the following format:

```
{rmres|rr} classNameresourceName
```

- *className*  
Specifies the name of the class the resource belongs to.
- *resourceName*  
Specifies the name of an existing Windows resource of class *className*. When removing more than one resource, enclose the list of user names in parentheses and separate the names with a space or a comma.

## rmusr Command Delete a Windows User

### Valid in the native Windows environment

The rmusr command removes one or more users from the Windows system database.

### NOTE

This command also exists in the AC environment but operates differently.

This command has the following format:

```
{rmusr|ru} userName
```

- *userName*  
Specifies the user name of an existing Windows user. When removing more than one user, enclose the list of user names in parentheses and separate the user names with a space or a comma.

## setoptions Command Set CA Privileged Access Manager Server Control Windows Options

The setoptions command dynamically sets system-wide Privileged Access Manager options related to the Windows operating system.

### NOTE

This command also exists in the AC environment, but operates differently there.

You need ADMIN attribute to use the setoptions command, with the exception that you need only AUDITOR or OPERATOR attribute to use the command setoptions list.

This command has the following format:

```
setoptions|so \
[audit_policy( \
[success(system|logon|access|rights \ |process|security|manage)] \[failure(system|logon|access|rights \ |
process|security|manage)] \
```

```

    ])
    [password([history(number-stored-passwords)][interval(nDays)][min_life(NDays)]
    )]

```

[audit\_policy( \

```

    [success(system|logon|access|rights \
    |process|security|manage)] \
    [failure(system|logon|access|rights \
    |process|security|manage)] \

```

- **audit\_policy{+|-}**  
Specifies whether auditing is enabled (+) or disabled (-).
- **audit\_policy(success(system|logon|access|rights|process|security|manage))**  
Specifies which detected authorized access events are logged. The types of access are:
  - **system**-attempts to shutdown or restart the computer.
  - **logon**-attempts to log on to or log off from the system.
  - **access**-attempts to access securable objects, such as files.
  - **rights**-attempts to use Windows Server privileges.
  - **process**-events such as program activation, some forms of handle duplication, indirect access to an object, and process exit.
  - **security**-attempts to change Policy object rules.
  - **manage**-attempts to create, delete, or change user or group accounts. Also, password changes.
- **audit\_policy(failure(system|logon|access|rights|process|security|manage))**  
Specifies which detected unauthorized access events are logged. The types of access are:
  - **system**-attempts to shutdown or restart the computer.
  - **logon**-attempts to log on to or log off from the system.
  - **access**-attempts to access securable objects, such as files.
  - **rights**-attempts to use Windows Server privileges.
  - **process**-events such as program activation, some forms of handle duplication, indirect access to an object, and process exit.
  - **security**-attempts to change Policy object rules.
  - **manage**-attempts to create, delete, or change user or group accounts. Also, password changes.
- **history(number-stored-passwords)**  
Specifies the number of previous passwords that are stored in the database. When supplying a new password, the user cannot specify any of the passwords stored in the history list. *NStoredPasswords* is an integer between 1 and 24. If you specify zero, no passwords are saved.
- **interval(nDays)**  
Sets the number of days that must pass after passwords are set or changed before the system prompts users for a new password.  
The value of *nDays* must be a positive integer or zero. An interval of zero disables password interval checking for users. Set the interval to zero if you do not want passwords to expire.
- **min\_life(NDays)**  
Sets the minimum number of days between password changes. *NDays* must be a positive integer.

## showfile Command Display Native File Properties (Windows)

### Valid in the native environments

The showfile command lists the native details of one or more system files.

**NOTE**

This command also exists in the AC environment but operates differently.

This command has the following format:

```
{showfile|sf} fileName [next] \
[{props|addprops} (propNames)]
```

- **addprops(propName)**  
Sets the properties (ruler) to be displayed. The list of properties is added to the current ruler. The ruler is set for this query only, and reverts to the previously set ruler.
- **fileName**  
Specifies the name of the file whose details are to be listed. Enter one or more UNIX file names. When specifying more than one file, enclose the list of file names in parentheses and separate the individual names with a space or a comma.
- **next**  
Displays parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the query\_size configuration setting. The query size default is set at 100.
- **props(all|propName)**  
Sets the properties (ruler) to be displayed.  
The ruler remains set for future queries.

**Example: Show the Details of a UNIX File**

You want to list the details of the UNIX file /tmp/foo.

```
showfile /tmp/foo
```

**Example: Show the Owner of a Windows File**

You want to know who the owner of the Windows file C:\tmp\foo.exe is.

```
showfile C:\tmp\foo.exe props (Owner)
```

**showgrp Command Display Native Group Properties (Windows)****Valid in the native environments**

The showgrp command displays the details of one or more groups in the native operating system.

**NOTE**

This command also exists in the AC environment but operates differently.

**NOTE**

On UNIX, groups are read, added, updated, and deleted from the file specified in the configuration settings (seos.ini); by default, this file is /etc/group. For more information, see the *Endpoint Administration Guide for UNIX*.

This command has the following format:

```
{showgrp|sg} groupName [next] \
[{props|addprops} (propNames)]
```

- **addprops(propName)**  
Sets the properties (ruler) to be displayed. The list of properties is added to the current ruler. The ruler is set for this query only, and reverts to the previously set ruler.
- **groupName**

Specifies the name of the group whose details are to be displayed. The group name must be an existing native group name. Specify one or more group names. When listing more than one group, enclose the list of group names in parentheses and separate the group names with a space or a comma.

- **next**  
Displays parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the `query_size` configuration setting. The query size default is set at 100.
- `props(all|propName)`  
Sets the properties (ruler) to be displayed.  
The ruler remains set for future queries.

### Example

To list details of the UNIX group *security* when you are in the *unix* environment, enter the following command:

```
showgrp security
```

## showres Command Display Native Resource Properties (Windows)

Displays the properties of Windows resources.

This command has the following format:

```
showres|sr classNameresourceName [next] \
[ {props|addprops} (propNames) ]
```

- `addprops(propName)`  
Sets the properties (ruler) to be displayed. The list of properties is added to the current ruler. The ruler is set for this query only, and reverts to the previously set ruler.
- `className`  
Specifies the name of the class the resource belongs to.
- **next**  
Displays parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the `query_size` configuration setting. The query size default is set at 100.
- `props(all|propName)`  
Sets the properties (ruler) to be displayed.  
The ruler remains set for future queries.
- `resourceName`  
Specifies the name of an existing Windows resource of class *className*.

## showusr Command Display Native User Properties (Windows)

### Valid in the native UNIX environment

The `showusr` command displays the properties of one or more users defined in the native operating system.

#### NOTE

This command also exists in the AC environment but operates differently.

#### NOTE

On UNIX, users are read, added, updated, and deleted from the file specified in the configuration settings (`seos.ini`); by default, this file is `/etc/passwd`. For more information, see the *Endpoint Administration Guide for UNIX*.

This command has the following format:

```
{showusr|su} userName [next] \
```

```
[ {props|addprops} (propNames) ]
```

- **addprops(*propName*)**  
Sets the properties (ruler) to be displayed. The list of properties is added to the current ruler. The ruler is set for this query only, and reverts to the previously set ruler.
- **userName**  
Specifies the name of the user whose native properties are to be displayed. Specify an existing native user name. When listing the properties of more than one user, enclose the list of user names in parentheses and separate the names with a space or a comma.
- **next**  
Displays parts of the requested data. This option is useful when the query data is larger than the set query size. The maximum query size is determined by the `query_size` configuration setting. The query size default is set at 100.
- **props(all|*propName*)**  
Sets the properties (ruler) to be displayed.  
The ruler remains set for future queries.

### Example

To list details of the UNIX user *leslie* when you are in the *unix* environment, enter the following command:

```
showusr leslie
```

### xaudit Command Modify System Access Control List

The `xaudit` command adds entries in the system access control list (SACL). Each entry in this list causes an audit message to be logged when a specified user or group attempts to gain access to the resource. The `xaudit-` command removes entries from the SACL, and is valid for resource types FILE, PRINTER, REGKEY, DISK, COM, or SHARE.

This command has the following format:

```
xaudit classNameresourceName \  
[failure(auditMode)] \  
[gid(groupName)] \  
[success(auditMode)] \  
[uid(userName)]
```

- **className**  
Specifies the name of the resource type to which the resource belongs.
- **failure(*auditMode*)**  
Logs unauthorized access attempts to the resource.  
Valid values for *auditmode* depend on the resource type to which it belongs:

#### NOTE

Only NTFS files can have audit modes

- **DISK** and **COM**: changePermissions, delete, modify, query, read, synchronize, takeOwnership.
- **FILE**: changePermissions, delete, execute, read, takeOwnership, and write.
- **PRINTER**: changePermissions, delete, print, and takeOwnership.
- **REGKEY**: delete, enumerate, link, notify, queryValue, readControl, setValue, subkey, and write.

For all resource types: *none* and *all*.

- **gid(*groupName*)**  
Specifies the groups whose access to the resource is being audited. When specifying more than one group, separate the names with spaces or commas.
- **resourceName**

Specifies the name of the resource record whose system access control list (SACL) is being modified.

- **success(*auditMode*)**

Logs authorized accesses to the resource.

Valid values for *auditmode* depend on the resource type to which it belongs:

#### NOTE

Only NTFS files can have audit modes

- **DISK** and **COM**: changePermissions, delete, modify, query, read, synchronize, takeownership.
- **FILE**: changePermissions, delete, execute, read, takeOwnership, and write.
- **PRINTER**: changePermissions, delete, print, and takeOwnership.
- **REGKEY**: delete, enumerate, link, notify, queryValue, readControl, setValue, subkey, and write.

For all resource types: *none* and *all*.

- **uid(*userName*)**

Specifies the user whose access to the resource is being audited. When specifying more than one user, separate the user names with spaces or commas. To specify all users who are defined in the Windows NT database, specify an asterisk (\*) for *userName*.

## xaudit- Command Remove System Access Control List

The xaudit- command removes entries from the SACL, and is valid for resource types FILE, PRINTER, REGKEY, DISK, COM, or SHARE.

This command has the following format:

```
xaudit-className, resourceName \
    [gid(groupName)] \
    [uid(userName)]
```

- **className**  
Specifies the name of the resource type to which the resource belongs.
- **gid(*groupName*)**  
Specifies the groups or groups whose access to the resource is being audited. When specifying more than one group, separate the names with spaces or commas.
- **resourceName**  
Specifies the name of the resource record whose system access control list (SACL) is being removed.
- **uid(*userName*)**  
Specifies the user whose access to the resource is being audited. When specifying more than one user, separate the user names with spaces or commas. To specify all users who are defined in the Windows NT database, specify an asterisk (\*) for *userName*.

## PAM SC selang Commands in the Policy Model Environment

This section contains a complete alphabetic reference to all the selang commands that operate on the Policy Model environment.

**Use the table of contents to access the topics in this section.**

### backuppmd Command Back up a PMDB

#### Valid in the pmd environment

The backuppmd command backs up the data in the PMDB database to a specified directory. All the data in the PMDB database is backed up, including policies, deployment information, and configuration files.

This command has the following format for DMSs:

```
backup pmdName destination(path)
```

This command has the following format for PMDBs:

```
backup pmdName [destination(path)|hir_host(name)]
```

- **destination(*path*)**  
Defines the directory that you want the backup files to be stored in.

**NOTE**

If you do not specify a path, the files will be backed up to the default location specified in the `_pmd_backup_directory_` token. Default: (UNIX) `ACInstallDir/data/policies_backup/pmdName`

Default: (Windows) `ACInstallDir\data\policies_backup\pmdName`

- **pmdName**  
Defines the name of the PMDB or DMS to back up.
- **hir\_host(*name*)**  
Backs up all the PMDBs in a hierarchy to the host *name* that you specify, and modifies the PMDB subscribers so that the subscription still works when the backup is moved to the *name* host.

**NOTE**

This command is only supported if the master and child PMDBs are deployed on the same host.

## createpmd Command Create a PMDB on a Host

### Valid in the pmd environment

The `createpmd` command defines a PMDB on a remote host. You can designate one or more users as administrator, auditor, and password managers for the PMDB. You can also define the PMDB's parent and subscriber PMDBs. You can run `createpmd` command from a remote host.

This command has the following format:

```
createpmd pmdname \
[admins(user [user ...])] \
[auditors(user [user ...])] \
[pwman(user [user ...])] \
[parentpmd(pmdname@host)] \
[desktop(host-names...)] \
[subscriber(host-names|pmdnames...)] \
[pwdfile(file-name)] \
[grpfile(file-name)] \
[nis] \
[xadmins(user [user ...])] \
[xauditors(user [user ...])] \
```

- **admins(*user [user ...]*)**  
Specifies one or more internal users to be PMDB administrators. Separate multiple users with spaces.
- **auditors(*user [user ...]*)**  
Specifies one or more internal users who can view the audit file of the PMDB. Separate multiple users with spaces.
- **pwmans(*user [user ...]*)**  
Specifies one or more users as PMDB password managers. Separate multiple users with spaces.
- **parentpmd(*pmdname@host*)**  
Specifies the name of the PMDB that is a parent to the one you are creating.

**NOTE**

If you want to define multiple parent Policy Models with a `selang` remote command, you must to use quotation marks. For example, to create a Policy Model and define its parent, use the following command:

```
createpmd subs2 admins(abc123 root) auditors(abc123 root) desktop(pcp36949) \
parentpmd("aa@pcp36949,bb@pcp36949")
```

- **desktop(*host [host ...]*)**  
Specifies one or more hosts from which administrators can administer the PMDB. Separate multiple hosts with spaces. The default is the host of the new PMDB.
- **subscribers(*host | pmd [host | pmd ...]*)**  
Specifies the hosts or PMDBs to be a subscriber of the new PMDB. Separate multiple hosts or pmds with spaces.
- **pwdfile(*filename*)**  
Specifies the PMDB password file.
- **grpfile(*filename*)**  
Specifies the PMDB group file.
- **nis**  
Performs an NIS setup on the new PMDB's host, and creates a filter file to filter out all UNIX updates.
- **xadmins(*user [user ...]*)**  
Specifies one or more enterprise users to be PMDB administrators. Separate multiple users with spaces.
- **xauditors(*user [user ...]*)**  
Specifies one or more enterprise users who can view the audit file of the PMDB. Separate multiple users with spaces.
- **pwmans(*user [user ...]*)**  
Specifies one or more enterprise users as PMDB password managers. Separate multiple users with spaces.

**deletepmd Command Remove a PMDB from a Host****Valid in the pmd environment**

The `deletepmd` command removes the following items from the host:

- The PMDB's `selang` protection files:
  - database files
  - registry entries
- The contents of the PMDB directory
- The PMDB directory

**WARNING**

To prevent serious operational problems, avoid removing the PMDB by manually deleting its files. Always use the `deletepmd` command for PMDBs.

This command has the following format:

```
deletepmd pmdname
```

**findpmd Command List PMDBs on the Host****Valid in the pmd environment**

The `findpmd` command lists the PMDBs in the host to which you are connected and whether their daemons are loaded.

This command has the following format:

```
findpmd
```

## listpmd Command List Information about a PMDB

### Valid in the pmd environment

The listpmd command lists information about the PMDB and its subscribers, update file, and error log. If no options are used, the command lists all subscribers of the Policy Model *pmdName*.

This command has the following format:

```
listpmd pmdName \
[info|subscriber(subNames)|cmd(offset) \
|errors|all_errors|log] \
[next]
```

- **cmd(offset)**

Displays all commands in the update file and their offsets.

The offset indicates the location of the update inside the file. If an offset is specified, the list starts from offset. If no offset is specified, the display begins from the beginning of the update file.

#### NOTE

The update file contains updates that must be, or have been, propagated by the PMDB. The offset indicates the location of the next update that must be sent to a subscriber. The update file's initial and latest offsets are displayed.

- **errors|all\_errors**

Displays the Policy Model error log. The *errors* parameter displays all types of errors except non-connection failure errors. *all\_errors* displays all errors.

- **info**

Displays general information about the Policy Model *pmdName*, including whether the Policy Model has a parent.

- **next** Display parts of the requested data. This option is useful when the query data is larger than the set query size.

The maximum query size is determined by the query\_size configuration setting located in the,

- (UNIX) [lang] section of the seos.ini file

- (Windows) lang subkey, as follows:

HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\lang

The query size default is set at 100.

- **pmdname**

Defines the name of the PMDB you want to list information for.

- **subscriber(subNames)**

Lists the subscribers of the Policy Model and their status, including number of errors, availability, offset, and the next command to be propagated. The *subNames* parameter lets you select a subset of subscribers.

- **log**

Displays the policy model general log file.

### Example: Display PMDB subscriber information for selected subscribers

To display a list of subscribers to the myPMDB Policy Model that begin with the letters *compInt*, enter the following command:

```
listpmd myPMDB subscriber(compInt*)
```

## pmd Command Control a PMDB

### Valid in the pmd environment

The pmd command clears the Policy Model error log, updates the subscriber list, starts and stops the Policy Model service, and truncates the update file.

This command has the following format:

```
pmd pmdName \
{[release(subname)|start|stop|truncate(offset)|lock|unlock \
|reloadini|startlog|killog|clrerror|backup|operation]}
```

- **backup**  
Moves the Policy Model to backup status.
- **clrerror|clrerr**  
Clears the Policy Model error log.
- **killog**  
Disables the Policy Model general log file. If you specify this option, no messages are written to the log.

#### **WARNING**

Do not use the kill command to shut down the PMDB service.

- **lock**  
Moves the Policy Model to lock status, and stops the Policy Model sending updates to its subscribers.
- **operation**  
Moves the Policy Model from backup to operational status.
- **pmdname**  
Defines the name of the PMDB that you want to execute the selected option on.
- **release(subName)**  
Removes the subscriber specified by *subName* from the list of unavailable subscribers. This means that the subscriber can receive updates immediately. *subName* specifies the subscriber that is to become available for update.
- **reloadini**  
(UNIX only) Rereads the policy model pmd.ini file and the seos.ini file, letting you change configuration settings without having to reload the policy model daemon.
- **startlog**  
Enables the Policy Model general log file for writing. Use this option if the log file has been disabled.
- **start**  
Starts the Privileged Access Manager Policy Model service. Use this option when there are no other commands to execute.
- **stop**  
Stops the Privileged Access Manager Policy Model daemon/service.
- **truncate|trunc[(offset)]**  
Deletes entries from the update file. If an offset is not specified, the file is truncated at the highest possible offset. The highest possible offset is the location of last command that successfully updated the subscriber. If *offset* is specified, all the entries up to the specified offset are deleted.

#### **NOTE**

You must now use the true offset provided by the *listpmd* command to truncate the file, and not an offset derived by subtracting from the start offset.

- **unlock**  
Moves the Policy Model from lock to unlock status, and lets the Policy Model send updates to its subscribers.

## **restorepmd Command Restore a PMDB**

### **Valid in the pmd environment**

The *restorepmd* command restores a PMDB on a local host. The backup files that you use to restore the PMDB must be from a host running the same platform, operating system, and version of Privileged Access Manager as the restoration host. Privileged Access Manager must be running on the restoration host.

**NOTE**

If you back up and restore the PMDB on different terminals, the PMDB does not automatically update the terminal resource in the restored PMDB database. You must add the new terminal resource to the restored PMDB. To add the new terminal resource, stop the restored PMDB, run the *selang -p pmdb* command, then start the restored PMDB.

This command has the following format:

```
restorepmd pmdName [source(path)] [admin(user)] [xadmin(user)] [parentpmd(name)]
```

- **admin(user)**  
(UNIX) Defines internal users as administrators of the restored PMDB.
- **pmdName**  
Defines the name of the PMDB to restore.
- **parentpmd(name)**  
(Optional) Defines the name of the restored PMDB's parent. Specify the name in the format *pmd@host*.
- **source(path)**  
(Optional) Defines the directory where the backup files are located. If you do not specify the source directory, the PMDB is restored from the files in the default location. The default location is defined in the *\_pmd\_backup\_directory\_* token.

**NOTE**

**Default:** (UNIX) *ACInstallDir/data/policies\_backup/pmdNameDefault*: (Windows) *ACInstallDir\data\policies\_backup\pmdName*

- **xadmin(user)**  
(UNIX) Defines enterprise users as administrators of the restored PMDB.

## subs Command Add Subscribers or Subscribe Databases

### Valid in the pmd environment

The subs command adds a subscriber to a parent PMDB or subscribes a database to a parent PMDB.

When you subscribe a host to a PMDB:

- The host must be up.
- Privileged Access Manager must be running on the host.
- The PMDB must be the parent PMDB of the subscribed host.

When you subscribe a PMDB to another PMDB:

- Privileged Access Manager must be running on the host in which the subscribed PMDB resides.
- Configure *parent\_pmd* as the parent of the subscribing PMDB.

**NOTE**

You can add a subscriber to a parent PMDB that resides on the same host only.

This command has the following format:

```
subs pmdname \  
[subs(subsname)] \  
[host_type(mfHost) sysid(sysID) mf_admin(mfAdmin) port(port)] \  
{offset(offset) }
```

or

```
subs pmdname [newsups(subsname)]
```

or

```
subs pmdname [parentpmd(pmdname2@host)]
```

- **host\_type(mfhost)**  
Specifies the mainframe host type of the subscriber.
- **mf\_admin(mfAdmin)**  
Specifies the mainframe administrator of the subscriber.
- **newsubs(subsname)**  
Subscribes *subsname* to policy model *pmdname*, and sends PMDB, password, and group files to the subscriber.
- **parentpmd(pmdName2@host)**  
Specifies the PMDB *pmdName2@host* the parent Policy Model of *pmdName*.
- **pmdname** Specifies the name of the PMDB you want to execute the selected option on.
- **port(port)**  
Specifies the port number of the subscriber.
- **subs(subsname)**  
Assigns a subscriber to the PMDB.
- **sysid(sysId)**  
Specifies the system ID of the subscriber.

## subspmd Command Change Parent PMDB

### Valid in the pmd environment

The subspmd command changes the parent of the Privileged Access Manager database in the host to which you are connected.

This command has the following format:

```
subspmd parentpmd(pmdname@host)
```

- **parentpmd(pmdname@host)**  
Makes *pmdname@host* the current host's parent policy model.

## unsubs Command Remove a Subscriber

### Valid in the pmd environment

The unsubs command removes a subscriber from the subscriber list of the Policy Model.

This command has the following format:

```
unsubs pmdName subs(subName)
```

- **pmdname**  
Defines the name of the PMDB you want to execute the selected option on.
- **subs(subName)**  
Defines the name of the subscriber you want to remove from the *pmdname* subscriber list.

## Classes and Properties

This section contains a description of each property in every class defined in the Privileged Access Manager database and in the native operating systems. Arranged in environments alphabetically by class, the chapter provides information on which properties you can modify, which selang parameters you use to update these properties, and which commands contain these parameters.

## Class and Property Information

The following conventions apply to the provided class and property information:

- In the descriptive material before the property lists, the *key* of the class record is defined. The key is the record identifier, which you specify when you create a new record. Once created, it becomes a non-modifiable property.
- The symbol [-] used with a parameter indicates that the parameter may be deleted from the database by typing it with a minus sign.  
For example, *comment* (with appropriate text) adds a comment to a database record; *comment-* removes the comment from the database. You cannot use parameters with a minus sign when creating a record.
- The two types of classes in the database are accessor classes and resource classes.  
You operate on records in the accessor classes (USER and GROUP) with different *selang* command sets than you use for the resource classes:
  - Use *chusr*, *editusr*, and *newusr* to operate on USER class records.
  - Use *chgrp*, *editgrp*, and *newgrp* to operate on GROUP class records.
  - Use *chres*, *editres*, and *newres* to operate on records in any of the resource classes. If the resource is a file, you may also use the *chfile* or *editfile* commands.
  - Use *showgrp*, *showres*, *showfile*, or *showusr* to list the properties of a record.
  - Use *authorize* and *authorize-* to add, change, or remove ACLs for resource records.

## Classes in the AC Environment

This section contains a complete alphabetic reference to all the classes and properties that exist in the Privileged Access Manager database (classes in the AC environment).

### ACVAR Class

Each record in the ACPVAR class defines a variable that is deployed on an endpoint. You cannot deactivate this class.

The key of the ACPVAR class is the name of the variable.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using *selang* or the administration interfaces. Non-modifiable properties are marked *informational*.

- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **OWNER**  
Defines the user or group that owns the record.
- **POLICIES**  
(Informational) The list of policies (POLICY objects) that use this variable.
- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.
- **VARIABLE\_TYPE**

Defines the variable type. Valid values are:

- **built-in**  
Specifies that the variable was created by Privileged Access Manager during installation. Static variables resolve based on the system settings of the endpoint.  
**Note:** You cannot modify or delete built-in variables.
- **osvar**  
Specifies that the variable resolves based on an operating system value.
- **regval**  
(Windows) Specifies that the variable resolves based on a registry value.  
**Note:** You can only define registry values that point to REG\_SZ or REG\_EXPAND\_SZ registry types.
- **static**  
Specifies that the variable resolves to the string value you define.

#### NOTE

You cannot change the variable type of an existing variable.

- **VARIABLE\_VALUE**  
Defines the values of the variable.  
**Note:** This property does not expand any nested variables within the variable value.
- **VARIABLE\_EXPANDED\_VALUE**  
(Informational) Defines the variable values and expands any nested variables within the variable values.

#### Examples:

To define a new static variable, specify:

```
nr ACVAR ACHOME type(static) value+("/opt/CA/PAMSC")
```

To define a new variable that is based on the system environment, specify:

```
nr ACVAR ACHOME type(OSVAR) value+(AC_HOME)
```

To add value to a variable, specify:

```
er ACVAR ACHOME value+("/opt/CA/PAMSC")
```

To remove value from a variable, specify:

```
er ACVAR ACHOME value-("/opt/CA/PAMSC")
```

## ADMIN Class

Each record in the ADMIN class contains definitions that allow non-ADMIN users to administer specific classes. You create an ADMIN record to represent each Privileged Access Manager class that delegated users administer. The record contains a list of accessors with the access authorities of each, and also supports Conditional Access Control Lists (CACLS). The key of the ADMIN class record is the name of the class being protected.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using Selang or the administration interfaces. Non-modifiable properties are marked as *informational*.

- **AAUDIT**(Informational) Displays the type of activity that Privileged Access Manager audits.
- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors access types. Each element in the Access Control List (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the access parameter with the authorize or authorize- command to modify the ACL.
- **CALACL**  
Defines a list of the accessors (users and groups) that are permitted to access the resource, and their access types according to the Unicenter NSM calendar status.  
Each element in the calendar access control list (CALACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Calendar**  
Defines a reference to a calendar in Unicenter TNG.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Access is permitted only when the calendar is ON. Access is denied in all other cases.  
Use the calendar parameter with the authorize command to permit user or group access to the resource according to the access defined in the calendar ACL.
- **CALENDAR**  
Represents a Unicenter TNG calendar object for user, group, and resource restrictions. Privileged Access Manager fetches Unicenter TNG active calendars at specified time intervals.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **NACL**  
The *NACL* property of a resource is an access control list that defines accessors with authorization denied to a resource, together with the type of access that they are denied (example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the type of access that is denied to the accessor.  
Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.
- **NOTIFY**  
Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters

- **OWNER**

Defines the user or group that owns the record.

- **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program Access Control List (PACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Program**

Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

**NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `Selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests

- **success**

Granted access requests

- **failure**

Denied access requests (default)

- **none**

No access requests

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

- **SECLABEL**

Defines the security label of a user or resource.

**NOTE**

The SECLABEL property corresponds to the `label[-]` parameter of the

`chres`

and

`ch[x]usr`

commands.

- **SECLEVEL** Defines the security level of an accessor or resource.

**NOTE**

This property corresponds to the `level[-]` parameter of the

`ch[x]usr`

and

`chres`

commands.

- **UACC**

Defines the default access authority for the resource, which indicates the access that is granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the `defaccess` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.
- **WARNING**  
Specifies whether Warning mode is enabled. If the Warning mode is enabled on a resource, then access requests to the resource are granted. If an access request violates an access rule, then a record is written to the audit log.

**Example:** This example shows how to assign "Password Change" privileges to a user "John" by using the ADMIN class in UNIX/Linux endpoint.

**Step 1:** Create a user "John".

```
PAMSC> eu John password(John_Pwd)
```

**Step 2:** Use the ADMIN class to authorize "John" with the administrative privileges to change the password of any other user. The user can be any other user (including Admin user) but not the superuser (example, root).

```
PAMSC> authorize ADMIN USER uid(John) access(password)
```

**Step 3:** View all the Admin users with administrative privileges.

```
PAMSC> showres ADMIN USER
(localhost)
Data for ADMIN 'USER'
-----
Defaccess : None
ACLs :
Accessor Access
John (USER ) PW
Peter (USER ) R, Modify, Cre, Del, Join
Audit mode : Failure
Update time : 16-Feb-2017 15:06
Updated by : root (USER )
```

**Step 4:** John tries to perform operations such as create a user (Louis), view other users in the database but fails as he is not authorize to do so.

```
PAMSC> nu Louis

(localhost)
ERROR: Operation not allowed

PAMSC> su *
```

```
(localhost)
ERROR: Operation not allowed
```

**Step 5:** John tries to modify the password of another Admin user (Peter) and succeeds as he is authorized to do so.

```
PAMSC> eu Peter password(Peter_Pwd)
(localhost)
Successfully updated USER Peter
(localhost)
Native:
===
Successfully updated USER Peter
```

## AGENT\_TYPE Class

Each record in the AGENT\_TYPE class defines an agent type used by CA SSO.

The key of the AGENT\_TYPE class record is the type of the agent.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked as *informational*.

- **AGENT\_FLAG**  
Contains information about the attribute. The flag can contain the following values:
  - **aznchk**-Indicates whether to use this attribute for authorization.
  - **predef** (predefined), **freetext** (free text), or **userdir** (user directory)-Specify the source of the user attributes.
  - **user** or **group**-These values indicate whether the attribute (accessor) is a user or a group.
- **AGENT\_LIST**  
A list of objects in the AGENT class that were created with this AGENT\_TYPE object as the value for the agent\_type parameter; for example, this property is updated implicitly when creating an object in the AGENT class.
- **CLASSES**  
A multi-string list of the classes or resources that are relevant to this agent.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **OWNER**  
Defines the user or group that owns the record.
- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.

## APPL Class

Each record in the APPL class defines an application used by CA SSO.

The key of the APPL class record is the name of the application.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked as *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the `access` parameter with the `authorize` or `authorize-` command to modify the ACL.
- **APPLTYPE**  
Used by CA SSO.
- **AZNACL**  
Defines the authorization ACL. The authorization ACL is an ACL that allows access to a resource based on the resource description. The description is sent to the authorization engine, not the object. Typically, when an AZNACL is used, the object is not in the database.
- **CAPTION**  
The text under the application's icon on the desktop. The default is the name of the APPL record.  
**Limit:** 47 alphanumeric characters.
- **CMDLINE**  
The file name of the application executable. Used by CA SSO.  
**Limit:** 255 characters.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CONTAINED\_ITEMS**  
The record names of the contained applications, if the record is a container.  
Use the `item[-](appName)` parameter with the `chres`, `editres`, and `newres` commands to modify this property.
- **CONTAINERS**  
The record names of container applications, if the record is contained in other applications.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the `restrictions` parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **DIALOG\_FILE**  
The name of the CA SSO script in the directory containing the login sequence for the application. The default directory location is `/usr/sso/scripts`. The default value is no script.  
Use the `script[-](fileName)` parameter with the `chres`, `editres`, and `newres` commands to modify this property.
- **GROUPS**  
A list of user groups authorized to use the application.
- **HOST**  
The name of the host where the application resides.

Use the `host[-](hostName)` parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **ICONFILE**

The file name or full path of the file containing the icon representing the application on the desktop. Privileged Access Manager expects to find the icon on the end user's workstation. If just a file name is entered, the search order for the file is as follows:

- a. Current directory
- b. Directories listed in the `PATH` environment variable

The default is the default icon of the workstation.

- **ICONID**

The numeric ID (if necessary) of the icon within the icon file. If the `ICONID` is not specified, the default icon is used.

- **IS\_CONTAINER**

Whether the application is a container. The default is no.

Use the `container[-]` parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **IS\_DISABLED**

Whether the application is disabled. If the application is disabled, users cannot log into it. This feature is useful when you change an application and you do not want any users to log in to the application while you make it. The disabled application appears in the application menu list, but if a user selects the application the login is terminated with an appropriate message. The default is not disabled.

- **IS\_HIDDEN**

Whether the application icon appears on the desktop even for users who can invoke it. You may want to hide a *master* application, for example an application that only serves the purpose of supplying passwords to other applications. The default is not hidden.

Use the `hidden[-]` parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **IS\_SENSITIVE**

Whether re-authentication is required when the user opens the application after a preset time. The default is not sensitive.

Use the `sensitive[-]` parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **LOGIN\_TYPE**

The way user passwords are provided. The value is *pwd* (plain password), *otp* (One Time Password), *appticket* (a proprietary ticket for mainframe application authentication), *none* (no password required), or *passticket* (a one-time password replacement format created by IBM and used by mainframe security packages). The default is *pwd*.

Use the `login_type(value)` parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **MASTER\_APPL**

The record name of the application that supplies the password to other applications. The default is no master.

Use the `master[-](appName)` parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also *ACL*, *CALACL*, *PACL*. Each entry in the *NACL* contains the following information:

#### Accessor

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

#### NOTIFY

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

## **OWNER**

Defines the user or group that owns the record.

## **PGMDIR**

A directory, or a list of directories, where the application's executable file resides. Used by CA SSO.

## **PWD\_AUTOGEN**

Indicates whether the application password is automatically generated by CA SSO. The default is no.

## **PWD\_SYNC**

Indicates whether the application password is automatically kept identical to those of the other applications. The default is no.

## **PWPOLICY**

The record name of the password policy for the application. A password policy is a set of rules for checking the validity of a new password and for defining when a password expires. The default is no validity check.

## **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## **SCRIPT\_POSTCMD**

Indicates whether to execute one or more commands after the login script.

## **SCRIPT\_PRECMD**

Indicates whether to execute one or more commands before the login script.

## **SCRIPT\_VARS**

Used by CA SSO, a variables list with the variable values of the application script that are saved per application.

## **TKTKEY**

Used by CA SSO only.

## **TKTPROFILE**

Used by CA SSO only.

## **UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

### UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

### UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

### WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## AUTHHOST Class

Each record in the AUTHHOST class defines an authentication host in CA SSO.

The key of the AUTHHOST class record is the name of the authorization host.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked as *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the access parameter with the authorize or authorize- command to modify the ACL.
- **AZNACL**  
Defines the authorization ACL. The authorization ACL is an ACL that allows access to a resource based on the resource description. The description is sent to the authorization engine, not the object. Typically, when an AZNACL is used, the object is not in the database.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **ETHINFO**  
Ethernet information for a host.
- **GROUPS**  
The list of GAUTHHOST or CONTAINER records a resource record belongs to.

To modify this property in an AUTHHOST class record, you must change the MEMBERS property in the appropriate CONTAINER or GAUTHHOST record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **KEY**  
Used by CA SSO only.
- **NACL**

The **NACL** property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**  
Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

#### **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

#### **OWNER**

Defines the user or group that owns the record.

#### **PATH**

Used by CA SSO only.

#### **PROPERTIES**

In UNIX dbdump only

#### **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

#### **SECLABEL**

Defines the security label of a user or resource.

**NOTE**

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

**SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

**SEED**

Used by CA SSO only.

**SERNUM**

The serial number of the authentication host.

**UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

**UNTRUST**

Defines whether the resource is untrusted or trusted. If the UNTRUST property is set, accessors cannot use the resource. If the UNTRUST property is not set, the other properties listed in the database for the resource are used to determine accessor's access authority. If a trusted resource is changed in any way, Privileged Access Manager automatically sets the UNTRUST property.

Use the trust[-] parameter with the chres, editres, or newres command to modify this property.

**UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

**UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

**USER\_DIR\_PROP**

(Informational). The name of the user's directory.

**USER\_FORMAT**

Used by CA SSO only.

**USERALIAS**

Contains all the user's aliases that are defined to a specific authhost.

**WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**CATEGORY Class**

Each record in the CATEGORY class defines a security category in the database.

The key of the CATEGORY class record is the name of the security category.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **OWNER**

Defines the user or group that owns the record.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## CONNECT Class

Each record in the CONNECT class defines a remote host that can use TCP over IPv4 or IPv6 to connect to that host from the local host.

### NOTE

If the CONNECT class is being used as a criterion for access, the TCP class cannot effectively control access. Use either the TCP class or the CONNECT class to protect a connection, not both.

The key of the CONNECT class record is the name of the remote host.

The following definitions describe the properties that are contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors access types.

Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access parameter with the authorize or authorize- command to modify the ACL.

- **CALACL**

Defines a list of the accessors (users and groups) that are permitted to access the resource, and their access types according to the Unicenter NSM calendar status.

Each element in the calendar access control list (CALACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Calendar**

Defines a reference to a calendar in Unicenter TNG.

- **Access**

Defines the access authority that the accessor has to the resource.

Access is permitted only when the calendar is ON. Access is denied in all other cases.

Use the calendar parameter with the authorize command to permit user or group access to the resource according to the access defined in the calendar ACL.

- **CALENDAR**

Represents a Unicenter TNG calendar object for user, group, and resource restrictions in Privileged Access Manager. Privileged Access Manager fetches Unicenter TNG active calendars at specified time intervals.

- **CATEGORY**

Defines one or more security categories that are assigned to a user or a resource.

- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.
- **NACL**  
The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also *ACL*, *CALACL*, *PACL*. Each entry in the *NACL* contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the type of access that is denied to the accessor.  
Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.
- **NOTIFY**  
Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.  
**Limit:** 30 characters.
- **OWNER**  
Defines the user or group that owns the record.
- **PACL**  
Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (*PACL*) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
  - **Access**  
Defines the access authority that the accessor has to the resource.

#### NOTE

You can use wildcard characters to specify the resource in a *PACL*.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a *PACL*. You can use the `authorize-` command to remove accessors from a *PACL*.

- **RAUDIT**  
Defines the types of access events that Privileged Access Manager records in the audit log. *RAUDIT* derives its name from Resource *AUDIT*. Valid values are:
  - **all**  
All access requests.
  - **success**

Granted access requests.

- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

- **SECLABEL**

Defines the security label of a user or resource.

**NOTE**

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

- **SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

- **UACC**

Defines the default access authority for the resource, which indicates the access that is granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**Example:** Control outgoing connections from Privileged Access Manager endpoint to a remote host.

**Step 1:** Add a remote host ([My\\_Remote\\_Host.example.com](#)) in /etc/hosts. Run the following command at the command prompt.

```
vi /etc/hosts
```

**Step 2:** For network interception, the lookahead database "ladb" must be properly entered with the remote host address. To ensure this works, run the following command at the command prompt.

```
./sebuildla -h
```

**Step 3:** Run the following command at the command prompt to verify that the remote host ([My\\_Remote\\_Host.example.com](#)) is added to /etc/hosts.

```
./sebuildla -H
```

**Step 4:** Define a rule that prevents Telnet connections from Privileged Access Manager endpoint to the specified remote host, by a specific user.

```
PAMSC> authorize CONNECT My\_Remote\_Host.ca.com uid(john) access(none)
```

To deny all user access to the remote host, use '\*' for uid.

```
PAMSC> authorize CONNECT My_Remote_Host.ca.com uid(*) access(none)
```

You can also specify a program on the remote host that a user is allowed to connect to.

```
PAMSC> authorize CONNECT My_Remote_Host.ca.com uid(john) via(pgm(/usr/bin/telnet))  
access(r)
```

**Step 5:** Log in as John user and try to connect to the remote host using Telnet. The connection fails but other connections are not affected.

## CONTAINER Class

Each record in the CONTAINER class defines a group of objects from other resource classes, thus simplifying the job of defining access rules when a rule applies to several different classes of objects. Members of a CONTAINER class record can be objects from any of the following classes:

- APPL
- AUTHHOST
- CONNECT
- CONTAINER
- DICTIONARY
- DOMAIN (Windows only)
- FILE
- GAPPL
- GAUTHHOST
- GFILE
- GHOST
- GSUDO
- GTERMINAL
- HNODE
- HOLIDAY
- HOST
- HOSTNET
- HOSTNP
- MFTERMINAL
- PARAM\_DESC
- POLICY
- PROCESS
- PROGRAM
- REGKEY (Windows only)
- RULESET
- SUDO
- SURROGATE
- TCP
- TERMINAL
- WEBSERVICE

**NOTE**

CONTAINER records can be nested in other CONTAINER records.

Before you specify an object as a member of a CONTAINER record, you must create a record for it in its appropriate class.

If an object in the container does not have an ACL in its appropriate class record, it inherits the ACL for the CONTAINER record of which it is a member.

The key of the CONTAINER class is the name of the CONTAINER record.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Access**  
Defines the access authority that the accessor has to the resource.

Use the access parameter with the authorize or authorize- command to modify the ACL.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **MEMBERS**

The list of objects from any class that are members of the group.

Use the mem+ or mem- parameter with the chres, editres, and newres commands to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

#### **OWNER**

Defines the user or group that owns the record.

#### **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Program**

Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

#### **NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the via(*pgm*) parameter with the selang authorize command to add programs, accessors, and their access types to a PACL. You can use the authorize- command to remove accessors from a PACL.

#### **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

### UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

### UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## DEPLOYMENT Class

Each record in the DEPLOYMENT class defines a deployment or undeployment task for an endpoint. A deployment task includes information that the endpoint needs to deploy or undeploy a policy as required.

The key of the DEPLOYMENT class is the name of the deployment task, which is usually generated automatically.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the access parameter with the authorize or authorize- command to modify the ACL.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **DMS\_NAME**

Defines the name of the DMS where the deployment task was created.

- **GPOLICY**  
Defines the name of the policy this deployment task was created for.
- **GROUPS**  
Defines the deployment package (GDEPLOYMENT) this deployment task is a member of.
- **HNODE**  
Defines the host this deployment task was created for.
- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**  
Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

#### **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

#### **OPERATION**

Specifies the type of operation that the endpoint should perform as a result of this deployment task. Can be one of: Deploy, Undeploy.

#### **OWNER**

Defines the user or group that owns the record.

#### **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

#### **NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

#### **POLICY\_VERSION**

Defines the policy version this deployment task was created for.

#### **RESULT\_MESSAGE**

Defines the output from the deployment or undeployment selang script. These are the messages selang outputs when the policy deployment or undeployment scripts are run.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from *Resource AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## SECLABEL

Defines the security label of a user or resource.

### NOTE

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

## SECLEVEL

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

## STATUS

Defines the status of the deployment task. Can be one of:

- **Success**Policy deployed without errors.
- **Warning**Deployment script executed with errors.
- **Fail**There was an error executing the deployment task.
- **No Action**The deployment package is effectively empty so there is nothing to do.

### NOTE

This can also be a result of the policy already being assigned to the host through a different deployment path.

- **Not Executed**Policy verification found one or more errors in the policy.
- **Out of Sync**The policy contains a variable and the variable value has changed on the endpoint.
- **Pending Deployment**The policy contains an undefined or unresolved variable.
- **Pending Prerequisite**The deployment task will be executed only after all prerequisite policies are deployed.
- **Pending Dependents**The deployment task will be executed (undeploy policy) only after all dependent policies are also undeployed.
- **Fix**The deployment task is waiting to be deployed again.

## TARGETTYPE

Defines the type of host (target) to limit the policyfetcher to process only Privileged Access Manager deployment packages. Can be one of: UNAB, AC, None.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the `defaccess` parameter with the `chres`, `editres`, or `newres` command to modify this property.

### UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

### UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

### WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## DICTIONARY Class

Each record in the **DICTIONARY** class defines a word in a common dictionary stored in the Privileged Access Manager database to compare passwords to. When users change their passwords, the passwords are checked against each record in this **DICTIONARY** class.

In addition to adding records (words) to the **DICTIONARY** class, you can import dictionary words from external files by running a utility or program.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **OWNER**

Defines the user or group that owns the record.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. **RAUDIT** derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## DOMAIN Class

### Valid on Windows

Each record in the DOMAIN class defines a domain in the Windows network.

The key to the DOMAIN record is the domain name.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.  
Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.
- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

### Accessor

Defines an accessor.

- **Access**  
Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

### NOTIFY

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

## OWNER

Defines the user or group that owns the record.

## PACL

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

### NOTE

You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

## SECLABEL

Defines the security label of a user or resource.

### NOTE

The SECLABEL property corresponds to the `label[-]` parameter of the `chres` and `ch[x]usr` commands.

## SECLEVEL

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the `level[-]` parameter of the `ch[x]usr` and `chres` commands.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the `defaccess` parameter with the `chres`, `editres`, or `newres` command to modify this property.

**UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

**UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

**WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**FILE Class**

Each record in the FILE class defines the access that is allowed to a specific file or directory, or to files that match a file name pattern. You can define a rule even though a file is not yet created.

Device files and symbolic links can be protected like any other file. However, by protecting a link, you do not automatically protect the file that the link points to.

**NOTE**

On the NTFS file system, a record in the FILE class also defines the access to the file streams.

When you define a script as a file, allow both *read* and *execute* access to the file. When you define a binary, *execute* access is sufficient.

For users outside the *special\_restricted* group, the *\_default* record in the FILE class (if *\_default* record does not exist then the record for FILE in the UACC class) *protects only files that are part of Privileged Access Manager* such as the seos.ini, seosd.trace, seos.audit, and seos.error files. These files are not explicitly defined to *Privileged Access Manager*, but are automatically protected by *Privileged Access Manager*.

**NOTE**

*Privileged Access Manager* uses the PROGRAM class and not the FILE class to protect

```
setuid
and
setgid
programs.
```

The key of the FILE class record is the name of the file or directory protected by the record. The full path must be specified.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using Selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessor access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Access**  
Defines the access authority that the accessor has to the resource. Use the Access parameter with the authorize or authorize- command to modify the ACL.

- **CALACL**

Defines a list of the accessors (users and groups) that are permitted to access the resource, and their access types according to the Unicenter NSM calendar status. Each element in the Calendar Access Control List (CALACL) contains the following information:

- **Accessor**

- Defines an accessor.
- **Calendar**  
Defines a reference to a calendar in Unicenter TNG. Use the Calendar parameter with the authorize command to permit user or group access to the resource according to the access defined in the calendar ACL.
- **Access**  
Defines the access authority that the accessor has to the resource. Access is permitted only when the calendar is ON. Access is denied in all other cases.
- **CALENDAR**  
Represents a Unicenter TNG calendar object for user, group, and resource restrictions in *Privileged Access Manager*. *Privileged Access Manager* fetches Unicenter TNG active calendars at specified time intervals.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. *Privileged Access Manager* does not use this information for authorization.  
**Limit:** 255 characters
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property. The resolution of daytime restrictions is one minute.
- **Groups**  
The list of GFILE or CONTAINER records a resource record belongs to.  
**DB property:** GROUPS  
To modify this property in a FILE class record, change the MEMBERS property in the appropriate CONTAINER or GFILE record.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres`, or `newres` command to modify this property.
- **NACL**  
The NACL property of a resource is an access control list. The list defines the accessors that are denied authorization to a resource, along with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the type of access that is denied to the accessor. Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.
- **NOTIFY**  
Defines the user to be notified when a resource or user generates an audit event. *Privileged Access Manager* can email the audit record to the specified user.  
**Limit:** 30 characters.
- **OWNER**  
Defines the user or group that owns the record.
- **PACL**  
Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Program**

Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

**NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `Selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

- **RAUDIT**

Defines the types of access events that *Privileged Access Manager* records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests

- **success**

Granted access requests

- **failure**

Denied access requests (default).

- **none**

No access requests

*Privileged Access Manager* records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member. Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

- **SECLABEL**

Defines the security label of a user or resource.

**NOTE**

The SECLABEL property corresponds to the `label[-]` parameter of the

`chres`

and

`ch[x]usr`

commands.

- **SECLEVEL**

Defines the security level of an accessor or resource. This property corresponds to the `level[-]` parameter of the `ch[x]usr` and `chres` commands.

- **UACC**

Defines the default access authority for the resource, which indicates the access that is granted to accessors who are not defined to *Privileged Access Manager* or who do not appear in the ACL of the resource.

Use the `defaccess` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **UNTRUST**

Defines whether the resource is untrusted or trusted. If the UNTRUST property is set, accessors cannot use the resource. If the UNTRUST property is not set, the other properties that are listed in the database for the resource are used to determine accessor access authority. If a trusted resource is changed in any way, *Privileged Access Manager* automatically sets the UNTRUST property.

Use the `trust[-]` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **WARNING**

Specifies whether Warning mode is enabled. If you enable the Warning mode on a resource, then all the access request to a resource is granted. If an access request violates an access rule, a record is written to the audit log.

**Example:** This example shows how to restrict user access to a file by using the FILE class in Unix/Linux endpoint.

**Step 1:** Create a file "/home/my\_home/hello.c".

```
PAMSC> nf /home/my_home/hello.c
```

**Step 2:** When a file is created, by default every one has read access. We create a policy that restricts default user access to the file "/home/my\_home/hello.c". This policy restricts even the superuser (example, root) from accessing the file.

```
PAMSC> er FILE("/home/my_home/hello.c") audit(all) owner(nobody) defaccess(none)
```

**Step 3:** View the file "/home/my\_home/hello.c" details.

```
PAMSC> sr FILE /home/my_home/hello.c
(localhost)
Data for FILE '/home/my_home/hello.c'
-----
Defaccess : None
Audit mode : All
Owner : nobody (USER )
Create time : 13-Feb-2017 14:58
Update time : 13-Feb-2017 15:04
Updated by : root (USER )
```

**Step 4:** A user logs in to the host and tries to access the file "/home/my\_home/hello.c". The policy restricts user from accessing the file.

```
Host_Machine_Name> ls -l /home/my_home/hello.c
/bin/ls: cannot access /home/my_home/hello.c: Permission denied
```

**Step 5:** Create a policy that authorizes superuser (root) to access this file.

```
PAMSC> AUTHORIZE FILE("/home/my_home/hello.c") uid(root) access(a)
```

**Step 6:** View the file "/home/my\_home/hello.c" details.

```
PAMSC> sr file /home/my_home/hello.c
(localhost)
Data for FILE '/home/my_home/hello.c'
-----
Defaccess : None
ACLs :
```

```

Accessor Access
root (USER ) R, W, X, Cre, Del, Chown, Chmod, Utime, Sec, Rename, Chdir
Audit mode : All
Owner : nobody (USER )
Create time : 13-Feb-2017 14:58
Update time : 16-Feb-2017 17:54
Updated by : root (USER )

```

## GAPPL Class

Each record in the GAPPL class defines a group of applications used by CA SSO. You must create an APPL class record for each application before adding it to a GAPPL record. You must then explicitly connect records of the APPL class to the GAPPL record in order to group them.

The key of the GAPPL class record is the name of the GAPPL record.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.
- **AZNACL**  
Defines the authorization ACL. The authorization ACL is an ACL that allows access to a resource based on the resource description. The description is sent to the authorization engine, not the object. Typically, when an AZNACL is used, the object is not in the database.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **GROUPS**  
The list of CONTAINER records a resource record belongs to.  
To modify this property in a GAPPL class record, you must change the MEMBERS property in the appropriate CONTAINER record.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.
- **MEMBERS**  
The list of objects from the APPL class that are members of the group.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres`, and `newres` commands to modify this property.
- **NACL**

The **NACL** property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also **ACL**, **CALACL**, **PACL**. Each entry in the **NACL** contains the following information:

### Accessor

Defines an accessor.

- **Access**  
Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

## OWNER

Defines the user or group that owns the record.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

## UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## GAUTHHOST Class

Each record in the GAUTHHOST class defines a group of authentication hosts used by CA SSO. You must create an AUTHHOST class record for each application before adding it to a GAUTHHOST record. You must then explicitly connect records of the AUTHHOST class to the GAUTHHOST record in order to group them.

The key of the GAUTHHOST class record is the name of the GAUTHHOST record.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the `access` parameter with the `authorize` or `authorize-` command to modify the ACL.
- **AZNACL**

Defines the authorization ACL. The authorization ACL is an ACL that allows access to a resource based on the resource description. The description is sent to the authorization engine, not the object. Typically, when an AZNACL is used, the object is not in the database.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **GROUPS**

The list of CONTAINER records a resource record belongs to.

To modify this property in a GAUTHHOST class record, you must change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **MEMBERS**

The list of objects from the AUTHHOST class that are members of the group.

Use the mem+ or mem- parameter with the chres, editres, and newres commands to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

#### **OWNER**

Defines the user or group that owns the record.

#### **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from *Resource AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

#### **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## GFILE Class

Each record in the GFILE class defines the access allowed to a group of specific files, specific directories, or files that match a name pattern. You must create a FILE class record for each application before adding it to a GFILE record. You must then explicitly connect records of the FILE class to the GFILE record in order to group them. A file need not have been created yet in order to have a FILE class record defined for it.

The key of the GFILE class record is the name of the GFILE record.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the `access` parameter with the `authorize` or `authorize-` command to modify the ACL.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the `restrictions` parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.
- **MEMBERS**  
The list of objects from the FILE class that are members of the group.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres`, and `newres` commands to modify this property.
- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

### Accessor

Defines an accessor.

- **Access**  
Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

## NOTIFY

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

## OWNER

Defines the user or group that owns the record.

## PACL

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

### NOTE

You can use wildcard characters to specify the resource in a PACL.

Use the *via(pgm)* parameter with the *selang authorize* command to add programs, accessors, and their access types to a PACL. You can use the *authorize-* command to remove accessors from a PACL.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the *audit* parameter of the *chres* and *chfile* commands to modify the audit mode.

## UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## GDEPLOYMENT Class

Each record in the GDEPLOYMENT class defines a deployment package. A deployment package is created automatically on the DMS. The package groups together all the deployment tasks that are created as a result of the same transaction

(policy assignment, upgrade, and so on) and for a particular host. This means that each transaction you make creates the required number of deployment tasks (DEPLOYMENT objects) and groups these by host (GDEPLOYMENT objects).

The key of the GDEPLOYMENT class is the name of the deployment package, which is generated automatically.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Nonmodifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the access types of the accessors.

Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.

- **CATEGORY**

Defines one or more security categories assigned to a user or a resource.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GHNODE**

Defines the host group this deployment package was created for.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the `mem+` or `mem-` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **HNODE**

Defines the host this deployment package was created for.

- **MEMBERS**

The list of objects from the DEPLOYMENT class that are members of the group.

Use the `mem+` or `mem-` parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource. The list also specifies the type of access that they are denied. Example: `write`. See also *ACL*, *CALACL*, *PACL*. Each entry in the NACL contains the following information:

**Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

**NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

## OWNER

Defines the user or group that owns the record.

## PACL

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

### NOTE

You can use wildcard characters to specify the resource in a PACL.

Use the *via(pgm)* parameter with the *selang authorize* command to add programs, accessors, and their access types to a PACL. You can use the *authorize-* command to remove accessors from a PACL.

## POLICY

Defines the policy this deployment package was created for.

## SECLABEL

Defines the security label of a user or resource.

### NOTE

The SECLABEL property corresponds to the *label[-]* parameter of the *chres* and *ch[x]usr* commands.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests
- **success**  
Granted access requests
- **failure**  
Denied access requests (default)
- **none**  
No access requests

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource. The product also does not record whether the access rules were applied to a group or class that had the resource as a member.

Use the *audit* parameter of the *chres* and *chfile* commands to modify the audit mode.

## SECLEVEL

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

## TRIGGER

Specifies the reason this deployment package was created:

- Assign - A result of assigning a policy to a host, or a host to a host group.
- AutoAssign - A result of the DMS automatically assigning a host to a host group.
- UnAssign - A result of unassigning a policy from a host, or a host from a host group.
- Direct Deploy - A result of a direct deploy action.
- Direct Undeploy - A result of a direct undeploy action.
- Upgrade - A result of an upgrade action.
- Restore - A result of a restore action on a host (HNODE).
- Hnode Deletion - A result of deleting a host (HNODE).
- Ghnode Deletion - A result of deleting a host group (GHNODE).
- Reset - A result of resetting a host.
- Downgrade - A result of policy downgrade on hosts.

## UACC

Defines the default access authority for the resource. The access authority indicates the access that is granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

## UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted. If an access request violates an access rule, a record is written to the audit log.

## GHNODE Class

Each record in the GHNODE class defines a host group-a group of hosts (HNODE objects). You must create a HNODE class record for each host before adding it to a GHOST record.

This class is used to manage policy deployment and assignment.

The key of the GHNODE class record is a logical name for the host group.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Access**  
Defines the access authority that the accessor has to the resource.

Use the access parameter with the authorize or authorize- command to modify the ACL.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **CRITERIA**

Defines the criteria that the DMS uses to automatically add hosts to this host group. You can specify criteria that matches or excludes the following HNODE properties: ATTRIBUTES, COMMENT, HNODE\_INFO, HNODE\_IP, HNODE\_VERSION, NODE\_TYPE

For example, the HNODE records for Windows endpoints have the property HNODE\_INFO=Windows. If the CRITERIA property for a GHNODE record has the value of HNODE\_INFO=Windows, the DMS automatically adds any new Windows HNODE to the GHNODE.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **MEMBERS**

The list of objects from the HNODE class that are members of the group.

Use the mem+ or mem- parameter with the chres, editres, and newres commands to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

#### **OWNER**

Defines the user or group that owns the record.

#### **POLICIES**

The list of policies that should be deployed on this object.

#### **POLICYASSIGN**

Defines the list of policies that are assigned to this object.

Display name: Assigned Policies

#### **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests.

- **success**

Granted access requests.

- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

## UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## GHOST Class

Each record in the GHOST class defines a group of hosts. You create a HOST class record for each host before adding it to a GHOST record. The services must be defined to the system using the /etc/services file (for UNIX), \system32\drivers\etc\services file (for Windows), or another service name resolution method. When authorizing services, you can identify the services by their port numbers in the TCP/IP protocol rather than by their names. When adding services, you can identify the services by their port numbers in the TCP/IP protocol rather than by their names. You then explicitly connect records of the HOST class to the GHOST record to group them.

GHOST records define access rules that govern the access other stations (hosts) belonging to the group of hosts have to the local host when using Internet communication. For each client group (GHOST record), the INETACL property lists the service rules that govern the services the local host may provide to hosts belonging to the client group.

The key of the GHOST class record is the name of the GHOST record.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **INETACL**

Defines the services the local host is allowed to provide to the group of client hosts and what their access types are.

Each element in the access control list contains the following information:

- **Services reference**

A reference to a service (a port number or name). To specify all the services, enter an asterisk (\*) as the services reference.

Privileged Access Manager supports dynamic port names as specified in the /etc/rpc file (for UNIX) or \etc\rpc file (for Windows).

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access(*type-of-access*), service, and stationName parameters with the authorize[-] command to modify accessors and their access types in the INETACL property.

- **INSERVNGE**

Specifies the range of services that the local host provides to the group of client hosts.

Performs a similar function to the INETACL property.

Use the service(*serviceRange*) parameter with the authorize[-] command to modify accessors and their access types in the INSERVNGE property.

- **MEMBERS**

The list of objects from the HOST class that are members of the group.

Use the mem+ or mem- parameter with the chres, editres, and newres commands to modify this property.

- **OWNER**

Defines the user or group that owns the record.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests.

- **success**

Granted access requests.

- **failure**

Denied access requests (default).

- **none**

No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## GPOLICY Class

Each record in the GPOLICY class defines a logical policy. It contains information about the policy versions (POLICY objects) that belong to this policy and the hosts and host groups it is assigned to.

The key of the GDEPLOYMENT class is the name of the logical policy.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.  
Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GHNODEASSIGN**  
Defines the host groups this policy is assigned to.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.
- **HNODEASSIGN**  
Defines the hosts this policy is assigned to.
- **LATEST\_FINALIZED\_VERSION**  
Defines the name of the latest policy version (POLICY object) that is finalized.
- **LATEST\_VERSION**  
Defines the name of the latest policy version (POLICY object) associated with this policy.
- **MEMBERS**  
The list of objects from the POLICY class (policy versions) that are members of the group.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres`, and `newres` commands to modify this property.
- **NACL**

The NACL property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

### Accessor

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

## NOTIFY

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

## OWNER

Defines the user or group that owns the record.

## PACL

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Program**

Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

### NOTE

You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

## POLICY TYPE

A value representing the group policy type. Valid values are:

- **None**
- **Login** Specifies that the policy is a UNAB login policy.
- **Configuration** Specifies that the policy is a UNAB configuration policy.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests.

- **success**

Granted access requests.

- **failure**

Denied access requests (default).

- **none**

No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

**SECLABEL**

Defines the security label of a user or resource.

**NOTE**

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

**SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

**UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

**UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

**UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

**WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**GROUP Class**

Each record in the GROUP class defines a group of users in the database.

The key of each GROUP class record is the name of the group.

**NOTE**

The properties of profile groups apply to each user associated with the profile group. However, if the same property is specified in a user (USER or XUSER) record, the user record overrides those in the profile group record.

You can change most of these properties from the Privileged Access Manager Endpoint Management, or by using the selang command chgrp.

**NOTE**

Usually, and unless otherwise indicated, to change a property using ch[x]grp, you use the property name as the command parameter.

You can view all properties from the Privileged Access Manager Endpoint Management, or by using the selang command showgrp.

- **APPLS**

(Informational) Displays the list of applications that the accessor is authorized to access. Used by CA SSO.

- **AUDIT\_MODE**

Defines the activities that Privileged Access Manager records in the audit log. You can specify any combination of the following activities:

- No logging
- All activities recorded in the trace file
- Unsuccessful login attempts
- Successful logins
- Failed access attempts to resources protected by Privileged Access Manager
- Successful accesses to resources protected by Privileged Access Manager
- Interactive logins

#### **NOTE**

This property corresponds to the audit parameter of the `ch[x]usr` and `ch[x]grp` commands. You can use `AUDIT_MODE` for a `GROUP` or `XGROUP` to set the audit mode for all members of the group. However, you cannot use `AUDIT_MODE` to set the audit mode for group members if the audit mode of a user is defined in a `USER` record, `XUSER` record, or profile group.

- **AUTHNMTHD**  
(Informational) Displays the authentication method or methods to be used with the group record; from method 1 to method 32, or none. Used by CA SSO.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the `restrictions` parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **EXPIRE\_DATE**  
Defines the date on which an accessor becomes invalid. A value for the `EXPIRE_DATE` property in a user record overrides a value in a group record.  
**Note:** This property corresponds to the `expire[-]` parameter of the `ch[x]usr` and `ch[x]grp` commands.
- **FULLNAME**  
Defines the full name associated with an accessor. Privileged Access Manager uses the full name to identify the accessor in audit log messages, but not for authorization.  
`FULLNAME` is an alphanumeric string. For groups, the maximum length is 255 characters. For users, the maximum length is 47 characters.
- **GAPPLS**  
Defines the list of application groups that the group is authorized to access. Used by CA SSO.
- **GROUP\_MEMBER**  
Defines the groups that are members of this group.
- **GROUP\_TYPE**  
Specifies the group authority attributes. Each of these attributes corresponds to the parameter of the same name in the `ch[x]grp` command. A group can have one or more of the following authority attributes:
  - **ADMIN**  
Specifies whether a user who belongs to the group can perform administrative functions, similar to root in the UNIX environment.
  - **AUDITOR**  
Specifies whether a user who belongs to the group can monitor the system, list information in the database, and can set the audit mode for existing records.
  - **OPERATOR**

Specifies whether a user who belongs to the group can list everything in the database and can use the `secons` utility.

- **PWMANAGER**

Specifies whether a user who belongs to the group can modify the password settings of other users and can enable a user account that the `serevu` utility has disabled.

- **SERVER**

Specifies whether a process can ask users who belong to the group for authorization and can issue the `SEOSROUTE_VerifyCreate` API call.

- **HOMEDIR**

Defines the path of the home directory assigned to a new group member.

Use the `homedir` parameter with the `chgrp`, `editgrp`, or `newgrp` command to modify this property.

**Limit:** 255 alphanumeric characters

- **INACTIVE**

Defines the number of days of inactivity that must pass before the system changes the status of a user to inactive. If the account status is inactive, the user cannot log in.

A value for the **INACTIVE** property in a **USER** record overrides a value in a **GROUP** record. Both override the **INACT** property in the **SEOS** class record.

**NOTE**

Privileged Access Manager does not store the status; it calculates the status dynamically. To identify inactive users, compare the **INACTIVE** value with the **LAST\_ACC\_TIME** value of the user.

**INACTIVE** is part of the profile feature.

- **MAXLOGINS**

Defines the maximum number of concurrent logins that a user is allowed. A zero value indicates that the user can have any number of concurrent logins.

A value for the **MAXLOGINS** property in a user record overrides a value in a group record. Both override the value of **MAXLOGINS** in the **SEOS** class record.

**MAXLOGINS** is part of the profile feature.

- **MEMBER\_OF**

Defines the groups that this group is a member of.

- **OWNER**

Defines the user or group that owns the record.

- **PASSWDRULES**

Specifies the password rules. This property contains several fields that determine how Privileged Access Manager handles password protection. For a complete list of the rules, see the modifiable property **PROFILE** of the **USER** class. Use the `passwordparameter` and the `rules` or `rules-` option with the `setoptions` command to modify this property.

**PASSWDRULES** is part of the profile feature.

- **POLICYMODEL**

Specifies the **PMDB** that receives new passwords when you change user passwords with the `sepass` utility. The passwords are *not* sent to the Policy Model defined by the `parent_pmd` or `passwd_pmd` configuration settings if a value is entered for this property.

**Note:** This property corresponds to the `pmdb[-]` parameter of the `ch[x]usr` and `ch[x]grp` commands.

**POLICYMODEL** is part of the profile feature.

- **PROFUSR**

Displays a list of the users associated with this profile group.

- **PWD\_AUTOGEN**

Indicates whether the group password is automatically generated. The default is `no`. Used by CA SSO.

- **PWD\_SYNC**

Indicates whether the group password is automatically kept identical for all group applications. The default is `no`. Used by CA SSO.

- **PWPOLICY**

Defines the record name of the password policy for the group. A password policy is a set of rules for checking the validity of a new password and for defining when a password expires. The default is no validity check. Used by CA SSO.

- **RESUME\_DATE**

Defines the date on which a suspended USER account becomes unsuspended.

RESUME\_DATE and SUSPEND\_DATE work together.

**NOTE**

This property corresponds to the resume[-] parameter of the ch[x]usr and ch[x]grp commands. RESUME\_DATE is part of the profile feature.

- **REVACL**

Displays the access control lists of the accessor.

- **SHELL**

(UNIX only) The shell program that is assigned to a new UNIX user when the user is a member of this group.

Use the shellprog parameter with the chxgrp command to modify this property.

- **SUBGROUP**

Displays the list of groups that have this group as a parent.

- **SUPGROUP**

Defines the name of the parent group (superior group).

Use the parent[-] parameter with the ch[x]grp command to modify this property.

- **SUSPEND\_DATE**

Defines the date on which a user account is suspended and so becomes invalid.

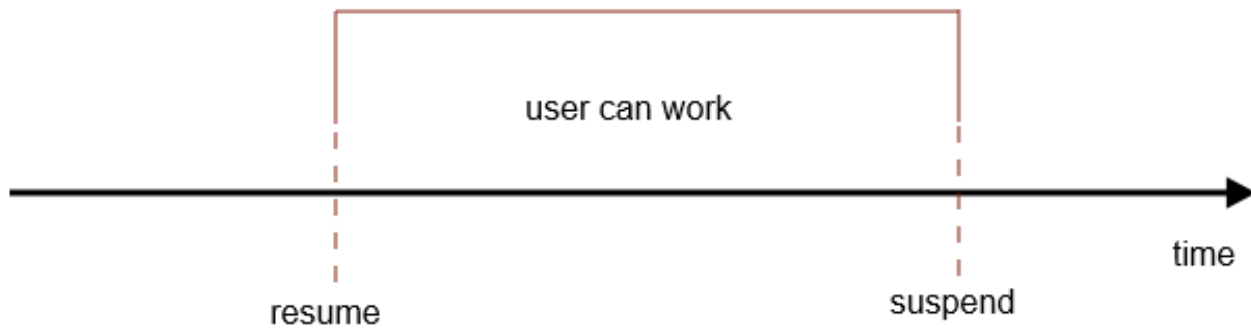

If the suspend date for a record precedes its resume date, the user can work before the suspend date and after the resume date.

**Figure 53: suspend\_date3a**

If a user has a resume date that is earlier than the suspend date, the record is also invalid *before* the resume date. The user can work only between the resume and suspend dates.

**Figure 54: suspend\_date4a**

A value for the SUSPEND\_DATE property in a user record overrides the value in a group record.

**NOTE**

This property corresponds to the suspend[-] parameter of the ch[x]usr and ch[x]grp commands.

- **SUSPEND\_WHO**  
Displays the administrator who activated the suspend date.
- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.
- **USERLIST**  
Defines the users that belong to the group.  
The user list that is contained in this property can be different from the one in the native environment USERS property.  
Use the join[x][-] commands to modify this property.

## GSUDO Class

Each record in the GSUDO class defines a group of actions that Task Delegation-the DO (sesudo)-allows a user to execute or prevents a user from executing. You must create a SUDO class record for each action before adding it to a GSUDO record.

Use GSUDO to define access rules for a group of SUDO resources rather than specifying the same access rule for each resource. You must explicitly connect records of the SUDO class to the GSUDO record in order to group them.

The key of the GSUDO class record is the name of the group.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the access parameter with the authorize or authorize- command to modify the ACL.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.  
Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.
- **MEMBERS**  
The list of objects from the SUDO class that are members of the group.  
Use the mem+ or mem- parameter with the chres, editres, and newres commands to modify this property.
- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**  
Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

#### **OWNER**

Defines the user or group that owns the record.

#### **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

#### **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

#### **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## GTERMINAL Class

Each record in the GTERMINAL class defines a group of terminals. You must create a TERMINAL class record for each terminal before adding it to a GTERMINAL record. You must then explicitly connect records of the TERMINAL class to the GTERMINAL record in order to group them.

Terminal groups are useful when defining access rules. You can use a single command to specify an access rule for a group of terminals rather than having to specify the same access rule for each terminal. Similarly, you may apply a rule for a group of terminals by a single command to a group of users.

The key of the GTERMINAL class record is the name of the terminal group.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the `access` parameter with the `authorize` or `authorize-` command to modify the ACL.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.

- **MEMBERS**

The list of objects from the TERMINAL class that are members of the group.

Use the `mem+` or `mem-` parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

### Accessor

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

### OWNER

Defines the user or group that owns the record.

### RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

### UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

### UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## GWINSERVICE Class

Each record in the GWINSERVICE class defines a group of Windows Services. Use records in the GWINSERVICE class to define access rules for a group of Windows Services.

The key of a GWINSERVICE class record is the name of the GWINSERVICE record.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the access parameter with the authorize or authorize- command to modify the ACL.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.  
Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.
- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

### **Accessor**

Defines an accessor.

- **Access**  
Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

### **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

### **OWNER**

Defines the user or group that owns the record.

### **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

### **NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

### **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

**UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

**UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

**HNODE Class**

The HNODE class contains information about the organization's Privileged Access Manager hosts. Each record in the class represents a node in the enterprise.

This class is used to manage the information uploaded from the various PMDBs and endpoints and stored on the DMS.

The key of the HNODE class record is the actual host name for an endpoint (for example, myHost.ca.com) or the PMDB name for a Policy Model node (for example, myPMD@myHost.ca.com).

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.

- **ATTRIBUTES**

Defines the custom criteria that the DMS uses to assess if the host is automatically added to a host group.

**NOTE**

The DMS also examines the following HNODE properties to assess if a host should be automatically added to a host group: `COMMENT`, `HNODE_INFO`, `HNODE_IP`, `HNODE_VERSION`, `NODE_TYPE`

- **CATEGORY**

Defines one or more security categories assigned to a user or a resource.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **COMPLIANT\_UPDATE\_TIME**

(Informational) Displays the date and time when the status was last changed.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.

The resolution of daytime restrictions is one minute.

- **EFFECTIVE\_POLICIES**

Defines the list of policy versions that should be deployed on this object.

Display name: Effective Policies

- **GHNODES**

Defines the list of host groups this object is a member of.

Display name: node groups

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **HNODE\_IP**

The IP address of the host.

Display name: IP

- **HNODE\_KEEP\_ALIVE**

Defines the last time the HNODE sent a heartbeat to the Distribution Host.

Display name: Last Heartbeat

- **HNODE\_EVENTS**

Displays a list of strings representing health recovery events that occurred on the endpoint. Health recovery events are, for example, restarting of an agent due to critical memory threshold breach, or bypassing of a program that deteriorates the performance of the endpoint.

- **HNODE\_INSTALL\_STATUS**

Displays the installation status of an endpoint. You can search endpoints by status in Privileged Access Manager Enterprise Management under World View.

**Values:** Success, Failure, Pending Reboot, Upgrading.

Display name: Install Status.

- **HNODE\_BYPASS\_EXIST**

Displays whether the endpoint is in bypass mode as a measure of precaution. In bypass mode, Privileged Access Manager policy handling is temporarily reduced. If this value is No then the endpoint is fully operational.

**Value:** Yes or No

Display name: Bypass exist.

- **LOGIN**

Defines the default access type to the host.

Display name: LOGIN

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

**Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

**NODE\_INFO**

(Informational) Specifies details of the node OS.

**NODE\_TYPE**

(Informational) Defines the type of Privileged Access Manager installation on the host. Valid values are:

- ACUCA ControlMinder for UNIX
- ACWCA ControlMinder for Windows
- UNABUNIX Authentication Broker (UNAB)

**NOTE**

A HNODE record can have a value of both ACU and UNAB for the NODE\_TYPE property.

**NODE\_VERSION****NOTE**

(Informational) Defines the Privileged Access Manager version installed on the host. The version number is preceded by the NODE\_TYPE. Example: ACU:12.50-00.647

**NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

**OWNER**

Defines the user or group that owns the record.

**PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

**NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the *via(pgm)* parameter with the *selang authorize* command to add programs, accessors, and their access types to a PACL. You can use the *authorize-* command to remove accessors from a PACL.

**PARENTS**

(Informational). The list of PMDBs that are the parents of the node in the propagation tree (also defined by the *parent\_pmd* configuration setting).

**POLICYASSIGN**

Defines the list of policies that are assigned to this object.

Display name: Assigned Policies

**POLICY**

The status of each of the policies listed in the POLICIES property. The value of the property is a structure with the following fields:

- **nNAME**  
Object ID of the POLICY object. Same as the value of the POLICIES property.
- **STATUS**  
An integer representing one of the following:
  - DeployedPolicy was deployed successfully on endpoint.
  - Deployed with FailuresPolicy was deployed with one or more rules from the deployment script failing to execute on the endpoint.
  - UndeployedPolicy was undeployed successfully from endpoint.

**Note:** If a policy is undeployed, no status appears for the host (that is, the status is empty).

- Undeployed with FailuresPolicy was undeployed with one or more rules from the undeployment script failing to execute on the endpoint.

- Failed DeploymentPolicy failed to deploy due to an error in the deployment script.

**Note:** This status can appear only if policy verification is enabled. Otherwise, policyfetcher deploys a policy even if the policy contains errors (Deployed with Failures status).

- UnknownPolicy status is unknown.
- Deploy PendingWaiting for a prerequisite policy to be deployed or the policy contains an undefined or unresolved variable.
- Undeploy PendingWaiting for a dependent policy to be undeployed.
- Out of SyncThe policy contains a variable and the variable value has changed on the endpoint.
- Not ExecutedPolicy verification found one or more errors with the policy.
- QueuedObsolete (for backward compatibility only.)
- TransferredObsolete (for backward compatibility only.)
- Transferred FailedObsolete (for backward compatibility only.)
- Signature FailedObsolete (for backward compatibility only.)

- **deviation**

A value representing whether there is a policy deviation on this node. Valid values are:

- Yes
- No
- Unset

- **dev\_time**

Last deviation status update time.

- **ptime**

Last policy status update time.

- **updater**

The name of the user that deployed or removed the policy.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## SECLABEL

Defines the security label of a user or resource.

### NOTE

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

## SECLEVEL

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

## SUBSCRIBER\_STATUS

The status of the node per parent. The value of the property is a structure with the following fields:

- **oidSubs**  
Object ID of the HNODE object. Same as the value of the SUBSCRIBERS property.
- **status**  
A value representing one of the following statuses:
  - Available
  - Unavailable
  - Sync (synchronizing)
  - Unknown
- **stime**  
Last status update time.

## SUBSCRIBERS

The list of subscribers of the node in the propagation tree. Updating this property, implicitly updates the PARENTS property with the value of the HNODE object name.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

## UNAB\_ID

(Informational) Displays the UNAB host ID for reporting purposes.

## UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## HOLIDAY Class

Each record in the HOLIDAY class defines one or more periods when users need extra permission to log in.

Each user has the same access for all the time periods in a record. This means that if you include more than one holiday period in a holiday record, you cannot allow a user to log in during some of those periods and prevent that user from logging in during others. For example, if you want to allow a specific user to log in during New Year's Day but not during Christmas, then the two holidays must be defined in different records.

If you do not specify the year, the holiday is considered annual.

You can override HOLIDAY class restrictions for individual users by specifying the IGN\_HOL attribute in the newusr, chusr, or editusr command.

The key of the HOLIDAY class record is the name of the HOLIDAY record.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.

- **CATEGORY**

Defines one or more security categories assigned to a user or a resource.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.

- **HOL\_DATE**

Specifies the period during which users cannot log in.

The following rules apply to the HOL\_DATE property:

- If you do not specify a year, it means the period or holiday is annual. You can specify the year with two digits or four digits, for example: 99 or 1999.
- If you do not specify a start time then the start of the day (midnight) is used; and if you do not specify an end time then the end of the day (midnight) is used.
- If you do not specify an interval of time, but only a date, then the holiday lasts for one whole day.

Use the dates parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **NACL**

The NACL property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

**Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

**NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

**OWNER**

Defines the user or group that owns the record.

## **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## **SECLABEL**

Defines the security label of a user or resource.

### **NOTE**

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

## **SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

## **UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

## **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

## **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## **HOST Class**

Each record in the HOST class defines the access that a host has to the local computer connected by IPv4 or IPv6.

Privileged Access Manager resolves the addresses of host names that you add to the HOST class. This means that the names must appear in the operating system hosts file, or must be defined to NIS or DNS.

For each HOST record, the INETACL property defines the services the local host can provide to that host.

Privileged Access Manager permits aliases for a host name, but records that represent aliases are not used for authorization checks. You must know the canonical name of a host for Privileged Access Manager to protect the connection with that host.

Privileged Access Manager resolves a hostname by one IP address. If multiple IP addresses are configured for one hostname, then use one of the following classes:

- GHOST
- HOSTNET
- HOSTNP

The key of the HOST class record is the name of the host.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Nonmodifiable properties are marked *informational*.

- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
The list of GHOST or CONTAINER records a resource record belongs to.  
To modify this property in a HOST class record, change the MEMBERS property in the appropriate CONTAINER or GHOST record.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.
- **INETACL**  
Defines the services the local host is allowed to provide to the group of client hosts and what their access types are. Each element in the access control list contains the following information:
  - **Services reference**  
A reference to a service (a port number or name). To specify all the services, enter an asterisk (\*) as the services reference.  
Privileged Access Manager supports dynamic port names as specified in the `/etc/rpc` file (for UNIX) or `\etc\rpc` file (for Windows).
  - **Access**  
Defines the access authority that the accessor has to the resource.  
Use the `access(type-of-access)`, `service`, and `stationName` parameters with the `authorize[-]` command to modify accessors and their access types in the INETACL property.
- **INSERVNGE**  
Specifies the range of services that the local host provides to the group of client hosts.  
Performs a similar function to the INETACL property.  
Use the `service(serviceRange)` parameter with the `authorize[-]` command to modify accessors and their access types in the INSERVNGE property.
- **OWNER**  
Defines the user or group that owns the record.
- **RAUDIT**  
Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:
  - **all**

All access requests.

- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the `chres` and `chfile` commands to modify the audit mode.

- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.
- **WARNING**  
Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**Example:** Prevent incoming connections to Privileged Access Manager endpoint from a restricted remote host using Telnet.

**Step 1:** Add a remote host ([My\\_Remote\\_Host.example.com](#)) in `/etc/hosts`. Run the following command at the command prompt.

```
vi /etc/hosts
```

**Step 2:** For network interception, the lookahead database "ladb" must be properly entered with the remote host address. To ensure this works, run the following command at the command prompt.

```
./sebuildda -h
```

**Step 3:** Run the following command at the command prompt to verify that the remote host ([My\\_Remote\\_Host.example.com](#)) is added to `/etc/hosts`.

```
./sebuildda -H
```

**Step 4:** Define a remote host ([My\\_Remote\\_Host.example.com](#)) from which we prevent incoming Telnet connections.

```
PAMSC> nr HOST My\_Remote\_Host.example.com
```

**Step 5:** Set a rule that prevents incoming connections from the remote host ([My\\_Remote\\_Host.example.com](#)) using Telnet.

```
PAMSC> authorize HOST My\_Remote\_Host.example.com service(telnet) access(none)
```

**Step 6:** Try connecting from the remote host to the Privileged Access Manager endpoint using Telnet. The connection fails but other connections are not affected.

To deny any type of connection from a remote host (([My\\_Remote\\_Host.example.com](#))), set the following rule.

```
PAMSC> authorize HOST My\_Remote\_Host.example.com service(*) access(none)
```

## HOSTNET Class

Each record in the HOSTNET class defines a group of hosts on a particular network. HOSTNET records define rules that govern the access other hosts in the group have to the local host when using IPv4 communication.

### NOTE

Privileged Access Manager access rules for IP communication apply only to IPv4. They do not control access by IPv6.

The INMASKMATCH determines which other hosts are subject to a HOSTNET record. The INETACL property defines which services the local host can provide to those hosts.

The key of the HOSTNET class record is the name of the HOSTNET record.

The following definitions describe the properties that are contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.

- **INETACL**

Defines the services that the local host is allowed to provide to the group of client hosts and what their access types are. Each element in the access control list contains the following information:

- **Services reference**

A reference to a service (a port number or name). To specify all the services, enter an asterisk (\*) as the services reference.

Privileged Access Manager supports dynamic port names as specified in the `/etc/rpc` file (for UNIX) or `\etc\rpc` file (for Windows).

- **Access**

Defines the access authority that the accessor has to the resource.

Use the `access(type-of-access)`, `service`, and `stationName` parameters with the `authorize[-]` command to modify accessors and their access types in the INETACL property.

- **INSERVNGE**

Specifies the range of services that the local host provides to the group of client hosts.

Performs a similar function to the INETACL property.

Use the `service(serviceRange)` parameter with the `authorize[-]` command to modify accessors and their access types in the `INSERVRange` property.

- **INMASKMATCH**

Defines the group of hosts to which this HOSTNET record applies. The property contains mask and match values, which are applied to the IP address of the requesting host to determine whether the requesting host belongs to the group.

The INMASKMATCH property only supports addresses that are in IPv4 format .

**NOTE**

This property corresponds to the mask and match parameters of the `chres` command.

- **OWNER**

Defines the user or group that owns the record.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**Example:** Prevent incoming connections to Privileged Access Manager endpoint from remote hosts in a given subnet.

**Step 1:** Add remote hosts in `/etc/hosts`. Run the following command at the command prompt.

```
vi /etc/hosts
```

**Step 2:** For network interception, the lookahead database "ladb" must be properly entered with the remote host address. To ensure this works, run the following command at the command prompt.

```
./sebuildla -h
```

**Step 3:** Run the following command at the command prompt to verify that the remote hosts are added to `/etc/hosts`.

```
./sebuildla -H
```

**Step 4:** Create the given rule. Assume 'engineering' defines the group of hosts in the subnet (10.131.33) belonging to engineering department. As per the rule, all incoming connections from IP addresses (10.131.33.\*) are considered using the 'Mask' value.

```
PAMSC> nr HOSTNET engineering mask(255.255.255.0) match(10.131.33.0)
```

**Step 5:** Set a rule that prevents incoming connections from remote hosts in a given subnet using Telnet.

```
PAMSC> authorize HOSTNET engineering service(telnet) access(none)
```

**Step 6:** Try connecting from the remote host (within the subnet) to the Privileged Access Manager endpoint using Telnet. The connection fails but other connections are not affected.

To deny any type of connection from a remote host within a given subnet, set the following rule.

```
PAMSC> authorize HOSTNET engineering service(*) access(none)
```

## HOSTNP Class

Each record in the HOSTNP class defines a group of hosts that have similar host names. HOSTNP records define access rules that govern the access other stations (hosts) that match name pattern in the record have to the local host when using IPv4 or IPv6. For each mask (HOSTNP record), the INETACL property lists the service rules that govern the services that the local host might provide to the group of hosts.

The key of the HOSTNP class record is the name pattern that is used to filter the host names of the hosts that are protected by this HOSTNP record.

The following definitions describe the properties that are contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.  
Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.
- **INETACL**  
Defines the services the local host is allowed to provide to the group of client hosts and what their access types are. Each element in the access control list contains the following information:
  - **Services reference**

A reference to a service (a port number or name). To specify all the services, enter an asterisk (\*) as the services reference.

Privileged Access Manager supports dynamic port names as specified in the `/etc/rpc` file (for UNIX) or `\etc\rpc` file (for Windows).

- **Access**

Defines the access authority that the accessor has to the resource.

Use the `access(type-of-access)`, `service`, and `stationName` parameters with the `authorize[-]` command to modify accessors and their access types in the `INETACL` property.

- **INSERVNGE**

Specifies the range of services that the local host provides to the group of client hosts.

Performs a similar function to the `INETACL` property.

Use the `service(serviceRange)` parameter with the `authorize[-]` command to modify accessors and their access types in the `INSERVNGE` property.

- **OWNER**

Defines the user or group that owns the record.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. `RAUDIT` derives its name from Resource `AUDIT`. Valid values are:

- **all**

All access requests.

- **success**

Granted access requests.

- **failure**

Denied access requests (default).

- **none**

No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**Example:** Prevent incoming connections to Privileged Access Manager endpoint from a restricted remote host, using host name pattern.

**Step 1:** Add remote hosts in `/etc/hosts`. Run the following command at the command prompt.

```
vi /etc/hosts
```

**Step 2:** For network interception, the lookahead database "ladb" must be properly entered with the remote host address. To ensure this works, run the following command at the command prompt.

```
./sebuildla -h
```

**Step 3:** Run the following command at the command prompt to verify that the remote hosts are added to `/etc/hosts`.

```
./sebuildla -H
```

**Step 4:** Define remote hosts (using host name pattern) from which we prevent incoming Telnet connections.

```
PAMSC> nr HOSTNP My_Remote_*
```

**Step 5:** Set a rule that prevents incoming connections from remote hosts using Telnet.

```
PAMSC> authorize HOSTNP My_Remote_* service(telnet) access(none)
```

**Step 6:** Try connecting from a remote host (with the defined host name pattern) to the Privileged Access Manager endpoint using Telnet. The connection fails but other connections are not affected.

To deny any type of connection from remote hosts, set the following rule.

```
PAMSC> authorize HOSTNP My_Remote_* service(*) access(none)
```

## KMODULE Class

Each record in the KMODULE class defines a kernel module of the operating system.

If a module is defined in the KMODULE class, any call to the operating system to load or unload that module, causes Privileged Access Manager to check the authorizations defined for that module.

The key of a KMODULE record is the name of the kernel module being protected.

Each KMODULE record contains the following properties:

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information: Accessor Defines an accessor. Access Defines the access authority that the accessor has to the resource. Use the access parameter with the authorize or authorize-command to modify the ACL. Valid access authorities for KMODULE records are load and unload.

- **CATEGORY**

Defines one or more security categories assigned to a user or a resource.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.

The resolution of daytime restrictions is one minute.

- **FILEPATH**

Defines a list of absolute paths to files, each of which contains a kernel module. Separate each file path with a colon (:).

Use more than one file path if you have different versions of the same module.

If no file path is provided, Privileged Access Manager does not perform file path checking on kernel module load.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **NACL**

The NACL property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

#### **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

#### **OWNER**

Defines the user or group that owns the record.

#### **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Program**

Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

#### **NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the via(*pgm*) parameter with the selang authorize command to add programs, accessors, and their access types to a PACL. You can use the authorize- command to remove accessors from a PACL.

#### **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests.

- **success**

Granted access requests.

- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## SECLABEL

Defines the security label of a user or resource.

### NOTE

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

## SECLEVEL

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

## SIGNATURE

Displays the unique values for kernel module files defined in the filepath property .

Privileged Access Manager calculates the signatures of kernel modules when it starts up, and when a KMODULE record is changed using selang commands. You can set the signatures yourself using the command seretrust -m.

### NOTE

Privileged Access Manager uses the SIGNATURE property for Linux systems only.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

## UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## LOGINAPPL Class

### Valid on UNIX

Each record in the LOGINAPPL class defines a login application, identifies who can use the program to log in, and controls the way the login program is used.

The key of the LOGINAPPL class record is the name of the application, that is, a logical name that represents a login application. This logical name is associated, in the LOGINPATH property, with the full path name of the executable.

Privileged Access Manager can also control and protect generic login applications; this means that you can protect groups of login applications that match a certain rule with a generic pattern. To define a generic login application with `selang`, use the same commands as setting regular login restrictions, except the `LOGINPATH` parameter, which should include a generic path composed of a regular expression using one or more of the following characters: `[, ], *, ?`.

Privileged Access Manager presets the property values for records in the `LOGINAPPL` class for standard login programs. You should list and verify the existing settings before making any changes.

### **WARNING**

`LOGINAPPL` does not use the `_default` entry.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the `access` parameter with the `authorize` or `authorize-` command to modify the ACL.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the `restrictions` parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.

The resolution of daytime restrictions is one minute.

- **LOGINFLAGS**

Controls special features of the login application, including changes in device number and decrements to the grace logins number. Valid values are:

- **execlogin**-Specifies that the login trigger is the first EXEC action that a process performs.

- **loginprefix**-Specifies that Privileged Access Manager adds the `LOGINAPPL` resource name as the prefix to the logged-in user name. For example, if you set this property and a user named `user1` schedules a CRON task, when CA Privileged Access Manager detects the CRON task login it sets the user name to `USR_SBIN_CRON_user1`.

**Note:** Privileged Access Manager does not add the `LOGINAPPL` resource name as a prefix to `root`.

- **nograce**-Indicates that grace logins should not be decremented when users log in through this application.

- **nograceroot**-Indicates that grace logins should not be decremented when root logs in through this application.

- **nologin**-Ensures that a login is entered for the user only. The login is not logged for parent programs.

A program like `rlogin` on some platforms causes `rlogin` to trigger the login and close the login sequence itself; this results in an actual login logged for root. After performing the login, `rlogin` forks to another program to perform the actual login.

This problem is apparent if you use a login program such as `rlogin` or `telnet` and run `seaudit -a`. You see that there are also login records for the same login with root as the uid.

- **pamlogin**-Indicates that Privileged Access Manager PAM login interception is used when users log in through this application.

Use the `loginflags` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **LOGINMETHOD**

Indicates whether the login application is a pseudo login program for the purposes of Privileged Access Manager protection. Valid values are:

- **normal**-Indicates that this login application executes `setuid` and `setgid` calls itself. `seosd` checks the rules of the specified program.
- **pseudo**-Indicates that this login application calls another program to execute `setuid` and `setgid` calls. `seosd` checks the rules on the other program.

Use the `loginmethod` parameter with the `chres`, `editres`, or `newres` command to modify this property.

#### **WARNING**

We recommend that you not modify this preset property.

- **LOGINPATH**

The full path (or generic path) to the login application.

Use the `loginpath` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **LOGINSEQUENCE**

Defines the sequence of `seteuid`, `setuid`, `setgid`, and `setgroups` events that `seosd` processes to set the user from the daemon starting the login process (usually `inetd` under `root`) to the user who is actually logged on. You can define up to eight system events.

The login interception sequence always starts with `setgid` or `setgroups` events, which are called *triggers*. It ends with a `setuid` event that changes the user's identity to the real user who logged in.

To successfully accomplish login, the program needs to perform all the specified processes in sequence starting with `setgroups` or `setgid` and ending with `setuid` or `seteuid`.

Setting the right `LoginSequence` for a program is a difficult task. Most login programs work well with the default `SGRP,SUID` setting; this setting means the program issues a `setgroups` system call and then a `setuid` command to change the user's identity to the target user.

However, if the `SGRP, SUID` setting does not work, you must use the following flags to specify the proper order:

- **SEID**-First `seteuid` event
- **SUID**-First `setuid` event
- **SGID**-First `setgid` event
- **SGRP**-First `setgroup` event
- **FEID**-Second `seteuid` event
- **FUID**-Second `setuid` event
- **FGID**-Second `setgid` event
- **FGRP**-Second `setgroup` event
- **N3EID**-Third `seteuid` event
- **N3UID**-Third `setuid` event
- **N3GID**-Third `setgid` event
- **N3GRP**-Third `setgroup` event

#### **WARNING**

You must use the flags to specify the correct login sequence. However, you can specify the flags in any order within the `LOGINSEQUENCE` parameter. For example, `SGRP, SEID, FEID, N3EID` is identical to `N3EID, FEID, SGRP, SEID`.

#### **NOTE**

If you do not know the sequence of system calls that the login program performs, you can view the trace and look for the `setuid` event that changed the user to the target uid, and then look at prior trace events starting with the first `setgid` or `setgroups` event.

For example, if you there is one `setgroups` event and then only the third `setuid` call sets the target user, you must set `LOGINSEQUENCE` to `SGRP,SUID,FUID,N3UID`. You can specify these flags in any order:

```
SETGRPS : P=565302 to 0,2,3,7,8,10,11,250,220,221,230
SUID > P=565302 U=0 (R=0 E=0 S=0 ) to (R=0 E=0 S=0 ) ( ) BYPASS
SUID > P=565302 U=0 (R=0 E=0 S=0 ) to (R=0 E=0 S=-1 ) ( ) BYPASS
```

LOGIN : P=565302 User=target Terminal=mercuryThe SETGRPS process indicates the trigger.The first SUID command should be discounted because you can see that the root simply changed back to root, not the trigger user. (This is the SUID in the sequence.)The second SUID command should be discounted as well because you can see that the root changed back to root, not the trigger user. (This is the FUID in the sequence.)The LOGIN event is the actual SETUID event causing the login. (Because it is the third event, it is the N3UID flag in the sequence.)

Use the loginsequence parameter with the chres, editres, or newres command to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also *ACL*, *CALACL*, *PACL*. Each entry in the *NACL* contains the following information:

**Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

**NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

**OWNER**

Defines the user or group that owns the record.

**RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. *RAUDIT* derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

**UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the *ACL* of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

**UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

**UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

**WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**MFTERMINAL Class**

Each record in the MFTERMINAL class defines a Mainframe computer that is used to administer Privileged Access Manager. It has the same characteristics as the TERMINAL class, but is not intercepted by Privileged Access Manager.

The key of the MFTERMINAL class is the name of the mainframe computer.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.  
Use the `access` parameter with the `authorize` or `authorize-` command to modify the ACL.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the `restrictions` parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.
- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

**Accessor**

Defines an accessor.

- **Access**  
Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

## NOTIFY

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

## OWNER

Defines the user or group that owns the record.

## PACL

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

### NOTE

You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

## SECLABEL

Defines the security label of a user or resource.

### NOTE

The SECLABEL property corresponds to the `label[-]` parameter of the `chres` and `ch[x]usr` commands.

## SECLEVEL

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the `level[-]` parameter of the `ch[x]usr` and `chres` commands.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the `defaccess` parameter with the `chres`, `editres`, or `newres` command to modify this property.

### UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

### UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

### WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## POLICY Class

Each record in the POLICY class defines the information required to deploy and undeploy a policy version. It includes a link to the RULESET objects that contain a list of the `selang` commands for deploying and undeploying the policy. When the policy is deployed, the `deploy selang` command is run, which executes all of the commands that define the policy and are stored in the linked RULESET object. When the policy is undeployed, the `deploy- selang` command is run, which executes all of the commands that refine policy undeployment and are stored in the linked RULESET object.

The key of the POLICY class is the name of the policy followed by the hash symbol (#) and a two-digit version number. For example, `mypolicy#13`.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the `access` parameter with the `authorize` or `authorize-` command to modify the ACL.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the `restrictions` parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **EFFECTS\_ON**  
Defines the list of hosts (HNODE objects) on which this policy is effective (should be deployed).
- **FINALIZE**

Specifies whether this policy version is finalized (can be deployed).

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to or the GPOLICY object this policy version belongs to.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **HNODES**

(Informational). The list of Privileged Access Manager nodes which should have this policy deployed.

- **NACL**

The NACL property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

#### **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

#### **OWNER**

Defines the user or group that owns the record.

#### **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Program**

Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

#### **NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the via(*pgm*) parameter with the selang authorize command to add programs, accessors, and their access types to a PACL. You can use the authorize- command to remove accessors from a PACL.

#### **POLICY\_BASE\_NAME**

Defines the name of the GPOLICY object this policy version is a member of.

#### **POLICY\_VERSION**

Defines the version number of this policy version.

#### **POLICY\_TYPE**

Defines the policy type. Valid values are:

- None
- Login Specifies that the policy is a UNAB login policy.
- Configuration Specifies that the policy is a UNAB configuration policy.

## **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## **RULESETS**

The list of RULESET objects which define the policy.

## **SECLABEL**

Defines the security label of a user or resource.

### **NOTE**

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

## **SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

## **SIGNATURE**

A hash value based on signatures of the RULESET objects associated with the policy.

## **UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

## **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

## **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## **VARIABLES**

(Informational) Displays all versions of the variables in the policy.

## **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## PROCESS Class

Each record in the PROCESS class defines a program—an executable file—that runs in its own address space and that needs to be protected from being killed or getting debugged. Major utilities and database servers are good candidates for such protection since these processes are the main targets for denial-of-service attacks.

**Note:** When defining a program in the PROCESS class, we recommend that you also define it in the FILE class. This protects the executable by preventing someone from modifying (replacing or corrupting) the executable without authorization.

The PROCESS class now contains the following two access control attributes:

- **read**  
Allows the process to be killed
- **attach**  
Allows the process to be attached

Both the attributes are mutually independent and can be set together.

**Note:** The ATTACH attribute of the PROCESS class that is introduced in the current release is not available in the Endpoint Management UI. The ATTACH access right is not applied to the rule even if the access right All is selected for the PROCESS class objects, in the Endpoint Management UI.

### KILL Attribute

Privileged Access Manager can protect against three terminate (kill) signals: the regular terminate signal (SIGTERM) and the two signals that an application cannot mask (SIGKILL and SIGSTOP):

Environment	Signal	Number
Windows	KILL	Win32 API
UNIX	Terminate Process	9
UNIX and Windows	STOP	Machine Dependent
UNIX and Windows	TERM	15

Other signals, such as SIGHUP or SIGUSR1, are passed to the process that they target and that process decides whether to ignore the terminate signal or whether to react to it in some way.

The key of the PROCESS class record is the name of the program the record protects. Specify the full path.

### ATTACH Attribute

The ATTACH attribute of the PROCESS class authorizes the defined process for being attached by other processes for debugging or tracing; provided those processes are running under an authorized user.

**Note:** Only the Linux and AIX operating systems support the ATTACH attribute.

To define the ATTACH attribute using the PROCESS class, create a record for a process that you want to authorize. Create the record without an owner and any access right defined. Using a Selang rule, you can authorize the process that you have created to be attached by any other process running under root.

### WARNING

If you had denied KILL access to a process and allowed ATTACH access to the same process, then the process can be killed by a process which has the access right ATTACH.

### PROCESS Class Properties

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Properties marked as *informational* cannot be modified.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.

- **CATEGORY**

Defines one or more security categories assigned to a user or a resource.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

**Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

**NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

**OWNER**

Defines the user or group that owns the record.

**PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

**Note:** You can use wildcard characters to specify the resource in a PACL.

Use the *via(pgm)* parameter with the *selang authorize* command to add programs, accessors, and their access types to a PACL. You can use the *authorize-* command to remove accessors from a PACL.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the *audit* parameter of the *chres* and *chfile* commands to modify the audit mode.

## SECLABEL

Defines the security label of a user or resource.

**Note:** The SECLABEL property corresponds to the *label[-]* parameter of the *chres* and *ch[x]usr* commands.

## SECLEVEL

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the *level[-]* parameter of the *ch[x]usr* and *chres* commands.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the *defaccess* parameter with the *chres*, *editres*, or *newres* command to modify this property.

## UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## PROGRAM Class

Each record in the PROGRAM class defines a program that is considered part of the trusted computing base. Programs in this class are trusted not to have security breaches because they are monitored by the Watchdog to ensure that they are not modified. If a trusted program is altered, Privileged Access Manager automatically marks the program as untrusted, and the program is prevented from executing. Optionally, you can also allow or prevent execution of untrusted programs using the BLOCKRUN property.

Each PROGRAM record contains several properties that define information about the trusted program file.

Usage notes:

- On UNIX, the PROGRAM class can also contain programs that are not marked as setuid or setgid.
- You can define any program as a trusted program within Privileged Access Manager.  
A program cannot be used in a program access control list (PACL) unless it is defined in the PROGRAM class. (However, a program is automatically added to the PROGRAM class when it is added to a PACL.)
- Directories cannot be defined in the PROGRAM class.

The key of the PROGRAM class record is the file name of the program the record protects. Specify the full path of the file as the objectname.

The following definitions describe the properties that are contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Properties marked *informational* cannot be modified.

- **ACCSTIME**  
(Informational). The date and time the record was last accessed.
- **ACCSWHO**  
(Informational). The administrator who last accessed the record.
- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the access types of the accessor. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the access parameter with the authorize or authorize- command to modify the ACL.
- **BLOCKRUN**  
Specifies whether to check if the program is trusted and blocks the execution of untrusted programs. The execution blocking is performed regardless whether the program is a setuid or a regular program.  
Use the blockrun[-] parameter with the chres, editres, and newres commands to modify this property for resources.
- **CATEGORY**  
Defines one or more security categories that are assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record. Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **MD5**  
(Informational). The RSA-MD5 signature of the file.
- **NACL**

The NACL property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**  
Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

#### **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

#### **OWNER**

Defines the user or group that owns the record.

#### **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

#### **NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the via(*pgm*) parameter with the selang authorize command to add programs, accessors, and their access types to a PACL. You can use the authorize- command to remove accessors from a PACL.

#### **NOTE**

For resources in PROGRAM class, PACL applies only to setuid/setgid programs on UNIX or programs with *file* resource on Windows. Privileged Access Manager first checks for the file resource record, and if the access is allowed, then it checks the program resource record.

#### **PGMINFO**

Defines the program information that is automatically generated by Privileged Access Manager.

The Watchdog automatically verifies the information that is stored in this property. If it is changed, Privileged Access Manager defines the program as untrusted.

You can select any of the following flags to *exclude* the associated information from this verification process:

- **crc**  
The cyclic redundancy check and MD5 signature.
- **ctime**  
(UNIX only) The time of the last file status change.
- **device**  
On UNIX, the logical disk that the file resides on. On Windows, the drive number of the disk containing the file.
- **group**  
The group that owns the program file.
- **inode**  
On UNIX, the file system address of the program file. On Windows, this flag has no meaning
- **mode**  
The associated security protection mode for the program file.
- **mtime**  
The time the program file was last modified.
- **owner**  
The user who owns the program file.
- **sha1, sha256, sha384, sha512**  
The SHA1, SHA256, SHA384, or SHA512 signature. Digital signature method called Secure Hash Algorithm that could be applied to the program or sensitive files.
- **size**  
The size of the program file.

Use the flags, flags+, or flags- parameter with the chres, editres, or newres command to modify the flags in this property.

## RAUDIT

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## SECLABEL

Defines the security label of a user or resource.

### NOTE

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

## SECLEVEL

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

### **UNTRUST**

Defines whether the resource is untrusted or trusted. If the UNTRUST property is set, accessors cannot use the resource. If the UNTRUST property is not set, the other properties listed in the database for the resource are used to determine accessor's access authority. If a trusted resource is changed in any way, Privileged Access Manager automatically sets the UNTRUST property.

Use the trust[-] parameter with the chres, editres, or newres command to modify this property.

### **UNTRUSTREASON**

(Informational). The reason why the program became untrusted.

### **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

### **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

### **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted. If an access request violates an access rule, a record is written to the audit log.

## **PWPOLICY Class**

Each record in the PWPOLICY class defines a password policy. These policies are sets of rules for both the validity of new passwords, and for the length of time the passwords are valid.

The key to the PWPOLICY class is the name of the password policy.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **APPLS**

(Informational). The list of CA SSO applications that are linked to the password policy.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **OWNER**

Defines the user or group that owns the record.

- **PASSWDRULES**

Specifies the password rules. This property contains a number of fields that determine how Privileged Access Manager handles password protection. For a complete list of the rules, see the modifiable property PROFILE of the USER class.

Use the `passwordparameter` and the `rules` or `rules-` option with the `setoptions` command to modify this property.

- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.

## REGKEY Class

### Valid on Windows

Each record in the REGKEY class defines a key in the Windows registry.

The key to a REGKEY record is the full registry path to the key.

#### NOTE

You can use wildcard characters as part of the path specification.

By default Privileged Access Manager protects the Privileged Access Manager registry entries. The root of this registry entry is:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl
```

Privileged Access Manager also protects the following key:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services
```

The REGKEY class and the REGVAL class have identical properties. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

#### NOTE

HKLM/CurrentControlSet is a reference to ControlSet001 which Privileged Access Manager does not monitor. Point REGKEY / REGVAL resources to ControlSet001 instead of CurrentControlSet.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the `access` parameter with the `authorize` or `authorize-` command to modify the ACL.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the `restrictions` parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also *ACL*, *CALACL*, *PACL*. Each entry in the *NACL* contains the following information:

**Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

**NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

**OWNER**

Defines the user or group that owns the record.

**PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (*PACL*) contains the following information:

- **Accessor**

Defines an accessor.

- **Program**

Defines a reference to a record in the *PROGRAM* class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

**NOTE**

You can use wildcard characters to specify the resource in a *PACL*.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a *PACL*. You can use the `authorize-` command to remove accessors from a *PACL*.

**RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. *RAUDIT* derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests.

- **success**

Granted access requests.

- **failure**

Denied access requests (default).

- **none**

No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

## UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## REGVAL Class

### Valid on Windows

Each record in the REGVAL class defines a value in the Windows registry

The key to a REGVAL record is the full registry path to the value.

**Note:** You can use wildcard characters as part of the path specification.

**Note:** The REGVAL class allows the following access types: NONE, READ, WRITE, DELETE.

The REGVAL class and the REGKEY class have identical properties. These properties are as follows. (Non-modifiable properties are marked *informational*.)

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access parameter with the authorize or authorize- command to modify the ACL.

- **COMMENT**

Defines additional information that you want to include in the record. The product does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also *ACL*, *CALACL*, *PACL*. Each entry in the *NACL* contains the following information:

**Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

**NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. The product can email the audit record to the specified user.

**Limit:** 30 characters.

**OWNER**

Defines the user or group that owns the record.

**PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (*PACL*) contains the following information:

- **Accessor**

Defines an accessor.

- **Program**

Defines a reference to a record in the *PROGRAM* class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

**Note:** You can use wildcard characters to specify the resource in a *PACL*.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a *PACL*. You can use the `authorize-` command to remove accessors from a *PACL*.

**RAUDIT**

Defines the types of access events that the product records in the audit log. *RAUDIT* derives its name from *Resource AUDIT*. Valid values are:

- **all**

All access requests.

- **success**

Granted access requests.

- **failure**

Denied access requests (default).

- **none**

No access requests.

The product records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## UACC

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to the product or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

## UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

## UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

## WARNING

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## RESOURCE\_DESC Class

Each record in the RESOURCE\_DESC class defines all of the names that new user-defined class objects are allowed to access in CA SSO. You cannot create a new object in the RESOURCE\_DESC class; you can only modify the existing ones.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **CLASS\_RIGHT**  
Of the 32 optional access rights; all are modifiable. The defaults for the first four rights are:
  - CLASS\_RIGHT1-read
  - CLASS\_RIGHT2-write
  - CLASS\_RIGHT3-execute
  - CLASS\_RIGHT4-rename
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **OWNER**  
Defines the user or group that owns the record.
- **RESPONSE\_LIST**  
The name of the object in the RESPONSE\_TAB class that contains this object's name.
- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.

## RESPONSE\_TAB Class

Each record in the RESPONSE\_TAB class defines a CA SSO response table to different authorization decisions.

A response is a personalized answer that is returned to application after an authorization request is granted or denied. It consists of KEY=VALUE pairs that are understood by the specific application. The response provides the ability to personalize the portal site according to the user's specific needs and authorization permissions.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using *selang* or the administration interfaces. Non-modifiable properties are marked *informational*.

- **CLASS\_RIGHT**  
32 optional response properties are lists of strings containing KEY=VALUE pairs (for example, button1=yes, picture2=no, and so on). There should be one property for each access value.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **OF\_RESOURCE**  
The name of the object in the RESOURCE\_DESC class that refers to the same user-defined class.
- **OWNER**  
Defines the user or group that owns the record.
- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.

## RULESET Class

Each record in the RULESET class represents a set of rules which define a policy.

The key of the RULESET class record is the name of the policy the record is linked to.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using *selang* or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**  
Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the access authority that the accessor has to the resource.
 Use the access parameter with the *authorize* or *authorize-* command to modify the ACL.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the *chres*, *ch[x]usr*, or *ch[x]grp* commands to modify this property.

The resolution of daytime restrictions is one minute.

- **EXPANDED COMMANDS**

(Informational) Displays the variable values of the commands in the deployed policy.

- **EXPANDED UNDO COMMANDS**

(Informational) Displays the variable values of the undo commands in the deployed policy.

- **FINALIZE**

Specifies whether the selang scripts have been finalized (and hence the policy version can be deployed).

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

#### **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

#### **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

#### **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Program**

Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

#### **NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the *via(pgm)* parameter with the selang authorize command to add programs, accessors, and their access types to a PACL. You can use the authorize- command to remove accessors from a PACL.

#### **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests.

- **success**

Granted access requests.

- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

## **RULESET\_DOCMD\_IDX**

(Informational). The command index; that is, a counter of the number of commands in the list of RULESET\_DOCMDS.

## **RULESET\_DOCMDS**

The list of selang commands which, together, define the policy. These are the commands that are executed to deploy the policy.

### **WARNING**

Policy deployment does not support commands that set user passwords. Do not include such commands in your deployment script file. UNIX (native) selang commands are supported but will not show in deviation reports.

## **RULESET\_POLICIES**

(Informational). The list of policies (POLICY objects) that use this set of rules.

## **RULESET\_UNDOCMD\_IDX**

(Informational). The command index; that is, a counter of the number of commands in the list of RULESET\_UNDOCMDS.

## **RULESET\_UNDOCMDS**

The list of selang commands which, together, define the policy undeployment script. These are the commands that are executed to undeploy the policy.

## **SECLABEL**

Defines the security label of a user or resource.

### **NOTE**

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

## **SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

## **SIGNATURE**

A hash value based on the RULESET\_DOCMDS and RULESET\_UNDOCMDS properties.

## **UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

## **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

## **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## **SECFILE Class**

Each record in the SECFILE class defines a file to be monitored. SECFILE class records provide verification for important files in the system. However, they cannot appear in a conditional access control list.

Add sensitive system files that are not frequently modified to this class to verify that an unauthorized user has not altered them. The following are some examples of the type of files to include in class SECFILE:

For UNIX	For Windows
/.rhosts	\system32\drivers\etc\hosts
/etc/services	\system32\drivers\etc\services
/etc/protocols	\system32\drivers\etc\protocols
/etc/hosts	
/etc/hosts.equiv	

The Watchdog scans these files and ensures the information known about these files is not modified.

### **NOTE**

Directories cannot be defined in the SECFILE class.

The key of the SECFILE class record is the name of the file that the SECFILE record protects. Specify the full path.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **AIXACL**  
AIX system ACLs.
- **AICEXTI**  
AIX system extended information.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **GROUPS**  
Defines the list of CONTAINER records that a resource record belongs to.  
To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.  
Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.
- **HPUXACL**  
HP-UX system ACLs.
- **MD5**  
(Informational). The RSA-MD5 signature of the file.
- **OWNER**  
Defines the user or group that owns the record.
- **PGMINFO**

Defines the program information automatically generated by Privileged Access Manager.

The Watchdog automatically verifies the information stored in this property. If it is changed, Privileged Access Manager defines the program as untrusted.

You can select any of the following flags to *exclude* the associated information from this verification process:

- **crc**  
The cyclic redundancy check and MD5 signature.
- **ctime**  
(UNIX only) The time of the last file status change.
- **device**  
On UNIX, the logical disk that the file resides on. On Windows, the drive number of the disk containing the file.
- **group**  
The group that owns the program file.
- **inode**  
On UNIX, the file system address of the program file. On Windows, this has no meaning
- **mode**  
The associated security protection mode for the program file.
- **mtime**  
The time the program file was last modified.
- **owner**  
The user who owns the program file.
- **sha1**  
The SHA1 signature. Digital signature method called Secure Hash Algorithm that could be applied to the program or sensitive files.
- **size**  
The size of the program file.

Use the flags, flags+, or flags- parameter with the chres, editres, or newres command to modify the flags in this property.

- **UNTRUST**

Defines whether the resource is untrusted or trusted. If the UNTRUST property is set, accessors cannot use the resource. If the UNTRUST property is not set, the other properties listed in the database for the resource are used to determine accessor's access authority. If a trusted resource is changed in any way, Privileged Access Manager automatically sets the UNTRUST property.

Use the trust[-] parameter with the chres, editres, or newres command to modify this property.

**Note:** The resource file is used to determine access authority, when the SECFILE resource is untrusted and no access authority is set to the SECFILE resource.

- **UNTRUSTREASON**

(Informational). The reason why the program became untrusted.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## SECLABEL Class

Each record in the SECLABEL class associates a security level with security categories. A security label overrides the specific security level and security category assignments in the USER record if the SECLABEL class is active. Assigning a security label is equivalent to explicitly assigning the security level and security categories of the security label to the user.

When a USER record includes a security label, the user is granted access to a resource only if the following conditions are met:

- The user security level specified in the security label is equal to or greater than the resource security level.
- All categories specified in the resource record are included in the security category list of the user security label.

#### **NOTE**

On Windows, each security label defined to Privileged Access Manager must have a record in the SECLABEL class.

The key of the SECLABEL class record is the name of the security label. This name is used to identify the security label when assigning it to a user or resource.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **OWNER**  
Defines the user or group that owns the record.
- **SECLEVEL**  
Defines the security level of an accessor or resource.  
**Note:** This property corresponds to the `level[-]` parameter of the `ch[x]usr` and `chres` commands.
- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.

## **SEOS Class**

The SEOS class controls the behavior of the Privileged Access Manager authorization system.

The class contains only one record, called SEOS, which specifies general security and authorization options. To view or change the status of SEOS class properties, use the `setoptions` command.

The following definitions describe the properties that are contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACCPACL**  
Indicates the order in which the UACC (`defaccess`) and PACL lists are scanned during authorization.  
When ACCPACL is active and explicit access is provided for a user through an ACL, then that accessor is the allowed access. If there is no explicit access through an ACL but explicit access is defined through a PACL, then the PACL access is the allowed access. If neither ACL or PACL contains explicit access, `defaccess` is checked for access definitions.  
If ACCPACL is not activated, the ACL is still checked first for explicit access. If the ACL contains no explicit access definitions for the resource being checked, `defaccess` definitions are checked next. If no explicit access is defined in `defaccess`, then the PACL access definitions are checked.  
When Privileged Access Manager is installed, the value of this property is set to yes.  
Use the `accpac` or `accpac-` parameter with the `setoptions` command to modify this property.
- **ADMIN**

Each record in the ADMIN class defines what authorization privileges non-admin users have to administer specific classes. Each Privileged Access Manager class that is to be administered by specific non-admin users is represented by an ADMIN record. The record contains a list of accessors with the access authority of each.

Example: To allow user John to view FILE class rules, specify "authorize ADMIN FILE uid(John) access(read)"

If ADMIN class is off, then a non-admin user cannot get administrator privileges using this ADMIN class.

- **APPL**  
Indicates whether the APPL class is active.
- **AUTHHOST**  
Indicates whether the AUTHHOST class is active.
- **CALENDAR**  
Indicates whether the CALENDAR class is active.
- **CATEGORY**  
Indicates whether the CATEGORY class is active.
- **CNG\_ADMIN\_PWD**  
Indicates whether a user with the PWMANAGER attribute can change an ADMIN user password using selang. The default is yes.  
Use the class+ or class- parameter and the *cng\_adminpwd* option with the setoptions command to activate or inactivate this property.
- **CNG\_OWN\_PWD**  
Indicates whether users can change their own passwords using selang.  
Use the class+ or class- parameter and the *cng\_ownpwd* option with the setoptions command to activate or inactivate this property.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CONNECT**  
Indicates whether the CONNECT class is active. When the CONNECT class is active, records in the class protect the outgoing connections.  
If the HOST class is active, the CONNECT class is not used as an active class, even when activated.  
If the TCP class is active, the CONNECT class is not used as an active class.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIMERES**  
(UNIX only) Indicates whether Privileged Access Manager checks the daytime restrictions on resources.
- **DMS**  
List of DMS servers this database should send notifications to.
- **DOMAIN**  
(Windows only) Indicates whether the DOMAIN class is active.
- **ENDTIME**  
(Informational). The date and time the database files were last closed in an orderly manner.
- **FILE**  
Indicates whether the FILE class is active. When the FILE class is active, records in the class protect files and directories.
- **ACCGRR**

The *accumulative group rights* option (ACCGRR) affects how Privileged Access Manager checks the ACL of a resource. If ACCGRR is enabled, Privileged Access Manager checks the ACL for the authorities that are granted from all the groups to which the user belongs. If ACCGRR is disabled, Privileged Access Manager checks the ACL to see if any of the applicable entries contain the value none. If so, access is denied. Otherwise Privileged Access Manager ignores all group

entries except the first applicable one in the access control list. Use the command setoptions ACCGRR command to enable or disable this property.

- **HOLIDAY**  
Indicates whether the HOLIDAY class is active. When the HOLIDAY class is active, users need extra permission to log in during defined Holiday periods.
- **HOST**  
Indicates whether the HOST class is active. When the HOST class is active, Privileged Access Manager protects incoming TCP/IP service requests from remote hosts.  
If the HOST class is active, the TCP and CONNECT classes are not used as active classes, even when activated. The default for the HOST class is active.
- **INACT**  
Indicates the number of inactive days after which user login is suspended. An inactive day is a day in which the user does not log in.  
A value for the INACTIVE property in a USER record overrides a value in a GROUP record. Both override the INACT property in the SEOS class record.  
Use the inactive or inactive- parameter with the setoptions command to update this property.
- **ISDMS**  
True if the PMDB serves as a DMS.
- **LOGINAPPL**  
(UNIX only) Indicates whether the LOGINAPPL class is active.
- **MAXLOGINS**  
The maximum number of concurrent logins (terminal sessions) a user is allowed, after which the user is denied access. A zero value indicates no maximum and the user can log in to any number of terminal sessions concurrently. The value must be either zero or greater than 1 if the user wants to log in and run selang or otherwise administer the database, because Privileged Access Manager considers each task (login, selang, GUI, and so forth) to be a terminal session.  
A value for the MAXLOGINS property in a USER record overrides a value in a GROUP record. Both override the MAXLOGINS property in the SEOS class record. The value in the SEOS record is the default value used when there is no explicit value in the accessor record.  
Use the maxlogins parameter with the chres, editres, and newres commands to modify this property for the SEOS class.
- **MFTERMINAL**  
Indicates whether the MFTERMINAL class is active.
- **PASSWDRULES**  
Indicates the password rules. This property contains a number of fields that determine how Privileged Access Manager handles password protection. For a complete list of the rules, see the modifiable property PROFILE of the USER class. Use the passwordparameter and the rules or rules- option with the setoptions command to modify this property.
- **PASSWORD**  
Indicates whether password checking is active.  
Use the class+ or class- parameter and the PASSWORD option with the setoptions command to activate or inactivate this property.
- **PROCESS**  
Indicates whether the PROCESS class is active. When the PROCESS class is active, records in the class protect defined processes from kill attempts.  
The file must also be defined in the FILE class.
- **PROGRAM**  
Indicates whether the PROGRAM class is active. When the PROGRAM class is active, records in the class protect defined programs that were marked as Trusted.
- **PWPOLICY**  
Indicates whether the PWPOLICY class is active.
- **REGKEY**

- (Windows only) Indicates whether the REGKEY class is active.
- **REGVAL**  
(Windows only) Indicates whether the REGVAL class is active.
- **RESOURCE\_DESC**  
Indicates whether the RESOURCE\_DESC class is active.
- **RESPONSE\_TAB**  
Indicates whether the RESPONSE\_TAB class is active.
- **SECLABEL**  
Indicates whether the SECLABEL class is active.
- **SECLEVEL**  
Indicates whether the SECLEVEL class is active.
- **STARTTIME**  
(Informational). The date and time the database files were last opened.
- **SUDO**  
Indicates whether the SUDO class, used by sesudo, is active.
- **SYSTEM\_AAUDIT\_MODE**  
Specifies the default audit mode (systemwide audit mode) for users and enterprise users.  
**Default:** Failure LoginSuccess LoginFailure
- **SURROGATE**  
Indicates whether the SURROGATE class is active. When the SURROGATE class is active, Privileged Access Manager protects surrogate requests.
- **TCP**  
Indicates whether the TCP class is active. When the TCP class is active, Privileged Access Manager protects incoming and outgoing TCP services such as mail, ftp, and http.  
If the HOST class is active, the TCP class is not used as an active class, even when activated.  
If the TCP class is active, the CONNECT class is not used as an active class.
- **TERMINAL**  
Indicates whether the TERMINAL class is active. When the TERMINAL class is active, Privileged Access Manager performs a terminal access check during sign-on and protects X-window sessions.
- **USER\_ATTR**  
Indicates whether the USER\_ATTR class is active.
- **USER\_DIR**  
Indicates whether the USER\_DIR class is active.
- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.

## SPECIALPGM Class

The SPECIALPGM class gives specified programs special security privileges.

Each record in the SPECIALPGM class has one of two functions:

- Registering backup, DCM, PBF, PBN, STOP, SURROGATE, REGISTRY, and KILL programs in Windows or registering xdm, backup, mail, DCM, PBF, PBN, stop, and surrogate programs in UNIX.
- Associating an application that needs special Privileged Access Manager authorization protection with a logical user ID. This effectively allows setting access permissions according to *what* is being done rather than *who* is doing it.

### NOTE

When defining a program in the SPECIALPGM class, we recommend that you also define it in the FILE class. The FILE resource protects the executable by preventing someone from modifying (replacing or corrupting) the

executable without authorization, and the PROGRAM resource verifies that the program does not run if it was modified when Privileged Access Manager was not running.

**NOTE**

You cannot define a record in the SPECIALPGM class for incoming network interception events. This is because the incoming network interception event does not have a process name in this context. To bypass writing an audit record for the interception event, set the AUDIT property to NONE for the corresponding record in the TCP class

Use the PGMTYPE property to register system services, daemons, or other special programs.

Use the SEOSUID and NATIVEUID properties to assign a logical user to a program.

The key of the SPECIALPGM class record is a path to the special program or to a range, or pattern, of special programs.

**NOTE**

The maximum number of rules that you can place in the specialpgm class table is 512.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non modifiable properties are marked *informational*.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **NATIVEUID**

Indicates the user invoking the program or process. Use \* to specify all Privileged Access Manager users.

Use the nativeuid parameter with the chres, editres, or newres command to modify this property.

**NOTE**

For backward compatibility with older versions of Privileged Access Manager, you can use the UNIXUID property instead of the NATIVEUID property.

- **OWNER**

Defines the user or group that owns the record.

- **PGMTYPE**

Determines the types of access checks that Privileged Access Manager bypasses when granting access.

- **backup**

Bypasses READ, CHDIR, and UTIME access.

**NOTE**

There are two ways to run a successful backup. If the backup program is executed by a non-root user, you have to define this user as an OPERATOR. If the backup program is executed by root, it is enough to register the backup program in the SPECIALPGM class as pgmtype(backup).

- **changeid**

(UNIX only) Bypass all the change identity tools except for the PAM enabled surrogate tool.

**NOTE**

For example: er specialpgm /bin/mail pgmtype(changeid)

- **dcm**

(Windows) Bypasses all security checks for all events except STOP events.

(UNIX) Bypasses security checks for READ and EXEC events.

- **fullbypass**

Fully bypasses all Privileged Access Manager authorization and database checks. Privileged Access Manager ignores a process that has this property, and no record of any process events appears in audit, trace, or debug logs.

- **kill**

(Windows only) Bypasses program termination for a process.

For example, the following rule provides a bypass to the services.exe if this process tries to open handles to Privileged Access Manager services (processes) with access mask KILL:

```
nr specialpgm c:\Windows\system32\services.exe pgmtype(kill)
```

On Windows Server 2008, the services.exe process, which manages the stopping and starting of services, opens handles to Privileged Access Manager services (processes) with access type KILL to manage process termination and startup. During installation on Windows Server 2008, Privileged Access Manager runs a discovery process to locate services.exe and creates a bypass rule for it. Without this bypass, you receive DENIED Privileged Access Manager audit events when services.exe is trying to open handles of Privileged Access Manager services.

- **mail**  
(UNIX only) Bypasses database checks for setuid and setgid events. The mail bypass allows you to trace mail access attempts.
- **none**  
Removes any PGMTYPE previously set.
- **pbf**  
Bypasses database checks for file handling events.
- **pbn**  
Bypasses database checks for network-related events.
- **propagate**  
Propagates its own security privileges to any programs that are called from a program with this PGMTYPE. If you do not specify this, SPECIALPGM privileges only affect the parent program. SPGM batch files, including propagate, are supported for executables only.

#### NOTE

Security privilege propagation works with PBF, PBN, DCM, FULLBYPASS, and SURROGATE privileges only.

### registry

(Windows only) Bypasses database checks for programs that manipulate the Windows registry.

- **stop**  
Bypasses database checks for the STOP feature.
- **surrogate**  
Bypasses database checks for identity changing events in the kernel. You cannot trace if you use the surrogate bypass.
- **xm**  
(UNIX only) Bypasses network events (such as TCP, HOST, and CONNECT classes) for a limited network range (6000-6010).

Use the pgmtype parameter with the chres, editres, or newres command to modify this property.

### SEOSUID

Defines the surrogate logical user authorized to run this special program. This logical user must be defined in the database with a USER record.

Use the seosuid parameter with the chres, editres, or newres command to modify this property.

### UPDATE\_TIME

(Informational) Displays the date and time when the record was last modified.

### UPDATE\_WHO

(Informational) Displays the administrator who performed the update.

### Example: Protect a UNIX file

To protect a file that resides in `/DATABASE/data/*`, the Database Manager uses a file server daemon named `firmdb_filemgr`. This file server resides on `/opt/dbfirm/bin/firmdb_filemgr`. This daemon usually runs under root, making the data accessible to any root-shell hack.

In the following example, the logical user is defined as the only accessor of these files; access by others is restricted:

1. Define the sensitive files to Privileged Access Manager using the command:

```
newres file /DATABASE/data/* defaccess(NONE) owner(nobody)
```

2. Define the logical user to access the files:

```
newusr firmDB_mgr
```

3. Allow only the logical user `firmDB_mgr` to access the files.

```
authorize file /DATABASE/data/* uid(firmDB_mgr) access(ALL)
```

4. Finally, make `firmdb_filemgr` run with logical user `firmDB_mgr`

```
newres SPECIALPGM /opt/dbfirm/bin/firmdb_filemgr unixuid(root) \
seosuid(firmDB_mgr)
```

Consequently, when the daemon accesses the files, Privileged Access Manager recognizes the logical user as the accessor of the files, and not root. A hacker who attempts to access the files as root does not succeed.

### Example: Protect a Windows file

To protect files that reside in `C:\DATABASE\data`, the Database Manager uses a file server service named `firmdb_filemgr.exe`. This file server resides on `C:\Program Files\dbfirm\bin\firmdb_filemgr.exe`. This service usually runs under the system account, making the data accessible to any system hack.

In the following example, the logical user is defined as the only accessor of these files; access by others is restricted:

1. Define the sensitive files to Privileged Access Manager using the following command:

```
newres file C:\DATABASE\data\* defaccess(NONE) owner(nobody)
```

2. Define a logical user to access the files:

```
newusr firmDB_mgr
```

3. Allow only the logical user `firmDB_mgr` to access the files:

```
authorize file C:\DATABASE\data\* uid(firmDB_mgr) access(ALL)
```

4. Finally, make `firmdb_filemgr` run with logical user `firmDB_mgr`:

```
newres SPECIALPGM ("C:\Program Files\dbfirm\bin\firmdb_filemgr.exe") \
nativeuid(system) seosuid(firmDB_mgr)
```

Consequently, when the service accesses the files, Privileged Access Manager recognizes the logical user as the accessor of the files, and not the system account. A hacker who attempts to access the files in the system account does not succeed.

## SUDO Class

Each record in the SUDO class identifies a command for which a user can borrow permissions from another user using the `sesudo` command.

The key of the SUDO class record is the name of the SUDO record. This name is used instead of the command name when a user executes the commands in the SUDO record.

### NOTE

If you create a SUDO record for an interactive Windows application, you must set the interactive flag for the SUDO record. If you do not set the interactive flag, the application runs in the background and you cannot interact with it. For more information, see the *Troubleshooting Guide*.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.

- **CATEGORY**

Defines one or more security categories assigned to a user or a resource.

- **COMMENT**

The command that `sesudo` executes.

The alphanumeric string can contain up to 255 characters, which include the command and also permitted and prohibited parameters.

For example, the following profile definition uses the **COMMENT** property properly:

```
newres SUDO profile_name comment('command;;NAME')
```

**NOTE**

This use of the **COMMENT** property is different than in other classes. For more information about defining SUDO records, see the *Endpoint Administration Guide* for your OS. This property was also known as **DATA** in earlier versions of Privileged Access Manager.

**Limit:** 255 characters.

Use the `comment[-]` parameter with the `chres`, `editres`, and `newres` commands to modify this property.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the `restrictions` parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GROUPS**

The list of GSUDO or CONTAINER records a resource record belongs to.

To modify this property in a SUDO class record, you must change the **MEMBERS** property in the appropriate CONTAINER or GSUDO record.

Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.

- **INTERACTIVE**

(Windows only). This switch should be marked when the application you intend to run via `sesudo` is an interactive Windows application (for example, `notepad.exe` or `cmd.exe`) and not a service application. If you are trying to run an interactive application using `sesudo` that is not marked as *interactive*, the application runs in the background without the ability to interact with it.

**NOTE**

Some Windows applications can not run in the foreground because of a Windows limitation.

- **NACL**

The **NACL** property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, `write`). See also **ACL**, **CALACL**, **PACL**. Each entry in the **NACL** contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

- **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

- **OWNER**

Defines the user or group that owns the record.

## **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- – **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

### **NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

- **PASSWORDREQ**

(UNIX only) Indicates whether the `sesudo` command requests the original user's password before executing.

Use the `password` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **POLICYMODEL**

Specifies the PMDB that receives new passwords when you change user passwords with the `sepass` utility. The passwords are *not* sent to the Policy Model defined by the `parent_pmd` or `passwd_pmd` configuration settings if a value is entered for this property.

**Note:** This property corresponds to the `pmdb[-]` parameter of the `ch[x]usr` and `ch[x]grp` commands.

- **SECLABEL**

Defines the security label of a user or resource.

### **NOTE**

The SECLABEL property corresponds to the `label[-]` parameter of the `chres` and `ch[x]usr` commands.

- **SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the `level[-]` parameter of the `ch[x]usr` and `chres` commands.

- **TARGUSR**

(UNIX only) Indicates the target uid, which identifies the user whose permissions are to be borrowed for executing the command. The default is `root`.

Use the `targuid` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## **SURROGATE Class**

Each record in the SURROGATE class defines restrictions that protect a user from other users when they try to change their identity to his or hers. Privileged Access Manager treats a change identity request as an abstract object that can be accessed only by authorized users.

A record in the SURROGATE class represents each user or group who has surrogate protection. Two special records-USER.\_default and GROUP.\_default-represent users and groups who do not have individual SURROGATE records. If there is no need to differentiate between the default for users and the default for groups, you may use the \_default record for the SURROGATE class instead.

### **NOTE**

Many Windows utilities and services (for example, Run As) identify as user *NT AUTHORITY\SYSTEM* and not as the original user running them. To let users who use these utilities and services as impersonate another user, you must create this SYSTEM user in the Privileged Access Manager database and authorize it to impersonate the target user.

The key of the SURROGATE class record is the name of the SURROGATE record.

The following definitions describe the properties that are contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors access types.

Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access parameter with the authorize or authorize- command to modify the ACL.

- **CALACL**

Defines a list of the accessors (users and groups) that are permitted to access the resource, and their access types according to the Unicenter NSM calendar status.

Each element in the calendar access control list (CALACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Calendar**

Defines a reference to a calendar in Unicenter TNG.

- **Access**

Defines the access authority that the accessor has to the resource.

Access is permitted only when the calendar is ON. Access is denied in all other cases.

Use the calendar parameter with the authorize command to permit user or group access to the resource according to the access defined in the calendar ACL.

- **CALENDAR**

Represents a Unicenter TNG calendar object for user, group, and resource restrictions in Privileged Access Manager. Privileged Access Manager fetches Unicenter TNG active calendars at specified time intervals.

- **CATEGORY**

Defines one or more security categories that are assigned to a user or a resource.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

- **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

- **OWNER**

Defines the user or group that owns the record.

- **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Program**

Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.

- **Access**

Defines the access authority that the accessor has to the resource.

**NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.
- Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

- **SECLABEL**

Defines the security label of a user or resource.

**NOTE**

The SECLABEL property corresponds to the `label[-]` parameter of the `chres` and `ch[x]usr` commands.

- **SECLEVEL**

Defines the security level of an accessor or resource.

**NOTE**

This property corresponds to the `level[-]` parameter of the `ch[x]usr` and `chres` commands.

- **UACC**

Defines the default access authority for the resource, which indicates the access that is granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the `defaccess` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**Example 1:** An example to show how the SURROGATE rule refrains user “john” from switching to the “root” user to perform privileged operations.

**Step 1:** Create a user “john”.

```
PAMSC> nu john pass(john)
```

**Step 2:** Write the SURROGATE rule to protect “root” from the user “John”.

```
PAMSC> er SURROGATE USER.root owner(root) defacc(r)
```

```
PAMSC> auth SURROGATE USER.root uid(john) access(n)
```

**Step 3:** Verify if “john” can switch to root using “su”.

The SURROGATE rule restricts “john” from switching to the “root” account.

**Example 2:** An example to show how the SURROGATE rule refrains user “smith” from switching to another user “john”.

**Step 1:** Create a user “smith”.

```
PAMSC> nu smith pass(smith)
```

**Step 2:** Create a user “john”.

```
PAMSC> nu john pass(john)
```

**Step 3:** Write a SURROGATE rule to protect “john” from “smith”.

```
PAMSC> er SURROGATE USER.john owner(john) defacc(r)
```

```
PAMSC> auth SURROGATE USER.john uid(smith) access(n)
```

**Step 4:** Verify if “smith” can switch to “john” using “su”.

The SURROGATE rule restricts “smith” from switching to the “john” account.

**Example 3:** An example to protect user groups using SURROGATE rule.

**Step 1:** Create a group “finance”.

```
PAMSC> ng finance unix
```

**Step 2:** Create a group “engineering”.

```
PAMSC> ng engineering unix
```

**Step 3:** Create a user “john” and join the user to the 'finance' group.

```
PAMSC> nu john pass(john)
```

```
PAMSC> eu john unix pgroup(finance)
```

**Step 4:** Create a user “smith” and join the user to the 'engineering' group.

```
PAMSC> nu smith pass(smith)
```

```
PAMSC> eu smith unix pgroup(engineering)
```

**Step 5:** Prevent users from “engineering” to switch to users in “finance” group.

```
PAMSC> er SURROGATE GROUP.finance defacc(r)
```

```
PAMSC> auth SURROGATE GROUP.finance gid(engineering) access(n)
```

**Step 6:** Log in as “smith” user from “engineering” and try to switch to the user “john” from the “finance” group. You notice that the access is denied due to the SURROGATE rule.

The ideal way to implement SURROGATE policy in an enterprise is to create SURROGATE rule with access via PROGRAM /opt/CA/PAMSC/bin/sesu.

The original 'su' program is backed up in a separate place and made as a link to /opt/CA/PAMSC/bin/sesu. This way, we force users to switch to other account only via 'sesu' PROGRAM. With this implementation, the example 1 changes as follows wherein we allow all users to switch to 'root' via 'sesu' PROGRAM and specifically deny access to the user "john" from switching to root.

```
PAMSC> SURROGATE USER.root owner(root) defacc(n)
```

```
PAMSC> auth SURROGATE USER.root uid(*) via(pgm(/opt/CA/PAMSC/bin/sesu))
```

```
PAMSC> auth SURROGATE USER.root uid(john) access(n)
```

## TCP Class

Each record in the TCP class defines a TCP/IP service such as mail, ftp, and http. When the TCP class is being used for authorization, hosts can obtain services from the local host only if the TCP resources grant access. Also, users or groups on a local host can use the TCP/IP services to access remote hosts only if the TCP resources grant access.

The ACL in a TCP record can specify access types for hosts (HOST), groups of hosts (GHOST), networks (HOSTNET), and sets of hosts (HOSTNP).

The CACL in a TCP record can specify access types for hosts (HOST), groups of hosts (GHOST), networks (HOSTNET), and sets of hosts (HOSTNP), and can also specify access types for users and groups.

You can set rules based on IPv4 or IPv6 addresses, not just on host names. This means that you can cater for a domain name change.

The key of the TCP record is the name of the TCP/IP service. The TCP class controls both outgoing services and incoming services.

The following definitions describe the properties contained in a TCP class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines the hosts for which the local host provides service and the access types that are allowed.

Each element in the access control list contains the following information:

- **Host reference**

Defines a HOST, GHOST, HOSTNET, or HOSTNP record.

- **Permitted access**

The access authority that the referenced host has to the resource. The valid access authorities are:

- **none** Does not allow the host to perform any operations.
- **read** Allows the host to obtain TCP service from the local host.

Use the access parameter of the authorize or authorize- command to modify this property

- **CACL**

A list of accessors (users and groups) permitted to access the resource and the host or hosts they can access. Each element in the conditional access control list (CACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Host reference**

Defines a HOST, GHOST, HOSTNET, or HOSTNP record

- **Access** Defines the access authority that the accessor has to the resource. The valid access types are:

- **write** Allows the accessor to use this service to access the host or group of hosts.
- **none** Does not allow the accessor to use this service to access the host or group of hosts.

Use the authorize or authorize- command to modify this property.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the mem+ or mem- parameter with the chres, editres or newres command to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the authorize deniedaccess command, or the authorize- deniedaccess- command, to modify this property.

- **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

- **OWNER**

Defines the user or group that owns the record.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests.

- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**
- No access requests. Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

- **UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

**Example 1:** Prevent incoming connections from a remote host by using Telnet.

**Step 1:** Disable HOST and CONNECT classes, and enable TCP class.

```
PAMSC> so class-(HOST)
PAMSC> so class-(CONNECT)
PAMSC> so class+(TCP)
```

**Step 2:** Add a remote host ([My\\_Remote\\_Host.example.com](#)) in /etc/hosts. Run the following command at the command prompt.

```
vi /etc/hosts
```

**Step 3:** For network interception, the lookahead database "ladb" must be properly entered with the remote host address. To ensure this works, run the following command at the command prompt.

```
./sebuildla -h
```

**Step 4:** Run the following command at the command prompt to verify that the remote host ([My\\_Remote\\_Host.example.com](#)) is added to /etc/hosts.

```
./sebuildla -H
```

**Step 5:** Define a remote host ([My\\_Remote\\_Host.example.com](#)) from which we prevent incoming Telnet connections.

```
PAMSC> nr HOST My\_Remote\_Host.example.com
```

**Step 6:** Define a TCP resource for the Telnet service which allows outgoing Telnet connections.

```
PAMSC> nr TCP telnet owner(nobody) defaccess(w)
```

**Step 7:** Set a rule that prevents incoming connections from the remote host ([My\\_Remote\\_Host.example.com](#)) by using Telnet.

```
PAMSC> authorize TCP telnet HOST(My\_Remote\_Host.example.com) access(n)
```

**Step 8:** Try connecting from the remote host to the Privileged Access Manager endpoint by using Telnet. The connection fails but other connections are not affected.

**Example 2:** Prevent a user from accessing all remote hosts by using Telnet service.

**Step 1:** Disable HOST and CONNECT classes, and enable TCP class.

```
PAMSC> so class-(HOST)
PAMSC> so class-(CONNECT)
PAMSC> so class+(TCP)
```

**Step 2:** Execute the following command at the command prompt and add all remote hosts to /etc/hosts.

```
vi /etc/hosts
```

**Step 3:** For network interception, the lookahead database "ladb" must be properly entered with the remote host address. To ensure this works, run the following command at the command prompt.

```
./sebuildla -h
```

**Step 4:** Define remote hosts as resources by creating a host name pattern that covers all the remote hosts.

```
PAMSC> nr HOSTNP *
```

**Step 5:** Set a rule that denies a user (john) from accessing all the remote hosts.

```
PAMSC> auth TCP telnet uid(john) hostnp(*) access(n)
```

**Step 6:** Log in as john and try to access any remote host by using Telnet. The connection fails.

## TERMINAL Class

Each record in the TERMINAL class defines a terminal of the local host, another host on the network, or an X terminal from which a login session can be made. A record also defines terminals that match a terminal name or IP

address *pattern* (using wildcards). Terminal permissions are checked during the user login procedure, so that users cannot succeed in logging in from terminals they have not been authorized to use.

The TERMINAL class also controls administrative access. ADMIN users can only administer Privileged Access Manager from terminals for which they have appropriate access permissions.

When you define a new TERMINAL record, Privileged Access Manager tries to convert the name you provide to a fully qualified name. If it succeeds, it stores the fully qualified name in the database. If it fails, it stores the name you specify. When you issue subsequent commands referencing this record (`chres`, `showres`, `rmres`, `authorize`, and so on), use the name as it appears in the database.

The key of the TERMINAL record is the name of the terminal. This name identifies the terminal to Privileged Access Manager.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessor access types. Each element in the Access Control List (ACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Access**  
Defines the access authority that the accessor has to the resource.

Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests
- **success**  
Granted access requests
- **failure**  
Denied access requests (default).
- **none**  
No access requests

Privileged Access Manager records events on each attempted access to a resource. Whether the access rules were applied directly to the resource, group or class that had the resource as a member is not recorded.

Use the audit parameter of the `chres` and `chfile` commands to modify the audit mode.

- **CALACL**

Defines a list of the accessors (users and groups) that are permitted to access the resource, and their access types according to the Unicenter NSM calendar status.

Each element in the calendar access control list (CALACL) contains the following information:

- **Accessor**  
Defines an accessor.
- **Calendar**  
Defines a reference to a calendar in Unicenter TNG.
- **Access**  
Defines the access authority that the accessor has to the resource.

Access is permitted only when the calendar is ON. Access is denied in all other cases.

Use the calendar parameter with the `authorize` command to permit user or group access to the resource according to the access defined in the calendar ACL.

- **CALENDAR**

Represents a Unicenter TNG calendar object for user, group, and resource restrictions in Privileged Access Manager. Privileged Access Manager fetches Unicenter TNG active calendars at specified time intervals.

- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource. Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **GROUPS**  
The list of GTERMINAL or CONTAINER records a resource record belongs to.  
To modify this property in a TERMINAL class record, change the MEMBERS property in the appropriate CONTAINER or GTERMINAL record.  
Use the `mem+` or `mem-` parameter with the `chres`, `editres`, or `newres` command to modify this property.
- **NACL**  
The *NACL* property of a resource is an access control list that defines the accessors with authorization denied to a resource, together with the type of access that they are denied (example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Access**  
Defines the type of access that is denied to the accessor.
 Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.
- **NOTIFY**  
Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.  
**Limit:** 30 characters
- **OWNER**  
Defines the user or group that owns the record.
- **PACL**  
Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program Access Control List (PACL) contains the following information:
  - **Accessor**  
Defines an accessor.
  - **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
  - **Access**  
Defines the access authority that the accessor has to the resource.  
**Note:** You can use wildcard characters to specify the resource in a PACL.

Use the `via(pgm)` parameter with the `selang authorize` command to add programs, accessors, and their access types to a PACL. You can use the `authorize-` command to remove accessors from a PACL.

- **SECLABEL**  
Defines the security label of a user or resource.  
**Note:** The SECLABEL property corresponds to the `label[-]` parameter of the `chres` and `ch[x]usr` commands.

- **SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the `ch[x]usr` and `chres` commands.

- **UACC**

Defines the default access authority for the resource. This indicates that the access is granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the `defaccess` parameter with the `chres`, `editres`, or `newres` command to modify this property.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **WARNING**

Specifies whether Warning mode is enabled. If Warning mode is enabled on a resource, then all access request to a resource is granted. If an access request violates an access rule, a record is written to the audit log.

**Example 1:** This example shows how to authorize a user to access Selang on a terminal on the local host by using the **TERMINAL** class on a Unix/Linux endpoint.

**Follow these steps:**

1. Create a user "John".

```
PAMSC> eu John password(John_Pwd)
```

2. Log in as "John" user in a different terminal on the same local host, and try to execute Selang commands. John fails to access Selang because by default all users are not authorized to access Selang.

```
ERROR: Initialization failed, EXITING!
(localhost)
ERROR: Login procedure failed
ERROR: You are not allowed to administer this site from terminal MyLocalHost.sample.com
```

3. The superuser (root) creates a policy using **TERMINAL** class that authorizes "John" to access Selang in a terminal on the local host.

```
PAMSC> authorize TERMINAL MyLocalHost.sample.com uid(John) access(r w) (localhost)
```

4. John attempts to access Selang in a terminal on the local host and succeeds.

```
MyLocalHost.sample.com:~> /opt/CA/PAMSC/bin/selang
CA PAMSC selang v12.81.0.2606 - CA PAMSC command line interpreter
Copyright (c) YYYY CA. All rights reserved.
```

**Example 2:** This example shows how to authorize a user to access Selang on a terminal on another host on the network by using the **TERMINAL** class on a Unix/Linux endpoint.

**Follow these steps:**

1. From the local host (MyLocalHost.sample.com), a root user logs in to another host (AnotherHost.sample.com) on the network.

```
MyLocalHost.sample.com:~> ssh root@ AnotherHost.sample.com
root@141.202.41.78's password:

# id
uid=0(root) gid=0(system) groups=2(bin),3(sys),7(security),8(cron),10(audit),11(lp)

# hostname
AnotherHost.sample.com
```

2. The root user accesses Selang, and creates a user "John" in another host on the network (AnotherHost.sample.com).

```
# ./opt/CA/PAMSC/bin/selang
```

```
PAMSC> eu John password(John_pwd)
```

3. From the local host (MyLocalHost.sample.com), John user opens a terminal and logs in to another host (AnotherHost.sample.com) on the network, and attempts to access Selang but fails.

```
MyLocalHost.sample.com:~> ssh John@ AnotherHost.sample.com
```

```
John@141.202.41.78's password:
```

```
$ id
```

```
uid=203(John) gid=1(staff)
```

```
$ hostname
```

```
AnotherHost.sample.com
```

```
$ /opt/CA/PAMSC/bin/selang
```

```
ERROR: Initialization failed, EXITING!
```

```
(localhost)
```

```
ERROR: Login procedure failed
```

```
ERROR: You are not allowed to administer this site from terminal AnotherHost.sample.com
```

4. The root user authorizes John to execute Selang commands in another terminal on the network.

```
PAMSC> authorize terminal AnotherHost.sample.com uid(John) access(r w)
```

5. John can now execute Selang commands in another terminal on the network.

```
$ /opt/CA/PAMSC/bin/selang
```

```
CA PAMSC selang v12.81.0.2690 - CA PAMSC command line interpreter
```

```

```

## UACC Class

Each record in the UACC class defines the default access allowed to a resource class. The UACC record also determines the access level allowed to a resource of that class that is not protected by Privileged Access Manager.

UACC is applicable to most, but not all, classes. The following table shows how each class uses the UACC class.

UACC Usage	Class
Standard	ADMIN, APPL, AUTHHOST, CALENDAR, CONNECT, CONTAINER, DOMAIN, GAPPL, GAUTHHOST, GHOST, GSUDO, GTERMINAL, HOLIDAY, HOST, HOSTNET, HOSTNP, MFTERMINAL, POLICY, PROCESS, PROGRAM, REGKEY, REGVAL, RULESET, SUDO, SURROGATE, TCP, TERMINAL, USER_DIR, User Defined Classes
Nonstandard	FILE, GFILE
None	AGENT, AGENT_TYPE, CATEGORY, GROUP, PWPOLICY, RESOURCE_DESC, RESPONSE_TAB, SECFILE, SECLABEL, SEOS, SPECIALPGM, USER, USER_ATTR

For users outside the special `_restricted` group, the record for `FILE` in the `UACC` class protects only files that are part of Privileged Access Manager. Examples: the `seos.ini`, `seosd.trace`, `seos.audit`, and `seos.error` files. These files are not explicitly defined to Privileged Access Manager, but are automatically protected by Privileged Access Manager.

The key of the `UACC` class record is the name of the class whose `UACC` properties are being defined.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types.

Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the `access` parameter with the `authorize` or `authorize-` command to modify the ACL.

- **ALLOWACCS**

A list of all allowed accesses for this class.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. `RAUDIT` derives its name from Resource *AUDIT*. Valid values are:

- **all**

All access requests.

- **success**

Granted access requests.

- **failure**

Denied access requests (default).

- **none**

No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the `audit` parameter of the `chres` and `chfile` commands to modify the audit mode.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **NACL**

The `NACL` property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also `ACL`, `CALACL`, `PACL`. Each entry in the `NACL` contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

- **OWNER**

Defines the user or group that owns the record.

- **UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## UNIX\_SOCKET Class

Each record in the UNIX\_SOCKET class defines the access that is allowed to a specific Unix Named Socket. You can define a rule even though a Named socket file is not yet created.

### NOTE

: The UNIX\_SOCKET class is not enabled by default.

The key of the UNIX\_SOCKET class record is the name of the socket pathname that is protected by the record. The full path must be specified.

### NOTE

Unix domain sockets with abstract namespaces, instead of pathnames, are also supported on Linux. The key of the UNIX\_SOCKET class, in this case, is the abstract name without the leading null character. For example, the key for unix socket with abstract name "\0hidden" is just "hidden".

The following definitions describe the properties that are contained in this class record. Most properties are modifiable and can be manipulated using Selang or the administration interfaces. Non-modifiable properties are marked informational:

- **ACL** Defines a list of accessors (users and groups) permitted to access the resource, and the accessor access types. Each element in the access control list (ACL) contains the following information:
  - **Accessor** Defines the user or group that is attempting to access the resource under protection.
  - **Access** Defines the access authority that the Accessor has to the resource. Use the Access Parameter with the Authorize or Authorize- command to modify the ACL.
- **CALACL**

Defines a list of the accessors (users and groups) that are permitted to access the resource, and their access types according to the CA Unicenter NSM calendar status. Each element in the Calendar Access Control List (CALACL) contains the following information:

  - **Accessor**

Defines the user or group that is attempting to access the resource under protection.
  - **Calendar**

Defines a reference to a calendar in Unicenter TNG. Use the Calendar parameter with the Authorize command to permit user or group access to the resource according to the access defined in the calendar ACL.
  - **Access**

Defines the access authority that the accessor has to the resource. Access is permitted only when the calendar is ON. Access is denied in all other cases.

- **CALENDAR** Represents a Unicenter TNG calendar object for user, group, and resource restrictions in Privileged Access Manager. Privileged Access Manager fetches Unicenter TNG active calendars at specified time intervals.
- **CATEGORY**  
Defines one or more security categories that are assigned to a user or resource.
- **COMMENT**  
Defines additional information that you can include in the record. Privileged Access Manager does not use this information for authorization. Limit: 255 characters.
- **CREATE\_TIME**  
Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource. Use the Restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property. The resolution of daytime restrictions is one minute.
- **GROUPS**  
The list of GFILE or CONTAINER records a resource record belongs to. DB property: GROUPS  
To modify this property in a FILE class record, change the MEMBERS property in the appropriate CONTAINER or GFILE record. Use the mem+ or mem- parameter with the chres, editres, or newres command to modify this property.
- **NACL**  
The NACL property of a resource is an access control list. The list defines the accessors that are denied authorization to a resource, along with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:
  - **Accessor**  
Defines the user or group that is attempting to access the resource under protection.
  - **Access**  
Defines the type of access that is denied to the accessor. Use the Authorize Deniedaccess command, or the Authorize- Deniedaccess- command, to modify this property.
- **NOTIFY**  
Defines the user to be notified when a resource or user generates an audit event. CA Privileged Identity Manager can email the audit record to the specified user. Limit: 30 characters.
- **Owner**  
Defines the user or group that owns that record.
- **PACL**  
Defines a list of accessors that can access the resource when the access request is made by a specific program, or a program that matches a name pattern and their access types. Each element in the program access control list (PACL) contains the following information:
  - **Accessor**  
Defines the user or group that is attempting to access the resource under protection.
  - **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wild card program matching.
  - **Access**  
Defines the access authority that the accessor has to the resource.  
Use the via(pgm) parameter with the Selang Authorize command to add programs, accessors, and their access types to a PACL. You can use the Authorize- command to remove accessors from a PACL.
- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource AUDIT. Valid values are the following:

- **all**All access requests.
- **success**Granted access requests.
- **failure**Denied access requests.
- **none**No access requests.Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member. Use the audit parameter of the chres and chfile commands to modify the audit mode.
- **SECLABEL**  
Defines the security label of a user or resource.

#### NOTE

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

- **SECLEVEL**Defines the security level of an accessor or resource. This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.
- **UUAC**Defines the default access authority for the resource. This access authority indicates the access tht is granted to accessors who are not defined to Privileged Access Manager or who do not appear inthe ACL of the resource. Use the Defaccess parameter with the chres, editres, or newres command to modify this property.
- **UNTRUST**  
Defines whether the resource is untrusted or trusted. If the UNTRUST property is set, accessors cannot use the resource. If the UNTRUST property is not set, the other properties that are listed in the database for the resource are used to determine accessor access authority. If a trusted resource is changed in any way, Privileged Access Manager sets the UNTRUST property automatically.

Use the trust[-] parameter with the chres, editres, or newres command to modify this property.

- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.
- **WARNING**  
Specifies whether Warning mode is enabled. If you enable the Warning mode on a resource, then all the access requests to a resource are granted. If an access request violates an access rule, a record is written to the audit log.

**Example:** This example shows how to restrict user access to allow only user1 to connect to UNIX socket /run/docker.sock and audit all access attempts:

```
AC> so class+(UNIX_SOCKET)
AC> nr UNIX_SOCKET /run/docker.sock owner(nobody) defaccess(none) audit(all)
AC> auth UNIX_SOCKET /run/docker.sock uid(user1) access(connect)
```

## USER Class

Each record in the USER class defines a user in the Privileged Access Manager database.

The key of the USER record is the name of the user entered by the user when logging in to the system.

You can change most of the USER properties from the Privileged Access Manager Endpoint Management, or by using the selang command chusr. Properties that you cannot change using chusr are labeled *informational*.

**NOTE**

Usually, and unless otherwise indicated, to change a property using `chusr`, you use the property name as the command parameter.

You can view all properties from the Privileged Access Manager Endpoint Management or by using the `selang` command `showusr`.

- **APPLIST**  
Used by CA SSO
- **APPLIST\_TIME**  
Used by CA SSO
- **APPLS**  
(Informational) Displays the list of applications that the accessor is authorized to access. Used by CA SSO.
- **AUDIT\_MODE**  
Defines the activities that Privileged Access Manager records in the audit log. You can specify any combination of the following activities:
  - No logging
  - All activities recorded in the trace file
  - Unsuccessful login attempts
  - Successful logins
  - Failed access attempts to resources protected by Privileged Access Manager
  - Successful accesses to resources protected by Privileged Access Manager
  - Interactive logins

**NOTE**

This property corresponds to the audit parameter of the `ch[x]usr` and `ch[x]grp` commands.

- **AUTHNMTHD**  
(Informational) Displays the authentication method or methods to be used with the group record; from method 1 to method 32, or none. Used by CA SSO.
- **BADPASSWD**  
Used by CA SSO
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **COUNTRY**  
A string that specifies a country descriptor for a user. This string is part of the X.500 naming scheme. Privileged Access Manager does not use it for authorization.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DAYTIME**  
Defines the day and time restrictions that govern when an accessor can access a resource.  
Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.  
The resolution of daytime restrictions is one minute.
- **EMAIL**  
Defines the email address of the user, up to 128 characters.
- **EXPIRE\_DATE**  
Defines the date on which an accessor becomes invalid. A value for the `EXPIRE_DATE` property in a user record overrides a value in a group record.

**Note:** This property corresponds to the expire[-] parameter of the ch[x]usr and ch[x]grp commands.

- **FULLNAME**

Defines the full name associated with an accessor. Privileged Access Manager uses the full name to identify the accessor in audit log messages, but not for authorization.

**NOTE**

FULLNAME is an alphanumeric string. The maximum length for groups and users is 255 characters.

- **GAPPLS**

(Informational) Indicates the list of application groups that the user is authorized to access. Used by CA SSO.

- **GRACELOGIN**

Defines the number of grace logins a user has after a password expires. When the number of grace logins is exceeded, the user is denied access to the system and must contact the system administrator for a new password.

The number of grace logins must be from 0 through 255. If this value is 0, the user cannot log in.

A value for the GRACELOGIN property in a USER record overrides a value for NGRACE in a GROUP record. Both override the PASSWDRULES property in the SEOS class record.

**NOTE**

This property corresponds to the grace parameter of the ch[x]usr command.

- **GROUPS**

(Informational) Displays the list of user groups that the user belongs to. This property also contains any group authorities, such as group administration authority (GROUP-ADMIN), assigned to the user for each group the user belongs to.

The group list that is contained in this property can be different from the one in the native environment GROUPS property.

**Note:** The ch[x]usr command does not modify this property. Instead, use the join[-] or joinx[-] command to modify this property.

- **HOMEDIR**

(UNIX only) Defines the home directory of the user. Used by CA SSO.

- **INACTIVE**

Defines the number of days of inactivity that must pass before the system changes the status of a user to inactive. If the account status is inactive, the user cannot log in.

A value for the INACTIVE property in a USER record overrides a value in a GROUP record. Both override the INACT property in the SEOS class record.

**NOTE**

Privileged Access Manager does not store the status; it calculates the status dynamically. To identify inactive users, you must compare the INACTIVE value with the LAST\_ACC\_TIME value of the user.

- **LAST\_ACC\_TERM**

Displays the terminal from which the last login was performed.

- **LAST\_ACC\_TIME**

Displays the date and time of the last login.

- **LOCALAPPS**

Used by CA SSO

- **LOCATION**

Defines a user location. Privileged Access Manager does not use this information for authorization.

- **LOGININFO**

Defines the information to log the user in to a specific application and audit data. LOGININFO contains a separate list for each application that the user is authorized to access. Used by CA SSO.

- **LOGSHIFT**

Indicates whether a login outside of the shift time frame is permitted. Privileged Access Manager writes an audit record in the audit log for this event.

- **MAXLOGINS**

Defines the maximum number of concurrent logins that a user is allowed. A zero value indicates that the user can have any number of concurrent logins.

A value for the MAXLOGINS property in a user record overrides a value in a group record. Both override the value of MAXLOGINS in the SEOS class record.

- **MIN\_TIME**

Defines the minimum time in days allowed between password changes for the user.

A value for the MIN\_TIME property in a USER record overrides a value in a GROUP record. Both override the PASSWDRULES property in the SEOS class record.

**Note:** This property corresponds to the min\_life parameter of the ch[x]usr command.

- **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters

- **OBJ\_TYPE**

Specifies the user authority attributes. Each of these attributes corresponds to the parameter of the same name in the ch[x]usr command. A user can have one or more of the following authority attributes:

- **ADMIN**

Specifies whether the user can perform administrative functions, similar to root in the UNIX environment.

- **AUDITOR**

Specifies whether the user can monitor the system, list information in the database, and can set the audit mode for existing records.

- **IGN\_HOL**

Specifies whether the user can log in during any timeframe defined in a HOLIDAY record.

- **LOGICAL**

Specifies that the user is only for internal Privileged Access Manager purposes and cannot be used by a real user to log in.

For example, the user nobody that you can use as the owner of resources to prevent even the resource owner from accessing the resource is a logical user by default. This means that no user can log in using this account.

- **OPERATOR**

Specifies whether the user can list everything in the database and can use the secons utility.

- **PWMANAGER**

Specifies whether the user can modify the password settings of other users and can enable a user account that the serevu utility has disabled.

- **SERVER**

Specifies whether a process can ask users for authorization and can issue the SEOSROUTE\_VerifyCreate API call.

- **OIDCRDDATA**

Used by CA SSO

- **OLD\_PASSWD**

Contains an encrypted list of the previous passwords of the user. The user cannot choose a new password from this list. The maximum number of passwords that are saved in OLD\_PASSWD is determined by the setoptions command.

- **ORG\_UNIT**

A string that stores information about the organizational unit in which the user works. This string is part of the X.500 naming scheme. Privileged Access Manager does not use it for authorization.

- **ORGANIZATION**

Defines the organization in which the user works. This string is part of the X.500 naming scheme. Privileged Access Manager does not use this string for authorization.

- **OWNER**

Defines the user or group that owns the record.

- **PASSWD\_A\_C\_W**

Indicates the ADMIN user who last changed the user password for this record.

- **PASSWD\_INT**

Defines the maximum time in days between password changes for users.

A value for the PASSWD\_INT property in a USER record overrides the value in a GROUP record. Both override the PASSWDRULES property in the SEOS class record.

#### NOTE

This property corresponds to the interval parameter of the ch[x]usr command.

- **PASSWD\_L\_A\_C**

Displays the date and time at which an administrator last updated the password.

- **PASSWD\_L\_C**

Displays the date and time at which a user last updated the password.

- **PGMINFO**

Defines the program information that Privileged Access Manager generates automatically.

The Watchdog automatically verifies the information stored in this property. If it is changed, Privileged Access Manager defines the program as untrusted.

You can select any of the following flags to *exclude* the associated information from this verification process:

- **crc**

The cyclic redundancy check and MD5 signature.

- **ctime**

(UNIX only) The time of the last file status change.

- **device**

On UNIX, the logical disk that the file resides on. On Windows, the drive number of the disk containing the file.

- **group**

The group that owns the program file.

- **inode**

On UNIX, the file system address of the program file. On Windows, this flag has no meaning

- **mode**

The associated security protection mode for the program file.

- **mtime**

The time the program file was last modified.

- **owner**

The user who owns the program file.

- **sha1**

The SHA1 signature. Digital signature method that is named Secure Hash Algorithm that could be applied to the program or sensitive files.

- **size**

The size of the program file.

Use the flags, flags+, or flags- parameter with the chres, editres, or newres command to modify the flags in this property.

- **PHONE**

Defines the user's telephone number. This information is not used for authorization.

- **POLICYMODEL**

Specifies the PMDB that receives new passwords when you change user passwords with the sepass utility. The passwords are *not* sent to the Policy Model defined by the parent\_pmd or passwd\_pmd configuration settings if a value is entered for this property.

**Note:** This property corresponds to the pmdb[-] parameter of the ch[x]usr and ch[x]grp commands.

- **PROFILE**

Defines the path to the profile of a user. This string can include a local absolute path, or a UNC path.

- **PWD\_AUTOGEN**

Displays whether the user password is automatically generated. Used by CA SSO.

The default is no.

- **PWD\_SYNC**

Displays whether the user password is automatically kept identical for all user applications. Used by CA SSO.  
The default is no.

- **RESUME\_DATE**

Defines the date on which a suspended USER account becomes unsuspended.  
RESUME\_DATE and SUSPEND\_DATE work together.

**NOTE**

This property corresponds to the resume[-] parameter of the ch[x]usr and ch[x]grp commands.

- **REVACL**

Displays the access control lists of the accessor.

- **REVOKE\_COUNT**

Used by CA SSO

- **SCRIPT\_VARS**

Used by CA SSO, Defines a variables list with the variable values of the application script that are saved per application.

- **SECLABEL**

Defines the security label of a user or resource.

**NOTE**

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

- **SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

- **SESSION\_GROUP**

Defines an SSO session group for a user. The SESSION\_GROUP property is a string with a maximum length of 16 characters.

In Windows, an administrator can enter a session group new name if the preferred name is not in the drop-down list.

Used by CA SSO

- **SHIFT**

Used by CA SSO

- **SUSPEND\_DATE**

Defines the date on which a user account is suspended and so becomes invalid.

If the suspend date for a record precedes its resume date, the user can work before the suspend date and after the resume date.

If a user has a resume date that is earlier than the suspend date, the record is also invalid *before* the resume date. The user can work only between the resume and suspend dates.

A value for the SUSPEND\_DATE property in a user record overrides the value in a group record.

**NOTE**

This property corresponds to the suspend[-] parameter of the ch[x]usr and ch[x]grp commands.

- **SUSPEND\_WHO**

Displays the administrator who activated the suspend date.

**Note:** This property corresponds to the suspend[-] parameter of the ch[x]usr command.

- **UALIAS**

Displays the aliases of a specific user-defined to one or more authentication hosts. Used by CA SSO.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

## USER\_ATTR Class

Each record in the USER\_ATTR class defines the valid user attributes of a CA SSO user directory.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ATTR\_PREDEFS**  
The list of allowed values for a specific attribute.
- **ATTRNAME**  
(Informational). The name of the attribute.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DBFIELD**  
The name of the field in the userdir database. Since different databases can contain different attributes, the attribute fields should be synchronized.
- **FIELDID**  
(Informational). The ID of the DB field
- **OWNER**  
Defines the user or group that owns the record.
- **PARAMETER\_TYPE**  
Indicates whether the user attribute is a string or numeric.
- **PRIORITY**  
The priority of the user attribute: when setting an authorization rule to a PARAM\_RULE object (such as APPL, URL) the rule is defined with the priority that the user attribute refers to.
- **RAUDIT**  
Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:
  - **all**  
All access requests.
  - **success**  
Granted access requests.
  - **failure**  
Denied access requests (default).
  - **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.
- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.
- **USER\_DIR\_PROP**  
(Informational). The name of the user's directory.
- **USERATTR\_FLAGS**

Contains information about the attribute. The flag can contain the following values:

- **aznchk**-Indicates whether to use this attribute for authorization.
- **predef** (predefined), **freetex** (free text), or **userdir** (user directory)-These three values specify the source of the user attributes.
- **user** or **group**-These values indicate whether the attribute (accessor) is a user or a group.
- **WARNING**  
Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## USER\_DIR Class

Each record in the USER\_DIR class defines a CA SSO user directory.

The key of the USER\_DIR record is the name of the directory.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ADMIN\_NAME**  
Login name of the administrator of the directory.
- **ADMIN\_PWD**  
Password of the administrator of the directory. The password is stored in clear text format. It is not displayed in selang but can be obtained with seadmap functions.
- **AZNACL**  
Defines the authorization ACL. The authorization ACL is an ACL that allows access to a resource based on the resource description. The description is sent to the authorization engine, not the object. Typically, when an AZNACL is used, the object is not in the database.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **CONTOBJ\_CLS**  
The names of the classes the container object inherits from (needed for creation of new login info containers in LDAP.)
- **CREATE\_TIME**  
(Informational) Displays the date and time when the record was created.
- **DIR\_TYPE**  
The type of directory. Valid values are: ETRUST\_AC, LDAP, ODBC, NT\_Domain or none.
- **GRPOBJ\_CLS**  
The names of the classes the group object inherits from (needed for creation of new groups in LDAP.)
- **LICONTOBJ\_CLS**  
The names of the classes the login info container object inherits from (needed for creation of new login info containers in LDAP.)
- **LIOBJ\_CLS**  
The names of the classes the login info object inherits from (needed for creation of new login information in LDAP.)
- **MAX\_RET\_ITEMS**  
The maximum number of items retrieved. The default depends on the directory type.
- **OWNER**  
Defines the user or group that owns the record.
- **PATH**  
The relative distinguishing name in the LDAP tree to begin all queries.
- **PORT\_NUM**

The port number on the host computer used to access the directory.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the audit parameter of the chres and chfile commands to modify the audit mode.

- **TIMEOUT\_CON**

The time (in seconds) the system waits to connect to the directory before issuing a Timeout error message.

- **UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the defaccess parameter with the chres, editres, or newres command to modify this property.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **USERATTR\_LIST**

The list of objects in the USER\_ATTR class that was created with this USER\_DIR object as the value for the USER\_DIR parameter.

- **USERDIR\_HOST**

The name of the host computer for the directory. This property must be defined in the class record.

- **USROBJ\_CLS**

The names of the classes the user object inherits from (needed for creation of new users in LDAP.)

- **VERSION**

The version number of the directory.

## WEBSERVICE Class

The WEBSERVICE class is obsolete; it is not used by Privileged Access Manager.

## WINSERVICE Class

Each record in the WINSERVICE class defines a Windows Service. Use records in the WINSERVICE class to define access rules for Windows Services.

The key of a WINSERVICE class record is the Windows name of the service.

**Note:** In most cases, and unless otherwise indicated, to change a property using the selang chres command, you use the property name as the command parameter.

You can view all properties from the Privileged Access Manager Endpoint Management or by using the `selang` command `showres WINSERVICE`.

- **ACL**

Defines a list of accessors (users and groups) permitted to access the resource, and the accessors' access types. Each element in the access control list (ACL) contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the access authority that the accessor has to the resource.

Use the access parameter with the `authorize` or `authorize-` command to modify the ACL.

- **CATEGORY**

Defines one or more security categories assigned to a user or a resource.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.

The resolution of daytime restrictions is one minute.

- **GROUPS**

Defines the list of CONTAINER records that a resource record belongs to.

To modify this property in a class record, change the MEMBERS property in the appropriate CONTAINER record.

Use the `mem+` or `mem-` parameter with the `chres`, `editres` or `newres` command to modify this property.

- **NACL**

The *NACL* property of a resource is an access control list that defines the accessors that are denied authorization to a resource, together with the type of access that they are denied (for example, write). See also ACL, CALACL, PACL. Each entry in the NACL contains the following information:

- **Accessor**

Defines an accessor.

- **Access**

Defines the type of access that is denied to the accessor.

Use the `authorize deniedaccess` command, or the `authorize- deniedaccess-` command, to modify this property.

- **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

- **OWNER**

Defines the user or group that owns the record.

- **PACL**

Defines a list of accessors that are permitted to access the resource when the access request is made by a specific program (or a program that matches a name-pattern) and their access types. Each element in the program access control list (PACL) contains the following information:

- – **Accessor**  
Defines an accessor.
- **Program**  
Defines a reference to a record in the PROGRAM class, either specifically or by wildcard pattern matching.
- **Access**  
Defines the access authority that the accessor has to the resource.

**NOTE**

You can use wildcard characters to specify the resource in a PACL.

Use the *via(pgm)* parameter with the *selang authorize* command to add programs, accessors, and their access types to a PACL. You can use the *authorize-* command to remove accessors from a PACL.

- **RAUDIT**

Defines the types of access events that Privileged Access Manager records in the audit log. RAUDIT derives its name from Resource *AUDIT*. Valid values are:

- – **all**  
All access requests.
- **success**  
Granted access requests.
- **failure**  
Denied access requests (default).
- **none**  
No access requests.

Privileged Access Manager records events on each attempted access to a resource, and does not record whether the access rules were applied directly to the resource, or were applied to a group or class that had the resource as a member.

Use the *audit* parameter of the *chres* and *chfile* commands to modify the audit mode.

- **SECLABEL**

Defines the security label of a user or resource.

**NOTE**

The SECLABEL property corresponds to the *label[-]* parameter of the *chres* and *ch[x]usr* commands.

- **SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the *level[-]* parameter of the *ch[x]usr* and *chres* commands.

- **UACC**

Defines the default access authority for the resource, which indicates the access granted to accessors who are not defined to Privileged Access Manager or who do not appear in the ACL of the resource.

Use the *defaccess* parameter with the *chres*, *editres*, or *newres* command to modify this property.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **WARNING**

Specifies whether Warning mode is enabled. When Warning mode is enabled on a resource, all access requests to the resource are granted, and if an access request violates an access rule, a record is written to the audit log.

## XGROUP Class

Each record in the XGROUP class defines a group of users in the database.

The key of each XGROUP class record is the name of the group.

### NOTE

The properties of profile groups apply to each user associated with the profile group. However, if the same property is specified in a user (USER or XUSER) record, the user record overrides those in the profile group record.

You can change most of these properties from the Privileged Access Manager Endpoint Management, or by using the `selang` command `chxgrp`.

### NOTE

Usually, and unless otherwise indicated, to change a property using `chxgrp`, you use the property name as the command parameter.

You can view all properties from the Privileged Access Manager Endpoint Management, or by using the `selang` command `showxgrp`.

- **APPLS**

(Informational) Displays the list of applications that the accessor is authorized to access. Used by CA SSO.

- **AUDIT\_MODE**

Defines the activities that Privileged Access Manager records in the audit log. You can specify any combination of the following activities:

- No logging
- All activities recorded in the trace file
- Unsuccessful login attempts
- Successful logins
- Failed access attempts to resources protected by Privileged Access Manager
- Successful accesses to resources protected by Privileged Access Manager
- Interactive logins

### NOTE

This property corresponds to the audit parameter of the `ch[x]usr` and `ch[x]grp` commands. You can use `AUDIT_MODE` for a GROUP or XGROUP to set the audit mode for all members of the group. However, you cannot use `AUDIT_MODE` to set the audit mode for group members if a user's audit mode is defined in a USER record, XUSER record, or profile group.

- **AUTHNMTHD**

(Informational) Displays the authentication method or methods to be used with the group record; from method 1 to method 32, or none. Used by CA SSO.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the `chres`, `ch[x]usr`, or `ch[x]grp` commands to modify this property.

The resolution of daytime restrictions is one minute.

- **EXPIRE\_DATE**  
Defines the date on which an accessor becomes invalid. A value for the EXPIRE\_DATE property in a user record overrides a value in a group record.  
**Note:** This property corresponds to the expire[-] parameter of the ch[x]usr and ch[x]grp commands.
- **FULLNAME**  
Defines the full name associated with an accessor. Privileged Access Manager uses the full name to identify the accessor in audit log messages, but not for authorization.  
FULLNAME is an alphanumeric string. For groups, the maximum length is 255 characters. For users, the maximum length is 47 characters.
- **GAPPLS**  
Defines the list of application groups that the group is authorized to access. Used by CA SSO.
- **GROUP\_MEMBER**  
Defines the groups that are members of this group.
- **GROUP\_TYPE**  
Specifies the group authority attributes. Each of these attributes corresponds to the parameter of the same name in the ch[x]grp command. A group can have one or more of the following authority attributes:
  - **ADMIN**  
Specifies whether a user who belongs to the group can perform administrative functions, similar to root in the UNIX environment.
  - **AUDITOR**  
Specifies whether a user who belongs to the group can monitor the system, list information in the database, and can set the audit mode for existing records.
  - **OPERATOR**  
Specifies whether a user who belongs to the group can list everything in the database and can use the secons utility.
  - **PWMANAGER**  
Specifies whether a user who belongs to the group can modify the password settings of other users and can enable a user account that the serevu utility has disabled.
  - **SERVER**  
Specifies whether a process can ask users who belong to the group for authorization and can issue the SEOSROUTE\_VerifyCreate API call.
- **MEMBER\_OF**  
Defines the groups that this group is a member of.
- **OWNER**  
Defines the user or group that owns the record.
- **PROFUSR**  
Displays a list of the users associated with this profile group.
- **PWD\_AUTOGEN**  
Indicates whether the group password is automatically generated. The default is no. Used by CA SSO.
- **PWD\_SYNC**  
Indicates whether the group password is automatically kept identical for all group applications. The default is no. Used by CA SSO.
- **PWPOLICY**  
Defines the record name of the password policy for the group. A password policy is a set of rules for checking the validity of a new password and for defining when a password expires. The default is no validity check. Used by CA SSO.
- **REVACL**  
Displays the access control lists of the accessor.
- **SHELL**  
(UNIX only) The shell program that is assigned to a new UNIX user when the user is a member of this group.

Use the shellprog parameter with the chxgrp command to modify this property.

- **SUBGROUP**

Displays the list of groups that have this group as a parent.

- **SUPGROUP**

Defines the name of the parent group (superior group).

Use the parent[-] parameter with the ch[x]grp command to modify this property.

- 

- **SUSPEND\_DATE**

Defines the date on which a user account is suspended and so becomes invalid.

If the suspend date for a record precedes its resume date, the user can work before the suspend date and after the resume date.

**NOTE**

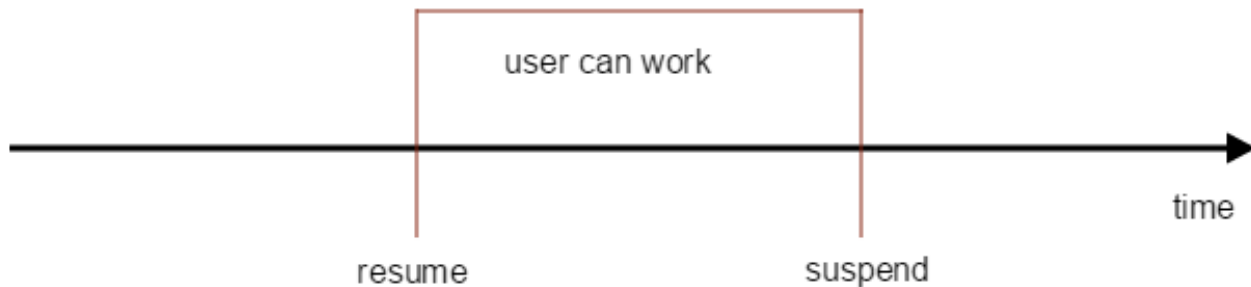

This property corresponds to the suspend[-] parameter of the ch[x]usr and ch[x]grp commands.

**Figure 55: XGROUP Class 1**

If a user has a resume date that is earlier than the suspend date, the record is also invalid *before* the resume date. The user can work only between the resume and suspend dates.

**Figure 56: XGROUP\_Class\_2**

- A value for the SUSPEND\_DATE property in a user record overrides the value in a group record.

- **SUSPEND\_WHO**

Displays the administrator who activated the suspend date.

- **UPDATE\_TIME**

(Informational) Displays the date and time when the record was last modified.

- **UPDATE\_WHO**

(Informational) Displays the administrator who performed the update.

- **USERLIST**

Displays the users that belong to the group.

The user list that is contained in this property may be different from the one in the native environment USERS property.

## XUSER Class

Each record in the XUSER class defines an enterprise user in the database.

The key of the XUSER record is the name of the user entered by the user when logging in to the system.

You can change most of these properties from the Privileged Access Manager Endpoint Management or by using the `selang` command `chxusr`.

### NOTE

Usually, and unless otherwise indicated, to change a property using `chxusr`, you use the property name as the command parameter.

You can view all properties from Privileged Access Manager Endpoint Management or by using the `selang` command `showxusr`.

- **APPLIST**  
Used by CA SSO.
- **APPLIST\_TIME**  
Used by CA SSO.
- **APPLS**  
(Informational) Displays the list of applications that the accessor is authorized to access. Used by CA SSO.
- **AUDIT\_MODE**  
Defines the activities that Privileged Access Manager records in the audit log. You can specify any combination of the following activities:
  - No logging
  - All activities recorded in the trace file
  - Unsuccessful login attempts
  - Successful logins
  - Failed access attempts to resources protected by Privileged Access Manager
  - Successful accesses to resources protected by Privileged Access Manager
  - Interactive logins

### NOTE

This property corresponds to the audit parameter of the `ch[x]usr` and `ch[x]grp` commands.

- **AUTHNMTD**  
(Informational) Displays the authentication method or methods to be used with the group record; from method 1 to method 32, or none. Used by CA SSO.
- **BADPASSWD**  
Used by CA SSO.
- **CATEGORY**  
Defines one or more security categories assigned to a user or a resource.
- **COMMENT**  
Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
**Limit:** 255 characters.
- **COUNTRY**  
A string that specifies a country descriptor for a user. This string is part of the X.500 naming scheme. Privileged Access Manager does not use it for authorization.
- **CREATE\_TIME**

(Informational) Displays the date and time when the record was created.

- **DAYTIME**

Defines the day and time restrictions that govern when an accessor can access a resource.

Use the restrictions parameter with the chres, ch[x]usr, or ch[x]grp commands to modify this property.

The resolution of daytime restrictions is one minute.

- **EMAIL**

Defines the email address of the user, up to 128 characters.

- **FULLNAME**

Defines the full name associated with an accessor. Privileged Access Manager uses the full name to identify the accessor in audit log messages, but not for authorization.

FULLNAME is an alphanumeric string. For groups the maximum length is 255 characters. For users, the maximum length is 47 characters.

- **GAPPLS**

(Informational) Indicates the list of application groups that the user is authorized to access. Used by CA SSO.

- **GRACELOGIN**

Defines the number of grace logins a user has after a password expires. When the number of grace logins is exceeded, the user is denied access to the system and must contact the system administrator for a new password.

The number of grace logins must be from 0 through 255. If this value is 0, the user cannot log in.

A value for the GRACELOGIN property in a USER record overrides a value for NGRACE in a GROUP record. Both override the PASSWDRULES property in the SEOS class record.

**NOTE**

This property corresponds to the grace parameter of the ch[x]usr command.

- **GROUPS**

(Informational) Displays the list of user groups that the user belongs to. This property also contains any group authorities, such as group administration authority (GROUP-ADMIN), assigned to the user for each group the user belongs to.

The group list that is contained in this property can be different from the one in the native environment GROUPS property.

**Note:** This property is not modified by the ch[x]usr command. Instead, use the join[-] or joinx[-] command to modify this property.

- **INACTIVE**

Defines the number of days of inactivity that must pass before the system changes the status of a user to inactive. If the account status is inactive, the user cannot log in.

A value for the INACTIVE property in a USER record overrides a value in a GROUP record. Both override the INACT property in the SEOS class record.

**NOTE**

Privileged Access Manager does not store the status; it calculates the status dynamically. To identify inactive users, you must compare the INACTIVE value with the LAST\_ACC\_TIME value of the user.

- **LAST\_ACC\_TERM**

Displays the terminal from which the last login was performed.

- **LAST\_ACC\_TIME**

Displays the date and time of the last login.

- **LOCALAPPS**

Used by CA SSO.

- **LOCATION**

Defines a user location. Privileged Access Manager does not use this information for authorization.

- **LOGININFO**

Defines the information to log the user in to a specific application and audit data. LOGININFO contains a separate list for each application that the user is authorized to access. Used by CA SSO.

- **LOGSHIFT**

Indicates whether a login outside of the shift time frame is permitted. Privileged Access Manager writes an audit record in the audit log for this event.

- **MAXLOGINS**

Defines the maximum number of concurrent logins that a user is allowed. A zero value indicates that the user can have any number of concurrent logins.

A value for the MAXLOGINS property in a user record overrides a value in a group record. Both override the value of MAXLOGINS in the SEOS class record.

- **MIN\_TIME**

Defines the minimum time in days allowed between password changes for the user.

A value for the MIN\_TIME property in a USER record overrides a value in a GROUP record. Both override the PASSWDRULES property in the SEOS class record.

**Note:** This property corresponds to the min\_life parameter of the ch[x]usr command.

- **NOTIFY**

Defines the user to be notified when a resource or user generates an audit event. Privileged Access Manager can email the audit record to the specified user.

**Limit:** 30 characters.

- **OBJ\_TYPE**

Specifies the user authority attributes. Each of these attributes corresponds to the parameter of the same name in the ch[x]usr command. A user can have one or more of the following authority attributes:

- **ADMIN**

Specifies whether the user can perform administrative functions, similar to root in the UNIX environment.

- **AUDITOR**

Specifies whether the user can monitor the system, list information in the database, and can set the audit mode for existing records.

- **IGN\_HOL**

Specifies whether the user can log in during any period of time defined in a HOLIDAY record.

- **LOGICAL**

Specifies that the user is only for internal Privileged Access Manager purposes, and cannot be used by a real user to log in.

For example, the user nobody that you can use as the owner of resources to prevent even the resource owner from accessing the resource is a logical user by default. This means that no user can log in using this account.

- **OPERATOR**

Specifies whether the user can list everything in the database and can use the secons utility.

- **PWMANAGER**

Specifies whether the user can modify the password settings of other users and can enable a user account that the serevu utility has disabled.

- **SERVER**

Specifies whether a process can ask users for authorization and can issue the SEOSROUTE\_VerifyCreate API call.

- **OIDCRDDATA**

Used by CA SSO.

- **OLD\_PASSWD**

Contains an encrypted list of the previous passwords of the user. The user cannot choose a new password from this list. The maximum number of passwords that are saved in OLD\_PASSWD is determined by the setoptions command.

- **ORG\_UNIT**

A string that stores information about the organizational unit in which the user works. This string is part of the X.500 naming scheme. Privileged Access Manager does not use it for authorization.

- **ORGANIZATION**

Defines the organization in which the user works. This string is part of the X.500 naming scheme. Privileged Access Manager does not use this for authorization.

- **PASSWD\_A\_C\_W**

Indicates the ADMIN user who last changed the user password for this record.

- **PASSWD\_INT**

Defines the maximum time in days between password changes for users.

A value for the PASSWD\_INT property in a USER record overrides the value in a GROUP record. Both override the PASSWDRULES property in the SEOS class record.

**NOTE**

This property corresponds to the interval parameter of the ch[x]usr command.

- **PASSWD\_L\_A\_C**

Displays the date and time at which an administrator last updated the password.

- **PASSWD\_L\_C**

Displays the date and time at which a user last updated the password.

- **PHONE**

Defines the telephone number of the user. This information is not used for authorization.

- **PWD\_AUTOGEN**

Displays whether the user password is automatically generated. Used by CA SSO.

The default is no.

- **PWD\_SYNC**

Displays whether the user password is automatically kept identical for all user applications. Used by CA SSO.

The default is no.

- **REVACL**

Displays the access control lists of the accessor.

- **REVOKE\_COUNT**

Used by CA SSO.

- **SCRIPT\_VARS**

Used by CA SSO, Defines a variables list with the variable values of the application script that are saved per application.

- **SECLABEL**

Defines the security label of a user or resource.

**NOTE**

The SECLABEL property corresponds to the label[-] parameter of the chres and ch[x]usr commands.

- **SECLEVEL**

Defines the security level of an accessor or resource.

**Note:** This property corresponds to the level[-] parameter of the ch[x]usr and chres commands.

- **SESSION\_GROUP**

Defines an SSO session group for a user. The SESSION\_GROUP property is a string with a maximum length of 16 characters.

In Windows, an administrator can enter a session group new name if the preferred name is not in the drop-down list.

Used by CA SSO.

- **SHIFT**

Used by CA SSO.

- **SUSPEND\_DATE**

Defines the date on which a user account is suspended and so becomes invalid.

If the suspend date for a record precedes its resume date, the user can work before the suspend date and after the resume date.

If a user has a resume date that is earlier than the suspend date, the record is also invalid *before* the resume date. The user can work only between the resume and suspend dates.

A value for the SUSPEND\_DATE property in a user record overrides the value in a group record.

**NOTE**

This property corresponds to the `suspend[-]` parameter of the `ch[x]usr` and `ch[x]grp` commands.

- **SUSPEND\_WHO**  
Displays the administrator who activated the suspend date.
- **UALIAS**  
Displays the aliases of a specific user defined to one or more authentication hosts. Used by CA SSO.
- **UPDATE\_TIME**  
(Informational) Displays the date and time when the record was last modified.
- **UPDATE\_WHO**  
(Informational) Displays the administrator who performed the update.

## Classes in the Windows Environment

The topics in this section describe the Windows classes and properties in the Windows database (classes in the *nt environment*).

**NOTE**

The term *nt environment* refers to the database accessed with the `selang env nt` command. This is the same database the Windows operating system maintains for users, groups, and resources.

Use the table of contents to the left to access the topics.

### COM Class

Each record in the COM class defines a device specifying a serial port (COM) or a parallel port (LPT) as listed in the Windows Control Panel, Ports.

**NOTE**

You cannot create new objects in the COM class using Privileged Access Manager.

The key of the COM class is the name of the port being controlled.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **DEV**  
(Informational). A string to indicate the device serial number.
- **DACL**  
Defines the standard access control list that contains the user names and group names authorized to access the resource, and the level of access granted to each.  
Users who want to modify this property must be the owner of the resource or have special access to the resource (to modify the ACL).  
Each element in the access control list contains the following information:
  - **Access Type**  
Specifies permissions to the resource:
    - a. **Allowed**-Permits special access to the resource.
    - b. **Denied**-Denies special access to the resource.
  - **Accessor**  
The user or group for whom the access rights are allowed or denied.
  - **Access**  
The access authority that the accessor has to the resource.

**NOTE**

In an empty ACL, no accesses are explicitly granted, so access is implicitly denied. For a resource that has no ACL, no protection is assigned to the object, so any access request is granted.

Use `auth` or `auth-` command to modify this property.

- **GID**  
Displays the group information for the file or device.
- **OWNER**  
Defines the user or group that owns the record.
- **SACL**  
Windows System Access Control List. Displays audit directives.

**DEVICE Class**

Each record in the DEVICE class defines a Windows hardware device as listed in the Windows Control Panel, Devices.

The key of the DEVICE class record is the name of the device being controlled.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **STARTUPTYPE**  
Defines how (when) the device is started. Options are:
  - **automatic**  
Starts the device automatically during system startup.
  - **boot**  
Starts the device every time the system starts, before any other devices start. Select this option for critical devices essential to system operation.
  - **disabled**  
Prevents users from starting the device. The system can still start disabled devices.
  - **manual**  
Allows the device to be started by a user or a dependent device.
  - **system**  
Starts the device every time the system starts, after the Boot devices start. Select this option for critical devices essential to system operation.

Use the `starttype` parameter with the `chres` or `editres` commands to modify this property.
- **STATUS**  
Changes the current service state. Options are: `started`, `stopped`, and `paused`.  
Use the `status` parameter with the `chres` or `editres` commands to modify this property.
- **IMAGEPATH**  
The fully qualified path for the specified device.
- **PROFILE**  
A string that specifies a path to the user's profile. This string can include a local absolute path, or a UNC path.  
Use the `profile` parameter with the `chusr`, `editusr`, or `newusr` command to modify this property.

**Example: Activate a modem**

To display the status of the modem, enter the `selang` command:

```
showres DEVICE modem
```

To activate the modem, enter the command:

```
chres device modem status(started)
```

## DISK Class

Each record in the DISK class defines a system volume. Volume is the general term that refers to any of the entities that you can create and use on a computer running Windows operating systems (Server editions) such as a primary partition, a logical drive in an extended partition, a volume set, a stripe set, a mirror set, or a stripe set with parity. A volume has a single drive letter assigned to it and is formatted for use by a file system.

### NOTE

You cannot create objects in the DISK class using Privileged Access Manager.

The key of the DISK class is the assigned drive letter (C:, D:, and so on).

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using *selang* or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ATIME**  
(Informational). The time the record was last accessed.
- **CTIME**  
(Informational). Created time.
- **DACL**  
Defines the standard access control list that contains the user names and group names authorized to access the resource, and the level of access granted to each.  
Users who want to modify this property must be the owner of the resource or have special access to the resource (to modify the ACL).  
Each element in the access control list contains the following information:
  - **Access Type**  
Specifies permissions to the resource:
    - a. **Allowed**-Permits special access to the resource.
    - b. **Denied**-Denies special access to the resource.
  - **Accessor**  
The user or group for whom the access rights are allowed or denied.
  - **Access**  
The access authority that the accessor has to the resource.

### NOTE

In an empty ACL, no accesses are explicitly granted, so access is implicitly denied. For a resource that has no ACL, no protection is assigned to the object, so any access request is granted.

Use *auth* or *auth-* command to modify this property.

- **FILE\_SYSTEM**  
(Informational). A name to designate the file system (such as FAT or NTFS).
- **FREE\_SPACE**  
(Informational). The total amount of free space (in KB) on the disk.
- **GID**  
Displays the group information for the file or device.
- **LABEL**  
(Informational). The name of the specified volume.
- **LINK\_NUMB**  
(Informational). Specifies the number of links. For non-NTFS file systems, this property is always one.
- **MTIME**  
(Informational). The time the record was last modified.
- **OWNER**  
Defines the user or group that owns the record.
- **SACL**

Windows System Access Control List. Displays audit directives.

- **TYPE**  
(Informational). Specifies whether the disk is removable, fixed, a CD-ROM, a RAM disk, or a network drive.
- **USED\_SPACE**  
(Informational). The total amount of used space (in KB) on the disk.

## DOMAIN Class (Windows Environment)

Each record in the DOMAIN class defines a collection of computers that share a common database and security policy (domain). A domain provides access to the centralized user accounts and group accounts maintained by the domain administrator. Each domain has a unique name.

### NOTE

You cannot create new objects in the DOMAIN class using Privileged Access Manager.

The key to the DOMAIN record is the domain name.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **BDC**  
(Informational). The name of the computer that receives a copy of the domain's directory database and contains all account and security policy information for the domain. The copy is synchronized periodically and automatically with the master copy on the primary domain controller (PDC). Backup domain controllers (BDCs) also authenticate user logins and can be promoted to function as PDCs as needed. Multiple BDCs can exist on a domain.
- **COMPUTERS**  
Lists computers that are the members of the specified domain.  
Use `computer` or `computer-` parameter with the `chres` and `editres` commands to modify this property.
- **DOMAIN\_NAME**  
Defines the domain name.
- **DOMAIN\_USERS**  
(Informational). Lists user and group accounts that are members of the specified domain.
- **PDC**  
(Informational). The name of the first computer created in the domain; this computer contains the primary storehouse for domain data. It authenticates domain logins and maintains the directory database for a domain. The primary domain controller (PDC) tracks changes made to accounts of all computers on a domain. It is the only computer to receive these changes directly. A domain has only one PDC.
- **TRUSTED**  
Lists trusted and trusting domains.  
A trust relationship is a link between domains that allows pass-through authentication, in which a trusting domain honors the login authentications of a trusted domain. With trust relationships, a user with only one user account in one domain can potentially access the entire network. You can give user accounts and global groups defined in a trusted domain rights and resource permissions in a trusting domain, even though those accounts do not exist in the trusting domain's directory database.  
Use the `trusted` or `trusting-` parameter with the `chres` and `editres` commands to modify this property. You should specify a password for this command.
- **TRUSTING**  
The Trusting domain are domains which trust the target domain.

## FILE Class (Windows Environment)

Valid in the Windows environment

Each record in the FILE class defines a file on a file system (for example, FAT, NTFS, or CDFS) on a physical or logical drive of a computer.

**NOTE**

You cannot use Privileged Access Manager to physically create files on disk.

The key of the FILE class record is the name of the file or directory protected by the record. The full path must be specified.

The following definitions describe the properties contained in a FILE record. You can use `selang` or the Web based GUI to change the record's modifiable properties.

- **ATIME**  
Displays the time the file was last accessed.
- **ATTRIB**  
Displays attributes for the file or directory. The attributes can be one or more of the following:
  - ARCHIVE
  - COMPRESSED
  - DIRECTORY
  - HIDDEN
  - NORMAL
  - OFFLINE
  - READONLY
  - SYSTEM
  - TEMPORARY
- **CTIME**  
Displays the created time.
- **DACL**  
Defines the standard access control list that contains the user names and group names authorized to access the resource, and the level of access granted to each.  
Users who want to modify this property must be the owner of the resource or have special access to the resource (to modify the ACL).  
Each element in the access control list contains the following information:
  - **Access Type**  
Specifies permissions to the resource:
    - a. **Allowed**-Permits special access to the resource.
    - b. **Denied**-Denies special access to the resource.
  - **Accessor**  
The user or group for whom the access rights are allowed or denied.
  - **Access**  
The access authority that the accessor has to the resource.

**NOTE**

In an empty ACL, no accesses are explicitly granted, so access is implicitly denied. For a resource that has no ACL, no protection is assigned to the object, so any access request is granted.

Use `auth` or `auth-` command to modify this property.

- **DEV**  
Displays the serial number of the volume where the file is located.
- **FILE\_SYSTEM**  
Displays the name of the file system where the file is located.
- **GID**

Displays the group information for the file or device.

- **INDEX**  
Displays the unique identifier associated with the file.
- **ISDIR**  
Indicates whether the file is a directory.
- **LINKS\_NUMB**  
Displays the number of links to the file. For the FAT file systems, this property is always one. For NTFS, it can be more than one.
- **MTIME**  
Displays the time the file was last modified.
- **NAME**  
Displays the file name.
- **OWNER**  
Defines the user or group that owns the record.
- **SACL**  
Windows System Access Control List. Displays audit directives.
- **SIZE**  
Displays the size of the file in bytes.

## GROUP Class (Windows Environment)

The GROUP class contains all group records defined to the Windows operating system. A record in the GROUP class represents every group of users.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Nonmodifiable properties are marked as *informational* and cannot be modified.

- **COMMENT**  
Additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.  
Use the `comment[-]` parameter with the `chgrp`, `editgrp`, and `newgrp` commands to modify this property.  
**Limit:** 255 characters
- **FULL\_NAME**  
The full name associated with a user. Privileged Access Manager uses the full name to identify the user in audit log messages, but not for authorization.  
Use the `name` parameter with the `chusr`, `editusr`, or `newusr` command to modify this property.
- **GID**  
(Informational). A value that contains the relative identifier of the group. The accounts database determines the relative identifier when the group is created. It uniquely identifies the group to the account manager within the domain.
- **GLOBAL**  
Indicates a global group. This property is only applicable to Windows groups. This property replaces the `ISGLOBAL` property of earlier Privileged Access Manager versions.  
Use the `global` parameter with the `newgrp (only)` command to add this property.
- **USERLIST**  
The list of users and global groups (for local groups only) that belong to the group. The list that is contained in this property can be different from the one in the Privileged Access Manager database.  
Use the `username(groupname)` parameter with the `join[-]` command to modify this property.
- **PRIVILEGES**  
The Windows rights assigned to the group.  
Use the `privileges` parameter with the `chgrp`, `editgrp`, or `newgrp` command to modify this property.

## OU Class

The OU (Organizational Unit) class contains objects such as user, group, or computer. Objects of class OU can be created on the primary domain controller and could have other objects as child objects (such as group), so an object of class OU is a container object.

### NOTE

The OU class is available only for Windows 2000 Advanced Server with Active Directory installed.

The OU class has no predefined properties (like other classes have). However, you can update the following OU properties:

- Country/Region
- Description
- Desktop
- City
- Display Name
- Folder (Read-only property)
- Fax number
- Managed objects (Read-only property)
- Member of (Read-only property)
- Name (Read-only property)
- Postal address
- Postal code
- P.O. box
- State/Province
- Street
- Telephone
- Object changed (Read-only property)
- Object created (Read-only property)
- Web page

## PRINTER Class

Each record in the PRINTER class defines a device connected to a Windows computer system that is capable of reproducing a visual image on a medium (as listed in Printers folder).

### NOTE

You cannot create new objects of class PRINTER using Privileged Access Manager.

The key of the PRINTER class record is the name of the local printer.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

### • DACL

Defines the standard access control list that contains the user names and group names authorized to access the resource, and the level of access granted to each.

Users who want to modify this property must be the owner of the resource or have special access to the resource (to modify the ACL).

Each element in the access control list contains the following information:

- **Access Type**

Specifies permissions to the resource:

- a. **Allowed**-Permits special access to the resource.
- b. **Denied**-Denies special access to the resource.

– **Accessor**

The user or group for whom the access rights are allowed or denied.

– **Access**

The access authority that the accessor has to the resource.

**NOTE**

In an empty ACL, no accesses are explicitly granted, so access is implicitly denied. For a resource that has no ACL, no protection is assigned to the object, so any access request is granted.

Use `auth` or `auth-` command to modify this property.

- **COMMENT**

Defines additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

**Limit:** 255 characters.

- **LOCATION**

A string that indicates the printer location. Privileged Access Manager does not use this information for authorization.

Use the `location` parameter with the `chres` or `editres` commands to modify this property. Use `()` with blanks to delete this property.

- **OWNER**

Defines the user or group that owns the record.

- **SHARE**

The name that identifies the share point for the printer. Users or groups that want to access the printer could use its share name.

Use the `share_name` or `share_name-` parameter with the `chres` or `editres` commands to modify this property.

- **NAME**

Printer name.

- **SACL**

Windows System Access Control List. Displays audit directives.

- **SERVER**

(Informational). A string to identify the server that controls the printer. If there is no such property, the printer is controlled locally.

## PROCESS Class (Windows Environment)

Each record in the PROCESS class defines an object consisting of an executable program, a set of virtual memory addresses, and a thread as listed in the Windows Task Manager.

**NOTE**

You cannot create new objects in the PROCESS class using Privileged Access Manager.

The key of the PROCESS class record is the name of the executable module of the running program.

The following definitions describe the properties contained in this class record. There are no modifiable properties in this class. Non-modifiable properties are marked *informational*.

- **IMAGE\_PATH**

(Informational). The fully qualified path for the specified executable module.

- **PROCESS\_ID**

(Informational). The unique identifier of the process. Process ID numbers are reused, so they identify a process only for the lifetime of that process.

Consider the following limitations when using the PROCESS class:

- Privileged Access Manager traces process creation in Windows. However, seosd fetches new process arguments and writes the arguments to the general trace only if the user who started the process is marked to be traced.
- When a new process is created, its arguments may not be available until the process finishes initialization. seosd attempts to trace the process arguments asynchronously; however if the process is very short, the process may terminate before seosd can fetch the process arguments and write them to the trace. In this case the following message appears in the trace:  
EXECARGS: Not available (87)
- Process IDs are reused in Windows. If a process is very short, it is theoretically possible that seosd will fetch process arguments for a different process that acquired the same process ID, and write these arguments to the trace.

## REGKEY Class (Windows Environment)

Each record in the REGKEY class defines a key in the Windows registry.

The key to the REGKEY record is the full registry path to the Windows registry key.

### NOTE

You can use wildcard characters as part of the path specification.

The following definitions describe the properties contained in a REGKEY record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **DACL**

The standard access control list that contains the user names and group names authorized to access the resource and the level of access granted to each.

Users who want to modify this property must be the owner of the resource or have special access to the resource (to modify the ACL).

Each element in the access control list contains the following information:

- **Access Type**

Specifies permissions to the resource:

- Allowed**-Permits special access to the resource
- Denied**-Denies special access to the resource

- **Accessor**

The name of the user or group for whom the access rights are allowed or denied.

- **Access**

The access authority the accessor has to the resource. Valid access authorities for the REGKEY class are:

- all**-Allows or denies the accessor to perform all operations permissible for the class
- delete**-Allows or denies the accessor to delete a resource
- read**-Allows or denies the accessor to read the key's contents, but prevents changes from being saved
- rite**-Allows or denies the accessor to change the registry key and its subkeys

### NOTE

It is important to note the differences between an ACL that is empty (that is, one that has no entries) and a resource without an ACL. In the case of an empty ACL, no accesses are explicitly granted, so access is implicitly denied. For a resource that has no ACL, no protection is assigned to the object, so any access request is granted.

Use auth or auth- command to modify this property.

- **OWNER**

The user or group designated as the owner of the resource.

**NOTE**

Use the owner parameter with the newres, chres, and editres commands to modify this property.

- **SACL**  
Windows System Access Control List specifies audit directives.
- **SUBKEYS**  
(Informational). A list of registry keys (subkeys) located under the key.
- **SUBVALUES**  
(Informational). A list of registry values described in the current registry key.

**REGVAL Class (Windows Environment)**

Each record in the REGVAL class defines data that describes the registry keys. This data stores information necessary to configure the system for one or more users, applications, and hardware devices. Registry values contain information that is constantly referenced during operation. Examples include:

- Profiles for each user
- Applications installed on the computer and the types of files each can create
- Property sheet settings for folders and application icons
- Hardware configuration
- Used ports

The key to the REGVAL record is the full registry key name and its value.

**NOTE**

Changing or deleting registry keys and their values incorrectly can cause serious, system-wide problems that may require you to reinstall Windows to correct them.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Non-modifiable properties are marked *informational*.

- **TYPE**

A format to store data. When you store data under a registry value you can specify one of the following values to indicate the type of data being stored:

**NOTE**

Specify the type when you create or modify the registry value.

- **DWORD**  
Data represented by a number that is four bytes long. Many parameters for device driver and services are this type, and can be displayed in binary, hexadecimal, or decimal format.
- **STRING**  
A sequence of characters representing readable text
- **MULTISTRING**  
A multiple string. Values that contain lists or multiple values in readable text. Entries are separated by null characters.
- **BINARY**  
Raw, binary data. Most hardware component information is stored as binary data and can be displayed in hexadecimal format or in an easy-to-read format.

Use one of these described types as a parameter with the newres, chres or editres to modify this property.

- **VALUE**

The value that the Windows registry value holds.

## SEOS Class (Windows Environment)

The SEOS class controls the behavior of the native local security system.

The class contains only one record, called SEOS, which specifies general native security options. To view or change the status of SEOS class properties, use the `setoptions` command.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **AuditCategory**  
Specifies which detected authorized and unauthorized events are audited.
  - **AccountLogon**  
Specifies whether to audit each instance of a user logging on to or logging off from another computer in which this computer is used to validate the account.
  - **AccountManagement**  
Specifies whether to audit each event of account management on a computer. Examples of account management events include:
    - A user account or group is created, changed, or deleted.
    - A user account is renamed, disabled, or enabled.
    - A password is set or changed.
  - **DirectoryAccess**  
Specifies whether to audit the event of a user accessing an Active Directory object that has its own system access control list (SACL) defined.
  - **Logon**  
Specifies whether to audit each instance of a user logging on to or logging off from a computer.
  - **ObjectAccess**  
Specifies whether to audit the event of a user accessing an object. For example, a file, folder, registry key, printer, and so on, that has its own system access control list (SACL) defined.
  - **PolicyChange**  
Specifies whether to audit every incident of a change to user rights assignment policies, audit policies, or trust policies.
  - **PrivilegeUse**  
Specifies whether to audit each instance of a user exercising a user right.
  - **DetailedTracking**  
Specifies whether to audit detailed tracking information for events such as program activation, process exit, handle duplication, and indirect object access.
  - **System**  
Specifies whether to audit when a user restarts or shuts down the computer or when an event occurs that affects either the system security or the security log.
- **History**  
Defines the number of unique new passwords that have to be associated with a user account before an old password can be reused.  
**Limits:** An integer between 1 and 24. If you specify zero, no passwords are saved.
- **Interval**  
Defines the period of time (in days) that a password can be used before the system requires the user to change it.
- **Min life**  
Defines the period of time (in days) that a password must be used before the user can change it.
- **Min length**  
Defines the least number of characters that a password for a user account may contain.
- **Password fails**

Defines the number of failed logon attempts that causes a user account to be locked out.

- **Reset count after**

Defines the number of minutes that must elapse after a failed logon attempt before the failed logon attempt counter is reset to 0 bad logon attempts.

## SERVICE Class

Each record in the SERVICE class defines a Windows service as listed in the Windows Control Panel, Services.

The key of the SERVICE class record is the name of the service being controlled.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **ACCOUNT**

Changes the login account for the service. Although most services must log in to the system account, some services can be configured to log in to special user accounts. For more information, see the relevant Microsoft Windows documentation. The default value is `LocalSystem`.

Use the `account` parameter with the `chres` or `editres` commands to modify this property.

- **BINARY\_NAME**

The full path which points to the location of the service's executable.

- **IMAGEPATH**

The fully qualified path for the specified executable module.

- **INTERACTIVE**

Provides a user interface on the desktop that can be used by whoever is logged in when the service is started. This is available only if the service is running as a `LocalSystem` account.

Use the `interactive` parameter with the `chres` or `editres` commands to modify this property.

- **PROFILE**

A string that specifies the path to the user's profile. This string can include a local absolute path, or a UNC path.

Use the `profile` parameter with the `chusr`, `editusr`, or `newusr` command to modify this property.

- **REG\_KEY**

This property points to the location of the service definition in Windows registry.

- **STARTUPTYPE**

Defines how (when) the service is started. Options are:

- **automatic**-Starts automatically during system startup.
- **disabled**-Prevents users or dependent services from starting the service.
- **manual**-Allows the service to be started by a user or a dependent service.
- Use the `startuptype` parameter with the `chres` or `editres` commands to modify this property.

- **STATUS**

Changes the current service state. Options are: `started`, `stopped`, and `paused`.

Use the `status` parameter with the `chres` or `editres` commands to modify this property.

### Example: Configure a service to start manually

To change the service `SeOSAgent` to start manually, enter the `selang` command:

```
chres SERVICE "SeosAgent" starttype(manual)
```

### Example: Change a directory login account

To change the login account of the Directory Replicator to `ReplAdmin` with password `abcde`, enter the `selang` command:

```
chres SERVICE directory replicator account(repladmin) domainpwd(abcde)
```

## SESSION Class

Each record in the SESSION class defines a user session on the local host. The record includes the user name, computer name, elapsed time of the connection, and the resources being used.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **CNAME**  
The host name where the session was established.
- **GUEST**  
Indicates whether the session was created on Guest account.
- **IDLE**  
Ends a network session between a server and a workstation.  
Use the `disconnect` parameter with the `chres` or `editres` commands to modify this property.
- **OPENS**  
Indicate the number of open sessions.
- **RESOURCES**  
A property that gives information about shared files on a server. This information includes the path of the opened shared resource and the user or computer that opened the resource.
- **TIME**  
The time elapsed since the session was established.
- **USER**  
A value that contains the relative ID (RID) of the user. The RID is determined by the Security Account Manager (SAM) when the user is created. It uniquely defines the user account to SAM within the domain.

### Example: Disconnect a user from a local session

To disconnect user ZORRO from a session on the local host, enter the `selang` command:

```
chres SESSION zorro disconnect
```

#### NOTE

Disconnecting users may result in loss of data. It is a good idea to warn connected users before disconnecting them.

## SHARE Class

Each record in the SHARE class defines a share resource that could be any device, data, or program used by one or more devices or programs. For Windows, shared resources refer to any resource that is made available to network users, such as directories, files, printers, and named pipes. A share also refers to a resource on a server that is available to network users.

The key of the SHARE class record is the share name of the resource.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using `selang` or the administration interfaces. Non-modifiable properties are marked *informational*.

- **CURR\_USERS**  
(Informational). The number of current connections to the resource.
- **DACL**  
Defines the standard access control list that contains the user names and group names authorized to access the resource, and the level of access granted to each.  
Users who want to modify this property must be the owner of the resource or have special access to the resource (to modify the ACL).  
Each element in the access control list contains the following information:

- **Access Type**

Specifies permissions to the resource:

- Allowed**-Permits special access to the resource.
- Denied**-Denies special access to the resource.

- **Accessor**

The user or group for whom the access rights are allowed or denied.

- **Access**

The access authority that the accessor has to the resource.

**NOTE**

In an empty ACL, no accesses are explicitly granted, so access is implicitly denied. For a resource that has no ACL, no protection is assigned to the object, so any access request is granted.

Use `auth` or `auth-` command to modify this property.

- **MAX\_USERS**

The maximum number of concurrent connections that the shared resource can accommodate.

**NOTE**

You cannot supply zero (0) as a value for this property. Windows ignores it.

Use the `max_users` parameter with the `newres`, `chres`, or `editres` commands to modify this property.

- **NAME**

Defines the name of the share.

**NOTE**

PATH

A string that specifies a local path for the shared resource. For disks, this is the path being shared. For print queues, this is the name of the print queue being shared.

Use the `path` parameter with the `newres`, `chres`, or `editres` commands to modify this property.

- **PERMISSION**

(Informational). A value that indicates the shared resource's permissions for servers running with share-level security. This property can be any of the values in the following table:

- **ACCESS\_READ**

Permission to read data from a resource and, by default, to execute the resource.

- **ACCESS\_WRITE**

Permission to write data to the resource.

- **ACCESS\_CREATE**

Permission to create an instance of the resource (such as a file); data can be written to the resource as the resource is created.

- **ACCESS\_EXEC**

Permission to execute the resource.

- **ACCESS\_DELETE**

Permission to delete the resource.

- **ACCESS\_ATTRIB**

Permission to modify the resource's attributes (such as the date and time when a file was last modified).

- **ACCESS\_PERM**

Permission to modify the permissions (read, write, create, execute, and delete) assigned to a resource for a user or application.

- **ACCESS\_ALL**

Permission to read, write, create, execute, and delete resources, and to modify their attributes and permissions.

- **ACCESS\_NONE**

Denies permissions.

- **REMARK**

Additional information you want to include in the record. The alphanumeric string can contain up to 255 characters. Privileged Access Manager does not use this information for authorization.

Use the comment or comment- parameter with the newres, chres, or editres commands to modify this property.

- **RESOURCES**

(Informational). A property that gives information about shared files on a server. This information includes the path of the opened shared resource and the user or computer that opened the resource.

- **TYPE**

(Informational). The type of share. Use one of the following types for a shared resource:

- **File Folder**

A disk drive. This can also refer to remote administration of the server (ADMIN\$) and to administrative shares such as C\$, D\$, and so on.

- **Print Queue**

A print queue

- **Communication device**

A communication device

- **Interprocess Communication (IPC)**

A special share reserved for interprocess communication (IPC\$)

- **USERS**

Information about users currently accessing the shared resource. This information includes the name of user who made the connection (USER), the share name of the server's shared resource, or the computer name of the client (MACHINE). It also includes the number of seconds that the connection has been established (TIME) and the number of files currently open as a result of the connection (INUSE).

## USER Class (Windows Environment)

The USER class contains all user records defined to the Windows operating system. The key of the USER record is the name of the user, which is the name that the user entered when logging in to the system.

The following definitions describe the properties contained in this class record. Most properties are modifiable and can be manipulated using selang or the administration interfaces. Nonmodifiable properties are marked *informational*.

- **BAD\_PW\_COUNT**

(Informational). The number of times the user tried to log in to the account using an incorrect password. A value of -1 indicates that the value is unknown.

- **COMMENT**

Additional information that you want to include in the record. Privileged Access Manager does not use this information for authorization.

Use the comment[-] parameter with the chusr, editusr, and newusr commands to modify this property.

**Limit:** 255 characters.

- **COUNTRY**

A string that specifies a country descriptor for a user. This string is part of the X.500 naming scheme. Privileged Access Manager does not use it for authorization.

Use the country parameter with the chusr, editusr, and newusr commands to modify this property.

- **DAYTIME**

The day and time restrictions that govern when a user can access the resource.

Use the restrictions parameter with the chusr, editusr, and newusr commands to modify this property.

**Note:** The information in this property is identical to the information in the DAYTIME property in the AC environment. However, any minute value that is entered is truncated.

- **DIAL\_CALLBACK**

The type of call-back privileges provided to the user. The following options are defined:

- **NoCallback**

The user has no call-back privileges.

- **SetByCaller**

The remote user can specify a call-back phone number when dialing in.

- **Call-back Phone Number**

The administrator sets the call-back number.

Use the `gen_prop` or `gen_val` parameters with the `chusr` or `editusr` command to modify this property.

- **DIAL\_PERMISSION**

Permission to dial in to the RAS server. When you specify 0 as value, the user cannot dial in to the RAS server.

Use the `gen_prop` or `gen_val` parameter with the `chusr` or `editusr` command to modify this property.

- **EXPIRE\_DATE**

The date on which a USER record expires and becomes invalid. A value for the EXPIRE\_DATE property in a USER record overrides a value in a GROUP record. To reinstate the expired record, use the `chusr` command with the `expire-` parameter. You cannot resume an expired user. You can resume a suspended user by specifying a resume date.

Use the `expire` or `expire-` parameter with the `chusr`, `editusr`, or `newusr` command to modify this property.

- **FLAGS**

Flags that you can assign to the account of a user to specify particular attributes. You can apply more than one flag to each account.

Use the `flags` parameter with the `chusr`, `editusr`, and `newusr` commands to modify this property.

- **FULL\_NAME**

The full name associated with a user. Privileged Access Manager uses the full name to identify the user in audit log messages, but not for authorization.

Use the `name` parameter with the `chusr`, `editusr`, or `newusr` command to modify this property.

- **GID**

A value that contains the relative identifier of the group. The accounts database determines the relative identifier when the group is created. The relative identifier uniquely identifies the group to the account manager within the domain.

- **GROUPS**

The list of groups a user belongs to. The group list that is contained in this property can be different from the one in the AC environment GROUPS property.

Use the `group` parameter with the `join[-]` command to modify this property.

- **HOME**

The home directory is the folder that is accessible to the user and contains files and programs for that user. The home directory can be assigned to an individual user or can be shared among many users.

- **HOMEDIR**

A string specifying the home directory of a user. Users log in to their home directories automatically.

Use the `homedir` parameter with the `chusr`, `editusr`, or `newusr` command to modify this property.

- **HOME\_DRIVE**

A string that specifies the drive of the home directory of a user. Users log in to their own home drives and home directories automatically.

Use the `homedrive` parameter with the `chusr`, `editusr`, or `newusr` command to modify this property.

- **ID**

A value that contains the relative ID (RID) of the user. The Security Account Manager (SAM) determines the RID when the user is created. The RID uniquely defines the user account to SAM within the domain.

- **LAST\_ACC\_TIME**

(Informational). The date and time of the last login.

- **LAST\_LOGOFF**

(Informational). The date and time of the last logoff.

- **LOCATION**

A string that is used to store a user location. Privileged Access Manager does not use this information for authorization.

Use the `location` parameter with the `chusr`, `editusr`, and `newusr` commands to modify this property.

- **LOGON\_SERVER**

A string that specifies the server that verifies the login information for the user. When the user logs in to the domain workstation, Privileged Access Manager transfers the login information to the server. The server gives the workstation permission for the user to work.

- **MAX\_LOGINS**  
(Informational). The number of times the user logged in successfully to this account. A value of -1 indicates that the value is unknown.
- **NAME**  
The name of the user.
- **ORGANIZATION**  
A string that stores information on the organization in which the user works. This string is part of the X.500 naming scheme. Privileged Access Manager does not use it for authorization.  
Use the organization parameter with the chusr, editusr, and newusr commands to modify this property.
- **ORG\_UNIT**  
A string that stores information about the organizational unit in which the user works. This string is part of the X.500 naming scheme. Privileged Access Manager does not use it for authorization.  
Use the org\_unit parameter with the chusr, editusr, and newusr commands to modify this property.
- **PASSWD\_EXPIRED**  
Expiration date for the user account.
- **PGROUP**  
A user's primary group ID. A primary group is one of the groups in which a user is defined. A primary group must be a global group. This string cannot include spaces or commas.  
Use the pgroup parameter with the chusr, editusr, or newusr command to modify this property.
- **PHONE**  
A string that can be used to store a user telephone number. This information is not used for authorization.  
Use the phone parameter with the chusr, editusr, and newusr commands to modify this property.
- **PRIVILEGES**  
The Windows rights assigned to the user.  
Use the privileges parameter with the chusr, editusr, or newusr command to modify this property.
- **PROFILE**  
A string that specifies a path to the profile of the user. This string can include a local absolute path, or a UNC path.  
Use the profile parameter with the chusr, editusr, or newusr command to modify this property.
- **PW\_LAST\_CHANGE**  
(Informational). The date and time on which the password was updated.
- **RESUME\_DATE**  
The date on which a suspended USER account becomes valid.  
See SUSPEND\_DATE for an explanation of how RESUME\_DATE and SUSPEND\_DATE work together.
- **SCRIPT**  
A string that specifies the path for the logon script file of the user. The script file can be a .CMD, .EXE, or .BAT file.
- **TERMINALS**  
A string that specifies a list of terminals from which the user can log in.  
Use the terminals parameter with the chusr, editusr, and newusr commands to modify this property.
- **TS\_CONFIG\_PGM**  
A value that indicates whether the client can specify the initial program.  
The TS\_INITIAL\_PGM user property indicates the initial program. If you specify the initial program of a user, it becomes the only program that user can run. The terminal server logs off the user when the user exits that program. When this value is set to 1, the client can specify the initial program. When this value is set to 0, the client cannot specify the initial program.  
Use the gen\_prop and gen\_val parameters with the chusr and editusr commands to modify this property.
- **TS\_HOME\_DIR**  
The path of the home directory of the user for terminal server logon. This string can specify a local path or a UNC path (\\machine\share\path).

Use the `gen_prop` and `gen_val` parameters with the `chusr` and `editusr` commands to modify this property.

- **TS\_HOME\_DRIVE**

A drive specification (a drive letter followed by a colon) to which the UNC path is specified in the `TS_HOME_DIR` property.

Use the `gen_prop` and `gen_val` parameters with the `chusr` and `editusr` commands to modify this property.

- **TS\_INITIAL\_PGM**

The path of the initial program that Terminal Services runs when the user logs on.

If you specify the initial program of a user, that is the only program that user can run. Terminal server logs off the user when the user exits that program.

When `TS_CONFIG_PGM` property is set to 1, the client can specify the initial program.

Use the `gen_prop` and `gen_val` parameters with the `chusr` and `editusr` commands to modify this property.

- **TS\_PROFILE\_PATH**

The path of the profile of the user for terminal server logon. The directory that is identified by the path must be created manually and must exist before the logon.

Use the `gen_prop` and `gen_val` parameters with the `chusr` and `editusr` commands to modify this property.

- **TS\_WORKING\_DIR**

The path of the working directory for the initial program that Terminal Services runs when the user logs on.

Use the `gen_prop` and `gen_val` parameters with the `chusr` and `editusr` commands to modify this property.

- **WORKSTATIONS**

A list of the workstations from which the user can log in.

Use the `workstations` parameter with the `chusr`, `editusr`, and `newusr` commands to modify this property.

## Classes in the UNIX Environment

This section contains a complete alphabetic reference to all the UNIX classes that exist in the UNIX system files (classes in the unix environment). The properties for these native classes are governed by the operating system and vary between systems.

### NOTE

The term *unix environment* refers to the system files accessed with the `selang` command `env unix`. These are the same system files the UNIX operating system maintains for users and groups and the files on the system.

Use the table of contents to access the topics in this section.

### FILE Class (UNIX Environment)

Each record in the FILE class defines a file located on a physical or logical drive of a computer on a file system.

### NOTE

You cannot create files physically on disk using Privileged Access Manager.

The key of the FILE class record is the name of the file or directory protected by the record. The full path must be specified.

The properties for the this native class are governed by the operating system and vary between systems. The `chfile` command lists the native properties you can modify using `selang`.

### GROUP Class (UNIX Environment)

The GROUP class contains all group records defined to the UNIX operating system. A record in the GROUP class represents every group of users.

The properties for the this native class are governed by the operating system and vary between systems. The `chgrp` command lists the native properties you can modify using `selang`.

## USER Class (UNIX Environment)

The USER class contains all user records defined to the UNIX operating system. The key of the USER record is the user's name, which is the name entered by the user when logging into the system.

The properties for the this native class are governed by the operating system and vary between systems. The `chusr` command lists the native properties you can modify using `selang`.

## Classes for Custom Purposes

This section contains user defined classes and properties.

**Use the table of contents to access the topics in this section**

### User Defined Class

Each record in the User Defined class defines access to a custom-made class that meets your own needs. The only restriction on the name of user-defined classes is that the name cannot be all uppercase letters.

The key of a User Defined class record is the name of the record.

## Windows Values for PAM SC `selang` Commands

This section contains information about Windows values for PAM SC `selang` commands.

**Use the table of contents to access the topics in this section.**

## File Attributes

Attributes can be assigned to a file by using the `chfile`, `editfile`, and `newfile` commands. Attributes determine the character of the file.

### NOTE

Although the full name for these file attributes is `FILE_ATTRIBUTE_name`, Privileged Access Manager only requires you to enter the *name* portion (for example, `ARCHIVE` or `COMPRESSED`).

The following lists and describes the file attributes that you can modify in Windows.

- **FILE\_ATTRIBUTE\_ARCHIVE**  
An archival file; a file marked for backup or removal.
- **FILE\_ATTRIBUTE\_HIDDEN**  
A hidden file. Hidden files are not normally included in an ordinary directory listing.
- **FILE\_ATTRIBUTE\_NORMAL**  
A file with no other attributes. This value is only valid when used alone.
- **FILE\_ATTRIBUTE\_READONLY**  
A read-only file. Applications can read the file, but cannot write in it or delete it.
- **FILE\_ATTRIBUTE\_SYSTEM**  
An operating system file or a file used exclusively by the operating system.
- **FILE\_ATTRIBUTE\_TEMPORARY**  
A file being used for temporary storage.

The following lists and describes the file attributes that you cannot modify in Windows.

- **FILE\_ATTRIBUTE\_COMPRESSED**

A compressed file or directory. For files, this means all the data in the file is compressed; for directories, this means that all newly created files and subdirectories are compressed by default.

- **FILE\_ATTRIBUTE\_DIRECTORY**

A directory.

## Account Flags

Flags can be assigned to a user's account to specify particular attributes of that account by using the `chusr`, `editusr`, and `newusr` commands. You can apply more than one flag to each account.

### NOTE

You do not need to enter the complete name of the flag. You can use the shortcuts provided in the table.

Following are the account flags available in Windows.

Shortcut	Flag	Description
blank	UF_PASSWRD_NOTREQD	Indicates that no password is required for the user's account.
cant_change	UF_PASSWORD_CANT_CHANGE	Indicates that the user cannot change the password for the account.
disable	UF_ACCOUNTDISABLE	Indicates the user's account is disabled.
dont_expire	UF_DONT_EXPIRE_PASSWORD	Indicates that the password for this account never expires.
homedir	UF_HOMEDIR_REQUIRED	Indicates the home directory is required. This value is ignored in Windows.
interdomain	UF_INTERDOMAIN_TRUST_ACCOUNT	Indicates a permit to trust account.
lockout	UF_LOCKOUT	Indicates that the user's account is currently locked out; to unlock a locked account, remove this flag
normal	UF_NORMAL_ACCOUNT	Indicates a default account type that represents a normal user.
notreq	UF_PASSWRD_NOTREQD	Indicates that no password is required for the user's account.
protect	UF_PASSWORD_CANT_CHANGE	Indicates that the user cannot change the password for the account.
script	UF_SCRIPT	Indicates that the login script, which executes disk mapping, is activated when the user starts an application. This flag must be set for LAN Manager 2.0 or Windows.
server	UF_SERVER_TRUST_ACCOUNT	Indicates an account for a Windows NT Backup Domain Controller in this domain.
temp	UF_TEMP_DUPLICATE_ACCOUNT	Indicates a user with an account in another domain; provides access to the domain for this account, but not a trust account.
trust	UF_INTERDOMAIN_TRUST_ACCOUNT	Indicates a permit to trust account.
workstation	UF_WORKSTATION_TRUST_ACCOUNT	Indicates an account for a workstation or server that is a member of this domain.

## Permissions

In the SHARE resource type, you can give access permissions to accessors.

Following are the access permissions available in Windows:

- **ACCESS\_ALL**  
Permission to read, write, create, execute, and delete resources and to modify their attributes and permissions.
- **ACCESS\_ATTRIB**  
Permission to modify the resource's attributes.
- **ACCESS\_CREATE**  
Permission to create a resource, including writing data to it as it's being created.
- **ACCESS\_DELETE**  
Permission to delete the resource.
- **ACCESS\_EXEC**  
Permission to execute the resource.
- **ACCESS\_NONE**  
No access.
- **ACCESS\_PERM**  
Permission to modify the permissions assigned to a user or an application for a resource.
- **ACCESS\_READ**  
Permission to read data from a resource and, by default, to execute in the resource.
- **ACCESS\_WRITE**  
Permission to write data to the resource.

## Privileges

Windows privileges can be assigned to individual user accounts and groups. Administrators can assign privileges to a user with the `chusr` or `editusr` command, or to a group with the `chgrp` or `editgrp` command. Users who are added to a group automatically gain all the privileges assigned to the group.

You can use the name of the privilege, or user right, exactly as it appears in the list, or you can add `Se` to the beginning and `Privilege` to the end of the name (except for `BatchLogon`, `InteractiveLogon`, `NetworkLogon`, and `ServiceLogon`, to which you add `Right` instead of `Privilege`).

Following are the privileges available in Windows.

Privilege	Default Assignment	Description
AssignPrimaryToken	None	Allows a user to modify the security access token of a process.
Audit	None	Generates security audits.
Backup	Administrators Backup Operators	Allows a user to back up files and directories. This privilege replaces all file and directory permissions.
BatchLogon	None	Allows a user to log in as a batch job.

ChangeNotify	Everyone	Usually, rights to files and subdirectories flow downward; that is, users who do not have rights to a specific directory do not also have rights to access the subdirectories below that directory. This privilege allows a user to access subdirectories, even if that user has no rights to the parent directories.
CreatePagefile	None	Allows a user to create a page file. Security is determined by a user's access to the key: \CurrentControlSet\Control\SessionManagement
CreatePermanent	None	Allows a user to create special permanent objects, such as \\Device
CreateToken	None	Creates a token object. Only the Local Security Authority can do this. The Local Security Authority ensures that the user has permission to access the system. It is not possible to audit the use of this right. For C2 certification, we recommend that it not be assigned to any user.
Debug	Administrator	Debugs programs or objects such as threads. You cannot audit this privilege. For C2 certification, we recommend that it not be assigned to any user, including system administrators.
IncreaseBasePriority	Administrators PowerUsers	Allows a user to increase the execution priority of a process.
IncreaseQuota	None	Allows a user to increase the object quotas.
InteractiveLogon	Most groups	Allows the user to log in interactively.
LoadDriver	Administrators	Allows a user to install and remove device drivers.
LockMemory	None	Allows a user to lock pages in the memory of the computer so the pages cannot be automatically backed up on a backing store like PAGEFILE.SYS.
MachineAccount	None	Allows a user to add a new machine to a domain.
NetworkLogon	Everyone	Allows users to connect to a computer from anywhere in the network. This means users do not have to be at a specific place or terminal to log into their computer.
ProfileSingleProcess	Administrators PowerUsers	Allows a user to use performance-monitoring tools in order to monitor the performance of a single process.
RemoteShutdownPrivilege	Administrators PowerUsers	Allows a user to shut down a Windows system remotely.
Restore	Administrators Backup Operators	Allows a user to restore backed-up files and directories. This right replaces all file and directory permissions.

Security	Administrators	Allows a user to specify what types of resource access (such as file access) are to be audited, and to view and clear the security log. <b>Note:</b> This privilege does not allow the user to set system auditing policies using the Audit command from the Policy menu in Microsoft's User Manager. Administrators always have the ability to view and clear the security log.
ServiceLogon	None	Enables a process to register with the system as a service.
Shutdown	Administrators BackupOperators Everyone PowerUsers Users	Allows the user to shut down the system from the system console.
SystemEnvironment	Administrators	Allows a user to modify the system environment variables. This enables the user to set up the system environment at their workstation, and ensure that all other users working on the same workstation use the same setup.
SystemProfile	Administrators	Allows a user to perform profiling (performance sampling) on the system.
SystemTime	Administrators Power Users	Allows a user to set the time for the internal clock of the computer.
TakeOwnership	Administrators	Allows a user to become the owner of files, directories, printers, and other objects on the computer. This right replaces all permissions protecting objects.
Tcb	None	Enables a process to perform as a secure, trusted part of the operating system. Some subsystems are granted this privilege.

## String Matching

This section describes the syntax that can be used to build wildcard expressions.

Privileged Access Manager performs string matching (globbing) using the wildcard matching and character lists.

## Examples Wildcard Matching

To make a single character a don't care character that matches any other single character, use a question mark (?):

Specify	To match
mmc?	mmc3, mmcX, mmc5
mmc?.t	mmc1.t, mmc2.t
mmc04.?	mmc04.a, mmc04.1

To match any string of zero or more characters, use an asterisk (\*):

Specify	To match
*i*.c	main.c, list.c, and so on

st*.h	stdio.h, stdlib.h, string.h, and so on
*	All records of the specified class

To match any character in a list, follow one of these examples:

Specify	To match
[abcgk]	a, b, c, g, or k
[^abcgk]	Any character other than a, b, c, g, or k, such as A, B, d, e, f, or @.
[a-z]	Any character between a and z, inclusive.
[^a-z]	Any character with an ASCII value less than a or greater than z.
[Z-]	Any character with an ASCII value greater than Z's, such as a, b, \, or ~.
[^A]	Any character with an ASCII value <i>not</i> lower than A's, such as B, a, c, or ~.

## Character Lists

A character list that is enclosed by square brackets ( [ ] ) can contain one or more characters. Privileged Access Manager uses these characters as positive or negative matching criteria.

A character list can be composed of one or more characters. For this type of list, Privileged Access Manager matches any single character in the list. If the list within the brackets is preceded by a caret (^), Privileged Access Manager matches any single character, which is *not* in the list.

A range is a type of character list that specifies a range of characters. Privileged Access Manager matches all the characters in the list, inclusively. If a caret (^) precedes the list, Privileged Access Manager excludes all the characters in the specified list. You can specify both ends of the range, or only its first or last character.

The following table describes the character lists that can be used. In this syntax, include the square brackets. Each of the expressions *ch1*, *ch2*, and *chN*, stands for a single character.

List	Matches
[ <i>ch1ch2...chN</i> ]	Any single character in the list enclosed by the square brackets
[^ <i>ch1ch2...chN</i> ]	Any single character that is <i>not</i> in the list enclosed by the square brackets
[ <i>ch1-ch2</i> ]	Any single character in the range, inclusive
[^ <i>ch1-ch2</i> ]	Any single character that is <i>not</i> in the inclusive range
[ - <i>ch2</i> ]	Any single character with an ASCII value lower than or equal to the specified character ( <i>ch2</i> )
[ ^ - <i>ch2</i> ]	Any single character with an ASCII value equal to or higher than the specified character ( <i>ch2</i> )
[ <i>ch1</i> - ]	Any single character with an ASCII value equal to or higher than the specified character ( <i>ch1</i> )
[ ^ <i>ch1</i> - ]	Any single character with an ASCII value equal to or lower than the specified character ( <i>ch1</i> )

## Registry

Privileged Access Manager creates its registry entries under the following registry key, which is called ACROOT in Privileged Access Manager Endpoint Management Remote Configuration:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl
```

The main registry key contains the following registry entries:

- **CurrentVersion**  
Defines the current version and build of product.
- **Encryption Package**  
Defines the full path name of the DLL used to implement symmetric encryption.  
**Default:** *ACInstallDir\bin\aes256enc.dll*

## Build Number

Privileged Access Manager defines the current version and build of product in the following registry key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Build_Number
```

This key is for internal use only.

## AccessControl

Privileged Access Manager maintains generic settings that it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\AccessControl
```

The AccessControl registry key contains the following registry entries:

- **AccessControl Services**  
Defines a list of Privileged Access Manager service names and the executable.  
**Default:** "SeOSAgent;SeOS Agent", "SeSudo;SeOS TD", "seoswd;SeOS Watchdog"  
**Note:** The endpoint that is part of the Enterprise Management Server also contains the following default values for this registry entry: "Sepmdd;SeOS Policy Model(DMS\_\_)", "Sepmdd;SeOS Policy Model(DH\_\_)", "Sepmdd;SeOS Policy Model(DH\_\_WRITER)"
- **admin\_default\_check**  
Specifies whether Privileged Access Manager is denied login access to the Privileged Access Manager server, even when the *defaccess* property for a remote terminal resource is set to *all*, or access to *\_default* terminal resource is permitted.  
Maintained for backward compatibility.  
**Default:** 0 (access is not denied)
- **AdminInst**  
Internal use only.  
**Default:** 0
- **auth\_login**  
Specifies how a user is authenticated for administration purposes.  
Valid values are:  
**native** - for native operating system users, checks the user password against OS.  
**eTrust** - for users that do not exist in the native operating system, checks the user password against Privileged Access Manager database.  
**Default:** native
- **auth\_module\_names**

The list of the language client modules that are allowed to authenticate outside of native authentication. Client module name is set by the client inside the lca API calls before the authentication. Changing this registry value can affect other clients authenticating in a nonnative mode.

**Default:** none

- **CPF\_TARGETS**

List of target mainframe CPF systems (remote CPF target nodes) that the CPF service communicates with.

**Default:** ACF2 TOP RACF

- **eACPipePrefix**

A value for part of the pipe name that the new pipe servers and pipe clients use. If a system has older clients of Privileged Access Manager, then this value is obligatory for those clients to work. Otherwise, change this value to a more secure pipe name.

**Default:** SEOS

- **eACPipeTranslator**

Obsolete.

- **full\_year**

Specifies whether years appear in two-digit (value=no) or four-digit (value=yes) format, when using the secons -tv, seaudit, and dbmgr utilities.

**Default:** yes

- **GenerateMemDump**

Specifies whether Privileged Access Manager creates a memory dump (1) when handling a code exception of a Privileged Access Manager service. Privileged Access Manager creates the memory dump in *ACInstallDir\bin\serviceProcessName.PID.dmp* Example: SeOSAgent.5704.dmp

**NOTE**

The memory dump is only for user mode and not kernel mode.

**Default:** 1

- **parent\_pmd**

The PMDB to which this workstation subscribes in the format of *pmdb@host*. This is the only policy model that can update the local database.

If you do not specify a value, the workstation does not accept updates from any PMDB. If you set the entry to *\_NO\_MASTER\_*, then any PMDB can update this workstation

No default.

**Example:** pmd1@host1;pmd2@host1;pmd3@host2

- **passwd\_pmd**

The target for password replacement on the policy model in the format *pmdb@host*.

The parent\_pmd and passwd\_pmd registry values can have the same value. If the parent\_pmd and passwd\_pmd registry values are not the same, the passwd\_pmd database sends its updates to the parent\_pmd database for distribution. The parent\_pmd database must be a subscriber of the passwd\_pmd database.

If you do not set this value, it inherits the value of the parent\_pmd registry key.

No default.

- **ReverseIpLookup**

Controls the way the client IP address is resolved to determine whether the user is allowed to log in from that terminal.

Valid values are:

**yes**-looks up the IP address of the open client's socket and logon is permitted accordingly.

**no**-uses the host name as received from the client and does not resolve any host names. (The same effect can be achieved by disabling class *TERMINAL*.)

**Default:** yes

- **secondary\_pmd**

Specifies the PMDB used as the secondary target for password replacement for users who are not defined in the primary target (passwd\_pmd).

The format is *pmd\_name@hostname*.

No default.

- **SeOSPath**  
The directory in which Privileged Access Manager is installed.
- **SplashEnable**  
The toggle to enable or disable a protection message during interactive (GINA) login process. This message tells the user that Privileged Access Manager protects the computer. A value of 1 indicates that the message is enabled; a value is 0 indicates that it is disabled.  
**Default:** 1
- **TrustedServices**  
List of trusted programs.  
No default.
- **UseFsiDrv**  
Toggle to enable or disable driver loading.  
**Values:** 1 - Enable driver loading, 0 - Disable driver loading  
**Default:** 1

## agent

Privileged Access Manager maintains agent settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Agent
```

Agent key entries (and any subkeys) are for internal use only.

- **ShutdownWaitingTimeout**  
Defines the timeout period, in milliseconds, the Privileged Access Manager Agent waits for its components to gracefully shut down. If Privileged Access Manager components do not shut down gracefully, the Agent shuts down forcefully.  
**Note:** This registry entry is for internal use only.  
**Default:** 60000

## Applications

Privileged Access Manager maintains application settings that it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Applications
```

The Applications registry key contains the following registry entries:

- **OperationMode**  
Specifies whether the controlled application mode is active (1).  
Set this value to 1.  
**Default:** 1

## Application Name

Privileged Access Manager maintains specific application settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Applications\Application_Name
```

Each Applications\*Application\_Name* registry key contains the following registry entries:

- **ApplicationName**  
Defines the name of controlled process.  
You must specify the full pathname in this format: *device:\path\name.exe*.

**Default:** Full pathname to executable

- **Arguments**  
Defines arguments Privileged Access Manager uses when starting the application.  
**Default:** "" (no arguments)
- **Desktop**  
Defines the workstation and session name.  
**Default:** No default
- **OperationMode**  
Specifies whether the application is active (1).  
**Default:** 1
- **RestartApplication**  
Specifies whether the application will be restarted (1) if it has been closed or terminated.  
**Default:** 1
- **StartApplication**  
Specifies whether Privileged Access Manager be starts the application (1) when the Watchdog wakes up.  
**Default:** 1
- **WorkingDirectory**  
Defines the working directory in which the application is started.  
**Default:** *ACInstallDir\bin*

## Client

Privileged Access Manager maintains client application settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Client
```

The Client registry key contains the following registry entries:

- **ConnectTo**  
Defines the host name Privileged Access Manager client administration applications (for example, selang) connect to by default.  
**Default:** localhost

## standalone

Privileged Access Manager maintains standalone client settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Client\Standalone
```

The Client\Standalone registry key contains the following registry entries:

- **full\_login\_check**  
The toggle to enable the Privileged Access Manager server to check additional user properties (grace and max\_login) and perform a login during a connection request from a standalone application.  
This value helps remote password changes if one is about to expire.  
If the value is set to 1, the checks are enabled.  
**Default:** 0

## Common

Privileged Access Manager maintains settings used by common components under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Common
```

The Common key does not contain any registry entries. It contains registry subkeys for common components.

## AgentManager (Windows)

Privileged Access Manager maintains the Agent Manager related settings in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\common\AgentManager
```

The Agent Manager registry key contains the following registry entries:

- **RefreshTimeout**  
Defines the Agent Manager refresh interval, in seconds.  
**Type:** REG\_DWORD  
**Default:** 600
- **StandAloneService**  
Specifies whether or not this service is a standalone service.  
**Type:** REG\_DWORD  
**Default:** 0
- **TraceEnabled**  
Defines the Privileged Access Manager Agent Manager trace mode.  
**Values:** 0,1  
**Default:** 1
- **TraceFileSize**  
Defines the maximum log files size.  
**Type:** REG\_DWORD  
**Default:** 20MB
- **Workspace**  
Specifies the full pathname of the Privileged Access Manager Agent Manager workspace.  
**Default:** ACInstallDir\Data\AgentManager

## Plugins

Privileged Access Manager maintains settings that are used by the plugins under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Common\AgentManager\Plugins
```

The Plugins key does not contain any registry entries. It contains registry subkeys for plugins.

## AccountManager

Privileged Access Manager maintains the Account Manager related settings in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\common\AgentManager\Plugins  
\AccountManager
```

The Account Manager registry key contains the following registry entries:

- **ComponentName**  
Specifies the name of the AgentManager plug-in.
- **Exclude\_Endpoint\_Types**  
Defines the endpoints types that the current AccountManager does not process.  
**Values:** A comma separated list of endpoint types.  
**Example:**

```
exclude_endpoint_types = Windows Agentless
```

- **Interval**  
Defines the plugin schedule in seconds.  
**Default:** 1  
**Note:** Applicable only when ScheduleType is set to 2.
- **JCS\_add\_timeout**  
Specifies JCS timeout in seconds during an *add* operation.  
**Default:** 300
- **JCS\_modify\_timeout** Specifies JCS timeout in seconds during a *modify* operation.  
**Default:** 300
- **JCS\_search\_timeout** Specifies JCS timeout in seconds during a *search* operation.  
**Default:** 300
- **max\_threads\_count**  
Defines the number of working threads in the pool.  
**Values:** 50  
**Type:** REG\_DWORD
- **OperationMode**  
Defines the plugin operation mode.  
**Options:** 0 - plugin disabled, 1 - plugin enabled  
**Default:** 0
- **PluginPath**  
Defines the full pathname of the plugin.  
**Type:** REG\_SZ  
**Default:** \ProgramFiles\CA\PAMSCServer\APMS\PAMSC\bin\AccountManager.dll
- **QueryFilter**  
Specifies additional values that are added to the Message Queue receive queue filter.  
**Options:** ENDPOINT\_CUSTOM 1...5=, ENDPOINT\_OWNER=, ENDPOINT\_DEPARTMENT=

#### NOTE

- Place property values in apostrophes
- Use AND and OR operands to specify more than a single property
- Use parenthesis when needed

- **Schedule**  
Defines the plugin scheduling string.  
**Default:** 00:00@Sun.Mon,Tue,Wed,Thu,Fri,Sat

#### NOTE

Applicable only when ScheduleType is set to 2.

- **ScheduleType**  
Defines the plugin schedule type.  
**Options:** 0 - execute once, 1 - execute on demand, 2 - execute on interval, 3 - execute on schedule  
**Default:** 1
- **wmi\_timeout**  
Defines in seconds how long WMI waits for a response from the endpoint before timeout.  
**Default:** 60

### PupmAgentManager

Privileged Access Manager maintains the PupmAgentManager related settings in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Common\AgentManager\Plugins
\PupmAgent
```

The PupmAgentManager registry key contains the following registry entries:

- **AutoRegister**  
Defines the auto registration interval in days.  
**Default:** 7
- **Interval**  
Defines the plugin schedule in seconds.  
**Default:** 1  
**Note:** Applicable only when ScheduleType is set to 2.
- **OperationMode**  
Defines the plugin operation mode.  
**Options:** 0 - plugin disabled, 1 - plugin enabled  
**Default:** 0
- **PluginPath**  
Defines the full pathname of the plugin.  
**Default:** /opt/CA/PAMSCShared/lib/AccountManager.so
- **RegistrationInterval**  
Specifies the registration schedule in intervals.  
**Default:** 7  
**Type:** REG\_DWORD
- **Schedule**  
Defines the plugin scheduling string.  
**Default:** 00:00@Sun.Mon,Tue,Wed,Thu,Fri,Sat  
  
**NOTE**  
Applicable only when ScheduleType is set to 2.
- **ScheduleType**  
Defines the plugin schedule type.  
**Options:** 0 - execute once, 1 - execute on demand, 2 - execute on interval, 3 - execute on schedule  
**Default:** 1

### **DiscoveryAgent**

Privileged Access Manager maintains settings that are related to the DiscoveryAgent in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Common\AgentManager\Plugins
\DiscoveryAgent
```

The DiscoveryAgent registry key contains the following registry entries:

- **ForwardRequest**  
Specifies whether to forward the discovery request to another active discovery plug-in. The request is forwarded when the current discovery plug-in fails to process the request.
- **Interval**  
Defines the plugin schedule in seconds.  
**Default:** 600

**Note:** Applicable only when ScheduleType is set to 2.

- **max\_threads\_count**  
Defines the threadpool threads count.  
**Default:** 10
- **OperationMode**  
Defines the plugin operation mode.  
**Options:** 0 - plugin disabled, 1 - plugin enabled  
**Default:** 1
- **PluginPath**  
Defines the full pathname of the plugin.  
**Default:** /opt/CA/bin/DiscoveryAgent.dll
- **Schedule**  
Defines the plugin scheduling string.  
**Default:** 00:00@Sun.Mon,Tue,Wed,Thu,Fri,Sat  
**Note:** Applicable only when ScheduleType is set to 2.
- **ScheduleType**  
Defines the plugin schedule type.  
**Options:** 0 - execute once, 1 - execute on demand, 2 - execute on interval, 3 - execute on schedule  
**Default:** 0

## communication

Privileged Access Manager maintains the message queue server communication settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\common\communication
```

The communication registry key contains the following registry entries:

- **certificate**  
Defines the certificate file for the SSL connection.  
**Limits:** The full pathname to a file containing the certificate data.
- **Distribution\_Server**  
Defines the Distribution Server URL. You can define more than one Distribution Server in a comma-separated list.  
**Example:** ssl://ds.comp.com:61616, ssl://ds\_dr.comp.com:61616  
**Default:** none
- **endpoint\_to\_server\_queue**  
Defines the name of the message queue that the endpoint uses to send information to Privileged Access Manager Enterprise Management.  
**Default:** ac\_endpoint\_to\_server
- **ServerVersion**  
Specifies the version of the Distribution Server. Consider that an endpoint is configured to work with a Distribution Server with build version lower than the endpoint. You can set the build version manually and provide the build version of the Distribution Server.  
**Example:** 12.01.0648  
The token is used for forward compatibility functionality in modules like policyfetcher, ReportAgent, Shared Account Management and UNAB.
- **server\_to\_endpoint\_broadcast\_queue**  
Defines the name of the message queue that Privileged Access Manager Enterprise Management uses to broadcast messages to all endpoints.  
**Default:** ac\_server\_to\_endpoint\_broadcast
- **server\_to\_endpoint\_queue**

Defines the name of the message queue that Privileged Access Manager Enterprise Management uses to send messages to the endpoint.

**Default:** ac\_server\_to\_endpoint

- **server\_to\_server\_broadcast\_queue**

Defines the name of the message queue that the Enterprise Management Server uses to broadcast topics and authenticates using the reportserver user.

**Default:** ac\_server\_to\_server\_broadcast

- **server\_to\_server\_local\_queue**

Defines the name of the queue on the Privileged Access Manager Message Queue used by the Distribution Server to get information from the Enterprise Server.

**Default:** ac\_server\_to\_server\_local

- **server\_to\_server\_queue**

Defines the name of the message queue that the Enterprise Management Server uses to send messages and authenticate using the reportserver user.

**Default:** ac\_server\_to\_server

- **ssl\_keystore**

Defines the keystore location and the location of the client certificate for the SSL.

**Limits:** The full pathname to the keystore location.

**Default:** none

- **ssl\_keystore\_pw**

**Default:** none

- **ssl\_noverifyhost**

Specifies whether to enable verification of the host certificate.

**Limits:** 0, disable host certificate verification; 1, enable host certificate verification

**Default:** 0

- **ssl\_noverifyhostname**

Specifies whether to enable verification of the host name.

**Limits:** 0, disable host name verification; 1, enable host name verification

**Default:** 0

- **ssl\_truststore**

Defines the truststore for server verification.

**Limits:** The full pathname to the truststore.

**Default:** none

- **ssl\_truststore\_pw**

**Default:** none

## crypto (Windows)

Privileged Access Manager maintains cryptography module settings that it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\crypto
```

The crypto registry key contains the following registry entries:

- **ca\_certificate**

Defines the full pathname to the Certificate Authority (CA) certificate database.

**Default:** ACInstallDir\data\crypto\def\_root.pem

- **cleanup\_schedule**

Specifies the interval to execute the cleanup task.

**Default:** 00:00@Sun,Mon,Tue,Wed,Thu,Fri,Sat (Running every day at midnight)

- **communication\_mode**

Specifies whether secure socket layer (SSL) protocols are enabled.

If you set this value to `ssl_only`, only SSL V2, SSL V3, and TLS connections are enabled. This means that this computer cannot communicate with computers that do not support SSL. This computer also cannot communicate with computers that are running versions of Privileged Access Manager earlier than r12.0, which do not support SSL.

#### NOTE

Computers that are running Privileged Access Manager r12.0 and later do support SSL.

If the `fips_only` token is set to 1, the actual communication mode is set to `ssl_only` in FIPS mode (that is, TLS). The `communication_mode` token is ignored.

Valid values are:

- `all_modes`
- `ssl_only`
- `non_ssl`

**Default:** `non_ssl`

- **encryption\_methods**

Specifies the encryption libraries that the Privileged Access Manager Agent uses to decrypt messages. The Agent attempts to use each library in the list, in turn, until the decryption is successful.

**Limits:** `aes256enc`, `aes192enc`, `aes128enc`, `desenc`, `tripledesenc`, `defenc`

**Default:** `aes256enc`, `aes192enc`, `aes128enc`, `desenc`, `tripledesenc`

- **fips\_only**

This token controls whether Privileged Access Manager works in FIPS only mode. In this mode, all non-FIPS functions are disabled.

Valid values:

**1** Privileged Access Manager works in FIPS only mode

**0** Privileged Access Manager works in non-FIPS mode

**Default:** 0

- **private\_key**

Defines the full pathname to the subject private key.

**Default:** `ACInstallDir\data\crypto\sub.key`

- **refresh\_timeout**

Specifies the interval to refresh an internal cache and resolve the IP address of the connected host.

**Default:** 86400 seconds (24 hours)

- **sha\_mode**

Defines the hashing mode for SHA signatures.

**Values:** `sha1`, `sha256`, `sha384`, `sha512`

**Default:** `sha512`

- **ssl\_hostname\_validation**

Specifies whether the certificate hostname validation is enabled during a secure connection.

**Default:** 0

#### NOTE

The certificate hostname validation is not performed during a secure connection.

- **ssl\_port**

Defines the port for SSL communications between Privileged Access Manager clients and services.

**Default:** 5249

- **subject\_certificate**

Defines the full pathname to the subject certificate.

**Default:** `ACInstallDir\data\crypto\sub.pem`

## Data

Privileged Access Manager maintains internal settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Data
```

Data key entries are for internal use only. You cannot open this key.

## Dependency (Registry Settings)

Privileged Access Manager maintains dependency settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Dependency
```

When the Privileged Access Manager component module is installed as an embedded component of another product, all subkeys of this registry key are the name of the product that is dependent on Privileged Access Manager. If you upgrade or uninstall Privileged Access Manager, it checks this registry and decides whether the process can continue or if it must be aborted.

## devcalc (Windows)

Privileged Access Manager maintains deviation calculator settings that it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\devcalc
```

The devcalc registry key contains the following registry entries:

- **dms\_cmd\_retry\_interval**  
Defines the number of seconds between each DMS notification command retry.  
**Default:** 60
- **max\_dms\_cmd\_retry**  
Defines the maximum number of times the policy deviation calculator retries to send update notifications to the DMS before stopping.  
**Default:** 3
- **max\_lines\_request**  
Defines the maximum number of lines (from the policy deviation data file) that the *get devcalc* selang command returns at any one time. You then retrieve more lines using the following command:

```
get devcalc params("offset=X")
```

X Defines the line offset returned by the previous *get devcalc* output.

```
get devcalc params("offset=X")
```

– X

Defines the line offset returned by the previous *get devcalc* output.

**Default:** 50

## Exits

Privileged Access Manager maintains agent exit settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Exits
```

The Exits registry key does not contain any registry entries. It contains registry subkeys for every agent exit.

## AuthenticatePassword

Privileged Access Manager maintains password authentication agent exit settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Exits\AuthenticatePassword
```

The Exits\AuthenticatePassword registry key contains the following registry entries:

- **Enable**  
The toggle to enable or disable the password rules enforcement agent exit. A value of 0 disables the exit. Any other value enables it.  
**Default: 0**
- **EnforcePasswordControl**  
The conditions for password rules enforcement using a Privileged Access Manager client:  
0 - no password rules enforcement  
1 - password rules enforcement is activated when regular users change their own passwords  
2 - password rules enforcement is activated when an admin or a password manager changes someone else's or their own password  
3 - accumulation of values 1 and 2  
**Default: 1**

## Engine

Privileged Access Manager maintains the engine (seos) agent exit settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Exits\Engine
```

The Exits\Engine registry key does not contain any registry entries by default.

## Remote Grace Info

Privileged Access Manager maintains remote grace information agent exit settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Exits\Remote Grace Info
```

The Exits\Remote Grace Info registry key contains the following registry entry:

- **DefaultWarningDays**  
Defines the default number of days for a password expiration warning display to users of segrace\SegraceW utilities. It means that if one of these utilities is being applied and the password of the user is to expire in fewer days than specified by this registry value, then a warning message for the user is displayed.  
**Default: 7**

## Remote Shutdown

Privileged Access Manager maintains remote shutdown agent exit settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Exits\Remote Shutdown
```

The Exits\Remote Shutdown registry key contains the following registry entries:

- **Path**  
The full path name of the remote shutdown DLL.  
**Default: AC\InstallDir\bin\remshut.dll**
- **Prefix**  
The defined prefix used by the remote shutdown DLL.  
**Default: SD**

## Script Engine

Privileged Access Manager maintains the script engine settings that it uses under the following key:

```
HKEY_CURRENT_USER\Software\ComputerAssociates\AccessControl\ScriptEngine
```

The script Engine registry key contains the following registry entries:

### Locale

**Type:** REG\_DWORD

**Values:** 0x409

#### NOTE

The Current user locale default value is English.

### PuttyLocation

**Type:** REG\_SZ

#### NOTE

ActiveX sets this value during the first SSH autologin attempt.

### TraceEnabled

**Type:** REG\_DWORD

**Values:** 1

#### NOTE

Trace messages are sent to the windows debugger or dbgview.exe for display.

## Sessions

Privileged Access Manager maintains the script engine sessions settings that it uses under the following key:

```
HKEY_CURRENT_USER\Software\ComputerAssociates\AccessControl\ScriptEngine\sessions
```

The sessions registry key contains the following registry entries:

**<user@hostname>**

**Type:** REG\_DWORD

#### NOTE

ActiveX maintains a counter of the number of open sessions to show the last closing session check-in dialog.

## FsiDrv

Privileged Access Manager maintains driver settings that it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\FsiDrv
```

The FsiDrv registry key contains the following registry entries:

- **AuditRefreshPeriod**  
Defines the minimum time in seconds between two consecutive audit events from the same source. Privileged Access Manager does not log audit messages for consecutive events from the same source that occur within this time period.  
**Default:** 0 (all audit events are logged)
- **BatchOplockStatus**  
Specifies whether to disable batch OpLocks (opportunistic locking) of an entire file. When disabled (value is zero), the driver collects 100 percent of audit information for file access but performance decreases. A non-zero value keeps

batch OpLocks operating regularly (enabled) and increases performance, but potentially provides incomplete audit information that may not include attempts to access related files.

**NOTE**

You must reload the driver to use the new setting. Unload the driver (net stop seosdrv) after you stop Privileged Access Manager (secons -s).

**Default:** 1 (enabled)

- **BypassDriversCount**

Defines how many drivers you want to add to your bypass list.

**Type:** REG\_DWORD

**Default:** 0

- **CacheLimit**

Defines the seosdrv kernel memory cache limit size in megabytes.

**Type:** REG\_DWORD

**Limits:** 8 - 64

**Default:** 16

- **CounterResolution**

Defines the time stamp measurement resolution using the following format: a:1000.

**Type:** DWORD

**Limits:** 1 - 1000 (decimal)

**Default:** 100

- **DefLookupThreads**

Defines the number of threads that Privileged Access Manager opens to resolve SIDs into account names.

**Default:** 5

- **directory**

The location of the driver.

**Default:** *system\_drive\Windows\_path\system32\drivers*

- **DriverName\_drvNumber**

Defines the name of a driver that you want to bypass. Example: thisdrv.sys.

**Values:** drvNumber - a number from 0 to BypassDriversCount - 1.

**Type:** REG\_SZ

**Limit:** 49 characters.

**NOTE**

Create one registry entry for each driver that you want to bypass and verify that the BypassDriversCount specifies the number of drivers you defined.

- **DynamicSysThreadDetection**

Specifies that Privileged Access Manager traces all kernel mode threads that are created by another product which creates system threads. Example: Trend Micro PC-cillin Antivirus.

**NOTE**

Enabling this registry value can cause performance issues. We recommend that you contact Broadcom Support before you enable this registry value. For assistance, contact Broadcom Support at <https://www.broadcom.com/support>.

**Type:** REG\_DWORD

**Default:** 0 (disabled)

- **FileCacheDisabled**

The toggle to enable or disable the generic file cache.

**Values:** 0enable the generic file cache, 1disable the generic file cache

**Default:** 0

- **LoopHoleProtectionDisabled**

Specifies whether to disable loophole protection, which protects Privileged Access Manager from applications such as Process Monitor (procmon.exe) that can close its handles.

**Values:** **0** - enable loophole protection; **1** - disable loophole protection.

**Default:** 0

- **MaxAuditRecordLimit**

Defines the audit queue limit. When the queue length exceeds this limit, Privileged Access Manager artificially slows down threads that generate audit events. In this way, it can read the queue and can write to the log file faster than new items are added to the queue.

**NOTE**

When new items are added to the queue faster than Privileged Access Manager can read and process them, the system's memory may be exhausted.

**Default:** 200

- **MaxTimeoutLimit**

Defines the number of consecutive timeouts that Privileged Access Manager detects before it triggers a driver bypass. Once reached, the driver stops sending authorization requests to the authorization engine until the engine indicates that it is ready to process events.

A value of zero disables this bypass.

**Default:** 5

- **QueueTimeout**

The maximum time in seconds to wait for seosd to respond.

**Default:** 10

- **QueueTimeoutAnswer**

The response of the driver after time-out.

**Default:** 0 (Deny)

- **RedRangeLimit**

Defines the range of accumulated authorization timeout in comparison to the queue timeout.

**Type:** DWORD

**Values:** 70 - 99

**Default:** 70

- **RegistryCacheDisabled**

The toggle to enable or disable the generic registry cache.

**Values:** 0 enable the generic registry cache, 1 disable the generic registry cache

**Default:** 0

- **SilentModeAdmins**

- Line separated list of user names who can administer the computer in maintenance mode (SilentModeEnabled = 1).  
No default

- **SilentModeEnabled**

Determines whether maintenance mode is active (1).

**Default:** 0 (disabled)

- **SystemBypassRestricted**

Specifies if Privileged Access Manager bypasses access checks for system processes. By default, Privileged Access Manager does not consider system processes to be trusted and does not bypass access checks for system processes.

**Values:** **0** - bypass access checks; **1** - do not bypass access checks.

**Default:** 1

- **YellowRangeLimit**

Defines the range of accumulated authorization timeout in comparison to the queue timeout value. For example, if the driver authorization queue contains 15 events and the average processing period is 0.1 seconds, then the accumulated authorization timeout is 1.5 seconds, which represents 15% of 10 seconds. The value below the yellow range sets the state to green. The value above the yellow range sets the state to red.

**Type:** DWORD

**Values:** 20 - 50

**Default:** 40

## Instrumentation

Privileged Access Manager maintains cainstrm.dll behavior settings (which apply to all loaded plug-ins) it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Instrumentation
```

The Instrumentation registry key contains the following registry entries:

- **Active**  
Specifies whether cainstrm.dll is active (1).  
If you specify 0, cainstrm.dll loads but does not process any plug-ins.  
**Type:** REG\_DWORD  
**Default:** 1
- **ApplyOnProcess**  
Specifies a list of processes on which cainstrm.dll is loaded/applied.  
If the list is empty then cainstrm.dll is applied on all processes not listed in ExcludeProcess.  
If the list is not empty then cainstrm.dll is applied on the listed processes only and ignores processes listed in ExcludeProcess.  
You can define the name of the service or the full pathname. Names are *not* case sensitive. For example, "services.exe", "\system32\services.exe", "c:\windows\system32\services.exe".  
**Type:** REG\_MULTI\_SZ  
By default, this token is not set (instrumentation applies to any process).
- **ExcludeProcess**  
Specifies a list of processes to which instrumentation does *not* apply.  
  
**NOTE**  
This entry is valid only if ApplyOnProcess is not set.  
**Type:** REG\_MULTI\_SZ  
By default, this token is not set.
- **OperationMode**  
Specifies whether cainstrm.dll loads plug-ins (1) or not (0).  
**Type:** REG\_DWORD  
**Default:** 1
- **RunTimeInstrumentationDisabled**  
Specifies the Privileged Access Manager instrumentation policy at run time.  
**Type:** REG\_DWORD  
**Limits:** 0 - runtime instrumentation enabled; 1 - runtime instrumentation disabled  
**Default:** 0
- **RunTimeInstrumentationIncludeList**  
Specifies a list of processes to apply the runtime instrumentation to.  
**Type:** REG\_MULTI\_SZ
- **TraceDbgEnable**  
Specifies whether to trace status flag for the cainstrm module. The key entry enables tracing into DbgView or Kernel Debugger.  
**Type:** REG\_DWORD  
**Limits:** 0 - false; 1 - true  
**Default:** 0
- **TraceFileIsCyclic**  
Specifies the type of the trace file.

**Type:** REG\_DWORD

**Limits:** 0 - trace file is not cyclic; 1 - trace file is cyclic

**Default:** 0

- **TraceFileSizeLimit**

Defines the maximum size of the trace file in bytes. A value of 0 means no maximum size limit is imposed on the trace file.

**Type:** REG\_DWORD

**Default:** 0

- **TraceFilteringMask**

Defines the filtering mask for each plug-in. The supported values for this registry value change depending on the status of the software component for which you define the registry value. Two values are predefined: 0, all information is filtered (display no information); 0x0fffffff, no information is filtered (display all information).

**Type:** REG\_DWORD

**Default:** 0

**NOTE**

We recommend that you do not change the value of this registry entry yourself. For assistance, contact CA Support at <http://ca.com/support>.

- **TraceFolderPath**

Defines the full pathname to the trace file.

**Type:** REG\_SZ

- **TraceOutputMask**

Defines the filtering mask for the trace output channels - debug stream, file, or ETW. You can specify that the trace outputs to file, to DbgView debug channel, or to WinDbg debug channel. A value of 0 disables any output.

**Type:** REG\_DWORD

**Default:** 0

**NOTE**

We recommend that you do not change the value of this registry entry yourself. For assistance, contact CA Support at <http://ca.com/support>.

- **UnloadIfNoPlugins**

Specifies whether cainstrm.dll is automatically unloaded (1) when no plug-ins are assigned to a current process. If you specify 0, cainstrm.dll loads but does not process plug-ins.

**Type:** REG\_DWORD

**Default:** 1

## **\_Dot NET**

Privileged Access Manager maintains .NET instrumentation under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Instrumentation\.NET
```

The .NET registry key contains the subkey - Profiler.

Described below are the registry entries in the Profiler subkey:

- **ApplyOnProcess** Defines a list of processes to load the .NET Profiler.

**Type:** REG\_MULTI\_SZ

- **CLSID** Specifies a globally unique identifier that identifies an object.

For internal use. Not changeable.

**Type:** REG\_SZ

- **OperationMode** Defines whether to load the .NET Profiler into the memory.

**Limits:** 0 - False; 1 - True

**Type:** REG\_DWORD

- **ReadConfigPeriodSec** Defines interval (in seconds) for the plugin to read its configuration from the Registry.  
**Type:** REG\_DWORD
- **TraceDbgEnable**  
Specifies whether to trace status flag for the cainstrm module. The key entry enables tracing into DbgView or Kernel Debugger.  
**Type:** REG\_DWORD  
**Limits:** 0 - False; 1 - True  
**Default:** 0
- **TraceFileEnable** Enables tracing into the file.  
**Type:** REG\_DWORD  
**Default:** 0 - disabled
- **TraceFileIsCyclic** Specifies the type of the trace file.  
**Type:** REG\_DWORD  
**Limits:** 0 - trace file is not cyclic; 1 - trace file is cyclic  
**Default:** 0
- **TraceFileSizeLimit** Defines the maximum size of the trace file in bytes. A value of 0 means no maximum size limit is imposed on the trace file.  
**Type:** REG\_DWORD  
**Default:** 0
- **TraceFilteringMask** Defines the filtering mask for each plug-in. The supported values for this registry value change depending on the status of the software component for which you define the registry value.  
**Limits:** 0 - all information is filtered (display no information); 0x0fffffff - no information is filtered (display all information).  
**Type:** REG\_DWORD  
**Default:** 0

#### NOTE

We recommend that you do not change the value of this registry entry yourself. For assistance, contact CA Support at <http://ca.com/support>.

- **TraceFolderPath** Defines the full pathname to the trace file.  
**Type:** REG\_SZ
- **TraceOutputMask**  
Defines the filtering mask for the trace output channels - debug stream, file, or ETW. You can specify that the trace outputs to file, to DbgView debug channel, or to WinDbg debug channel. A value of 0 disables any output.  
**Type:** REG\_DWORD  
**Default:** 0

#### NOTE

We recommend that you do not change the value of this registry entry yourself. For assistance, contact CA Support at <http://ca.com/support>.

- **TraceReadParamsSec** Specifies the time taken to read the trace parameters from the registry.  
**Type:** REG\_DWORD  
**Default:** 60 seconds

The Profile sub key contains the following subkeys with registry entries for internal use only and are not changeable:

- Assemblies
- Plugins

## Plugins

Privileged Access Manager maintains settings that are used by the plugins under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Common\AgentManager\Plugins
```

The Plugins key does not contain any registry entries. It contains registry subkeys for plugins.

### **AccountManager**

Privileged Access Manager maintains the Account Manager related settings in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\common\AgentManager\Plugins
\AccountManager
```

The Account Manager registry key contains the following registry entries:

- **ComponentName**  
Specifies the name of the AgentManager plug-in.
- **Exclude\_Endpoint\_Types**  
Defines the endpoints types that the current AccountManager does not process.  
**Values:** A comma separated list of endpoint types.  
**Example:**  
  

```
exclude_endpoint_types = Windows Agentless
```
- **Interval**  
Defines the plugin schedule in seconds.  
**Default:** 1  
**Note:** Applicable only when ScheduleType is set to 2.
- **JCS\_add\_timeout**  
Specifies JCS timeout in seconds during an *add* operation.  
**Default:** 300
- **JCS\_modify\_timeout** Specifies JCS timeout in seconds during a *modify* operation.  
**Default:** 300
- **JCS\_search\_timeout** Specifies JCS timeout in seconds during a *search* operation.  
**Default:** 300
- **max\_threads\_count**  
Defines the number of working threads in the pool.  
**Values:** 50  
**Type:** REG\_DWORD
- **OperationMode**  
Defines the plugin operation mode.  
**Options:** 0 - plugin disabled, 1 - plugin enabled  
**Default:** 0
- **PluginPath**  
Defines the full pathname of the plugin.  
**Type:** REG\_SZ  
**Default:** \ProgramFiles\CA\PAMSCServer\APMS\PAMSC\bin\AccountManager.dll
- **QueryFilter**  
Specifies additional values that are added to the Message Queue receive queue filter.  
**Options:** ENDPOINT\_CUSTOM 1...5=, ENDPOINT\_OWNER=, ENDPOINT\_DEPARTMENT=

**NOTE**

- Place property values in apostrophes
- Use AND and OR operands to specify more than a single property
- Use parenthesis when needed
- **Schedule**  
Defines the plugin scheduling string.  
**Default:** 00:00@Sun.Mon,Tue,Wed,Thu,Fri,Sat

**NOTE**

Applicable only when ScheduleType is set to 2.

- **ScheduleType**  
Defines the plugin schedule type.  
**Options:** 0 - execute once, 1 - execute on demand, 2 - execute on interval, 3 - execute on schedule  
**Default:** 1
- **wmi\_timeout**  
Defines in seconds how long WMI waits for a response from the endpoint before timeout.  
**Default:** 60

**PupmAgentManager**

Privileged Access Manager maintains the PupmAgentManager related settings in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Common\AgentManager\Plugins
\PupmAgent
```

The PupmAgentManager registry key contains the following registry entries:

- **AutoRegister**  
Defines the auto registration interval in days.  
**Default:** 7
- **Interval**  
Defines the plugin schedule in seconds.  
**Default:** 1  
**Note:** Applicable only when ScheduleType is set to 2.
- **OperationMode**  
Defines the plugin operation mode.  
**Options:** 0 - plugin disabled, 1 - plugin enabled  
**Default:** 0
- **PluginPath**  
Defines the full pathname of the plugin.  
**Default:** /opt/CA/PAMSCShared/lib/AccountManager.so
- **RegistrationInterval**  
Specifies the registration schedule in intervals.  
**Default:** 7  
**Type:** REG\_DWORD
- **Schedule**  
Defines the plugin scheduling string.  
**Default:** 00:00@Sun.Mon,Tue,Wed,Thu,Fri,Sat

**NOTE**

Applicable only when ScheduleType is set to 2.

- **ScheduleType**  
Defines the plugin schedule type.  
**Options:** 0 - execute once, 1 - execute on demand, 2 - execute on interval, 3 - execute on schedule  
**Default:** 1

**DiscoveryAgent**

Privileged Access Manager maintains settings that are related to the DiscoveryAgent in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Common\AgentManager\Plugins
\DiscoveryAgent
```

The DiscoveryAgent registry key contains the following registry entries:

- **ForwardRequest**  
Specifies whether to forward the discovery request to another active discovery plug-in. The request is forwarded when the current discovery plug-in fails to process the request.
- **Interval**  
Defines the plugin schedule in seconds.  
**Default:** 600  
**Note:** Applicable only when ScheduleType is set to 2.
- **max\_threads\_count**  
Defines the threadpool threads count.  
**Default:** 10
- **OperationMode**  
Defines the plugin operation mode.  
**Options:** 0 - plugin disabled, 1 - plugin enabled  
**Default:** 1
- **PluginPath**  
Defines the full pathname of the plugin.  
**Default:** /opt/CA/bin/DiscoveryAgent.dll
- **Schedule**  
Defines the plugin scheduling string.  
**Default:** 00:00@Sun.Mon,Tue,Wed,Thu,Fri,Sat  
**Note:** Applicable only when ScheduleType is set to 2.
- **ScheduleType**  
Defines the plugin schedule type.  
**Options:** 0 - execute once, 1 - execute on demand, 2 - execute on interval, 3 - execute on schedule  
**Default:** 0

**PluginManagement**

Privileged Access Manager maintains internal plugin management under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Instrumentation\PluginManagement
```

The PluginManagement key contains the following registry entries:

- **Active**  
Internal use only and not changeable.

Specifies whether cainstrm.dll is active (1).

**Type:** REG\_DWORD

**Default:** 1

- **Altitude** Internal use only and not changeable.  
Defines the order to load the plug-in.  
**Type:** REG\_DWORD
- **ApplyOnDLL** Internal use only and not changeable.  
Defines the DLL names (modules) to load the plug-in.  
**Type:** REG\_MULTI\_SZ
- **ApplyOnProcess** Internal use only and not changeable.  
Specifies a list of processes on which cainstrm.dll is loaded/applied.  
If the list is empty then cainstrm.dll is applied on all processes not listed in ExcludeProcess.  
If the list is not empty then cainstrm.dll is applied on the listed processes only and ignores processes listed in ExcludeProcess.  
**Type:** REG\_MULTI\_SZ  
By default, this token is not set (instrumentation applies to any process).
- **ExcludeProcess** Internal use only and not changeable.  
Specifies a list of processes to which instrumentation does *not* apply.

#### NOTE

This entry is valid only if ApplyOnProcess is not set.

**Type:** REG\_MULTI\_SZ

By default, this token is not set.

- **LoadLibraryA** Internal use only and not changeable.  
**Type:** REG\_DWORD
- **LoadLibraryExA** Internal use only and not changeable.  
**Type:** REG\_DWORD
- **LoadLibraryExW** Internal use only and not changeable.  
**Type:** REG\_DWORD
- **LoadLibraryW** Internal use only and not changeable.  
**Type:** REG\_DWORD
- **OperationMode** Internal use only and not changeable.  
Specifies whether cainstrm.dll loads plug-ins (1) or not (0).  
**Type:** REG\_DWORD  
**Default:** 1
- **PluginName** Internal use only and not changeable.  
Defines the name of the Dynamic Link Library (DLL) for the plug-in.  
**Type:** REG\_SZ
- **ProcessCommandArguments** Internal use only and not changeable.  
**Type:** REG\_DWORD

#### NOTE

The PluginManagement registry entries are for internal use only. Do not change their value.

## lang Registry

Privileged Access Manager maintains management language (selang) settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\lang
```

The lang registry key contains the following registry entries:

- **HandleHomeDir**

The value that determines whether property HOME\_DIR for native user account is updated and home directory created.

If the value is set to 0, only user's property HOME\_DIR is updated. If the value is set to 1, user's property is updated and home directory is physically created in the file system.

**Default:** 1

- **help\_path**

The directory in which the lang help files are located.

**Default:** *ACInstallDir\data\help*

- **HNODE\_MAX\_EVENTS**

Defines the maximum number of health status events being written to the HNODE record. If the number of events exceeds the maximum, the product removes the oldest events and leaves the newest events only.

**Default:** 10

- **ModifiableClassFlags**

Specifies the flags that an Privileged Access Manager administrator can change using the following selang command: `setoptions class className flags{+ | -} (flag)`

**Values:** W - Set Warning mode for the specified class; I - Change case sensitivity for resources in the specified class; WI - Set Warning mode and change case sensitivity for resources in the specified class

**Default:** W

- **query\_size**

The maximum number of records to be listed in a database query.

**Default:** 100

- **SetBlockRun**

Specifies whether to check if a program is trusted and block the execution of untrusted programs.

**Values:**

**yes**-All programs defined with viapgm authorization rules have the blockrun property set to yes.

**no**-All programs defined with viapgm authorization rules have the blockrun property set to no.

**Default:** Yes

- **SpaceReplace**

For internal use only. This key should always be empty.

**Default:** ""

- **use\_old\_commands**

Specifies whether to disable old ACF2 compatibility commands (ag, lg, rg, lu, au, and so on).

**Limits:** 0 - do not support old commands, 1 - support old commands

**Default:** 1 (support old commands)

## logmgr Registry

Privileged Access Manager maintains logging settings that it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\logmgr
```

The logmgr registry key contains the following registry entries:

- **audit\_back**

The name of the Privileged Access Manager audit backup file. Only Privileged Access Manager can write to this file.

**Default:** *ACInstallDir\log\seos.audit.bak*

- **audit\_group**

The group that can read the audit logs.

**Default:** ComputerAssociates

- **audit\_log**

The name of the Privileged Access Manager audit log file. When this file reaches the size that is specified in `audit_size`, Privileged Access Manager closes the file, renames it with the name in `audit_back`, and creates an audit log. Only Privileged Access Manager can write to this file.

**Default:** *AC\InstallDir\log\seos.audit*

- **audit\_max\_files**

Defines the maximal number of audit log backup files Privileged Access Manager accumulates when it performs date-triggered backups. When the *BackUp\_Date* configuration setting is set to anything other than *none*, Privileged Access Manager continuously accumulates date-triggered backup files. This configuration setting lets you reduce disk space Privileged Access Manager uses for audit log backups. When the number of audit log backup files reaches the limit that you set, Privileged Access Manager deletes the oldest backup file when it creates the newest.

**Values:**

**0** - keep all audit log backup files.

***n*** - a positive integer greater than zero.

**Note:** You cannot remove redundant audit log backup files manually because Privileged Access Manager protects these files automatically. Also, if the audit reporting is enabled, Privileged Access Manager does not delete a backup file until the Report Agent finishes processing it.

**Default:** 50

- **audit\_size**

The maximum size, in KB, of the Privileged Access Manager audit log file. Do not specify less than 50 KB.

**Default:** 10240

**NOTE**

Privileged Access Manager stops writing audit records to the audit file when the audit file size exceeds 2 GB.

- **AuditFiltersFile**

The name of the Privileged Access Manager audit filter file.

**Default:** *AC\InstallDir\data\audit.cfg*

- **BackUp\_Date**

Specifies the criterion by which Privileged Access Manager backs up the audit log file, and if Privileged Access Manager adds a timestamp to the backup file name.

Privileged Access Manager *always* backs up the audit log file when it reaches the size specified in the *audit\_size* configuration setting.

**Values:** none, yes, daily, weekly, monthly

- **yes** - Privileged Access Manager backs up the audit log file when it reaches the size specified in *audit\_size* and adds a timestamp to the backup file name.

- **none** - Privileged Access Manager backs up the audit log file when it reaches the size specified in *audit\_size* and does not add a timestamp to the backup file name.

- **daily, weekly, monthly** - Privileged Access Manager backs up the audit log file whenever the specified interval has elapsed *and* when it reaches the size specified in *audit\_size*, and adds a timestamp to the backup file name. However, if no audit events are written to the audit log file in the specified interval, Privileged Access Manager does not back up the file after the interval elapses.

**Note:** Privileged Access Manager counts the specified interval from the time that it creates the first audit log file, and backs up the file at midnight on the appropriate day.

**Example:** The configuration setting has a value of *weekly* and Privileged Access Manager creates the audit log file at 9:00 am on Friday April 1. Many audit events occur this week and the audit log file exceeds the *audit\_size* configuration setting on Monday 4 April. Privileged Access Manager backs up the audit log file on 4 April and adds a timestamp to the backup file name. A week after the audit log file was first created, at midnight Friday 8 April, Privileged Access Manager again backs up the audit log file and adds a timestamp to the backup file name.

**Limits:** Specify values in all uppercase or all lowercase.

**Default:** none

- **error\_back**

The name of the Privileged Access Manager error backup file.

**Default:** *AC\InstallDir\log\seos.error.bak*

- **error\_group**

The group that can read the error log files.

If this value is set to *none*, only Administrators can read the file.

**Default:** none

- **error\_log**  
The name of the Privileged Access Manager error log file. When this file reaches the size specified in `error_size`, Privileged Access Manager closes the file, renames it with the name in `error_back`, and creates an error log. Only Privileged Access Manager can write to this file.  
**Default:** *ACInstallDir\log\seos.error*
- **error\_size**  
The maximum size, in KB, of the Privileged Access Manager error log file.  
**Default:** 50
- **irecorder\_audit**  
Specifies whether the IR API library routes audit events of existing PMDs in addition to the local security service audit events.  
**all** - routes audit events of Policy Models in addition to the local security service audit events.  
**localhost** - routes audit events of the local security service only.  
**Default:** all
- **SendAuditToNativeChannel**  
(Windows 2008 only) Specifies whether seosd sends audit events to the Windows 2008 event log channel for Privileged Access Manager.  
**Default:** 0 (no)
- **SendAuditToNativeLog**  
Specifies whether seosd sends audit events to the Windows event log.  
**Default:** 0 (no)

## message Registry

Privileged Access Manager maintains messaging settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\message
```

The message registry key contains the following registry entries:

- **filename**  
The name of the file that supplies most of the messages that appear in response to Privileged Access Manager commands.  
**Default:** *ACInstallDir\Data\SeOS.msg*
- **MessagesDirectory**  
Specifies the location of the Privileged Access Manager messages file.  
**Default:** *ACInstallDir\Data\Messages*

## OS\_User

Privileged Access Manager maintains enterprise user settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\OS_user
```

The OS\_user registry key contains the following registry entries:

- **create\_user\_in\_db**  
Specifies whether Privileged Access Manager creates an XUSER record for an undefined user, when that user logs in.  
**Note:** This setting applies only if you use enterprise users (`osuser_enabled` is set to 1).  
Following are the valid values:  
**0** - Privileged Access Manager does not automatically create an XUSER record.  
**1** - Privileged Access Manager automatically creates an XUSER record

**Default:** 1

- **osuser\_enabled**

Specifies whether enterprise users and groups are enabled.

Following are the valid values:

**0** - The use of enterprise users and groups is disabled.

**1** - The use of enterprise users and groups is enabled.

**Default:** 1

## passwd Registry

Privileged Access Manager maintains password settings that it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\passwd
```

The passwd registry key contains the following registry entries:

- **DefaultPgroup**

Internal use only

**Default:** other

- **Dictionary**

Defines the full pathname of the file containing the words that *cannot* be used as passwords.

**NOTE**

To use this file, set the dictionary format password rule (use\_dbdict) to *file* and set UseDict setting to *yes*.

If the dictionary format is set to *db*, passwords that cannot be used are taken from the Privileged Access Manager database and this setting is ignored.

**Default:** *ACInstallDir\data\words*

- **EnforceViaEtrust**

Specifies whether to enforce updating or creating user passwords through Privileged Access Manager only.

**Default:** 0 (do not have to use Privileged Access Manager)

- **NativePasswordPropagation**

Specifies that a Password filter propagates passwords in Privileged Access Manager and native environments.

**Default:** 1

If 0 is set, the password propagation is done into the Privileged Access Manager environment only. If 1 is set, the Password filter propagates passwords into Privileged Access Manager and native environments.

- **PasswordTimeout**

Defines the maximum number of milliseconds that the Privileged Access Manager password filter waits for authorization response.

**Default:** 4000

- **PasswordTimeoutAnswer**

Specifies the answer to send back to the LSA if the authorization process does not respond in the time-out given.

If 0 is set, the password change is refused. If 1 is set, the password change is approved.

**Default:** 0

- **UseDict**

Specifies whether to use the dictionary file (set with the Dictionary setting) when verifying a password.

**NOTE**

To use the dictionary file, you must also set the dictionary format password rule (use\_dbdict) to *file*. If the dictionary format is set to *db*, passwords that cannot be used are taken from the Privileged Access Manager database and this setting is ignored.

**Default:** no

## pmd

Privileged Access Manager maintains generic Policy Model settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Pmd
```

The Pmd registry key contains the following registry entries:

- **\_\_pmd\_backup\_directory\_\_**  
Defines the directory that Privileged Access Manager uses to store Policy Model backups. Privileged Access Manager stores each PMD backup in a subdirectory named *pmd\_name*.  
**Default:** *ACInstallDir\Data\policies\_backup*
- **\_Pmd\_directory\_**  
Defines the directory in which PMDB database files are located.  
**Default:** *ACInstallDir\Data*
- **ClientOperationTimeout**  
Defines the number of seconds a Policy Model client on this computer waits for a response from the Policy Model. If the Policy Model does not respond within this time frame, the Policy Model client assumes that the Policy Model is nonresponsive.  
**Default:** 60
- **MaximumPolicyModels**  
Defines the maximum number of policy models you can create.  
**Default:** 16
- **SendAuditToNativeChannel**  
(Windows 2008 only) Specifies whether PMDB sends audit events to the Windows 2008 event log channel for Privileged Access Manager.  
**Default:** 0
- **SendAuditToNativeLog**  
Specifies if Privileged Access Manager sends Policy Model audit events to the Windows event log.  
**Values:** 0 - do not send audit events to the Windows event log, 1 - send audit events to the Windows event log  
**Default:** 0
- **ShutdownWaitingTimeout**  
Defines the number of milliseconds a Policy Model on this computer waits for its components to shut down gracefully. If Policy Model components do not shut down gracefully within this time frame, the Policy Model forces them to shut down.  
**Default:** 60000 (1 minute)
- **TCPReceiveTimeout**  
Defines the number of seconds a Policy Model on this computer waits for a response from its subscribers. If a Policy Model subscriber does not respond within this time frame, the Policy Model closes its connection to it.  
**Default:** 60

## <PMDB\_Name>

Privileged Access Manager maintains specific Policy Model settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Pmd\PMDB_Name
```

Each Pmd\PMDB\_Name registry key contains the following registry entries:

- **\_Min\_Retries**  
Defines the number of failed attempts the Policy Model makes to connect to a subscriber before it considers it unavailable.  
**Default:** 4
- **\_Retry\_Timeout**

Defines the time, in minutes, that the Policy Model waits before trying to resend an update to an unavailable subscriber, after the minimum number of attempts specified in `_Min_Retries` has been made.

**Default:** 30

- **\_Shutoff\_Time\_**  
Obsolete.
- **Active\_Policy**  
Defines the Policy Model name.
- **Always\_Propagate**  
Specifies whether the Policy Model propagates commands when there is an error. By default, the Policy Model always sends commands for propagation. If you set this to *no* the Policy Model will not send command when there is an error.  
**Default:** Yes
- **Auto\_Truncate**  
Specifies if `sepm` truncates the updates file if you execute `sepm -t` without specifying either `auto` or the offset.  
**Values:** Yes `sepm` automatically truncates the update file if no `sepm -t` parameter is specified, No `sepm` does not truncate the update file if no `sepm -t` parameter is specified  
**Default:** Yes
- **Filter**  
Defines the full pathname of the filter file for the update file.  
No default.
- **force\_auto\_truncate**  
Specifies whether Privileged Access Manager truncates the update file even if there are no subscribers to the Policy Model.  
You can truncate the update file manually (`sepm -t`), and Privileged Access Manager also truncates the file automatically based on a separate configuration setting (`trigger_auto_truncate`) that defines the event that triggers automatic truncation.  
**Note:** If all subscribers to the Policy Model are "Out of sync", the Policy Model effectively has no subscribers.  
**Default:** Yes
- **Parent\_Pmd**  
Defines the names of parent PMDBs from which this Policy Model accepts updates.  
No default.
- **trigger\_auto\_truncate**  
Defines the size of the Policy Model update file, in megabytes, that triggers an automatic truncating of the update file. If you set this entry to 0, Privileged Access Manager uses the hard-coded default value (100 MB). If you use a value that is greater than the upper limit, Privileged Access Manager uses the upper limit value.  
**Type:** REG\_DWORD  
**Limits:** 1 - 2000 MB  
**Default (DMS\_\_ and DH\_\_WRITER):** 1024 MB  
**Default (all other PMDBs):** 100 MB
- **UseEncryption**  
Specifies whether update information that is saved to the `updates.dat` file is encrypted.  
**Values:** 0 Do not encrypt the `updates.dat` file, 1 encrypt the `updates.dat` file  
**Default:** 0

## logmgr key

Privileged Access Manager maintains specific Policy Model log settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Pmd\PMDB_Name\logmgr
```

Each `Pmd\PMDB_Name\logmgr` registry key contains the following registry entries:

- **audit\_back**  
Defines the name of the Policy Model audit backup file. Only Privileged Access Manager can write to this file.

- Default:** pmd\_audit.bak
- **audit\_group**  
Defines the group that can read the audit logs.  
**Default:** Computer Associates
- **audit\_log**  
Defines the name of the Policy Model audit log file. When this file reaches the size specified in `audit_size`, Privileged Access Manager closes the file, renames it with the name set in `audit_back`, and creates a new audit log.  
Only Privileged Access Manager can write to this file.  
**Default:** pmd.audit
- **audit\_size**  
Defines the maximum size, in KB, of the Policy Model audit log file. Do not specify a value that is less than 50 KB.  
**Default:** 1024
- **error\_back**  
Defines the name of the Policy Model error backup file.  
**Default:** pmd\_error.back
- **error\_group**  
Defines the group that can read the error log files.  
If this value is set to *none*, only Administrators can read the file.  
**Default:** none
- **error\_log**  
Specifies the name of the Policy Model error log file. When this file reaches the size specified in `error_size`, Privileged Access Manager closes the file, renames it with the name in `error_back`, and creates a new error log. Only Privileged Access Manager can write to this file.  
**Default:** pmd.error
- **error\_size**  
Defines the maximum size, in KB, of the Privileged Access Manager error log file.  
**Default:** 1024

## DMS Name

Privileged Access Manager maintains specific DMS settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Pmd\DMS_Name
```

The `Pmd\DMS_Name` registry key contains the following registry entries:

- **\_Min\_Retries**  
Defines the number of failed attempts the Policy Model makes to connect to a subscriber before it considers it unavailable.  
**Default:** 4
- **\_Retry\_Timeout**  
Defines the time, in minutes, that the Policy Model waits before trying to resend an update to an unavailable subscriber, after the minimum number of attempts specified in `_Min_Retries` has been made.  
**Default:** 30
- **\_Shutoff\_Time\_**  
Obsolete.
- **Active\_Policy**  
Defines the Policy Model name.
- **Always\_Propagate**  
Specifies whether the Policy Model propagates commands when there is an error. By default, the Policy Model always sends commands for propagation. If you set this to *no* the Policy Model will not send command when there is an error.

**Default:** Yes

- **Auto\_Truncate**  
Specifies if sepmd truncates the updates file if you execute sepmd -t without specifying either auto or the offset.  
**Values:** Yessepmd automatically truncates the update file if no sepmd -t parameter is specified, Nosepmd does not truncate the update file if no sepmd -t parameter is specified  
**Default:** Yes
- **Filter**  
Defines the full pathname of the filter file for the update file.  
No default.
- **force\_auto\_truncate**  
Specifies whether Privileged Access Manager truncates the update file even if there are no subscribers to the Policy Model.  
You can truncate the update file manually (sepmd -t), and Privileged Access Manager also truncates the file automatically based on a separate configuration setting (trigger\_auto\_truncate) that defines the event that triggers automatic truncation.  
**Note:** If all subscribers to the Policy Model are "Out of sync", the Policy Model effectively has no subscribers.  
**Default:** Yes
- **Parent\_Pmd**  
Defines the names of parent PMDBs from which this Policy Model accepts updates.  
No default.
- **trigger\_auto\_truncate**  
Defines the size of the Policy Model update file, in megabytes, that triggers an automatic truncating of the update file. If you set this entry to 0, Privileged Access Manager uses the hard-coded default value (100 MB). If you use a value that is greater than the upper limit, Privileged Access Manager uses the upper limit value.  
**Type:** REG\_DWORD  
**Limits:** 1 - 2000 MB  
**Default (DMS\_\_ and DH\_\_WRITER):** 1024 MB  
**Default (all other PMDBs):** 100 MB
- **UseEncryption**  
Specifies whether update information that is saved to the updates.dat file is encrypted.  
**Values:** 0Do not encrypt the updates.dat file, 1encrypt the updates.dat file  
**Default:** 0

## endpoint\_management key

Privileged Access Manager maintains specific DMS Endpoint Management settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Pmd\  
DMS_NAME\endpoint_management
```

dmsmgr defines the registry values in this key when it creates a DMS. This key is not defined if a DMS does not exist on the host.

The Pmd\DMS\_Name\endpoint\_management registry key contains the following registry entries:

- **AutoSync**  
Specifies to automatically synchronize the Distribution Host with the Message Queue server.  
**Limits:** 0,1  
**Default:** 0 (disabled)
- **commands\_to\_exec\_before\_sleep**  
Specifies the number of endpoint commands that the DMS executes in a loop before sleeping.  
**Default:** 10
- **debug\_mode**

Specifies if Privileged Access Manager writes debug messages to the endpoint\_management.log file in the DMS directory (1).

**Limits :** 0,1

**Default :** 0 (debugging is disabled)

#### NOTE

The log file is located at *DMS\Install\Directory\endpoint\_management.log*

- **deployment\_lifetime**  
Specifies the deployment lifetime in days. Older deployments are removed at 2 am. To disable deployment cleanup, set this value to 0.  
**Default:** 30 days
- **operation\_mode**  
Specifies whether central (DMS) endpoint management through the Privileged Access Manager Message Queue is enabled.  
**Limits:** 0,1  
**Default:** 1 (enabled)
- **sleep\_between\_exec\_commands**

#### NOTE

Specifies the length of time, in milliseconds, that the DMS sleeps. When the DMS wakes it performs the number of endpoint commands specified in the commands\_to\_exec\_before\_sleep registry value. Default: 100

## policyfetcher (Windows)

Privileged Access Manager maintains policyfetcher service settings it uses under the following key:

`HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\policyfetcher`

The policyfetcher registry key contains the following registry entries:

- **check\_deployment\_tasks**  
Defines how often, in seconds, policyfetcher checks for new deployment tasks (DEPLOYMENT resources) on the Distribution Host.  
**Default:** 3600 (every 10 minutes)
- **deploy\_timeout**  
Defines the number of seconds policyfetcher waits for a deployment or undeployment task to complete on the endpoint.  
**Default:** 900
- **devcalc\_command**  
Defines the selang command that policyfetcher uses to run the deviation calculation.  
**Default:** start DEVCALC params(-nonotify)  
**Example:** start DEVCALC params(-nonotify -precise)
- **dh\_command\_retry\_interval**  
Defines the number of seconds between each DH notification command retry.  
**Default:** 60
- **endpoint\_heartbeat**  
Defines the frequency at which policyfetcher sends a heartbeat to the Distribution Host (DH). The frequency is a factor of the check\_deployment\_task setting, and determines how many times policyfetcher checks deployment tasks before it sends a heartbeat. For example, if check\_deployment\_task is set to the default 600 seconds (10 minutes) and you set this to 6, policyfetcher sends a heartbeat every 3600 seconds (1 hour).  
After sending the heartbeat, the policyfetcher also runs the deviation calculator (start devcalc command) and then waits 60 seconds for the deviation calculation to complete. After 60 seconds, policyfetcher continues to check that local endpoint information is identical to DH information.

**Default:** 6

- **max\_deployment\_errors**

Defines the maximum number of deployment errors that the endpoint sends to the DMS.

**Default:** 10

- **max\_dh\_command\_retry**

Defines the maximum number of times policyfetcher retries to get update notifications from DH before giving up.

**Default:** 10

- **max\_dh\_retry\_cycles**

Defines the maximum number of cycles policyfetcher retries to get update notifications from production DHs before moving to disaster recovery DHs.

**Default:** 5

- **policy\_verification**

Specifies whether policyfetcher verifies new deployment tasks on a backup Privileged Access Manager database before executing the tasks.

Valid values:

**1** - Run policy verification

**0** - Disable policy verification

**Default:** 0

- **policyfetcher\_enabled**

Specifies whether to run the policyfetcher service.

Valid values:

**1** - Run policyfetcher

**0** - Disable policyfetcher

**Default:** 1

## PUPMAgent Registry

Privileged Access Manager maintains the Shared Account Management Agent settings it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\PUPMAgent
```

The Shared Account Management Agent registry key contains the following registry entries:

- **EnableLogonIntegration**

Specifies that terminal integration is enabled.

**Limits:** 0, terminal integration is disabled; 1, terminal integration is enabled.

**Default:** 1

- **EnableRunAsInterface**

Specifies whether the Shared Account Management Agent is prompted for the target user password.

**Limits:** 0, the Shared Account Management Agent is not installed, 1 the Shared Account Management Agent is installed.

**Default:** 1

- **InterfaceName**

Defines the interface name that the Shared Account Management Agent uses to handle requests.

**Default:** PUPMAgentInterface

- **OperationMode**

Specifies the Shared Account Management Agent work mode.

**Limits:** 0, the Shared Account Management Agent is disabled and not running; 1, the Shared Account Management Agent is enabled, running but not logging data to trace files; 2, the Shared Account Management Agent is enabled, running, and logging data to trace files.

**Default:** 0

- **ProcessArgumentsReplacement**

Specifies whether the Shared Account Management Agent support Process Arguments Replacement.

**Limits:** 0,1

**Default:** 0

**Note:** If choose to support Process Arguments Replacement, that is, you set the value of this registry entry to 1, you must also enable the CMD Plugin. To enable the CMD Plugin, set the following registry entry to 1:

HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Instrumentation\plugins\CMDPlg\OperationMode

- **RegistrationInterval**

Defines the registration lifetime in days.

**Limits:** 0-365

**Default:** 7

**NOTE**

To not auto register the endpoint, set the Autoregister token to 0

## Report

Privileged Access Manager maintains sereport settings it uses under the following key:

HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Reports

The Reports registry key does not contain any registry entries. It contains registry subkeys for every report sereport produces.

**NOTE**

For information about registry entries for each of the reports sereport produces, see the [sereport utility](#).

## ReportAgent Registry

Privileged Access Manager maintains Report Agent settings that it uses under the following key:

HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\ReportAgent

The ReportAgent registry key contains the following registry entries:

- **audit\_enabled**  
Specifies whether you want to send endpoint audit data to the Distribution Server.  
**Values:** 0 no; 1 yes  
**Default:** 0
- **audit\_filter**  
Defines the full pathname to the file that contains filtering rules for audit records that the Report Agent routes to an external source (such as the Audit Log). This file determines which records the Report Agent routes.  
**Default:** *ACInstallDir\Data\AuditRouteFlt.cfg*
- **audit\_queue**  
Defines the name of the queue to which the Report Agent sends endpoint audit data.  
**Default:** queue/audit
- **audit\_read\_chunk**  
Defines the maximal audit records the Report Agent tries to collect in a single read of the audit files.  
**Limits:** A positive integer  
**Default:** 300
- **audit\_send\_chunk**  
Defines the maximal audit records that the Report Agent sends to the Distribution Server in each connection. When the number of audit records the Report Agent collects reaches this number, it sends these records to the Distribution Server.  
**Limits:** A positive integer

**Default:** 1800

- **audit\_sleep**

Define the length of time the Report Agent sleeps between generating audit reports.

**Limits:** A positive integer representing a number of seconds.

**Default:** 10

- **audit\_timeout**

Defines the cycle at which the Report Agent must send endpoint audit data to the Distribution Server. If this amount of time passes from the last send, the Report Agent sends audit data to the Distribution Server. The Report Agent does this data even if the number of records it collected is less than the audit\_send\_chunk value.

**Limits:** A positive integer representing a number of seconds.

**Default:** 300

- **interval**

Defines the interval, in minutes, at which Privileged Access Manager generates and sends reports to the Distribution Server.

The *schedule* setting defines the interval start time and the days it operates on. If the Report Agent starts later than a scheduled occurrence, it sends a report at the next calculated interval (from the schedule) and then at the defined intervals after that on scheduled days.

**Example:** If you have schedule=8:30@Mon,Tue, Wed, and interval=5 and the Report Agent loads on Tuesday at 8:47 am, the Report Agent generates and sends a report at 8:50 am. This is the earliest cycle calculated from the scheduled start using the 5-minute interval.

**Values:** 0 No interval (use scheduled occurrences only); *positive integer* number of minutes to use as interval

**Default:** 0

- **reportagent\_enabled**

Specifies whether reporting is enabled (1) on the local computer.

**Default:** 0

- **restart\_enabled**

Specifies restart of the ReportAgent daemon. Specify 1 to enable the restart.

**Default:** 0

- **schedule**

Defines when reports are generated and sent to the Distribution Server.

You specify this setting in the following format: time@day[,day2][...]

For example, "19:22@Sun,Mon" generates reports every Sunday and Monday at 7:22 pm.

**Default:** 00:00@Sun,Mon,Tue,Wed,Thu,Fri,Sat

- **send\_queue**

Defines the name of the reporting queue on the Distribution Server to which the Report Agent sends snapshots of the local database and any PMDBs.

**Default:** queue/snapshots

## SeOSD Registry

Privileged Access Manager maintains generic settings that it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\SeOSD
```

The SeOSD registry key contains the following registry entries:

- **AuditCollectorInterfaceName**

Defines the pipe name which functions as an audit interface between the audit collector component (within seosd) and the different clients of the audit collector (kernel).

**Default:** AuditCollector

- **AuditServerCacheSize**

Defines the size of the audit cache, in number of entries.

**Default:** 1024

- **CreateNewClasses**

Specifies whether you can add new classes, which are created with the seclassadm utility, to a Privileged Access Manager database.

**Default:** yes

- **CreateNewProps**

Determines whether you can add new properties, which are created with the sepropadm utility, to a Privileged Access Manager database.

**Default:** yes

- **dbdir**

The directory in which the Privileged Access Manager database is located.

**Default:** *AC/InstallDir\data\seosdb*

- **DefLookupThreads**

Defines the number of threads that Privileged Access Manager can use to resolve SIDs into account names.

**Default:** 5

- **DefLookupTimeout**

Defines the timeout, in milliseconds, before Privileged Access Manager stops trying to resolve an SID into an account name.

**Default:** 2000

- **domain\_names**

The list of name suffixes used for matching purposes.

Privileged Access Manager appends these suffixes to short host names to create long, fully qualified host names.

These names can be authorized in the relevant HOST, CONNECT, or TERMINAL classes. To identify a full name, Privileged Access Manager tries to append domain names in the domain\_names list to the short name for authorization purposes. For class HOSTNP, Privileged Access Manager matches all domain names (listed in this registry) with pattern to resolve into real IP addresses.

No default.

- **EnableCachedLogonInfo**

(Optional) Controls logon cache information in the CA ControlMinderSubAuth.dll and defines whether the product enables keeping data for authorization in runtime tables for performance tuning.

**Values:**

**0** - Logon caching is disabled. All logon events are passed to seosd for authorization.

**1** - Logon caching is enabled.

**Default:** 0

**NOTE**

This value is set to 1 when installing the Enterprise Management Server on a domain controller. After the upgrade, the value is restored to the same value as before the upgrade.

- **EnableIPv6Resolving**

Controls whether the host name to the IP address resolution is applied on IPv6 protocol in addition to IPv4.

**Values:**

**0** - Disables host name resolving over IPv6 protocol.

**1** - Enables host name resolving over IPv6 protocol.

**Default:** 0

- **EnablePolicyCache**

This value controls whether the authorization engine uses cached records or records directly from the database.

Valid values:

**no** - Authorization engine uses database records.

**yes** - Authorization engine uses cache records.

**Default:** no

- **EnvVarResolvingMode**

The method of resolving embedded environment variables (for objects in the FILE, SECFILE, PROGRAM, PROCESS, SPECIALPGM, TERMINAL, or USER classes). For example:

newfile %SystemRoot%\temp.txt. Privileged Access Manager does the following actions, depending on the value you select:

- 0** - Tries to resolve all environment variables, issues an error message to the user, and does not create the object.
- 1** - Tries to resolve all environment variables, issues a warning message to the user, and creates the object.
- 2** - Tries to resolve all environment variables and creates the object with no messages.
- 3** - Does not try to resolve environment variables.

#### NOTE

The PMDB assumes that there are no environment variables, so resolving is never tried. Default: 2

- **GeneralInterceptionMode**  
Specifies whether to use Full Enforcement mode (0) or Audit Only mode (1).  
**Default:** 0
  - **GraceCountForMessage**  
Defines the number of remaining grace logins at which the Change Password dialog appears.  
**Default:** 0
  - **HostResolutionMode**  
Specifies the method Privileged Access Manager uses to resolve host names.  
**Values:**
    - 0** - HOST resolution is synchronous (current behavior).
    - 1** - HOST resolution is asynchronous (with 'Event Log' reporting)

The effects of this setting are:

    - a. a. Control is returned to selang immediately.
    - b. If a HOST record cannot be resolved, a selang message is not displayed (same as 0).
    - c. A notification message is written into the 'Event Log'.  - 2** - HOST resolution is asynchronous (without 'Event Log' reporting).  
Same as '1' with the exception that notification messages are *not* written anywhere.  
**Default:** 0
- **HostResolutionRenewal**  
The time for internal cache refresh. The network interception authorization events use the registry value.  
**Default:** 30000
- **HostResolutionTimeout**  
The time the authorization engine waits for reverse IP lookup requests, upon network interception event.  
**Default:** 2000
- **LogonTimeOut**  
Defines the time in milliseconds Privileged Access Manager waits for transactions with the sub authentication DLL (eACSubAuth.dll) before giving up. When this time passes, Privileged Access Manager replies with the value set in LogonTimeOutAnswer.  
**Default:** 4000
- **LogonTimeOutAnswer**  
Defines the logon answer to the operating system when the LogonTimeOut setting elapses without an answer from Privileged Access Manager.  
**Default:** 1 (true)
- **MaximumDiscreteFILELimit**  
The number of discrete FILE records you can create in the Privileged Access Manager database.  
The minimum value is default; if a user sets this value to be less than the default, Privileged Access Manager acts as if a minimum were set.  
**Default:** 4096
- **MaximumGenericFILELimit**

The number of generic FILE records (name pattern-based records) you can create in the Privileged Access Manager database.

The minimum value is default; if a user sets this value to be less than the default, Privileged Access Manager acts as if a minimum were set.

**Default:** 512

- **ProcessCreationNotificationMode**

Specifies whether to intercept process creation and notify seosd either using kernel or instrumentation mode.

**Type:** REG\_DWORD

**Values:**

0 - Process creation is performed using kernel module

1 - Process creation is performed using instrumentation module

**Default:** 0

**NOTE**

If you set the key to 1, Privileged Access Manager intercepts process creation through the Windows API only.

- **RebuildSuspiciousDatabase**

This value is addressed only if database was not properly closed on previous session.

If the value is set to 0, the database is verified in a heuristic procedure for correctness (during startup). If the check finds a problem in the database, the database is rebuilt.

If the value is set to 1, the heuristic procedure check function is skipped. The database is rebuilt according to the database integrity check.

**Default:** 1

- **RefreshIPInterval**

The time (in minutes) between consecutive automatic IP refresh requests.

If the value is set to 0, IP refreshes are not automatically performed. If you use a value from 1 through 30, Privileged Access Manager uses 30 minutes, which is the minimum amount of time you can set, as the value.

**NOTE**

Refresh requests can be time consuming. For more information, see the secons utility -refIP option.

**Default:** 0

- **ResponseFile**

The location where the response.ini, used by eACOexist.exe utility, resides.

**Default:** *ACInstallDir\data\response.ini*

- **Service\_ACE\_Count** Specifies the list of service names that are protected and monitored by Privileged Access Manager. Each entry represents service name and its respective DACL count. The registry entry is updated by Privileged Access Manager internally.

- **sim\_login\_timeout**

Defines the timeout (in minutes) before Privileged Access Manager removes unused simulated login user entries from the Accessor Element Entry table (ACEE).

Privileged Access Manager simulates a login to create ACEE entries when it needs access to information that can be found in the ACEE.

**Default:** 60

- **SurrogateInterceptionMode**

Specifies the SURROGATE class interception mode.

**Type:** REG\_DWORD

**Limits:** 0 - user mode interception, Privileged Access Manager intercepts only the impersonation requests that originate from the RunAs utility; 1 - kernel mode interception, Privileged Access Manager intercepts all impersonation requests.

**Default:** 0

- **SusrauthReadParamsSec**

Defines how often trace parameters are updated.

**Default:** 30

- **SusrauthTraceDbgEnable**

Specifies whether tracing into DbgView or kernel debugger is enabled (1).

**Default:** 0

- **SusrauthTraceFileEnable**

Specifies whether tracing into a trace file (SusrauthTraceFileName) is enabled (1).

**Default:** 0

- **SusrauthTraceFileName**

Defines the full pathname to the trace file.

No default

- **TerminalSearchOrder**

Specifies how the authorization engine determines which TERMINAL record it verifies during the authorization process.

Values:

**name** - Authorization engine first looks for a TERMINAL record by name and if one is not found, it looks for an IP address match.

**nameonly** - Authorization engine looks for a TERMINAL record by name and if one is not found, ceases searching. It ignores TERMINAL records with an IP address format.

**IP** - Authorization engine first looks for a TERMINAL record by IP address and if one is not found, it looks for a name match.

**NOTE**

TERMINAL class supports generic rules that are defined by wildcards (IP address or host name pattern match). Generic rules are always verified after specific (full-name) rules. For example, if you set this to IP, seosd looks for a TERMINAL resource in the following order: complete IP address match, complete host name match, IP address pattern match, host name pattern match.

**Default:** nameonly

- **TermSrvTimeout**

Specifies the timeout (in milliseconds) that the authorization engine waits for the second consecutive login, upon a Terminal Services connection.

**Default:** 2000

**NOTE**

When a user logs in using a local account, Privileged Access Manager receives two login attempt notifications: the first from the local terminal and the second from the terminal server. If the user is assigned grace login count, two login attempts are logged and subtracted from the grace count. Therefore, Privileged Access Manager does not update the grace count with the second login if the login attempt occurred within the specified timeout period.

- **trace\_file**

The name of the file to which the trace messages are sent, if trace messages are requested.

**Default:** *ACInstallDir\log\seosd.trace*

- **trace\_file\_type**

Type of trace file.

If you do change the value of the value and a trace file exists, the existing trace file is saved with the file name extension .backup and then a new trace file is started in the format you specified.

**Default:** text

- **trace\_filter**

The name of the file that contains the filter data that is used to filter the trace messages. Specify the full path of the file.

**Default:** *ACInstallDir\log\trcfilter.ini*

- **trace\_space\_saver**

The amount of free space, in KB, to be left in the file system. When the amount of free space is less than this number, Privileged Access Manager disables the trace.

**NOTE**

Trace is never automatically enabled, even if more space becomes available later.

**Default:** 5120

- **trace\_to**

The destination of trace messages. Privileged Access Manager does the following, based on the value you select:

none - Does not generate trace messages.

file - Generates trace messages and sends them to the file listed in the registry trace\_file as soon as Privileged Access Manager becomes active.

stop - Generates trace messages during the period of service initialization. Once the service is initialized, no more trace messages are generated.

**Default:** file, stop

## SeOSWD

Privileged Access Manager maintains watchdog settings that are used under the following key:

HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\SeOSWD

The SeOSWD registry key contains the following registry entries:

- **PgmRest** Specifies the period, in seconds, after the last event and before checking programs again. The program rests to prevent system overload.

**Default:** 10

- **PgmTestInterval**

The period, in seconds, between rescanning of programs.

**Default:** 18000

- **ProcDumpCreate**

Specifies if process mini dump is generated (1) or not (0) on restart service that reached the threshold.

**Default:** 0

- **ProcHandlesCritical**

Specifies the process critical handle count. The watchdog restarts the process when the critical handle count exceeds.

**Values:** 0 (disables token), 800 (minimum value)

**Default:** 1500

- **ProcHandlesHigh** Specifies the high watermark for the process handle count. The watchdog restarts the process during the restart hours when the defined handle count exceeds.

**Values:** 0 (disables token), 800 (minimum value)

**NOTE**

The *ProcHandlesHigh* registry key is disabled when the value is greater than *ProcHandlesCritical* value.

**Default:** 1000

- **ProcRestartHours** Specifies the hours when the watchdog restarts the high handle count process.

**Values:** 0 - 23 (value in hours)

**Default:** 0 - 5

- **ProcVSizeCritical** Specifies the process critical memory size in megabytes. The watchdog restarts the process immediately when the specified limit exceeds.

**Default:** 500 MB

- **ProcVSizeHigh** Specifies the high watermark for process memory size. The watchdog restarts during the restart hours.

**Default:** 300 (value in megabytes)

- **ProcVSizeInterval**

Specifies the interval, in seconds, between the process performance counters verification for services that the watchdog checks.

**Default:** 900 seconds

- **SecFileRest**

Specifies the period, in seconds, after the last event and before checking secured files again. The program rests to prevent system overload.

**Default:** 10

- **SecFileTestInterval**

The period, in seconds, between rescanning of secured files.

**Default:** 36000

- **WatchdogRequestsInterfaceName**

Specifies the pipe server name which communicates with the watchdog.

**Default:** WatchdogRequests

## STOP

Privileged Access Manager maintains Stack Overflow Protection (STOP) settings it uses under the following key:

`HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\STOP`

The STOP registry key contains the following registry entries:

- **STOPIniFileName**

Defines the full path and name of the STOP initialization file. This file contains the list of functions for which STOP is enabled.

**Default:** *ACInstallDir\Data\stop.ini*

- **STOPLearningModeEnabled**

Specifies whether STOP runs in a special learning mode. In this mode, incidents are logged but always permitted. That is, a denial incident is logged appropriately, but is permitted to continue.

**Default:** 0 (disabled)

- **STOPLogFileName**

Defines the full path and name of the dynamic incident database for stack overflow protection (STOP).

**Default:** *ACInstallDir\Log\STOPRTEvents.dat*

- **STOPServerTraceEnabled**

Specifies whether the STOP server module has trace logging enabled.

**Default:** 0 (disabled)

- **STOPSignatureBrokerName**

Defines the host name of the computer that (if defined) is used to retrieve STOP signatures database from. No default.

- **STOPSignatureFileName**

Defines the full path and name of the STOP signature file (a trusted incident database).

**Default:** *ACInstallDir\Data\stopsignature.dat*

- **STOPUpdateInterval**

Defines the period of time, in minutes, between two consecutive attempts to update the STOP signatures database.

**Default:** 60

- **STOPZeroSnapshotBypassEnabled**

Specifies whether STOP should permit incidents with a zero-size code snapshot.

**Default:** 0 (not permitted)

## Tracer

Privileged Access Manager maintains tracing module settings it uses under the following key:

`HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Tracer`

The Tracer registry key contains the following registry entries:

- **TraceCfgFile**  
Defines the full path of the file containing the initialized configuration settings for tracing Privileged Access Manager modules.  
**Default:** *ACInstallDir\Data\tracer.ini*
- **TraceEnabled**  
Specifies whether to enable the Trace mechanism.  
**Default:** 0 (disabled)

## uxauth Key Registry Settings

UNIX Authentication Broker maintains Active Directory schema settings that it uses under the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\uxauth
```

UNIX Authentication Broker installs this registry key when you install the Privileged Access Manager UNIX Attributes plug-in on an Active Directory server. This registry key is not installed as part of Privileged Access Manager.

### NOTE

The default attributes are for the Active Directory 2003 R2 schema.

The uxauth registry key contains the following registry entries:

- **group\_gid\_attr\_name**  
Specifies the Active Directory attribute to which UNIX Authentication Broker maps the GID for a migrated UNIX group.  
**Default:** gidNumber
- **Trace\_Enabled**  
Specifies if tracing is enabled for the Privileged Access Manager UNIX Attributes plug-in.  
**Values:** 0 tracing is disabled, 1 tracing is enabled  
**Default:** 0
- **user\_gecos\_attr\_name**  
Specifies the Active Directory attribute to which UNIX Authentication Broker maps the geocos property for a migrated UNIX user.  
**Default:** geocos
- **user\_gid\_attr\_name**  
Specifies the Active Directory attribute to which UNIX Authentication Broker maps the GID for a migrated UNIX user.  
**Default:** gidNumber
- **user\_homedir\_attr\_name**  
Specifies the Active Directory attribute to which UNIX Authentication Broker maps the home directory property for a migrated UNIX user.  
**Default:** unixHomeDirectory
- **user\_loginshell\_attr\_name**  
Specifies the Active Directory attribute to which UNIX Authentication Broker maps the login shell property for a migrated UNIX user.  
**Default:** loginShell
- **user\_uid\_attr\_name**  
Specifies the Active Directory attribute to which UNIX Authentication Broker maps the UID of a migrated UNIX user.  
**Default:** uidNumber

## WebService

Privileged Access Manager maintains Web Service settings that it uses under the following key:

---

HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\WebService

### NOTE

The WebService registry key and related entries are added as part of the Privileged Access Manager Endpoint Management installation.

The WebService registry key contains the following registry entries:

- **auditFileCheckInterval**  
Defines how often, in seconds, the Privileged Access Manager Web Service checks if the audit file size has reached the defined limit.  
**Default:** 60
- **auditFileMaxSize**  
Defines the maximum size in KB of the Privileged Access Manager Web Service audit log file.  
When the file reaches this size, the Web Service renames the file to "*Backup\_of\_logFileName*" and it creates an audit log file.  
**Default:** 20000
- **backLog**  
Defines the maximum size of the request queue the Privileged Access Manager Web Service maintains.  
**Default:** 101
- **localPortNumber**  
Defines the port Privileged Access Manager Web Service uses to open a non-SSL listener to accept SOAP requests from the local machine.  
**Default:** 0
- **logFileName**  
Defines the name of the Privileged Access Manager Web Service audit log file name.  
If you leave this value empty string (""), the Web Service sends log messages to the terminal when you run the Web Service with the -debug option.  
**Default:** *ACServerInstallDir\WebService\log\WebService.log*
- **machineName**  
Defines the name of the computer the Privileged Access Manager Web Service is installed on.  
**Default:** 127.0.0.1
- **maxRequestsQueue**  
Defines the size of the global request queue of sockets.  
**Default:** 1001
- **maxThreads**  
Defines the number of threads Privileged Access Manager Web Service uses.  
**Default:** 7
- **portNumber**  
Defines the port Privileged Access Manager Web Service uses to communicate.  
**Default:** 5248
- **sessionTimeout**  
Defines the number of seconds before Privileged Access Manager Web Service terminates a session when there is no operation.  
**Default:** 601
- **StandAloneService**  
Specifies whether the Privileged Access Manager Web Service operates as a standalone service.  
If the Web Service operates as a standalone service, the service is not stopped or started when you use secons to stop or seosd to start Privileged Access Manager services. Instead, you use Windows native tools to start and stop the Privileged Access Manager Web Service.  
If the Web Service does not operate as a standalone service, the service is stopped and started when you use secons to stop or seosd to start Privileged Access Manager services. You cannot use Windows native tools to start and stop

the Privileged Access Manager Web Service. However, to use `seosd -start` to start the Privileged Access Manager Web Service, define the Web Service in the `AccessControl\AccessControlServices` registry entry.

**Values:** 1 Operates as a standalone service; 0 Does not operate as a standalone service

**Default:** 1

- **TraceEnabled**

Specifies if tracing is enabled for the Privileged Access Manager Web Service components.

**Values:** 0 tracing is disabled, 1 tracing is enabled

**Default:** 0

## Additional Registry Keys

You can also add or modify the following registry keys and values to change the way Privileged Access Manager performs:

- `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\drveng\Parameters\DisableFileInterception`  
Specifies whether the file interception hooking is disabled (relevant functions are not initialized at boot time).  
**Type:** REG\_DWORD  
**Value:** 1 (disabled)**Note:** If this registry entry does not exist (the default), or is set to any value other than 1, file interception is initialized at boot time.
- `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\drveng\Parameters\DisableNetworkInterception`  
Specifies whether network interception hooking is disabled (relevant functions are not initialized at boot time).  
**Type:** REG\_DWORD  
**Value:** 1 (disabled)**Note:** If this registry entry does not exist (the default), or is set to any value other than 1, network interception is initialized at boot time.
- `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\drveng\Parameters\DisableProcessInterception`  
Specifies whether process interception hooking is disabled (relevant functions are not initialized at boot time).  
**Type:** REG\_DWORD  
**Value:** 1 (disabled)**Note:** If this registry entry does not exist (the default), or is set to any value other than 1, process interception is initialized at boot time.
- `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\drveng\Parameters\DisableRegistryInterception`  
Specifies whether the registry interception hooking is disabled (relevant functions are not initialized at boot time).  
**Type:** REG\_DWORD  
**Value:** 1 (disabled)**Note:** If this registry entry does not exist (the default), or is set to any value other than 1, registry interception is initialized at boot time.
- `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\drveng\Parameters\use_wfp_perf`  
Defines performance improvement in network issues that are related to packets with zero payload.  
**Type:** REG\_DWORD  
**Default:** 1
- `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SeosDrv\Parameters\KernelBuffersSize`  
When the Privileged Access Manager kernel driver (`seosdrv.sys`) starts, it allocates, by default, memory for its internal use, according to the following formula:  $\text{number\_of\_buffers} = \text{amount\_of\_RAM}$  For example, 256 buffers are allocated for 256 MB of RAM. Each buffer is 4096 bytes long. If you want to control the number of buffers that `seos.drv` allocates, create this registry key and set the value to the number of buffers to allocate.  
**Type:** REG\_DWORD  
**Note:** 32 is the minimum number of buffers.
- `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Eventlog\System\SeosDrv\EventMessageFile`  
Defines the pathname to the `seosdrv.sys` driver.  
**Type:** REG\_EXPAND\_SZ  
**Default:** %SystemRoot%\System32\drivers\seosdrv.sys
- `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Eventlog\System\SeosDrv\TypesSupported`  
A standard Windows entry that defines the bitmask of supported event types.  
**Type:** REG\_DWORD  
**Default:** 7
- `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\cainstrm\parameters\DIIScanList`  
Defines a list of comma-separated DLLs (by name) that trigger injection by `cainstrm.sys`  
**Type:** REG\_SZ  
**Default:** No default
- `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\cainstrm\parameters\DIIScanListRefreshPeriod`

Defines the interval, in seconds, for scanning the cainstrm registry entry.

**Type:** REG\_DWORD**Default:** 600

- HKEY\_LOCAL\_MACHINE\System\CCS\Services\Cainstrm\parameters\ExcludeProcess

Specifies processes by name to be excluded from native instrumentation by the driver.

**Type:** REG\_MULTI\_SZ**Default:** none

- HKEY\_LOCAL\_MACHINE\SYSTEM\CCS\Services\Cainstrm\Parameters

Specifies the Privileged Access Manager low-level instrumentation policy towards .Net assemblies.

**Type:** REG\_DWORD**Default:** 1 (1 implies that the instrumentation of .Net assemblies is enabled.)

- HKLM\SYSTEM\CurrentControlSet\Services\cainstrm\Parameters\DotNetOperationMode

Defines the Privileged Access Manager low-level instrumentation policy toward .Net assemblies.

**Type:** REG\_DWORD**Default:** 1 (1 enables the instrumentation of .Net assemblies. Any value different from 1 disables the instrumentation of .Net assemblies.)

## Trace Messages

In the log files, all messages begin with a date and time prefix, followed by an event-type word in uppercase and a symbol such as :, !, or >.

Symbol	Means
:	Privileged Access Manager was signaled for an event or performed an action.
>	Privileged Access Manager made an authorization decision resulting in D (Deny), P, (Permit), or BYPASS (The event did not require the interpretation of an access rule-for example, a setuid request to the same UID as the current UID.)
!	Privileged Access Manager detected an error-for example, a request from an unknown process.

## APIAUTH Messages

Message	Means
APIAUTH ! P=ppp U=uuu ChangePasswd(user) Error 0xerr	Process ppp, associated with user uu, wants to change the password of user. The result of this request was an error with its code specified in hex. Use the semsgtool utility to determine the nature of the error.
APIAUTH ! P=ppp U=uuu CheckPasswd(user) Error 0xerr	Process ppp, associated with user uu, wants to check the validity of a new password for user. The result of this request was an error with its code specified in hex. Use the semsgtool utility to determine the nature of the error.
APIAUTH ! P=ppp U=uuu Error, Unknown API Service nnn	Process ppp used the Application Interface and passed a service code that Privileged Access Manager Programming Interface does not support, probably because of user error. Check the cause of the error, correct the source, and recompile it.
APIAUTH ! P=ppp U=uuu GeneralResourceProc Error nnn >description	Process ppp, working under UID uu, issued a request to access a general resource; however, the specified resource cannot be resolved. Either the specified class is not defined or the specified access is not known, probably because of user error. Check your code, correct it, and recompile.

APIAUTH ! P=ppp U=uuu in VerifyCreate only for ROOT	Process ppp, working under UID uuu, issued a VerifyCreate request to build an ACEE. This operation is permitted only to multiuser processes that are associated with UID 0 (root). If the specified process is to run as a multiuser process, rerun the process under root authorities. If not, determine why the process issued the request.
APIAUTH P=ppp U=uuu in VerifyDelete only for ROOT	Process ppp, working under UID uuu, issued a VerifyDelete request to remove an ACEE. This operation is allowed only to multiuser processes that are associated with UID 0 (root). If the specified process is supposed to run as a multiuser process, rerun it under root authorities. If not, determine why the request was issued.
APIAUTH ! P=ppp U=uuu LoginProc Error nnn >description	Process ppp, working under UID uuu, requested to verify a user's login. The Privileged Access Manager login verification procedure failed. Contact your vendor's technical support.
APIAUTH ! P=ppp U=uuu NULL ACEE Error VerifyCreate (ACEEH=hhh)	A user process marked as server made a request to create an ACEE (probably as the server process was handling login for an accessor). The result is a NULL ACEE for one of the following reasons: <ul style="list-style-type: none"> <li>• The specified user is not defined in the central database.</li> <li>• The issuer of the VerifyCreate request did not provide all the information correctly.</li> <li>• The specified user is not allowed to log in.</li> </ul>
APIAUTH ! P=ppp U=uuu NULL ACEE Error VerifyDelete (ACEEH=hhh)	Process ppp, associated with user uuu, and which is probably marked as a 'server' process, has requested to delete the ACEE handle hhh (probably as part of handling the user's signoff). However, no ACEE is associated with this handle, so Privileged Access Manager cannot delete it.
APIAUTH P=ppp U=uuu Request with ACEEH=1 > New ACEEH=hhh	Process ppp, working under UID uuu, requested access to a general resource and supplied an ACEE handle of -1. Privileged Access Manager used the ACEE handle associated with the requesting process. This message is typical of single user processes that request access to a resource. No action is required.
APIAUTH ! P=ppp U=uuu VerifyCreate(ACEEH=hhh) Error nnn	Process ppp, working under UID uuu, issued a request to VerifyCreate (to build an ACEE). The VerifyCreate procedure failed. Contact your vendor's technical support.
APIAUTH > P=ppp U=uuu VerifyCreate DENY (Result= P D C ) string	The VerifyCreate request was denied for one of the following reasons: <ul style="list-style-type: none"> <li>• The specified user cannot login due to time or day rules</li> <li>• The user cannot work from the specified terminal</li> <li>• The specified password (if supplied) is incorrect</li> <li>• One of the reasons described in the messages that follow.</li> </ul>
APIAUTH > P=ppp U=uuu VerifyCreate OK (ACEEH=hhh)!	The VerifyCreate request was granted. An Accessor Environment Element (ACEE) was built in storage. Privileged Access Manager returned an ACEE handle (ACEEH) to the calling program. If the specified user is not defined to Privileged Access Manager, the function returned an ACEEH of -1.

APIAUTH ! P=ppp U=uuu VerifyDelete(ACEEH=hhh) OK Error 0xerr	Process ppp, associated with user uuu, which is probably marked as a 'server' process, has requested the deletion of the ACEE handle hhh (probably as part of handling the user's signoff). The result of the VerifyDelete request is either OK or error; if the latter, the error code appears in hex as err. Use the utility semsgtool to determine the nature of the error.
APIAUTH > P=ppp U=uuu VerifyRequest(ACEEH=hhh, C=ccc, R=rrr, A=nnn) DENY (Result='D')Why ? detaileddenialreason	The request to access resource rrr of class ccc with access xxx was denied. If the ACEEH is -1, the denial was based on universal-access rules. If the ACEEH is not -1, the denial was based on the user associated with the specified handle. The second line provides a detailed reason for the denial.
APIAUTH > P=ppp U=uuu VerifyRequest(ACEEH=hhh, C=ccc R=rrr, A=xxx) PASS	The request to access a resource rrr of class ccc with access xxx was granted. If the ACEEH is -1 (the user is not defined), the permission to access the resource was based on universal-access rules. If the ACEEH is not -1, the permission was based on access rules relating to the user associated with the specified handle.

## CONNECT Messages

Message	Means
CONNECT P=ppp U=uuu ACEEH=hhh from ipip port1 to socket 6000 host=iiii	A request to open a window on host <i>iiii</i> (X-Terminal or station) was made by process <i>ppp</i> associated with UID <i>uuu</i> . The port number is always 6000; all other TCP/IP connection requests are ignored by Privileged Access Manager.
CONNECT > P=ppp U=uuu from ipip port1 to socket 6000 host=iiii BYPASS	Privileged Access Manager bypassed the CONNECT request without interpreting access rules, because the program executing in process ppp is the registered XDM program.
CONNECT > Result P D C P=ppp ACEEH=hhh TERM=tttWhy ? detaileddecisiontext	The CONNECT result is D (Deny) or P (Permit). The second line provides a reason for the decision.

## ERROR Messages

Error	Means
ERROR ! Cannot fork. Errno nnn.	During initialization, Privileged Access Manager forks a few times to become a daemon. The fork request failed with the specified error number.  If you cannot determine the cause of the problem, contact your vendor's technical support.
ERROR ! Exec of Privileged Access Manager agent failed ddd	The Engine cannot start up the Agent daemon. Check that the seagent executable is located in the right place, usually <i>ACInstallDir/bin/seagent</i> . If this file exists in the correct location, report the problem to your vendor's technical staff. In the message text, <i>ddd</i> is the error number that Privileged Access Manager received from the operating system when trying to execute seagent.
ERROR ! Failed to get memory for LOGIN programsERROR ! Failed to get memory for NFS devicesERROR ! Failed to get memory for PRIV programsERROR ! Failed to get memory for XDM programs	These messages imply a severe shortage of memory. Either your computer does not meet the minimum memory requirements to run Privileged Access Manager, or a software bug was found. Contact your vendor's technical support.

ERROR ! Failed to get memory for PROC table	When seosd starts up, it must scan all the running processes to resolve all required information on each running process. seosd failed to allocate memory for this purpose; therefore, it terminates execution. This is caused by a severe memory shortage.
ERROR ! Failed to register login pgm programname	<p>During startup, Privileged Access Manager registers all executable files that are to be treated as login programs. The list of login programs are defined in the code for each operating system environment.</p> <p>The specified <i>programname</i> cannot be located on the file system during startup. Privileged Access Manager ignores the program and startup continues.</p>
ERROR ! Failed to register privileged pgm programname	<p>During startup, Privileged Access Manager registers all executable files that are to be treated as privileged programs. The specified <i>programname</i> cannot be located on the file system during startup. Privileged Access Manager ignores the program and startup continues.</p> <p>The list of privileged programs are defined in the code for each operating system environment.</p>
ERROR ! Failed to register XDM pgm programname	<p>During startup, Privileged Access Manager registers all executable files that are to be treated as XDM programs. The list of XDM programs is defined in the code for each operating system environment.</p> <p>The specified <i>programname</i> cannot be located on the file system during startup. Privileged Access Manager ignores the program and startup continues.</p>
ERROR No Memory for FileDb List	During startup, seosd cannot allocate memory to hold the list of protected files. This is probably due to a severe shortage of memory. The seosd daemon is terminated.
ERROR ! No Memory for GroupDb List ERROR ! No Memory for HostDb List ERROR ! No Memory for ServDb List ERROR ! No Memory for UserDb List	These messages imply a severe shortage of memory. Either your computer does not have the minimum memory required to run Privileged Access Manager, or a software bug was found. Contact your vendor's technical support.
ERROR ! PreMatureExec Assuming FORK Child=ppp Parent=PPP	<p>This message indicates that process ID (<i>ppp</i>) issued an EXEC system call, which is not known to seosd. Normally, such messages indicate that seosd was not yet informed of the FORK system call that preceded the EXEC request. It may indicate a problem in the serialization locks that the Privileged Access Manager extension to the UNIX kernel, SEOS_syscall, must maintain.</p> <p>If the <i>ppp</i> in the message text is the pid of seagent, you can ignore the message. If you get the message more than once, report the problem to your vendor's technical support.</p>
ERROR ! P=ppp Exec Failed	Privileged Access Manager received an EXEC event, but the inode number of the executable was zero. This message occurs when invoking a script file that does not contain the <code>#!/</code> shell-program declaration line at the beginning. No action is necessary.

ERROR ! Privileged Access Manager file table set failed	seosd attempted to set the file table (a table of all Privileged Access Manager protected files); however, SEOS_syscall refused this request. The most likely causes are insufficient memory in the kernel, or different versions of seosd and SEOS_syscall. Privileged Access Manager file protection cannot continue to function properly.  If you can, resolve the version mismatch. If everything looks fine, report the problem to your vendor's technical support.
ERROR ! seosini_ShutDown rv=errorno	Privileged Access Manager encountered an error during shutdown. Report the error to your vendor's technical support.
ERROR ! String too general 'path'	An attempt was made to define a generic rule for file protection, probably through a newfile or newres FILE command. However, the specified path cannot be a generic file access rule. The file rule is not defined.
ERROR ! Unknown request Type ttt Pid=ppp, Buff=bbb	Privileged Access Manager received a request from its system call, but the request type ttt is not recognizable. This can be due to a software version mismatch between the system call and seosd, or because of a software error. The request came from process ppp, and bbb is a printout of the request buffer. Report the problem to your vendor's technical support.

## EXEC Messages

Message	Means
EXEC P=ppp U=uuu G=ggg (D=ddd I=iii) Pgm ProgramName Attached to ipaddress	Privileged Access Manager received a program execution event from process ppp associated with UID uuu and GID ggg. (A ggg value of -1 indicates that Privileged Access Manager has not yet registered the GID of that process). In the message text, ddd and iii are the file's device number and inode, respectively. Program-Name is the zero argument used when invoking the program. The specified program is a regular program (that is, not setuid or setgid); therefore, Privileged Access Manager grants its execution without invoking the database access rule decision mechanism. If the ip-address to which the process is attached is extractable, Privileged Access Manager reports this in the message text.
EXEC sg P=ppp U=uuu G=ggg (D=ddd I=iii) Pgm ProgramName Attached to ipaddress	Privileged Access Manager received a program execution event from process ppp associated with UID uuu and GID ggg. (A ggg value of -1 means Privileged Access Manager has not yet registered the GID of that process). In the message text, ddd and iii are the file's device number and inode, respectively. Program-Name is the zero argument used when invoking the program. The specified program is a setgid program; Privileged Access Manager determines whether to grant its execution by invoking the database access rule decision mechanism. If the ip-address to which the process is attached is extractable, Privileged Access Manager reports this in the message text.

EXECsu P=ppp U=uuu G=ggg (D=ddd I=iii) Pgm ProgramName Attached to ipaddress	Privileged Access Manager received a program execution event from process ppp associated with UID uuu and GID ggg. (A ggg value of -1 means Privileged Access Manager has not yet registered the GID of that process). In the message text, ddd and iii are the file's device number and inode, respectively. Program-Name is the zero argument used when invoking the program. The specified program is a setuid program; Privileged Access Manager determines whether to grant its execution by invoking the database access rule decision mechanism. If the ip-address to which the process is attached is extractable, Privileged Access Manager reports this in the message text.
EXECsusg P=ppp U=uuu G=ggg (D=ddd I=iii) Pgm ProgramName Attached to ipaddress	Privileged Access Manager received a program execution event from process ppp associated with UID uuu and GID ggg. (A ggg value of -1 means Privileged Access Manager has not yet registered the GID of that process). In the message text, ddd and iii are the file's device number and inode, respectively. Program-Name is the zero argument used when invoking the program. The specified program is a setuid and setgid program; Privileged Access Manager determines whether to grant its execution by invoking the database access rule decision mechanism. If the ip-address to which the process is attached is extractable, Privileged Access Manager reports this in the message text.
EXEC > P=ppp U=uuu (R=rrr E=eee S=sss) to (E=EEE) BYPASS	Although the program is setuid, setgid, or both, and its execution should have invoked the access rule decision mechanism, Privileged Access Manager bypassed this check because the owner of the file EEE is the same as the current effective UID (eee). The program execution cannot change the scope of the privileges of the process. If the program is defined in the database as a trusted program and was modified or otherwise tampered with, program execution is not granted.
EXEC > Result 'R' stage=sss gstag=ggg ACEEH=hhh rv=rc Why? DetailedDecisiontext	Privileged Access Manager checked the authority of the user to execute the program and the result R, where R is either D (deny) or P (permit). The stage sss and the granting-stage ggg indicate which phase of the decision flow determined the result. The ACEE handle hhh was used as the accessor to the program. If the result is 'C' (check) it means Privileged Access Manager did not make a decision, probably because of a software error-contact your vendor's technical support and provide them with the return value rc. Detailed-Decision-text is a textual description of the stage and granting-stage. If the result was P, the program is executed successfully. If the result is D, the program will not be executed and the user receives a permission denied message.
EXECARGS 'execution arguments'	Because of an EXEC syscall, Privileged Access Manager displays the executed command line with all the arguments passed to it.

## FILE Messages

Message	Means
FILE P=ppp U=uuu (D=dev I=inode) acc pathname	Process ppp associated with userid uuu attempted to access a Privileged Access Manager protected file. In the message text, dev and inode are the device and inode of the file being accessed, respectively; acc is the access mode (that is, READ, WRITE, and so on); and pathname is the real path name of the file being accessed.

FILE > Result 'D' Privileged Access Manager File Only 'filename'	The result of the file access request is D (denial) because only Privileged Access Manager can access this file. Even if the access rules permit access, Privileged Access Manager is hard-coded to deny access to this file.
FILE > Result 'R' stage=sss gstag=gs ACEEH=hhh rv=rv (recordname)Why? detailedreasonstext	The result R of the file access request is either D (deny) or P (permit). The stage sss and granting stage gs are mapped to a text-string reason, on the second line (following Why?). In the message text hhh is the accessor handle associated with the request's accessor and record-name is the name of the access rule record that triggered the decision to deny or permit access.

## INET Messages

Message	Means
INET P=ppp, from ipaddress localport to port portnumber	Privileged Access Manager intercepted an incoming Internet accept request that was issued by the remote ip-address requesting the TCP/IP service port-number.
INET > Result 'R' ipaddr>locport, stg=stage gtsg=gstageWHY ? DetailedReasonText	The result R of the Internet request is P (permit) or D (deny). In the message text, ip_addr is the IP address of the request. Detailed-Reason-Text is the textual description that indicates which stage and granting stage phase of the decision flow made the final decision to deny or allow the TCP/IP service for the requesting host.

## INFO Messages

Message	Means
INFO AutoDisabling Tracedue to tight fsspace (space)	The trace facility automatically disables itself when the amount of free space left in the file system where the trace file resides, goes below a threshold specified by the trace_space_saver token in the seos.ini file. In the message text, space is the amount of free space left on the file system.
INFO Can't fetch fs freespace (errno=err)	The Auto Disable feature of the trace facility cannot determine the amount of free space in the file system. In the message text, err is the error integer received from the UNIX statfs() call. Report the problem to your vendor's technical support.
INFO DB Query	The seosd daemon received a request to extract information from the Privileged Access Manager database.
INFO DB Request	The seosd daemon received a request to modify or query data in the Privileged Access Manager database.
INFO Filter Mask 'mask' is registered	The seosd daemon registers each filter mask that is read from the trcfilter.init file, so that messages matching the mask are not sent to the trace file.
INFO GroupList Registered with nnn entries	When seosd runs under the NIS server, it caches all group entries (from /etc/group and NIS maps) at startup, so that seosd can solve GID to group name translations without invoking ypserv processes and TCP/IP requests. This message also indicates that the under_NIS_server token in seos.ini is set to YES. If the station where Privileged Access Manager is running is not the NIS server, set the under_NIS_server token to NO. In the message text, nnn is the number of group entries that were cached.

INFO HostList Registered with nnn entries	The seosd daemon caches all entries from /etc/hosts at startup. In the message text, nnn is the number of host entries cached.
INFO Login program programname is registered	The seosd daemon must recognize all the programs through which users log in to the system. Privileged Access Manager treats a setuid system call invoked by a login program as a login request, and not as a setuid request. In the message text, programname is the full path of the login program that was registered. The seosd daemon takes the names of the login programs internally, from the Privileged Access Manager startup code.
INFO NFS Device Majors Registered, nnn entries	The checks that the Watchdog performs for trusted programs include checking the device number on which the file resides. This check can lead to errors if the file resides on an NFS mounted file system-especially an auto-mounted file system-for which device numbers can have a different value after boot. For this reason, Privileged Access Manager registers the major device numbers of NFS file systems so that they can ignore the non-stable minor device number. Privileged Access Manager has a list of major device numbers for NFS mounted file systems in each environment. If your installation uses a network mounted file system that Privileged Access Manager does not recognize, contact your vendor's technical support for instructions about adding major device numbers to the list. In the message text, nnn is the number of major device numbers registered as NFS mounted file systems.
INFO P=ppp ended	Process ppp ended. seosd disassociates this process number from its ACEE (accessor environment element). If process ppp was the last process associated with its ACEE, (that is, no other parent processes or subprocesses use the same environment), then the ACEE is removed from storage. This message is not issued immediately after the process has terminated; it is issued only when Privileged Access Manager performs some garbage collection to reuse process entries in its internal tables.
INFO P=ppp Exec Failed	This message indicates that process ppp failed to execute the last EXEC syscall, because UNIX refused this request (after Privileged Access Manager granted the execution). Therefore, Privileged Access Manager restores the value of the former executable that was associated with this process, as the program running under this process ID. In most cases, the process terminates. This is not necessarily an error, and you need not take any special action. However, you should use UNIX tools to isolate the reason that execution failed. In most cases, the reason is that a shell script does not have the #!/bin/sh header on the first line.
INFO P=ppp Unknown TTY type typename	The seosd daemon cannot determine if the process ppp is using a real TTY or a pseudo TTY. Contact your vendor's technical support.
INFO Privileged program programname is registered	The seosd daemon registers a few privileged programs. Such programs are allowed to setuid to any user without checking the SURROGATE class. Currently, you can only make /bin/sendmail a privileged program, due to its flow requirements. You must keep this list as small as possible; we recommended that seoswd monitor all privileged programs to make sure they remain trusted. In the message text, programname is the full path of the registered program.

INFO Restricted File Table set with nnn entries	During startup, seosd found nnn entries for Privileged Access Manager protected files, and successfully passed this list to the Privileged Access Manager extension of the UNIX kernel. This is an information-only message.
INFO SEOS_syscall UnRegister rc=nnn	During shutdown, seosd unregisters itself to the kernel so that it can start up again. In the message text, nnn is the return code, which should be zero. If the return code is not zero, report the problem to your vendor's technical support.
INFO ServList Registered with nnn entries	The seosd daemon caches all entries from /etc/services at startup. In the message text, nnn is the number of host entries that were cached.
INFO ServList registered with nnn portmapper entries	While starting up, seosd registered nnn TCP/IP services that are resolved by the portmapper. This is an information-only message.
INFO Set site	The seagent daemon, the Privileged Access Manager daemon responsible for communication with other Privileged Access Manager stations, sent seosd a connection request from a remote station.
INFO Setting PV C=ccc O=ooo P=ppp	The seoswd daemon set the value of property ppp in object ooo of class ccc.
INFO UserList Registered with nnn entries	When seosd runs under the NIS server, it caches all user entries (from /etc/passwd and NIS maps) at startup, so that seosd can solve UID to user name translations without invoking ypserv processes and TCP/IP requests. This message also indicates the under_NIS_server token in seos.ini is set to YES. If the computer where Privileged Access Manager is running is not an NIS server, set under_NIS_server token to NO in seos.ini. In the message text, nnn is the number of user entries that were cached.
INFO XDM program programname is registered	XDM programs are those programs that display the userid and password box on X-terminals. XDM programs run under superuser, who usually cannot open windows on X-terminals. However, the XDM program must open a window on an X-terminal to present a box with the userid and password for the user to specify. seosd therefore bypasses terminal checking if the program issuing the CONNECT request is a registered XDM program.

## KILL Messages

Message	Means
KILL P=ppp U=uuu kill Process All Except (nn) (proclist)	Process ppp associated with user uuu attempted to kill all the processes listed in proclist (or all the processes except the processes in the list). In the message text, nn is the number of target processes.
KILL > Result 'R' stage=sss gstag=gs rv=rr ACEEH=hhhWhy? detailedreason-text	The result R of the kill event is either D (deny) or P (permit). In the message text, sss, gs, and rr are the stage, granting stage, and return value of the Privileged Access Manager decision routines, and hhh is the accessor handle associated with the kill event. The detailed-reason-text appears in the second line and is a derivation of the stage and granting stage codes.

## LOGIN Messages

Message	Means
LOGIN P=ppp User=uuu Terminal=ttt	The seosd daemon intercepted a login request from user uuu working on terminal ttt under process number ppp. A Login Result message should follow this message.
LOGIN > Result 'R' stage=stage gstage=gstage rv=nnn ACEEH=hhh Why ?detaileddenialreason	The result of the login request R is either D (deny) or P (permit). In the message text, stage and gstage are numbers indicating the phase in the Privileged Access Manager flow that made the decision to grant or deny the login request. If the login was permitted, hhh is the ACEE handle that is now associated with the issuing process. If the login was denied, hhh is set to -1 and a detailed-denial-reason appears in the second line. If the detailed-denial-reason relates to resource access (such as no rule granting access to resource), the resource in question is the terminal from which the user issued the login request.
LOGIN > Result 'D' Login Disabled for ALL	The login request was denied because login is currently disabled for all users.
LOGIN > Result 'D' Login Disabled for U=uuu	The login request was denied because login is currently disabled for the specific user. The reason can possibly be that this user is already logged in.

## SCONSOLE Messages

Message	Means
SCONSOLE Login Disabled For UID uuu	The Privileged Access Manager console utility, secons, issued a request to disable a login request for the userid uuu. From this point, login requests for the specified userid are denied.
SCONSOLE Login is already Disabled for U=uuu	The secons utility issued a request to disable login request for the userid uuu. However, login is already disabled for this userid.
SCONSOLE Login is not Disabled for U=uuu	The secons utility issued a request to re-enable login for the userid uuu. However, login is already enabled for this userid.
SCONSOLE Login Is Now Disabled	The secons utility issued a request to disable login for all users. From this point on, login requests by any user are denied.
SCONSOLE Login Is Now Enabled	The secons utility issued a request to re-enable login for all users. From this point on, login requests are allowed.
SCONSOLE Login ReEnabled for U=uuu	The secons utility issued a request to re-enable login for a specified user. From this point on, login requests for this specific user are allowed.
SCONSOLE No more space in Disabled Logins Table	The secons utility issued a request to disable login for a particular user. However, the login disable table is full. Contact your vendor's technical support.
SCONSOLE U=uuu is not allowed for operation	A user without the OPERATIONS attribute tried to use one of the secons switches that are not allowed for non-OPERATIONS users.
SCONSOLE U=uuu is not allowed to disable login for U=uuu2	The user uuu tried to disable login for user uuu2 through secons. However, only root and user uuu2 are allowed to disable login for uuu2.

SCONSOLE U=uuu is not allowed to Reenable login for U=uuu2	The user uuu tried to re-enable login for user uuu2 through secons. However, only root and uuu2 are allowed to re-enable login for uuu2.

## SGID Messages

Message	Means
SGID P=ppp U=uuu G=ggg to GGG (GROUP.groupname) ACEEH=hhh D=devnum I=inode	Process ppp, running with the authorities of UID uuu and GID ggg, issued a setgid system call for the GID GGG. Privileged Access Manager checks the authority of that process using the SURROGATE class and object GROUP.groupname, and uses hhh as the accessor handle for the request. In the message text, devnum and inode are the device and inode of the issuing program, respectively. A SGID Result message should follow this one.
SGID > P=ppp U=uuu (RG=rg EG=eg SG=sg) to (RG=trg EG=teg SG=tsg) () BYPASS	Privileged Access Manager granted the setgid request without checking any SURROGATE access rules. In the message text, ppp is the issuing process id; uuu is the userid associated with this process; rg, eg, and sg are the real, effective, and saved GID of that process; and trg, teg, and tsg are the target effective, real, and saved GID with which the setgid request was issued. The reason for the bypass is usually because the current real or saved GID is the same as the target GID, and therefore the setgid request does not change the security scope of the user.
SGID > Result 'R' stage=stage gstag=gstage ACEEH=hhh Why? detailedreason-text	Privileged Access Manager checked the setgid request against a SURROGATE access rule and the result R is P (permit) or D (deny). The decision was made on behalf of the accessor handle hhh. In the message text, detailed-reason-text is the reason for the denial or grant.

## SHUTDOWN and STARTUP Messages

Message	Means
SHUTDOWN! Request Denied. U=uuu not allowed to SHUTDOWN the Server	The userid uuu tried to shut down seosd using secons; however, profile of the user does not have the OPERATIONS attribute. The request was therefore denied.
SHUTDOWN Server going down upon operator's request	The seosd daemon started shutting down following a request from an authorized operator.
SHUTDOWN Terminating Privileged Access Manager daemon daemonname P=ppp RV=nnn	Privileged Access Manager terminated its daemon ppp as part of its shutdown process; Privileged Access Manager also shuts down seoswd and seagent.
STARTUP Privileged Access Manager daemon PID=ppp	The seosd daemon was started; its process ID is ppp.

## SUID Messages

Message	Means
SUID > P=ppp U=uuu (R=r E=e S=s) to (R=tr E=te S=ts) (reason) BYPASS	Privileged Access Manager granted the setuid request without checking any SURROGATE access rules. In the message text, ppp is the issuing process id; uuu is the userid associated with this process; r, e, and s are the real, effective and saved UIDs of process ppp; and tr, te, and ts are the target effective, real, and saved UIDs with which the setuid request was issued. The reason for the bypass is usually because the current real or saved UID is the same as the target UID, and therefore the setuid request does not change the security scope of the user. Other possible reasons are that the program issuing the setuid system call is a privileged program (in which case reason is For Priv), or that the issuing program is a login program that switches UIDs several times before and after the actual login ( in which case reason is specified as For Login).
SUID P=ppp U=uuu (R=r E=e S=s) to USER.username (R=tr E=te S=ts)D=devnum I=inode	Process ppp, running with the authority of userid uuu, issued a setuid system call to change the current real, effective, or saved UID to UID uuu. Privileged Access Manager checks the authority of that process using the SURROGATE class and object USER.username for that request. In the message text, devnum and inode are the device and inode of the issuing program, respectively. A SUID Result message should follow this one.
SUID > Result 'R' stage=stage gstag=gstage ACEEH=hhh rv=rv Why? detailedreasontext	Privileged Access Manager checked the setuid request against a SURROGATE access rule and the result R is P (permit) or D (deny). The decision was made on behalf of the accessor handle hhh. In the message text, detailed-reason-text is the reason for the denial or grant.

## WARNING Messages

Message	Means
WARNING Associate P=ppp ACEEH=hhh	Privileged Access Manager performs an association between a process and an accessor handle (ACEEH) for any fork request. This message indicates that the association cannot be performed, either because the handle hhh is -1 or because hhh is not a valid accessor handle. In the latter case, contact your vendor's technical support.
WARNING Can't verify P=ppp	This message follows an Unknown P= message that indicates a fork request from an unknown process. Privileged Access Manager tries to determine who the user is that UNIX associates with that user. This verification task cannot be completed. A possible reason is that the process has already terminated. If not, contact your vendor's technical support.
WARNING DeAssociate P=ppp ACEEH=hhh	Privileged Access Manager performs a dissociation between a process and an accessor handle (ACEEH) for any process that is terminated. This message indicates that the dissociation cannot be performed, either because the handle hhh is -1 or because hhh does not exist as a valid accessor handle. In the latter case, report the problem to your vendor's technical support.

WARNING ExecArg for entry with P=ppp not NULL	This warning appears when the product finds a new process that was not known to the system, and for which the executing program is not known. In most cases, you can ignore the message. If the system does not produce the expected results, contact your vendor's technical support.
WARNING Failed to get ACEEH of P=ppp	Privileged Access Manager was requested to check the authority of process ppp but there was no valid accessor handle for that process. In most cases, the reason is that the user who is associated with the process is not a Privileged Access Manager defined user, or that the process is unknown to the product. In both cases, the product gives this process only universal access rights. If the system does not produce the expected results, contact your vendor's technical support.
WARNING Login for P=0 ???	When this message appears during startup in systems other than AIX, you can ignore it. If it appears during normal work (after seosd is started and functions), or during startup under AIX, then it identifies a software error, in which case you should contact your vendor's technical support.
WARNING CA PAMSC failed to kill P=ppp reason=nnn	As a measure of caution, the product kills processes trying to get sensitive privileges that may create loopholes. Such events can be attempts to surrogate the UID (setuid system-call) with no permission. Privileged Access Manager attempted to kill the violating process, but failed to do so. The reason for the failure is detailed in the reason code that is returned by the kill system call.
WARNING Terminal for entry with P=ppp not NULL	This warning appears when the product finds a new process that was not known to the system and for which the executing program is not known. In most cases, you can ignore the message. If the system does not produce the expected results, contact your vendor's technical support.
WARNING Unknown P=ppp	This message indicates a fork request that was issued by a process that is not known to the product. If this message appears for seoswd or seagent during startup, you can ignore it. At other times, it can imply a software error because the product cannot verify the actual authority of that process. For the latter case, contact your vendor's technical support.

## WATCHDOG Messages

Message	Means
WATCHDOG Ask if I'm Here (AYT)	The seoswd daemon tried to verify whether seosd is alive and give the expected response. In the message text, AYT is the seoswd are you there challenge. You can and should ignore this message; filter it out using the trcfilter.init file. The message implies normal behavior of seoswd.
WATCHDOG Init initializationtext	The seoswd initialization message, which you can ignore.
WATCHDOG Log logtext	The seoswd daemon issued a log request. The log request is detailed in log-text.

WATCHDOG SecFile operation result	The seoswd daemon requested the daemon to extract information regarding secured files. In the message text, operation can be GETFIRST or GETNEXT; the result can be OK if such information was extracted, or NOFOUND if there are no more secured files in the product database. This message signifies normal behavior of seoswd to scan secured files.
WATCHDOG Timer	The seoswd daemon issues a timer request every few seconds (as set by the seos.ini file). You can and should filter out this message using the trcfilter.init file.
WATCHDOG Trust Pgm programname OK NOTOK	The seoswd daemon marked the specified program as a trusted program. This implies that the specified program passed the digital signature tests. In the message text, OK means the trust operation completed successfully, and NOTOK means that seoswd failed to mark the program as trusted. The reason for NOTOK is probably a corrupted database, in which case you should contact your vendor's technical support.
WATCHDOG Untrust Pgm programname OK NOTOK	The seoswd daemon marked the specified program as untrusted. This implies that the specified program did not pass the digital signature checks of seoswd. In the message text, OK means that the untrust operation has completed successfully, and NOTOK means that seoswd failed to mark the program as untrusted. A possible reason for NOTOK can be a corrupted database, in which case you should contact your vendor's technical support.

## Other Trace Messages

Message	Means
ACTION CA ControlMinder killed P=ppp	Privileged Access Manager denied a setuid or login request and killed the requesting process (ppp) as a precautionary measure.
ALARM ! Uid uuu breached the system!!!	An unknown process made a request such as fork, exec, or setuid. The process is unknown to Privileged Access Manager and the UID assigned to the process is not assigned to any other process in the system. This implies that the user logged in without Privileged Access Manager being notified. This situation can occur as a result of a software bug or if the user logged in immediately after the product scanned the current process status but before completing initialization.
EXIT Going down...	Privileged Access Manager started the shutdown process and disabled the interception of system calls.
FATAL ! in seosrt_InitDatabase (nnn) Layer = nnn Stage = nnn Return Code = 0xnnn	Privileged Access Manager cannot initialize the database I/O routines. The possible reasons are: <ul style="list-style-type: none"> <li>No database in the directory is identified by the dbdir token in the seos.ini file.</li> <li>The user invoking Privileged Access Manager is not root.</li> <li>The database is corrupt.</li> </ul> If you cannot correct the problem, contact your vendor's technical support.

FORK P=ppp U=uuu G=ggg Child=cppp Pgm ProgramName	Privileged Access Manager intercepted a fork request made by process ppp associated with UID uuu and GID ggg. The child process id is cppp. Program-Name is the program running in the parent process (and, initially, also in the child process). The product never denies a fork request; it is always granted. Variations of the fork system call, such as vfork and kfork, are also reported as fork requests.
GETCRED P=ppp, Get Credentials by Ticket	This is an information-only message, which indicates that ppp (usually the process ID of the Policy Model daemon, sepmdd) requested the credentials of a specific ticket holder (a client process that requests the services of sepmdd). For more information, see the description of GTICKET in this appendix, and the description of sepmdd in the chapter Utilities in Detail.
GPEERNAM P=ppp, ADDR=addr, N=desc	Privileged Access Manager intercepted the getpeername() system call to verify which IP address is associated with the current process. This system call is always granted. In the message text, ppp is the process id issuing the getpeername() call and addr is the IP address associated with the socket descriptor desc.
GTICKET P=ppp, Get Authentication Ticket	This is an information-only message, which indicates that ppp requested seosd to issue an authentication ticket for it. Whenever the Policy Model client, sepmdd, communicates with sepmdd, the server verifies the identity of the client through the passed ticket. The client sends the acquired ticket to the server using socket communication. The server then passes this ticket to seosd to get the credentials of the ticket holder with the GETCRED request. In this way, sepmdd ensures the identity of the client requesting its services.
MESSAGE string	A marker message is placed in the trace file by console request.
NEWPASS Set new password	The sepass utility requested to set a new password for a user id.
PW_ATTCK P=ppp make nnn attempts in sss seconds from terminal	The seosd daemon detected that process ppp, which is running one of the registered login programs, made nnn attempts to specify a user/password combination with no success. Privileged Access Manager concluded that a password guess attack originated at the terminal specified in the message text, and wrote an audit record to the audit file. PWATTACK audit records can trigger actions by the log routing daemons (selogrcd and selogrd).
RESTART DBSERV restarted by Watchdog (P=ppp)	The seoswd daemon has restarted seosd. In the message text, ppp is the process ID of seosd.
SETGRPS P=ppp to grouplist	The process ppp issued the setgroups system call for the groups specified in grouplist.
STREAM c P=ppp Closes Stream Id=iii	Process ppp closed a stream with stream ID iii. Privileged Access Manager keeps track of all stream-open and stream-close operations to determine later-when a TCP/IP request is processed on behalf of a specific stream-id-which process ID owns the stream.
STREAM o P=ppp Opens Stream Id=iii	Process ppp opened a stream with stream ID iii. Privileged Access Manager keeps track of all stream-open and stream-close operations to determine later-when a TCP/IP request is processed on behalf of a specific stream-id-which process ID owns the stream.
VERPASS Verify password	Privileged Access Manager received a request to verify password validity for a user.
WAKE_UP Server going up	The seosd daemon started to initialize.

## PAM SC Communication Ports

This section contains detailed information on the communication ports that are used by the PAM SC components.

Use the table of contents to access the topics in this section.

### PAM SC UNIX Endpoint Used Ports

The following table lists and describes the ports used by PAM SC UNIX endpoints.

Port Number	Description	Direction	Protocol	Source	Target	Comments
8891	PAM SC Client Applications	Incoming	TCP	Remote PAM SC Utilities	PAM SC Agent	You can change the default port number by modifying the <code>/etc/services</code> file settings. To modify the default port number, add the following line, then restart PAM SC daemons:  <pre>seoslang2   port- number/ tcp</pre>
5249	SSL Communications	Incoming	TCP	Remote PAM SC Utilities	PAM SC Agent	FIPS 140-2 compliant. For more information about SSL communication, see the SSL, Authentication, and Certificates section in the <i>Implementation Guide</i> .

8892	Starting seosd from a remote computer	Incoming	TCP		seosload	<p>When seload loads daemons on a remote computer, inetd (internet services daemon) on the remote computer executes the rseload program. This program executes seload locally and exits; it receives the parameters on this port. You can change the default port number by modifying the /etc/services file settings. To modify the default port number, add the following line, then restart PAM SC daemons:</p> <pre>seosload     port- number/ tcp</pre> <p><b>Note:</b> The communication on this port is not encrypted since it does not send any sensitive information.</p>
61616	Reports and Audit Events	Outgoing	TCP	ReportAgent	Distribution Server	
8891	PAM SC Client Applications	Outgoing	TCP	Policyfetcher	Distribution Server	Distributing AC policies to endpoints through Advanced Policy Management.
5249	SSL Communications	Outgoing	TCP	Policyfetcher	Distribution Server	Distributing AC policies to endpoints through Advanced Policy Management when SSL is enabled.

## Windows Endpoint Used Ports

Privileged Access Manager uses the following TCP ports on Windows by default:

Port Number	Description	Direction	Source	Target	Comments
8891	Privileged Access Manager client applications	Incoming	selang.exe, sepmdd.exe (PMD), eACSigUpdate.exe, SegraceW.exe (grace login and password settings), secons.exe (remote shutdown and IP address refresh), policydeploy.exe, devcalc.exe, policyfetcher.exe	CA ControlMinder Agent	You can change the default port number by modifying the %SystemRoot%\drivers\etc\services file settings. To change the default port number, add the following line, then restart Privileged Access Manager services:  seoslang2 port-number/ tcp
5249	SSL Communications	Incoming	For information about the components which provide FIPS-compliant communications, see the Release Notes.	CA ControlMinder Agent	FIPS 140-2 compliant
61616	Reports and audit events	Outgoing	ReportAgent	Distribution Server	
8891	Privileged Access Manager Client Applications	Outgoing	Policyfetcher	Distribution Server	Distributing AC policies to endpoints through Advanced Policy Management.
5249	SSL Communications	Outgoing	Policyfetcher	Distribution Server	Distributing AC policies to endpoints through Advanced Policy Management when SSL is enabled.

## Default TCP Ports Used by PAM SC Server Components

Privileged Access Manager uses the following TCP ports for its server components by default:

Port Number	Description	Direction	Source	Target
61616	Report snapshots using SSL	Outgoing	Enterprise Management Server	Utility Appliance
5248	Local web-based interface communications	Outgoing	Enterprise Management	Web Service
9095	Used for login integration from PAM SC	Outgoing		Utility Appliance

9091	Policy orchestration from PAM SC	Outgoing		Utility Appliance
------	----------------------------------	----------	--	-------------------

In addition to the default ports, you may need to open the following ports:

- On the computer of the central database for communication with the Privileged Access Manager Enterprise Management, if these components are on separate computers.
- On the Report Portal (BusinessObjects) computer to access the InfoView application from remote computers (8080 by default).
- On the Privileged Access Manager Endpoint Management and Privileged Access Manager Enterprise Management computer to access the web-based interfaces from remote computers (18080 by default).
- On the computer where you install Oracle Database to access the web-based interface from remote computers (by default, 8080 or 61616 for SSL).
- On the computer of the central database for communication with the PAM Server Control Enterprise Management, if these components are on separate computers.
- On the Report Portal (BusinessObjects) computer to access the InfoView application from remote computers (8080 by default).
- On the PAM Server Control Endpoint Management and PAM Server Control Enterprise Management computer to access the web-based interfaces from remote computers (18080 by default).
- On the computer where you install Oracle Database to access the web-based interface from remote computers (by default, 8080 or 61616 for SSL).

## UNIX Authentication Broker Used Ports

UNIX Authentication Broker uses the following TCP ports on UNIX by default:

Number	Description	Source	Target
53	DNS	UNIX Authentication Broker Agent	Active Directory
88	Kerberos traffic	UNIX Authentication Broker Agent	Active Directory
389	Kerberized LDAP	UNIX Authentication Broker Agent	Active Directory
445	Microsoft directory services	UNIX Authentication Broker Agent	Active Directory
464	Kerberos kpasswd	UNIX Authentication Broker Agent	Active Directory
3268	Global Catalog	UNIX Authentication Broker Agent	Active Directory
61616	Report snapshots using SSL	Report Agent	Utility Appliance

UNIX Authentication Broker uses the following UDP ports on UNIX by default:

Number	Description	Source	Target
53	DNS	UNIX Authentication Broker Agent	Active Directory
88	Kerberos traffic	UNIX Authentication Broker Agent	Active Directory

123	NTP	UNIX Authentication Broker Agent	Active Directory
389	Kerberized LDAP	UNIX Authentication Broker Agent	Active Directory
464	Kerberos kpasswd	UNIX Authentication Broker Agent	Active Directory

## Endpoint Management Used Ports

Privileged Access Manager uses the following TCP ports to manage automatically registered endpoints by default:

Number	Description	Direction	Source	Target	Comments
135	Remote Procedure Call	Incoming	Distribution Server	Windows Endpoints	Remote Procedure Call (RPC) needed for WMI.
445	Remote registry access	Incoming	Distribution Server	Windows Endpoints	Remote registry access that is needed for WMI.
139	Optional Port	Incoming	Distribution Server	Windows Endpoints	This port is required when Windows endpoint uses the NETBIOS protocol. WMI can use NETBIOS over port 139 in case of failure to use port 445 over TCP. If you did not configure the endpoint to use NETBIOS, you do not need to open port 139.
<WMI fixed port>	WMI communications	Incoming	Distribution Server	Windows Endpoints	Configure the endpoint with the WMI fixed port when configuring Active Directory endpoint only.
389	ADSI Communication	Incoming	ENTM	Windows Endpoint	This port is required for managing Windows endpoint
<ADSI fixed port>	ADSI communications		ENTM	Windows Endpoints	Configure the endpoint with the ADSI port.
22	SSH Port	Incoming	ENTM	SSH Endpoint or Network Device	This port is required for managing SSH devices through the SSH protocol.

23	Telnet Port	Incoming	ENTM	SSH Endpoint or Network Device	This port is required for managing SSH devices through the Telnet protocol.
1521	Oracle database port	Incoming	ENTM	Oracle Endpoint	This port is required for managing Oracle endpoints.
1433	Microsoft SQL Server database port	Incoming	ENTM	Microsoft SQL Server Endpoint	This port is required for managing Microsoft SQL Server endpoints.
18080,18443	Optional Port	Incoming	Browser	ENTM	Use this port when using the ENTM web UI from a machine which is behind a firewall.

## ObserveIT Used Ports

ObserveIT uses the following TCP ports:

Number	Description	Listener	Sender	Comments
4884	ObserveIT Agent	ObserveIT Application Server	ObserveIT Agent	By default, the communication is not SSL-enabled. Use port 443 if you enable SSL communication.
4884	ObserveIT Web Console	ObserveIT Application Server	ObserveIT Agent	By default, the communication is not SSL-enabled. Use port 443 if you enable SSL communication.
1433		Database Server	ObserveIT Application Server and ObserveIT Web Console	

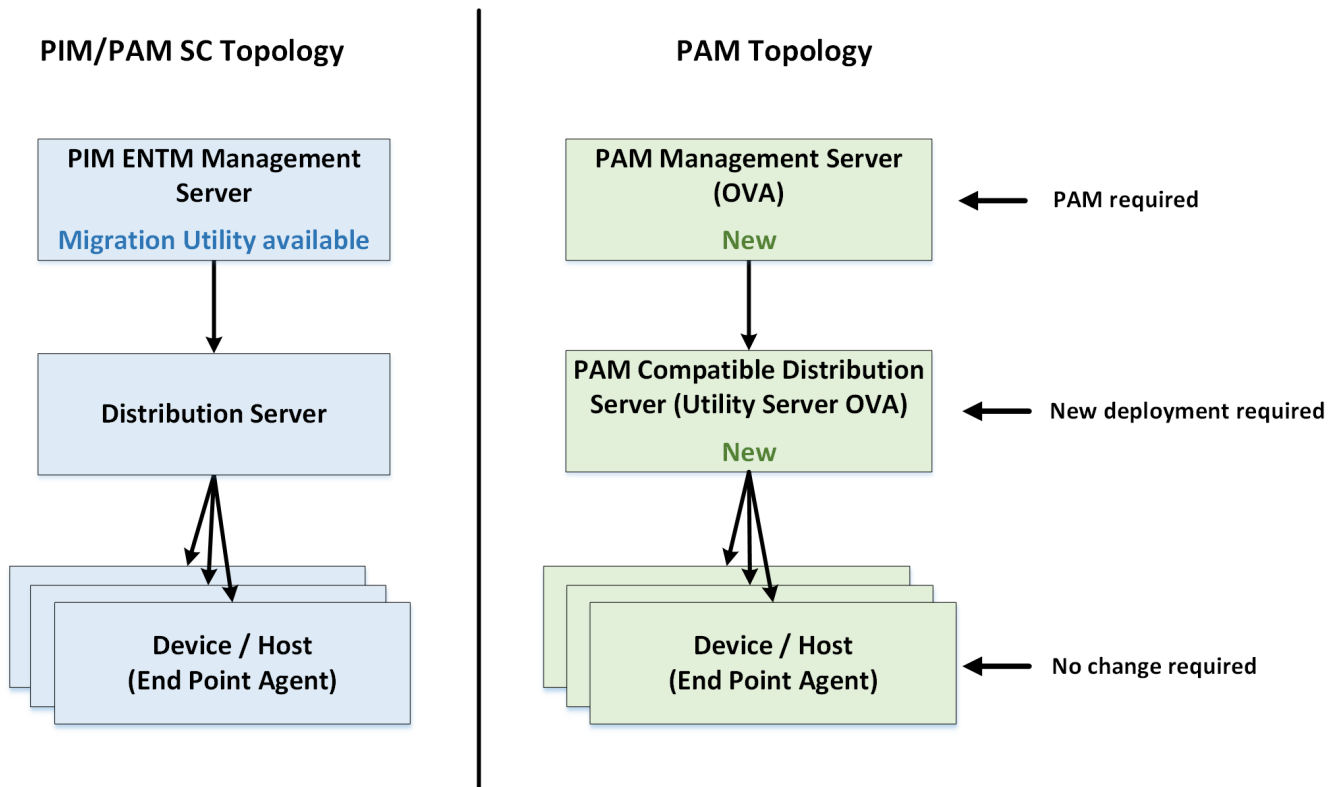

## PAM SC Frequently Asked Questions

This content answers common questions that PIM or PAM SC administrators may have when migrating to PAM:

### **If I use Advanced Policy Management with the ENTM and endpoints, what changes in the new PAM framework?**

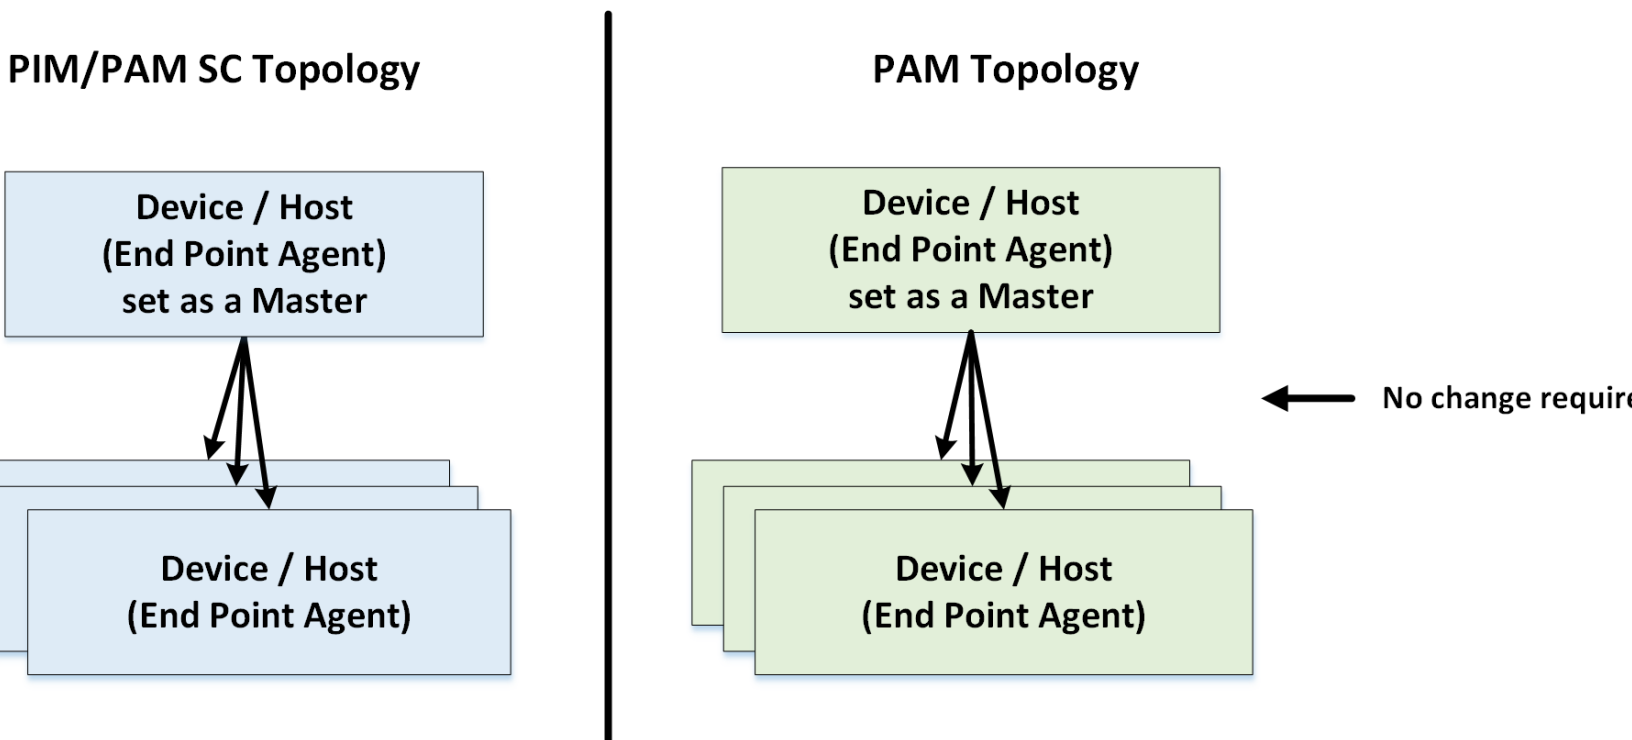

The endpoints remain the same, but ENTM is integrated into the PAM server. The Distribution Server is replaced by the new Utility Appliance.

**Figure 57: Difference between PIM/PAM SC and PAM Advanced Policy Management****If I use PMDB, can I still use endpoints only and assign one of the endpoints as a master to set policies?**

You can continue to use the endpoints as you have been doing with no impact.

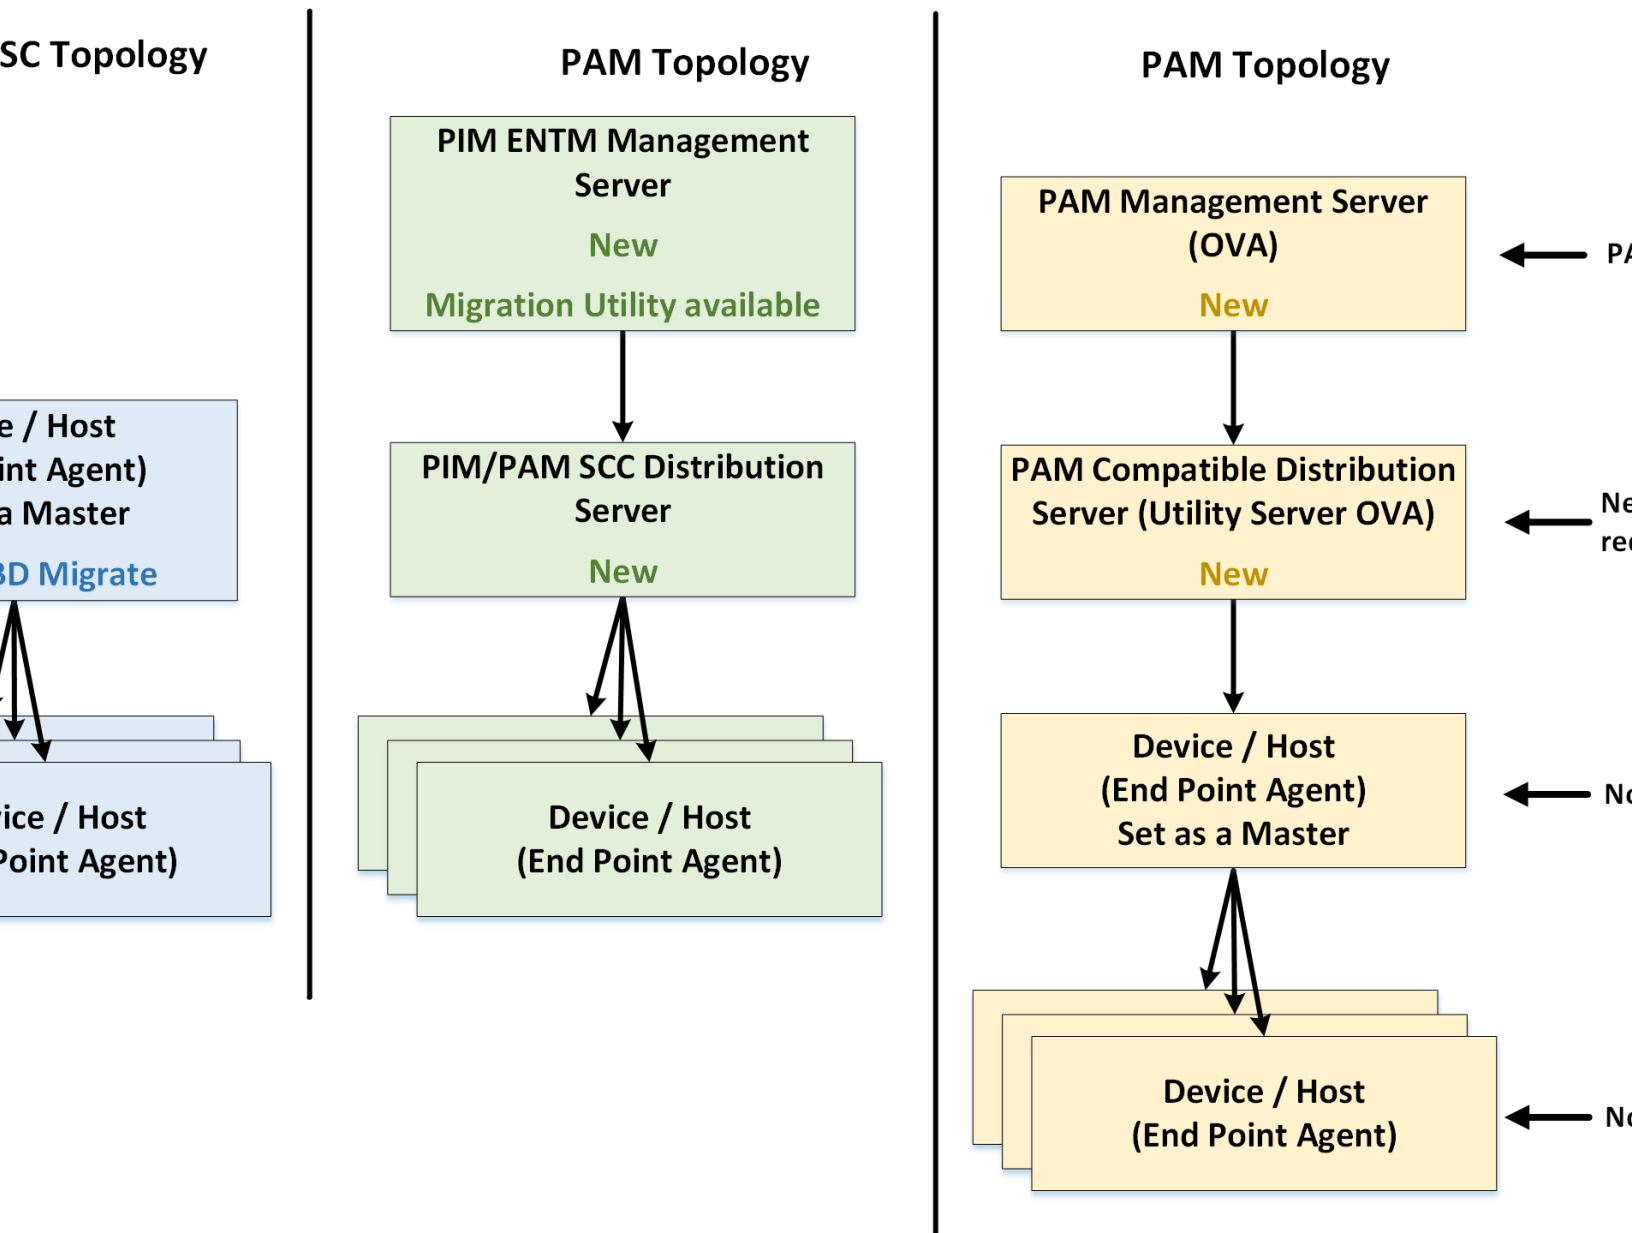

To use Server Control functionality in PAM, you must first upgrade to Advanced Policy Manager with a Distribution Server. Then use the Migration Utility to migrate to PAM 4.0 and the new Utility Appliance.

**Figure 58: Difference between PIM/PAM SC and PAM PMBD**

Another PMBD option is to change the configuration to an Advanced Policy Management setup. To change the configuration, follow two processes:

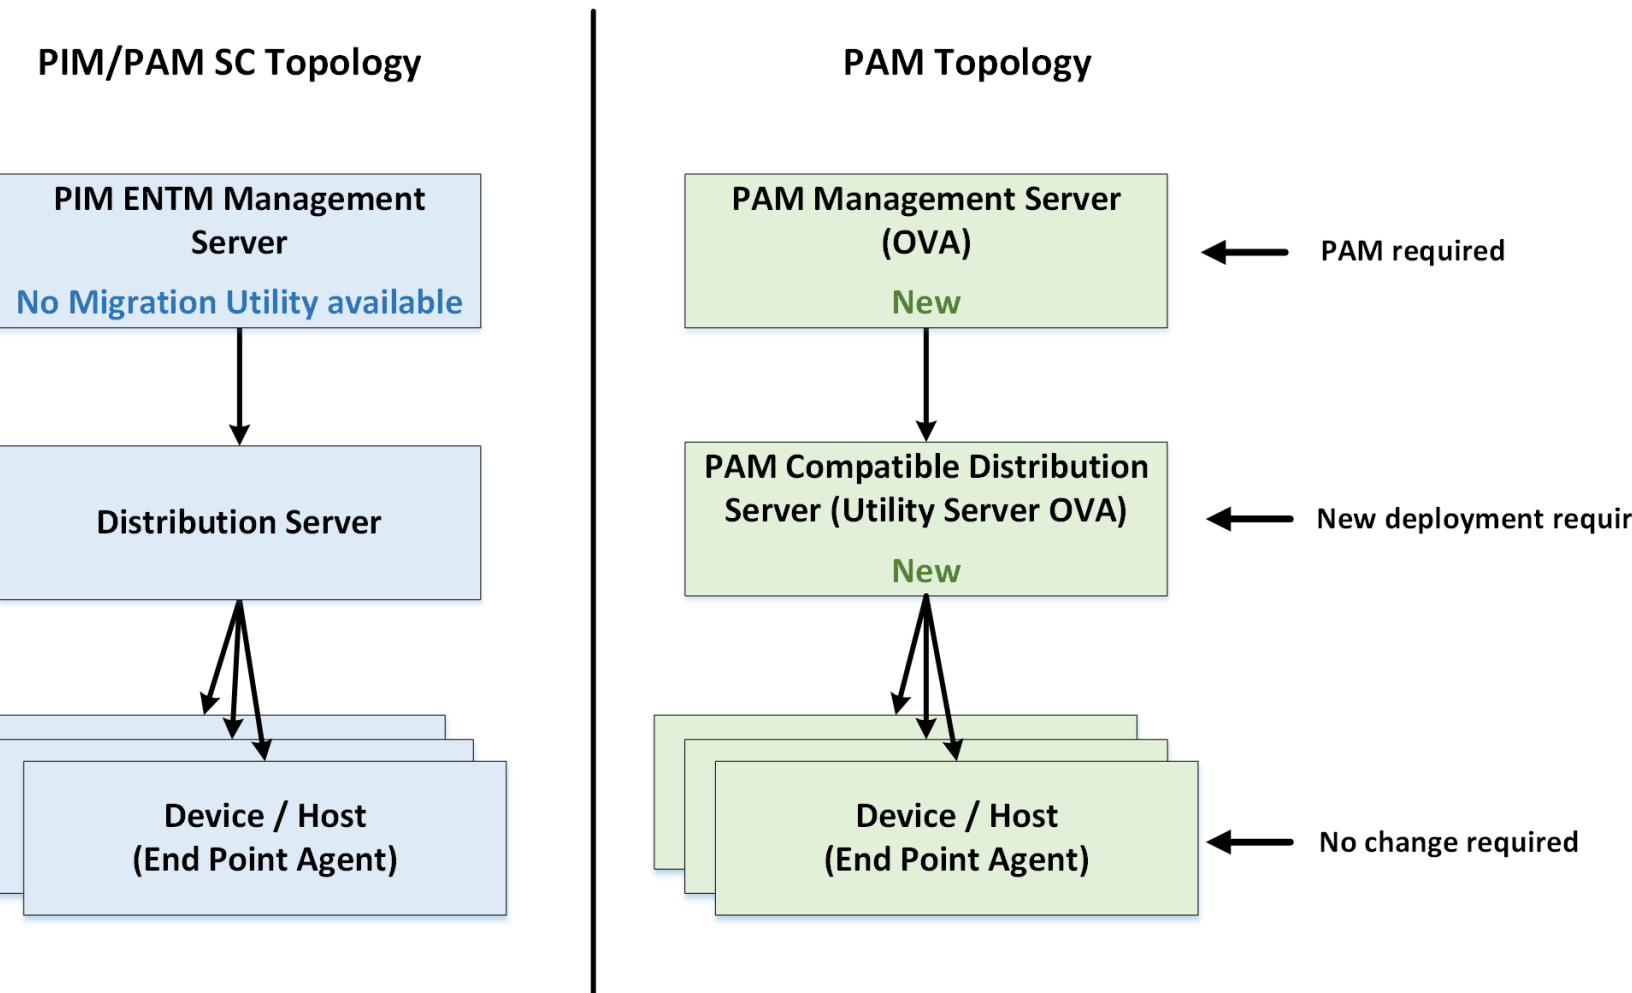

1. Add an ENTM management server plus the distribution server.
2. Migrate to the PAM configuration shown in the following diagram. This option uses the PAM architecture and its benefits.

Figure 59: Migrating to PAM PMBD through PAM Advanced Policy Management

**Is Share Account Management (SAM) supported in PAM 4.0?**

SAM is supported in PAM 4.0. However, PAM 4.0 does not include a utility to migrate SAM information, so the only way to use SAM is to manually migrate all the required data.

Figure 60: Difference between PIM/PAM SC and PAM Share Account Management

**What are the legacy PIM and PAM SC components, and how does PAM fit into PAM 4.0?**

See the following table for information on the legacy PIM and PAM SC components:

**Legacy Components:**

Legacy Component	New Component	Migration Utility Available?
ENTM (Enterprise Manager)	PAM server	Yes
DS (Distribution Server)	Utility Appliance	Yes
PMDB (Policy Model Database)	PAM server & Utility Appliance	Yes
SAM (Shared Account Management)	PAM server	No, manual migration

- **ENTM: Enterprise Manager:** The Enterprise Management Server was the central management server. This server contained components and tools that let you deploy policies to endpoints and define resources, accessors, and access levels. The server also contained components that manage the communication between the Enterprise Management Server, the endpoints, and other components. An embedded Privileged Access Manager Server Control endpoint was silently installed when installing the Enterprise Management Server. The embedded Privileged Access Manager Server Control endpoint protected and supported the applications in the Enterprise Management Server.

The Enterprise Manager is replaced by the PAM 4.0 server.

- **DS: Distribution Server:** The Distribution Server handled communication between the Enterprise Management Server and the endpoints. By default, an embedded Distribution Server was installed on the Enterprise Management Server. The Distribution Server is replaced by the Utility Appliance.
- **PMDB: Policy Model Database (Replaced by PAM server and Utility Appliance):** The PMDB contained users, groups, protected resources, and rules governing access to the resources. In addition, the PMDB contains a list of subscriber databases. Each subscriber is a Privileged Access Manager Server Control database that resides on a separate computer, or another PMDB that resides on the same or another computer. A PMDB that updates a subscriber is the parent of the subscriber.  
The PMDB is replaced by the PAM server and Utility Appliance.
- **SAM: Shared Accounts Management (No Migration Utility - Only Manual Migration):** SAM previously provided role-based access management for privileged accounts on target endpoints from a central location. SAM provided secure storage of privileged accounts and application ID passwords. SAM also controlled access to privileged accounts and passwords that are based on policies you define. Further, SAM managed privileged accounts and application password lifecycle and let you remove passwords from configuration files and scripts.  
Only manual migration is available for SAM.
- **UNAB: Unix Authentication Broker:** The Unix Authentication Broker is used when you want to manage and control access to UNIX hosts through Active Directory users and groups. UNAB lets you log into UNIX hosts using an Active Directory user name and password. Users and groups do not need to be defined on NIS or `/etc/passwd`. Information can be taken from Active directory.  
UNAB does not require Access Control Endpoint in order to operate; it is supplied as a stand-alone installation.

### **Where can I find the new architecture?**

See the [PAM 4.0 Architectural Overview](#).

### **Which virtual deployment platforms and hardware are supported?**

PAM 4.0 supports VMware OVA and physical hardware. Azure, AWS, and Google Cloud are NOT supported in this release.

### **Is ActiveMQ still used by PAM 4.0?**

ActiveMQ is still used, but the list of use cases has changed. Each Utility Appliance runs an ActiveMQ instance, but it is a single standalone component that is in place to support the current endpoint technology stacks.

### **Is Tibco supported in PAM 4.0?**

PAM 4.0 supports Tibco / 12.x agents. TIBCO is not supported by default. For more information, see [TIBCO Configuration in PAM](#).

### **I do not use Enterprise Manager in my deployment today; can I still migrate to PAM?**

If you do not use Enterprise Manager, you can still migrate to PAM 4.0. If you are managing your endpoints and policies from disconnected Distribution Servers, you can install and run the Migration Utility on the Distribution Server. Then extract the data to import into PAM. Repeat this migration on each Utility Appliance.

# Implementing Threat Analytics

---

Threat Analytics is a powerful tool for identifying anomalies in PAM user behavior and implementing policies to dynamically mitigate potential insider threats or breaches by external threat actors. As a PAM administrator, you interact with the Threat Analytics utility using the [Threat Analytics Console](#).

## Threat Analytics Capabilities

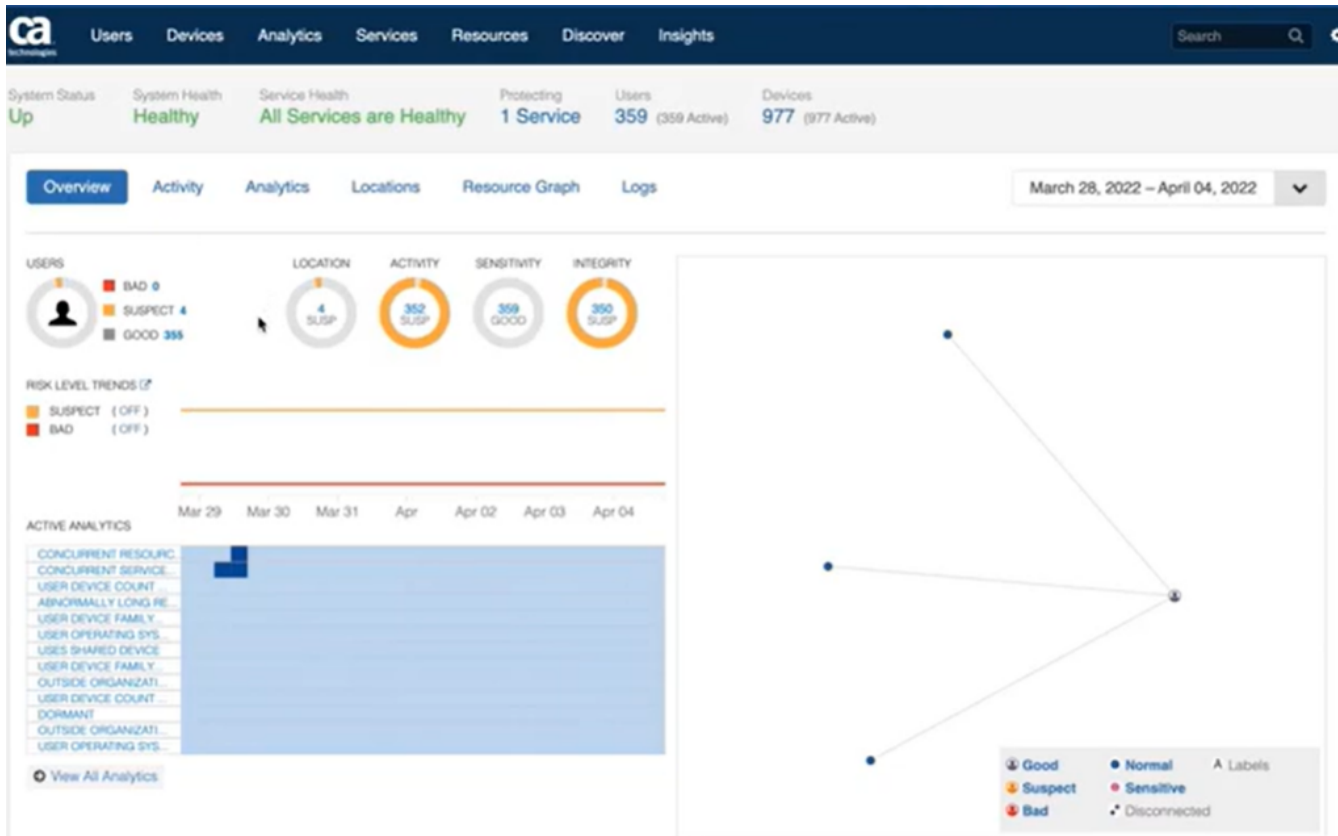

Threat Analytics provides capabilities that enable you to perform the following tasks:

- **Gather information on the threat landscape over time, from past events to the current moment:**
  - Zero in on [specific users](#) and [devices](#).
  - View the [services](#) and [resources](#) being used.
  - Get a [summary of risky activity within a selected time span](#), zeroing in on suspicious events.
- **Set the policies and thresholds that trigger a threat assessment for a user or device:**
  - View in detail all [58 analytics](#) that can be applied; each one can be enabled or disabled as needed.
  - [Modify the parameters](#) used to make risk status decisions.
  - See all [analysis and status decisions](#) that have been made on the PAM network at different slices of time.
- **Interpret, summarize, and filter any and all network activity:**
  - See visual [mapping of potential threats](#) and risky users.
  - [View the Data Insights](#), which includes key summary data for all PAM operations.
- **Identify the threat landscape across an entire organization, from the overall threat snapshot down to the threat assessment for an individual user or device.**
  - Enable or disable users based on their [IP location](#) or [country](#).
  - Configure the logging and reporting (via email notification that is managed by the [STMP protocol](#) and [Syslog/SIEM logging](#)) of all threats that are captured by the console.
  - Export the threat assessment and share it with appropriate audiences.

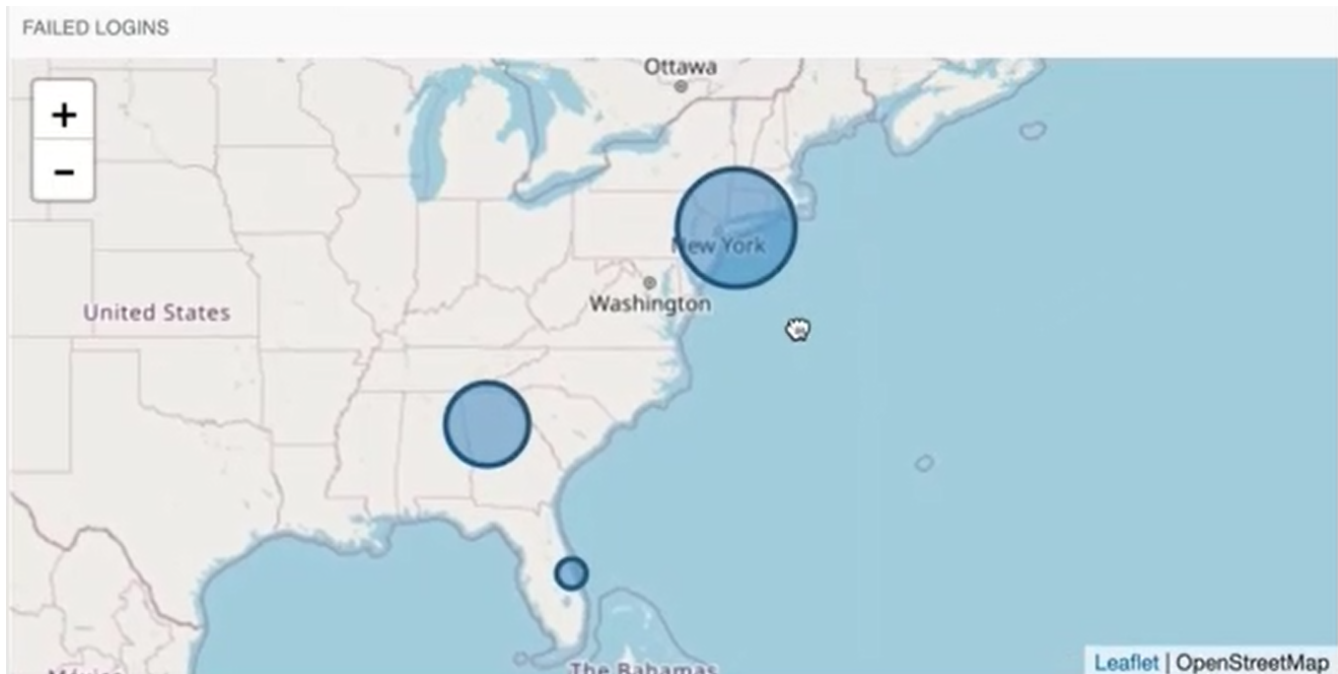

## Threat Analytics Console

You interact with Threat Analytics using the *Threat Analytics Console*. The console provides graphs, maps, and other rich visualizations to help you analyze the threat data, as shown in the following examples:

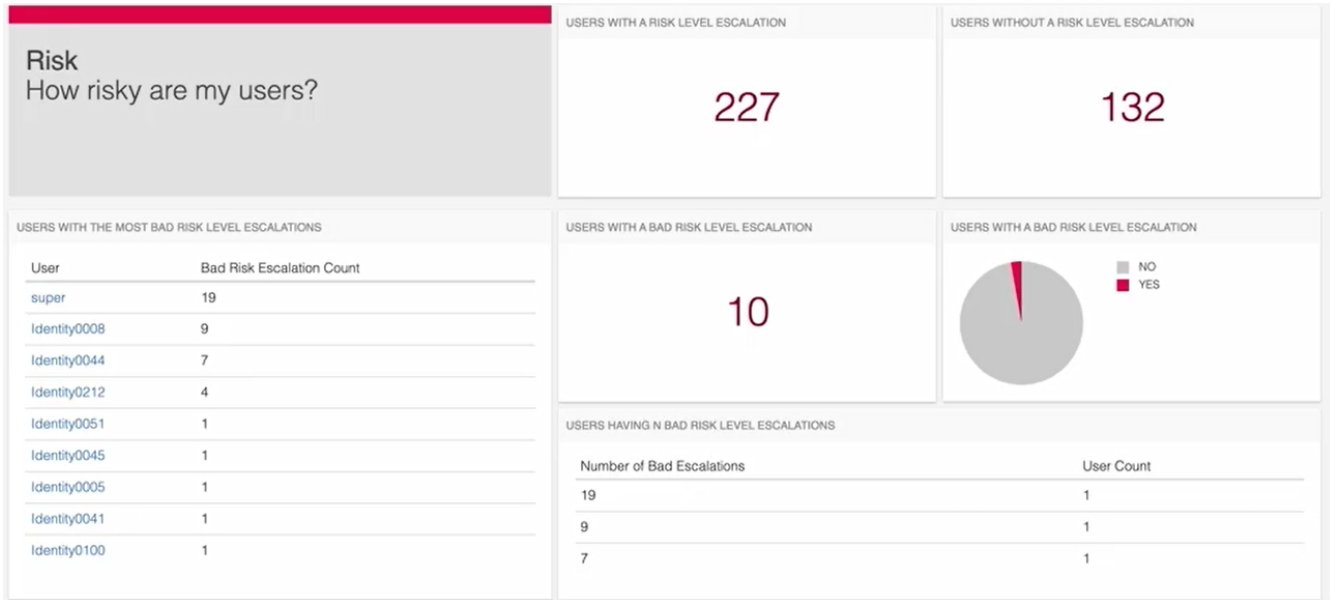

- View user and network threat activity at a glance:

- Use a geolocation view of the PAM network to see clusters of suspect users.

- Risk view shows counts of users with and without new risk level escalations and the number of users with Bad and Suspect risk-level escalations.

## Integrate Threat Analytics

Symantec Threat Analytics integrates with Privileged Access Manager to evaluate the risk of privileged user activity to detect and mitigate threats from suspicious activity. Evaluation factors include the location of a privileged user, time and duration of activity, the system connections, and user history for security.

By persistently monitoring activity, Threat Analytics identifies the anomalies based on historical user behavior. The analytics server returns a risk level to PAM. The risk level can dynamically trigger activities, such as starting session recording or prompting the user to reauthenticate.

The integration of Symantec Threat Analytics and PAM is explained in the following topics:

### Threat Analytics and PAM Server Interaction

The two servers interact following this sequence:

#### 1. **PAM collect event data.**

PAM collects event data and forwards it to the threat analytics server. Events include:

- Logging in and out of the PAM appliance.
- Opening or closing a connection to a target device or endpoint

New event data is forwarded immediately. Entities other than PAM might also forward events for the same users.

#### 2. **Threat Analytics analyzes event data.**

The threat analytics server performs continuous analysis on the collected data. Each existing user has a *risk level* that is assigned one of the following values:

- Good
- Suspect
- Bad

For each new event, the received data is compared against past behavior for that same user. If the data is for a user without a threat server records, Symantec Threat Analytics prepares a new record. The service then begins compiling data for that user.

Based on continuous analysis and the historical data for a user, Symantec Threat Analytics might change the risk level. The server then return the result to Privileged Access Manager. Risk level changes do not always happen immediately after receiving event data; the change might occur later.

### 3. PAM applies mitigations

Depending on the returned risk level or changes to the risk level, PAM can take actions against users. These actions are called *mitigations*.

#### Mitigations Applied Against Threats

The risk level that Symantec Threat Analytics returns determines the actions which PAM takes against the user.

Risk Level	Mitigation
Good	None
Suspect	Session Recording Recording begins for any current connection session until the end of the session. The server records all future connection sessions in their entirety.
Bad	Re-authentication and Session Recording Any current login and device-connection sessions are suspended. PAM forces the user to re-authenticate by displaying a login window.  For all applets, session activity pauses and the applet window disappears. The reauthenticate window then opens. For any TCP service, such as PuTTY or OpenSSH, the terminal window remains open, but you cannot enter anything in it.

#### Session Recording Mitigations When Risk Level Changes

Session recordings span over time. When the user has a connection session in progress that is being recorded, the following rules also apply:

Risk Level	Changes To	Behavior
Good	Suspect or Bad	<ul style="list-style-type: none"> <li>A new recording of that session begins immediately.</li> <li>Recording continues until the end of that session.</li> <li>Subsequent connection sessions are recorded from beginning to end.</li> </ul>
Suspect or Bad	Good	<ul style="list-style-type: none"> <li>Recording continues until the end of that session.</li> <li>Subsequent connection sessions are not recorded, unless an applicable policy specifies session recording.</li> </ul>

#### NOTE

- [Deploy the Symantec Threat Analytics Server](#)
- [Enable Mitigation Actions](#)
- [Set up SAML Punch-Through Authentication \(Optional\)](#)

## Deploy the Symantec Threat Analytics Server

The Symantec Threat Analytics Server is distributed as an OVA virtual machine (VM) image. To integrate Privileged Access Manager with Threat Analytics, deploy the Threat Analytics Server as a VM image on a compatible virtualization environment in your network.

**WARNING**

If PAM is operating in FIPS mode, PAM servers can integrate only with Symantec Threat Analytics version 2.2.3 or later.

Beginning with version 2.2.3, the Symantec Threat Analytics server supports the TLS v1.2 protocol for secure communications. TLS v1.2 is required to work with PAM in FIPS mode.

To integrate PAM with Threat Analytics, complete the following procedures in order.

**Apply the Symantec Threat Analytics License**

Threat Analytics is a separately licensed component of Privileged Access Manager. If you are deploying a new appliance independently or in a cluster, you might already have a Symantec Threat Analytics license. Otherwise, follow these steps, to be done in the PAM UI, to activate Symantec Threat Analytics on your currently installed appliance.

1. Obtain a PAM license file with **Threat Analytics** licensing activated from Broadcom support.
2. Log in to PAM UI as **super**, or an account with an equivalent role such as Global Administrator.
3. Navigate to **Configuration, Licensing**.
4. In the **Install New License** tab, use **Choose File** to browse for the license file.
5. Select the correct file, and then select **Upload License File**.
6. In the pop-up dialog, select **Save New License**.
7. Under **Configuration, Licensing, Current License**, confirm that the "Threat Analytics Capability" item is set to "Enabled."
8. Repeat these steps for each appliance in a cluster.

**Deploy the Symantec Threat Analytics Server VM**

Deploy the Threat Analytics Server virtual machine image on any virtualization environment that supports OVAs.

Complete the following steps to install the server in a virtual environment:

1. [Verify the Virtual Machine Requirements](#)
2. [Download the Symantec Threat Analytics software](#)
3. [Deploy the Threat Analytics VM on the Virtualization Environment](#)
4. [Configure NTP for the system time](#)
5. [Set up networking](#)
6. [Configure the Threat Server SSL Settings](#)

***Verify That the Virtualization Environment Can Support the Threat Analytics VM Requirements***

For a production environment, verify that the virtualization environment can support the following minimum requirements for the Threat Analytics Server VM:

- CPU: Eight cores
- Memory: 16 GB
- Storage: One TB

***Download the Symantec Threat Analytics Software***

Download the software for this component from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

***Deploy the Threat Analytics VM on the Virtualization Environment***

Do this procedure to deploy the Threat Analytics VM on your virtualization environment.

**Follow these steps:**

1. Using the import tools available in your virtualization environment, import the Symantec Threat Analytics OVA. Create a virtual machine with at least the minimum production requirements. For more guidance on how to size the virtual machine, contact Broadcom Support.
2. Start the virtual machine.
3. In the VM console window, a blue menu screen is displayed. Click the blue screen and switch to the login screen by pressing the **Ctrl+Alt+F2** keys simultaneously. If that fails to open the Linux console, press **Alt+Fn+F2** simultaneously.
4. Log in to the Linux console.
  - The default login credentials for the 2.4.x version are *interlock/interlock*.
  - The default login credentials for the 2.3.x version are *root/8iyhko6kx*.
5. After first-time login using default credentials, change the password of the system users as follows:
  - For the 2.4.x version, run *sudo bash* to become the root user.
  - Run *passwd interlock* to set the interlock user password.
  - Run *passwd root* to set the root user password.

**NOTE**

SSH access to the Symantec Threat Analytics server is disabled by default. Use the VM console to access the Linux console for SSH access if necessary.

**Configure NTP for the System Time**

Symantec Threat Analytics requires the system time to be set, and is preconfigured to use public NTP. If you do not have access to public NTP servers, use an internal NTP server to enable the time synchronization with the virtualization host.

**Follow these steps to configure NTP for the System Time:**

1. Log in to the Symantec Threat Analytics Linux console as a root user.
2. Type `date -R` to see the current date and time. Use the `-R` to get a standard unambiguous format.
3. Edit the `ntp.conf` file using the following command on a terminal with root privileges:  
 Command to run on 2.4.x: `sudo vi /etc/ntpsec/ntp.conf`  
 Command to run on 2.3.x: `sudo vi /etc/ntp.conf`
4. Add the following line to the configuration file:  
`server <IP_of_NTP_Server> prefer iburst`
5. Restart the NTP service by running the following command on a terminal with root privileges:  
 Command to run on 2.4.x: `sudo systemctl restart ntpsec`  
 Command to run on 2.3.x: `sudo service ntp restart`
6. To check the NTP service, run the following command:  
`sudo ntpq -p`
7. Log out of the VM console by typing **exit** to return to the login prompt.
8. Return to the network configuration screen by pressing the **Ctrl+Alt+F1** keys simultaneously. If that fails to return to the configuration screen, press **Alt+Fn+F1** simultaneously.

**Set up Networking for the VM**

Networking for the VM environment can be set from the main VM console window, with no need to log in.

**IPv6 is supported in Symantec Threat Analytics 2.4.0 onwards. Support for IPv6 is not added to Symantec Threat Analytics 2.3.x versions.**

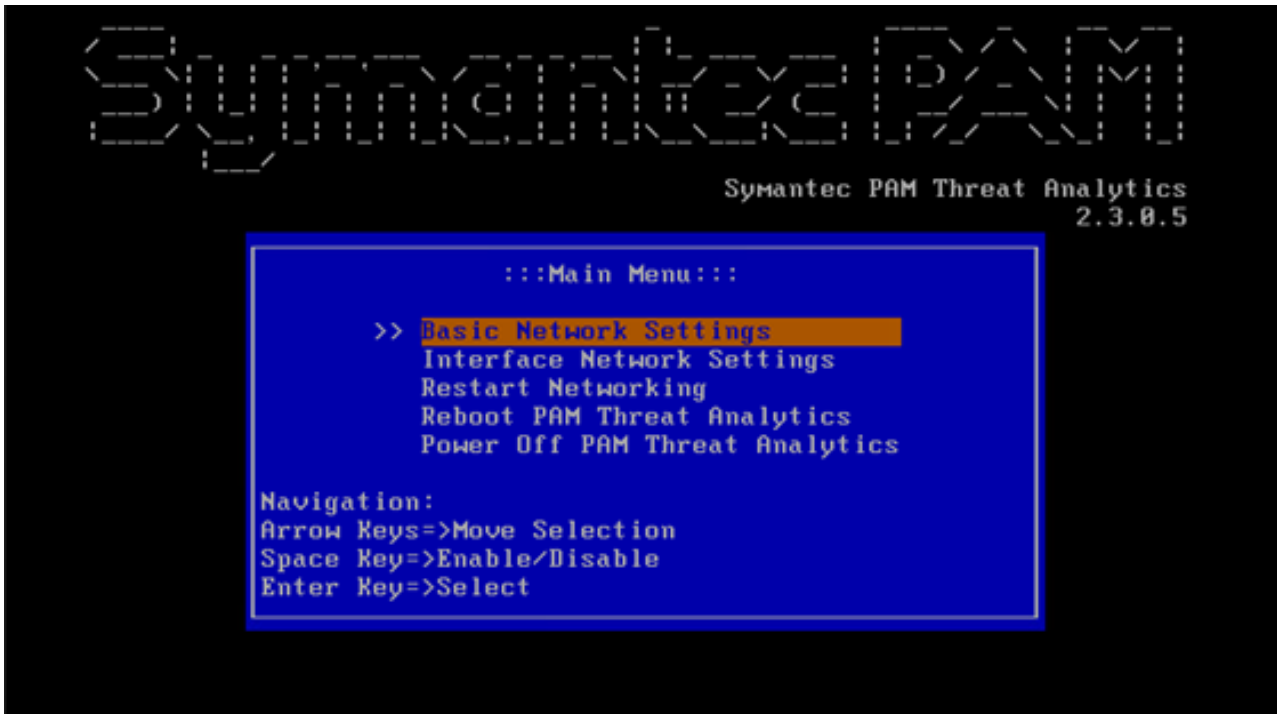

The 2.4.x console UI is shown in the following screen:

Six options are listed on this screen:

- Basic network settings
- IPv4 interface network settings
- IPv6 interface network settings
- Restart networking
- Reboot PAM Threat Analytics
- Power off PAM Threat Analytics

The 2.3.x console UI is shown in the following screen:

Five options are listed on this screen:

- Basic network settings
- IPv4 interface network settings
- Restart networking
- Reboot PAM Threat Analytics
- Power off PAM Threat Analytics

Use the following controls to navigate the menu:

- Use the Arrow keys to move the selection.
- Use the Space key to enable/disable.
- Use the Enter key to select.

### ***Configure the Threat Server SSL Settings***

The Symantec Threat Analytics OVA ships with a default JKS that contains a self-signed certificate. This JKS allows the threat server to work after the initial installation, and it is appropriate for test instances. To be cryptographically secure and trusted in production, replace the default JKS with one containing your own security certificate. If you decide not to use SSL, select the **SSL Validation off** box during the configuration of PAM for Symantec Threat Analytics.

Use one of the following procedures to set up SSL on the Threat Server:

1. [Create a Java Key Store file](#)
2. [Set up SSL settings](#)

### **Create a Java Key Store File**

The Symantec Threat Analytics OVA ships with a default JKS that contains a self-signed certificate. This JKS file allows Symantec Threat Analytics to work upon the initial installation, and is appropriate for test instances. To be cryptographically secure and trusted in production, replace the default JKS with one containing your own security certificate.

**To create a JKS file, follow these example steps:**

The sample commands use the following placeholders:

- **CA**: PEM-encoded issuing certificate authority
  - **crt\_file**: PEM-encoded X.509 signed certificate file; **key\_file**: PEM-encoded X.509 private key file
  - **alias**: An arbitrary name (letters, numbers, dashes)
  - **p12\_file**: Filename for the temporary .p12 file
  - **jks\_file**: Filename for the resulting JKS file
1. Use the **openssl** command to combine the Certificate Authority, the signed certificate, and a private key into a p12 file.
 

```
openssl pkcs12 -export -in <crt_file> -inkey <key_file> -out <p12_file> -name <alias> -CAfile <CA> -caname root
```
  2. Use the **keytool** commands to convert the p12 file into a keystore.
 

```
keytool -importkeystore -destkeystore <jks_file> -srckeystore <p12_file> -srcstoretype PKCS12 -alias <alias>
keytool -import -alias root -keystore <jks_file> -trustcacerts -file <crt_file>
```

**Set up the SSL Settings**

After you generate a new JKS file, set up the SSL configuration.

**Follow these steps:**

1. Access the Symantec Threat Analytics Administration UI. For example: **https://ServerIPaddress:3000**
2. Log in with the user name *admin* and password P@ssword1234.
3. Change the password using the Password tab.
4. Go to the **Security** tab.
5. In the **JKS File** field, select **Choose File** and upload a JKS file. A valid JKS file has an X.509 server certificate and trust chain. For more information, see [Create a Java Key Store File](#).
6. In the **Server Alias** and **JKS Password** fields, enter the appropriate values.
7. Verify that the **SSL Protocols** field is set appropriately. The default values are TLS v1 and TLS v1.2.
 

**NOTE**

If PAM is operating in FIPS mode, TLS v1.2 is required for secure communications. TLS v1.2 is available only with Symantec Threat Analytics version 2.2.3 onwards.
8. Select **Save**.
9. Navigate to the Symantec Threat Analytics Administration home.
10. Restart the Threat Analytics Engine by clicking its **Restart** button.

**Deploy Symantec Threat Analytics in Azure*****Prerequisites***

Privileged Access Manager instance or cluster that is deployed in Azure and licensed for Symantec Threat Analytics.

***Upload Symantec Threat Analytics VHD to a Storage Account***

The following steps assume you have access to a **Storage Account** previously created for storing a Privileged Access Manager VHD as outlined in [Deploy a VHD to Azure](#). If you must create a new **Storage Account**, ensure that its **Resource Group** and **Location** are the same as the **Resource Group** and **Location** containing your Privileged Access Manager instance or the Primary Site of your Privileged Access Manager cluster.

**Follow these steps:**

1. From the Azure Portal, navigate to the **Storage Browser** panel.
2. On the left-hand menu, select the storage bucket from the Storage Browser.

3. Select the **Container** bucket used to store the Privileged Access Manager VHD. If no bucket exists, you can create a new one.
4. In the selected **Blob Containers**, select the folder that you would like to choose and click **Upload**.
5. Under **Files**, select the Symantec Threat Analytics VHD on your local system, and then click the Upload button to upload the VHD to Azure.

### **Create a Managed Disk for Symantec Threat Analytics**

Follow these steps:

1. Enter "disks" in the search field at the top of the Azure Portal.
2. Select **Disks**.
3. On the **Disks** page, select the **+Add** button to add a new Disk.
4. Provide a **Name** for the disk.
5. For **Resource Group**, select "Use Existing," and then select a Resource Group.
6. For **Region**, select the same location as your Storage Account. Create a disk in the same location as the storage account where you uploaded your VHD.
7. For **Account Type**, select "Premium (SSD)."
8. For **Source Type**, select "Storage Blob."
9. In the **Source Blob** field, use the Browse button to select the VHD you uploaded in the previous step. Select the Storage Containers and then VHD. Click **Select**.
10. For **OS**, select Linux.
11. For **VM generation**, select Gen 1.
12. For **Size (GiB)**, enter at least 1024.
13. Select **Create**.

### **Create the Symantec Threat Analytics Virtual Machine**

Follow these steps:

1. On the **Disks** page, select the newly created Symantec Threat Analytics disk.
2. Select **+Create VM**. The **Create Virtual Machine** panel appears.
3. In the **Basics** tab, enter a Name for your VM.
4. For **Resource Group**, select "Use Existing" and select your Resource Group.
5. **Region** is disabled because it is determined by the disk Storage Account Location.
6. Select a machine Size that meets the minimum requirements for Symantec Threat Analytics. See Machine Requirements for more information.
7. Under **Select Inbound Ports**, ensure that only ssh (22) and https (443) are selected.
8. Select the **Networking** tab.
9. For **Virtual Network** and **Subnet**, use the same Virtual Network and Subnet that contains your Privileged Access Manager instance or the Primary Site of your Privileged Access Manager cluster.
10. For **NIC Network Security Group**, select Advanced.
11. Under **Configure Network Security Group**, select **Create New**.
12. Select **Add an inbound Rule**.
13. To access the Symantec Threat Analytics Administration UI, add a rule for **Destination Port** of 3000 with TCP selected for **Protocol**.

#### **NOTE**

Create public IPv6 in Azure "All Services" and select the IPv6 resource in the **Networking** tab. This step is optional.

14. Select **OK** to return to the Network tab.
15. Select the **Tags** tab.

16. Add a new **Tag** with the **Name** "PAMIgnore" and the **Value** of "true." Under **Resources**, ensure that only "Virtual Machine" is selected. This setting prevents PAM from importing the Symantec Threat Analytics VM as a standard target device if the "Sync Virtual Machines" option is enabled for the PAM Azure Connection.
17. Select **Review + Create**.
18. Verify the settings on the **Summary** page and then select **Create** to finish. Deployment begins. To monitor its progress, you can select the **Notifications** bell icon in the upper right.

### **Configure Symantec Threat Analytics**

Configuring Symantec Threat Analytics requires configuration on the PAM appliance and the Symantec Threat Analytics. The final steps to configure Symantec Threat Analytics are to:

1. [Enable the PAM External API](#)
2. [Configure the Threat Engine to use the Adapter](#)
3. [Specify the Symantec Threat Analytics Server to Use](#)
4. [Threat Analytics and Admin Users](#)

#### ***Enable the External API***

Enable Symantec Threat Analytics to communicate with Privileged Access Manager using its API. The account password can be updated and used for the Threat Analytics configuration. **Follow these steps:**

1. In the PAM UI, navigate to **Configuration, Security, Access**.
2. Select **Enable** for the **External REST API** setting.
3. Select **Save**. This message appears: External API Access has been updated successfully.
4. Select **Configuration, Licensing, Current License**. Confirm that the PAM license has "Threat Analytics Capability" set to "Enabled."
5. Select **Credentials, Manage Targets, Accounts**.  
After applying a PAM license that enables Threat Analytics Capability, an API key with an account name of the format CATapApiUser-x (for example, CATapApiUser-2001 ) is created automatically.  
This account contains credentials that are used by Symantec Threat Analytics to complete the configuration. Under the **Action** column, select the **eye** icon to view the password and copy it for later use.
6. The password for this account can be updated by selecting this account and clicking the Update button. This password is used later while configuring the Threat Analytics engine for PAM.

#### ***Configure the Threat Engine to Use the Adapter***

Specify the PAM adapter for the Threat Server on the Symantec Threat Analytics server. **Follow these steps:**

1. From a browser, access the Symantec Threat Analytics engine. For example, `https://threat_server_ip_address`
2. Log in as **admin** with password **P@ssword1234**. (Change this default password!)
3. Navigate to **Services**.
4. Select Privileged Access Manager from the Services list.
5. Select the **Configuration** tab.
6. Specify the values for the following API connection parameters:
  - **Host:** The IP Address or hostname of the PAM instance (Do not include https://)

#### **NOTE**

If PAM is a cluster configuration, then the PAM primary VIP address must be used as the host. If a literal IPv6 address is used to identify the PAM instance, then the literal IPv6 address should be enclosed in square brackets. For example: `[fd6d:8d64:af0c:1::13ad]`

**IPv6 support is added in Symantec Threat Analytics 2.4.x onwards.**

- **Username:** The username of a user with Symantec Threat Analytics API Access (such as CATapApiUser-x ; for example: CATapApiUser-2001 )
  - **Password:** The password of the user with access to the Symantec Threat Analytics API. Use the password that you copied from the CATapApiUser-x Account in PAM.
7. Select **Test** to validate the provided parameters and verify connectivity to PAM.
  8. Once validated, select **Save Configuration**.
  9. While still in Services Privileged Access Manager, select the **Auth Tokens** tab. This step generates the API Auth Token.
  10. Select **New Auth Token**.
  11. In the window, provide a token **Name** and an optional **Description**.
  12. Select **Create Token**.  
A page displays with the generated token and Service Identifier.
  13. Save the token.
  14. Copy or download the token and Service Identifier. You need both to set up the Symantec Threat Analytics server in the PAM UI.
    - To copy the token, copy both strings from the token confirmation window that is displayed after saving it.
    - To download the token to another location, select **Download Token**.
  15. Close the New Auth Token confirmation window.

**Specify the Symantec Threat Analytics Server to Use**

Specify the Symantec Threat Analytics service that receives the user data from PAM for processing. **Follow these steps on each instance:**

1. Log in to the PAM UI and navigate to **Configuration, Symantec Modules, Threat Analytics**.
2. Enter values for the following fields:
  - **Threat Analytics Address:** Enter an IP address or FQDN for the server hosting the service.

**NOTE**

For IPv6 addresses, do not enclose the address in square brackets. For example, fd8d:8d64:af0c:1::

**IPv6 support is added in Symantec Threat Analytics 2.4.x onwards.**

- **Threat Analytics Authentication Token:** Enter the authentication token string that is generated by the Symantec Threat Analytics server. Get this string from the Threat Server administrator. This token is analogous to a password for access to that server.
- **Threat Analytics Service ID:** Enter the service identifier string that is generated by the Symantec Threat Analytics server. Get this string from the Threat Server administrator. This identifier is analogous to a username for the server.

**NOTE**

A Threat Analytics Server administrator can find the Authentication Token and Service Identifier in the downloaded Token file.

- Optionally, to turn **SSL Validation off**, select this checkbox.
3. Select **Save**.
  4. Test the validity of the connection by selecting **Test**. Wait for a configuration message that the connection is successful.

**Threat Analytics and Admin Users**

Licensing Threat Analytics creates the TAP Administrators group (Threat Analytic for PAM Administrators Group).

**NOTE**

If you already have a User group named "TAP Administrators" in your environment, delete it or rename it to avoid a duplicate group name violation error.

All new or existing users with either the Global Administrator or the Operational Administrator role are automatically added to this group. Similarly, users that lose these roles are automatically removed from this group. Removing the Threat Analytics license deletes the TAP/Threat Analytics for PAM Group. This group cannot otherwise be modified or deleted. The TAP policy gets created with this TAP group and TAP device.

**NOTE****Next Steps:**

- [Enable Mitigation Actions](#)
- [Set up SAML Punch-Through Authentication \(Optional\)](#)

## Enable Threat Analytics Mitigation Actions

Enable mitigations to configure Privileged Access Manager to act in response to the risk level returned by the Symantec Threat Analytics server. For more information about mitigation actions, see [Integrate with Symantec Threat Analytics](#).

### Enable Mitigations

To enable mitigations, follow these steps:

1. From the Privileged Access Manager UI, navigate to **Settings, Global Settings**.
2. Select the **Threat Analytics** tab.
3. Set the **Enable Mitigations** option.
4. Select the **Save** button at the bottom of the pane to activate mitigation actions, effective immediately.

### *Display a Warning Message*

Optionally, display a message near the top of their landing page when a user logs in warning them that data about their activities is being collected.

Follow these steps:

1. Navigate to **Settings, Global Settings**.
2. Select the **Threat Analytics** tab.
3. Set the **Show Analytics Warning** option.  
Optionally, enter a custom warning message in the text field that appears or accept the default message.
4. Select the **Save** button at the bottom of the pane to activate warning messages, effective immediately.

### Risk Level Color Indicators for Session Recordings

To identify sessions that are indicated as a risk, PAM uses color indicators for the session recording entries.

Privileged Access Manager starts session recording in response to a Suspect or Bad risk level assessment. Each recording entry is marked with a color-coded dot (.) in the Risk column. This indicator identifies the threat level at the time recording was activated.

**NOTE**

These indicators only apply when Symantec Threat Analytics is enabled. No color indicators are applied when the relevant user-device policy specifies session recording.

The following table lists the color indicator for the risk level of a new recording. All entries are for a user with a connection session to a target device. The user is already being recorded and the risk level changed.

Changed Risk Level	Color Indicator	Notes
Good to Suspect	Yellow dot	Indicator remains following completion of the recording, even when the risk level changes back from Suspect to Good.
Good to Bad	Red dot	Indicator remains following completion of the recording, even when the risk threat level changes from Bad to Suspect or to Good.
Suspect to Bad	Yellow dot (Red only if Bad level remains)	The ongoing recording is uninterrupted, and the recording entry remains marked with a yellow dot. This indicator remains even when the level changes back from Bad to Suspect or to Good.  If the threat level remains Bad at the time a new recording is started, that recording is marked with a red square.

In general, when the risk level is elevated as a session recording starts, the applicable indicator is applied to that recording entry.

### Filter Recordings

You can filter the Session Recordings page to display only those recordings that are triggered following an increase in the risk level. You can also filter by timestamp and violation tags.

#### Follow these steps:

1. Navigate to **Sessions, Session Recordings**.
2. Select in the **Search** field. A drop-down panel appears.
3. Apply one or more filters to restrict the list of entries:
  - **Date and Time:** Enter a date or time in one or both of the **From** and **To** fields. Enter the value as formatted in the recordings list. Use a full date-time specification. For example: 2016-10-26 15:01:36 GMT +0300 or a portion of that string that can be interpreted starting from the left, such as:
    - Date and time only: 2016-10-26 15:01:36
    - Date only: 2016-10-26
  - **Socket or command filter violations:** Restrict the list to only socket or command filter violations. Select the **Contains violation** filter to display only those entries.
  - **Risk level.** Restrict the list to a specific risk level. Select one or more risk levels to see only those entries. To select more than one value, hold down the Ctrl key and select each option.

To remove a filter, select the corresponding **Clear** link.

## Set up SAML Authentication (Optional)

To allow authorized Privileged Access Manager users to authenticate seamlessly to the Threat Analytics server, set up SAML-based authentication on the server. This seamless authentication is known as *punch-through authentication*. SAML authentication is optional, but it is a convenient way to connect to the threat analytics server.

**NOTE**

After you configure SAML authentication, you can still log in to the Threat Analytics UI as the local admin user. Keep the admin user account. If the SAML integration fails, you might need to access the Threat Analytics UI as the admin user. To log in as the admin user, navigate to [https:// server\\_ip\\_address/users/sign\\_in](https://server_ip_address/users/sign_in).

To set up SAML authentication between the appliance and the Symantec Threat Analytics UI, complete these tasks:

**Enable the Appliance SAML IdP Configuration**

**Follow these steps to enable the IdP:**

1. In the UI, select **Configuration, Security, SAML**.
2. On the SAML page, select **IdP Configuration**.
3. Select the **Enable IdP** button.  
A message appears indicating that the system is rebooting. You are returned to the log in screen.
4. Log in again and return to the IdP Configuration page.
5. Set the **Entity ID**. The Entity ID must be an HTTPS URL that identifies this appliance instance. This ID is included in assertions that the IdP generates to identify itself. The ID is also included in the metadata file. Example: <https://idp.forwardinc.com>.
6. Specify the **Fully Qualified Hostname**. Specify the Privileged Access Manager domain without the protocol prefix. For example: [idp.forwardinc.com](https://idp.forwardinc.com)
7. Select the **Signature Algorithm**.
8. Select the **IdP Certificate** from the drop-down list.  
If PAM is operating in FIPS mode, use your own FIPS-compliant certificate. Do not use the default certificate that is provided with PAM.
9. After the fields are complete, select **Update IdP Configuration**.  
An update confirmation message appears.
10. Select **Download IdP Metadata** and save the XML metadata file.

**Configure SAML Authentication on the Symantec Threat Analytics Server**

**On the Symantec Threat Analytics server, follow these steps to configure SAML authentication:**

1. Launch the Symantec Threat Analytics Administrative Application. For example: [https://server\\_ip\\_address:3000](https://server_ip_address:3000)
2. Log in with the username "admin" with the default password "P@ssword1234."
3. Change the default admin password on the **Password** tab.
4. Navigate to the **Security** page.
5. In the lower half of the page, complete the following fields:
  - **Authentication Mode:** SAML
  - **SAML Metadata File:** Select Browse and locate the metadata file from Privileged Access Manager. For example: [idp-metadata.xml](#)
  - **Domain name or IP address or TAP server:** Enter the fully qualified domain name or IP address of the Symantec Threat Analytics server.

**Authentication Mode**

**SAML Metadata File**

**Domain name or IP address of TAP server**

6. Select **Save**.  
The content of the IdP metadata file appears in the fields. Select the status of the services. Ensure that you see **active** next to the services before continuing. You might need to refresh the page.
7. Select the Threat Analytics Administration next to the CA logo to return to the main page of the application.
8. Restart the following Symantec Threat Analytics services *in the following order*:
  - PostgreSQL Database
  - Threat Analytics Engine
 Each service has a **Restart** button.

### Access the Threat Analytics Server

After you configure SAML punch-through authentication and SAML authentication at the Threat Analytics Server, you can access the server through the UI.

#### **Follow these steps:**

1. Access the appliance UI. Note the following requirements when you access the appliance:
  - If you access the appliance from a web browser, the URL must contain the same value as the **Fully Qualified Hostname** setting in the IdP configuration. For example, if the Fully Qualified Hostname value is **idp.forwardinc.local**, the URL must be **https://idp.forwardinc.local/cspm/home**.
  - If you access the appliance from the CA PAM Client, on the Client login page, set the **Address** field to **idp.forwardinc.local**.
2. Log in to the UI. Inspect the **Dashboard Overview Tab** that now includes a **Threat Analytics** icon located at the center/bottom of the dashboard.
3. Select this icon to connect to the Symantec Threat Analytics server. Successful access to the server verifies that users can authenticate to the server.

## Configure Threat Analytics Using the Admin Dashboard

This content describes how to configure required Threat Analytics configuration settings using the Threat Analytics Admin Dashboard.

### Log in to the Threat Analytics Admin Dashboard

To login to the Threat Analytics Admin Dashboard, follow these steps:

1. Log in to the Privileged Access Manager UI using an account with Threat Analytics administration privileges.

2. Select the **Access** link on the menu bar to open the **Access** pane, which should include Threat Analytics-related entries as shown in the following screen capture:

Symantec Privileged Access Manager

First name Last Name System Info Logout

Dashboard Access Sessions Users Services Devices Credentials Policies Secrets Settings Configuration

Warning: PAM-CMN-1018: Configuration Password is still the default value.

Devices

Column: Value: Filter Reset Add Filter My Views

Restart Session

Device Name	Address	Operatin	Access Methods	Web Portal	RDP Applications	Services	Target Applications
TAP	10.17.40.160	Other		TAP Admin Dashboard			
tap.ca.com	10.17.40.160	Other		TAP-SAML-Service			

3. Select the **TAP Admin Dashboard** button.
4. When prompted, log in as "admin" using the Threat Analytics administrator password. (The default is "P@ssword1234," which is only intended for the first-time access).

#### NOTE

After initially logging in using the default password, immediately create a new password, as described in [Changing the Admin Password](#).

5. Select the **Sign In** button.

The **Current Status** pane opens, providing the following information:

- The status of the Threat Analytics engine
- The Threat Analytics Admin application
- The Postgre SQL database
- Restart buttons for all three functions if needed.
- All current system information, which is grouped by the following statistics:
  - Current system information, describing the number of cores installed, the current load, and three load averages
  - Current memory statistics, including the total size, how much is being used and how much is available
  - The size of the actual free and shared space in the system
  - The buffer and cache sizes
  - How many Threat Analytics services are running and how much CPU and memory that they are consuming
  - A summary of current disk usage

### Change the Admin Password

To change the Threat Analytics Dashboard password, use the **Password** menu on the **Current Status** pane.

#### IMPORTANT

Change the default password ("P@ssword1234"), immediately after you use it to log in to the dashboard for the first time.

#### Follow these steps:

1. Log in to the PAM UI using an administrator account with the required privileges.
2. Navigate to Configuration, Diagnostics, **Diagnostics Logs**.
3. Enter a new password in the **New Password** field.
4. Enter the new password again in the **New Password Confirmation** field.
5. Select the **Save** button.

### **Upload PAM Analytics Log Files**

By default, Threat Analytics must read all the analytic data from PAM to obtain the previous history of the network. This task must only be done once when Threat Analytics is initially deployed. Loading this data is not required, since Threat Analytics can acquire this data from PAM on its own. However, adding this step dramatically increases how fast Threat Analytics completes its initial "learning" of the PAM environment.

**To obtain the analytics log from the PAM server, follow these steps:**

1. Log in to the PAM UI using an administrator account with the required privileges.
2. Navigate to **Configuration, Diagnostics, Diagnostics Logs**. The **Diagnostic Logs** pane opens.
3. Select the **Download** tab.
4. Select the **Download** button beside the **Analytics Logs** entry.
5. On the **Save** dialog that opens, specify a download directory for the `analytics.logs` file and select the **Save** button.

**To upload the analytics log file into Threat Analytics, follow these steps:**

1. From the Threat Analytics Admin Dashboard **Current Status** pane, select the **Reference Data** menu.
2. Select the **Choose File** button and then locate and select the `analytics.logs` file that you downloaded from PAM.
3. Select **Save**.

The analytics log file is uploaded.

### **Execute Custom Task Files**

If requested to do so by Broadcom Support, you can execute custom task files on the Threat Analytics SQL databases.

**To execute custom threat analytics tasks on the Threat Analytics SQL data base, follow these steps:**

1. From the Threat Analytics Admin Dashboard **Current Status** pane, select the **Tasks** menu.
2. Enter the name of the task that you want to run in the **Tasks** text block.
3. Select the **Run** icon.

The task is executed.

### **Set Up the Security Environment**

To upload Threat Analytics SSL security certificates that are stored in a Java Key Store (JKS) file, use the **Security** menu. On the top section of the pane, you can browse to a JKS file, select it, and then provide your service alias and the key store password. After you select **Save**, you will see detailed information about the security of your network.

**To access information about the security of your PAM network, follow these steps:**

1. From the Threat Analytics Admin Dashboard **Current Status** pane, select the **Security** menu on the Status pane
2. Select the **Browse** button and select the name of the JKS file.
3. Enter the name of the Java Key Store file in the **JKS File** field.
4. Provide the **Server Alias** name (typically "admin").
5. Enter the password for the JKS in the **JKS Password** field.
6. Select the **Save** button.

The following key characteristics of the security environment are displayed:

- **Authentication Mode:** Typically Security Assertion Markup Language (SAML)
- **Assertion Consumer Service URL:** For example, `https://pamtap22.forwardinc.ca/users/saml/auth`.
- **Identity Provider SSO (Single Sign-On) Target URL:** For example, `https://pam34.forwardinc.ca/idp/profile/SAML2/Redirect/SSO`.
- **Identity Provider Entity ID:** For example, `https://pamtap34.forwardinc.ca`.
- **Identity Provider Certificate Fingerprint :** For example, `bfa95c8a41354b1i43ae6bed0d7853a6774bc1`.
- **Assertion Customer Service Binding :** For example, `urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect`.
- **Identity Provider Certificate:** Approximately 25 lines of alpha-numeric characters.
- **Issuer:** For example, `https://pamtap22.forwardinc.ca`.
- **Compress Request?:** Yes or No.
- **Sign Authentication Requests?:** Yes or No.

To clear the fields in the security pane so that new information (JKS, alias, etc.) can be entered, select the **Reset** button. This step essentially deletes the current configuration if you click **Reset** and then saves it.

To verify the existing security setup so that the connection between PAM and TAP is verified, select the **Test Connection** button. If the customer is seeing errors in their environment, knowing that the connection is successful and verified greatly reduces troubleshooting time.

### **Set Up a Database Backup Schedule**

To set up where and when to save your remote backups and to restore backup data, use the **Backups** menu. In three sections, you can specify daily the **Backup Destination**, specify the **Backup Schedule**, and perform **Restore Backup** operations.

**To set up and restore backups, follow these steps:**

1. At the top right of the screen, select the **Create a New Backup** button.
2. In the **Backup Destination** section, select the **Enable remote backups?** checkbox and enter a Secure Copy Protocol (SCP) user name.
3. Enter the private key in the **Private Key** text box.
4. Enter the hostname of the target server in the **Target Server** field and the path of the target directory.
5. Select the **Set Destination** button at the right.
6. In the **Backup Schedule** section, enter the time of each day's backup and select the **Reschedule** button.
7. In the **Restore Backup** section, select the **Browse** button and choose the files that you want to restore. Then select the **Restore** button.

In the section at the bottom of the **Backups** menu, you see the date and time of the last restore operation. Following that entry is a list of compressed backup files and their creation date, time, and size, each with their own set of **Download**, **Delete**, and **Restore** buttons.

### **Sign Out from the Settings Menus**

To return to the sign-in page, select the **Sign Out** menu. Then select the **TAP-SAML-Service** button from the **Access** menu and you return to the main PAM display, from which you can open the Threat Analytics Console (described in [Launching the Threat Analytics Console](#)).

### **Enable Admin Privileges for Users**

To provide Threat Analytics administration privileges to other existing users, use the **Access** pane. This example enables an existing user named "super."

**Follow these steps:**

1. Select the **Access** menu from the PAM menu bar at the top left of the screen. This menu offers the choice of going to the Admin Dashboard or going directly to the Threat Analysis Console.
2. Switch from **TAP-SAML-Service** to the **TAP Admin Dashboard**.
3. Log in as "admin" using the administrator password. (The default is P@ssword1234).
4. Select the gear icon in the top right of the window and then select **Settings**.
5. Under the **User Accounts** menu tab, find the "super" user that is generated from the SAML logins from PAM, as shown in the following table:

[+ Add User](#)

Login	Email	Admin	Enabled	Locked	Source	Last Login Time	Last Login IP	Actions
admin	admin@localhost.local	✓	✓		interlock	Jul 1, 2022 11:14 AM	127.0.0.1	<a href="#">Edit</a> <a href="#">Delete</a>
sg912053	sam.grant@broadcom.com	✓	✓		interlock	No Logins	N/A	<a href="#">Edit</a> <a href="#">Delete</a>
super	super@pam.local	✓	✓		saml	Jul 5, 2022 7:33 PM	127.0.0.1	<a href="#">Edit</a>

6. In the "Actions" column of the table, select the **Edit** button for the user you want to have admin privileges.
7. On the **Edit User** page, select the "Enabled" and the "Admin" buttons, specify the priority of the **System Alerts**, **Service Alerts**, and **Risk Escalation Alerts**, and then select **Save**.
8. Log back into Admin Dashboard and change the authentication back from **TAP Admin Dashboard** to **TAP-SAML-Service**.

**Launch the Threat Analytics Console**

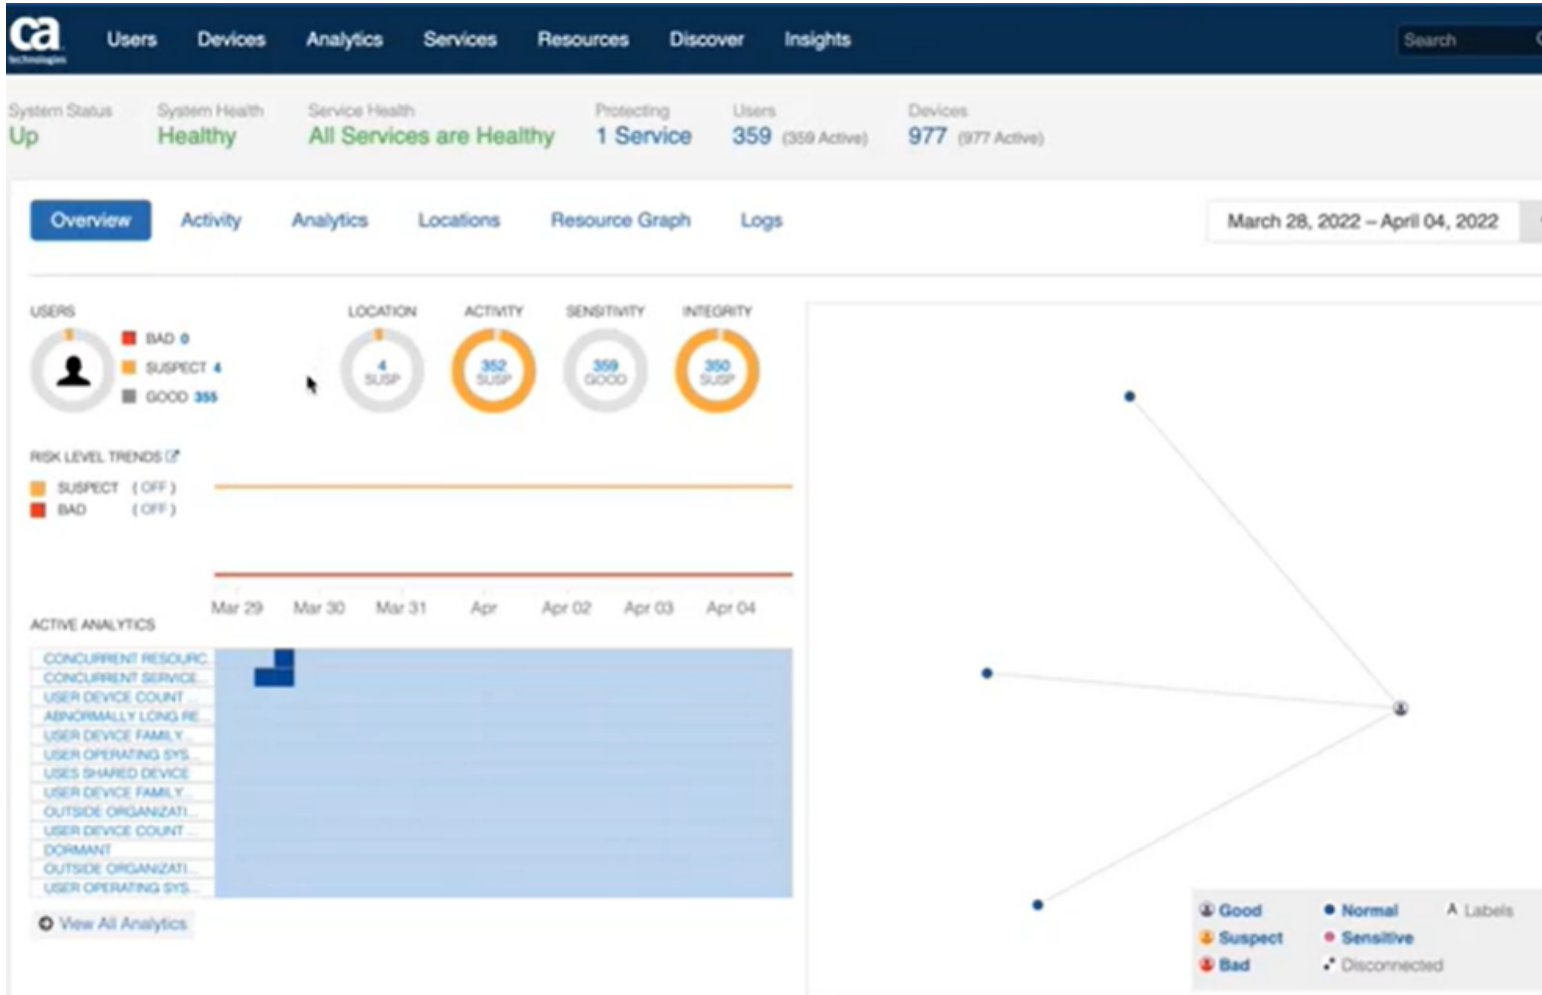

To launch the Threat Analytics Console, open the PAM UI and select the **Threat Analytics** button that is located at the bottom center of the PAM **Dashboard** panel located on the **Dashboard Overview Tab**.

**Analyze User Activity and Analytics**

The Threat Analytics Console opens with a set of six "Home" tabs that provide a big-picture view of the network threats that are encountered over a range of dates you can set (**Overview**), information about activity that is detected on the network (**Activity**), a list of analytics that have been triggered (**Analytics**), the locations of all users (**Locations**), a map of network resources (**Resource Graph**), and detailed logs of network traffic (**Logs**).

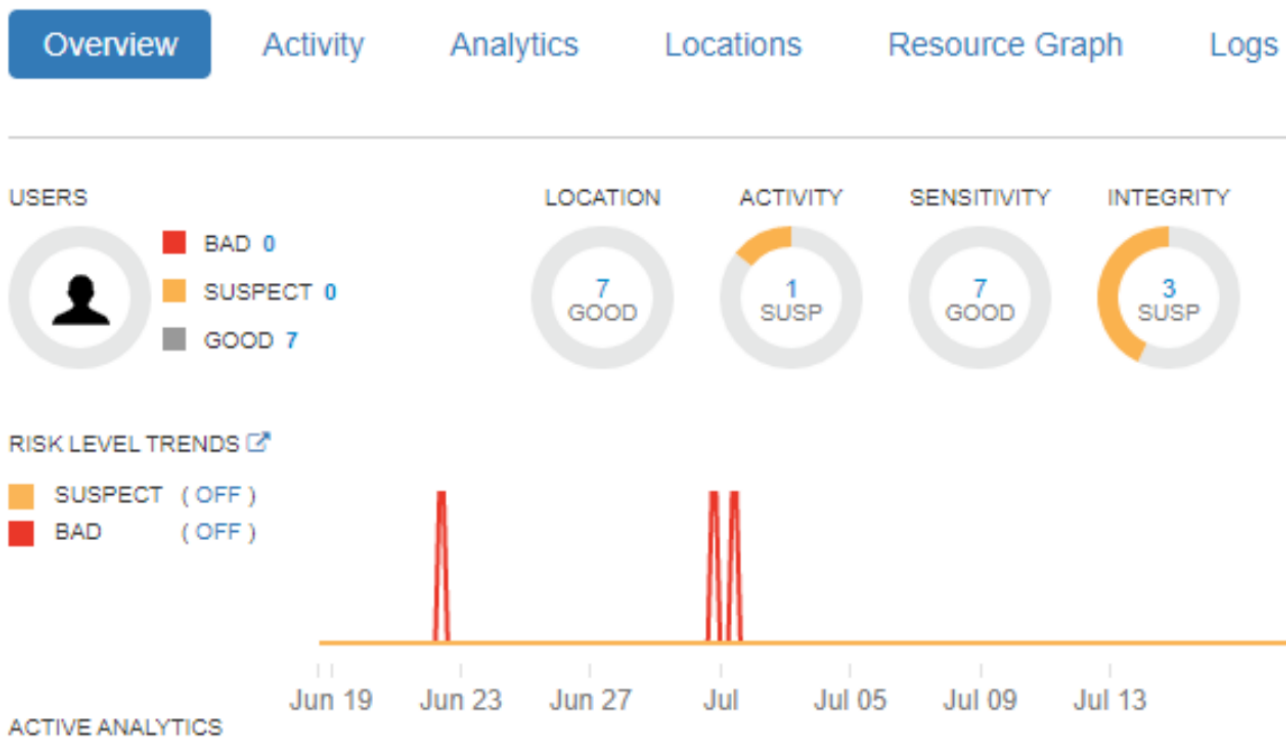

**View User and Network Threat Activity at a Glance**

The Threat Analytics Console appears with the **Overview** tab. This window presents a summary of network activity that is detected over a time period. This range of dates can be specified in the upper-right corner. You can set the start and end dates for the time to analyze, going back to the time you first installed PAM.

## Users and Security Classes

The total number of users in the PAM network appears in the top-left section of the **Overview** window. They are divided into three security categories: **Bad** (in red), **Suspect** (in yellow-orange), and **Good** (in gray). The four circles to the right of the **Users** icon represent how many users have triggered one of four different classifications of the 58 analytics: **Location**, **Activity**, **Sensitivity**, and **Integrity**. The classification of the analytics is described in detail in [Monitor Risk Analytics](#).

Select the blue numbers in each circle to see a list of all individual users that fall into each category. The red and yellow-orange bar graph below them highlights trends and incidents of possible threat activity over the selected time period. The preceding example shows a user with more associated devices than is typical, raising the status of the user to **Bad**. When that particular session ends, the status of the user returns to **Suspect**.

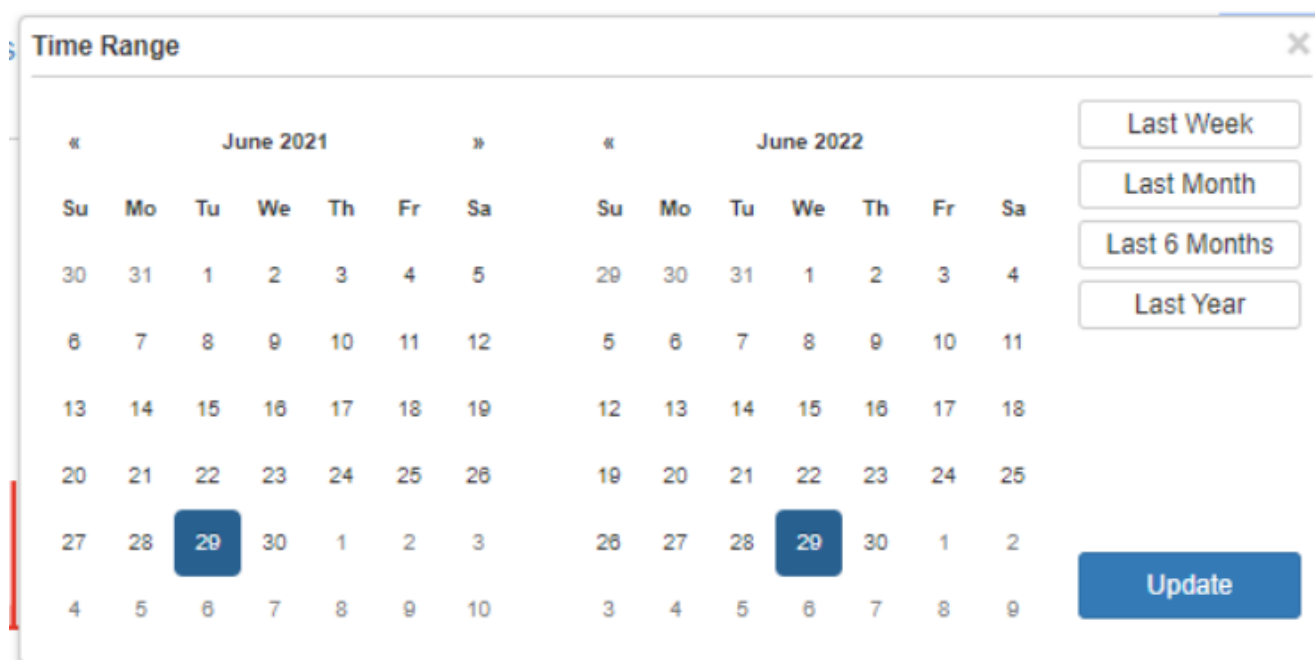

### Active Analytics and the Heat Map

The **Heat Map** on the **Overview** tab provides a list of analytics that were triggered over the designated time period that is specified at the top right of the screen.

When you select the down arrow, a **Time Range** panel that is similar to a calendar shows the starting year, month, and day and the ending year, month, and day of the desired range.

**Figure 61:**

In the heat map, the level of activity for each detected analytic in the time range is rendered as a bar graph. The activities include all four categories of analytics: **Location**, **Activity**, **Sensitivity**, and **Integrity**. The darker blue blocks show more frequent occurrences of the triggered analytic, the lighter shades of blue show fewer occurrences, and the white color means no occurrences on those days. Undetected analytics do not appear in the **Heat Map**. The example heat map shows 12 analytics that are detected over four weeks. Some analytics in the list are relatively minor, such as new users, new devices, and new device families. But others, such as “Bad Associated Risk Subject,” “Concurrent Resource Sessions,” “User Device Count—Population Limit,” and “New Risk Subject” could indicate potentially dangerous activity.

From the blue Active Analytics column on the left, you can select a particular analytic in the heat map to view each instance detected on the time line. The following example shows a list of five different devices that were “Associated with a Bad User” in a single day.

**Bad Associated Risk Subject Analytic Active Between Jun 22, 2022 12:00 AM - Jun 23, 2022 12:00 AM**

Object	Description	Time

You can also select the colored bars of each analytic in the **Heat Map** on the specific date and time to see all the analytics that were triggered that day.

Selecting specific analytics and dates in the heat map timeline can quickly isolate the exact moment when an analytic was triggered and why.

## Network Topology

The **Overview** tab includes a graph on the right pane that depicts the topology of the currently active PAM network, with head-and-shoulder silhouettes colored black (**Good**), yellow-orange (**Suspect**), and red (**Bad**). **Sensitive** and **Normal** users are designated by magenta and blue solid dots, respectively, and disconnected users are shown as a blue and a black dot.

The following example depicts a new **Suspect** user (in yellow-orange) who has accessed the network through one of the **Normal** users.

You can select any icon to get a **User Quick View** that displays the following information:

- The user name
- The date and time of last analytically detected
- The latest IP address of the user
- All the devices used

**User Quick View**

**Overview** Activity Analytics Locations Resource Graph Logs

## Examine All Network Activity in Detail

The **Activity** tab opens a list of network PAM sessions during the time period that is specified at the upper right, and also presents a bar graph that shows when and where those particular activities have been detected.

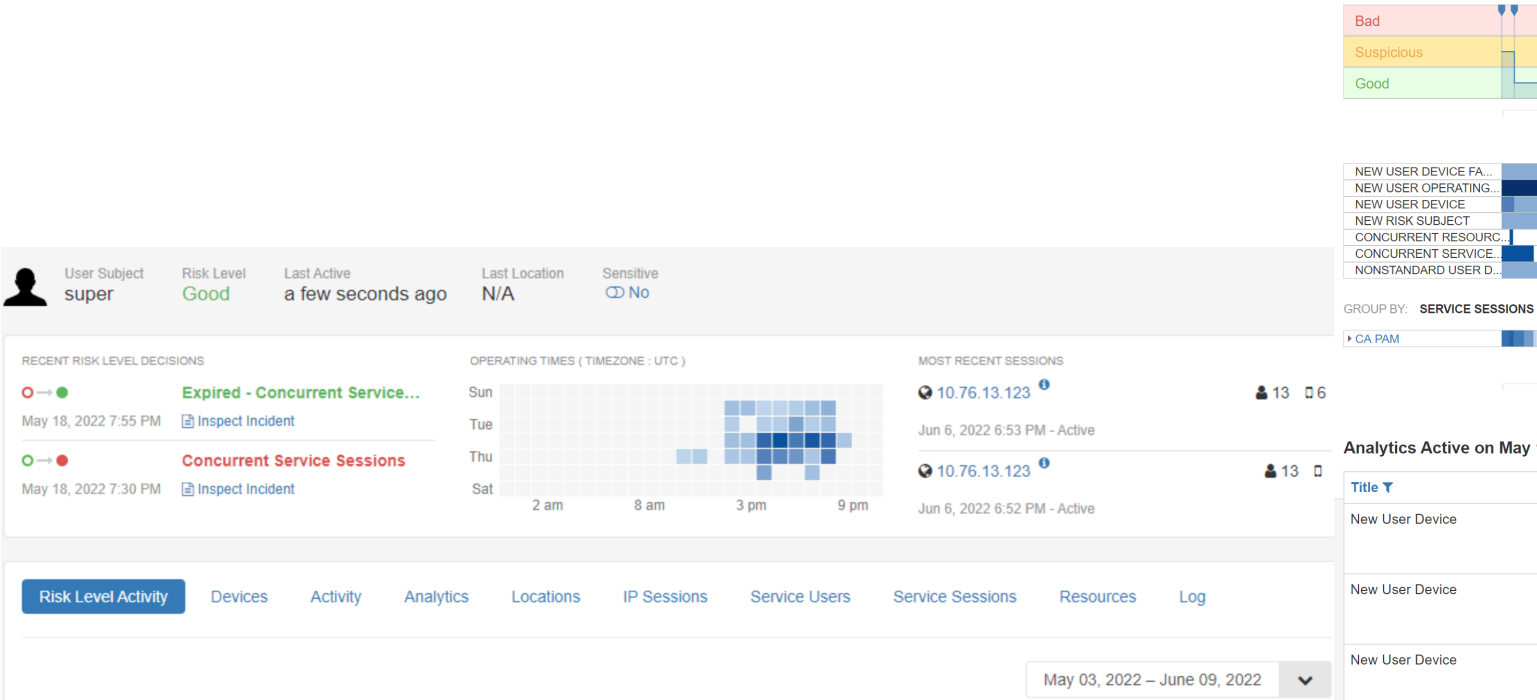

The **Activity** tab lists all activity in the PAM environment, providing the following attributes:

- **Timestamp:** the Coordinated Universal Time code (UTC) for the session
- **User:** the Privileged Access Manager user name
- **Device:** the identity of the system used to log in to PAM
- **Action – Resource:** the action performed (for example, LOGIN or LOGOUT) and the PAM resource used
- **IP/Location:** the IP or location that is used for the activity
- **Client:** the software that allows PAM to establish connectivity with services running on servers.

You can double-click on any user, device, resource, or location on the activity list and can view the **Risk Level Activity** tab, which displays the analytics that are detected over a specific time period. It is similar to the **Overview** pane but adds a top-of-the-screen “header” for the particular user, device, or resource. This area includes some basic status indicators and provides the most recent analytic decision, in this case “Concurrent Service Sessions.” This panel also provides a miniature heat map for the current week and the IP addresses used.

The lower part of the **Risk Level Activity** pane includes the same heat map and table of analytics that were detected over a specified period of time, but it adds a bar graph that shows when this user or device that is changed from **Good** to **Suspicious** or from **Suspicious** to **Bad**, and then back again. This example shows the risk activity for a user who began running concurrent service sessions (displayed in red) and then logged out of the concurrent session. This action then changed the status of the analytic from red back to green. The “Inspect incident” link under the name of each analytic provides a fuller explanation of what was detected.

This heat map also adds an extra separate heat map for the service used (in this case, CA Privileged Access Manager) over the specified time period. The **Risk Level Activity** screens are fully described in [Track Risk Level Activity for All Users and Devices](#).

## Monitor Risk Analytics

The **Analytics** tab provides a list of risk factors that were triggered during the selected period of time, and their associated users or devices. Brief descriptions of the analytics are also provided, along with timestamps.

In the previous list, for example, the user was running concurrent resource and service sessions and was also accessing a device associated with a **Bad** user.

If you select the user name, you see a full list of all the analytics that have been detected in that account user in the **Risk Level Activity** pane, and also a timeline and heat map showing when and how often the analytics were detected over time. If you select a device in the **Object** column of the main **Analytics** table, you can see an assessment of **Risk Level Activity** for devices that have questionable status.

The **Annotate** buttons in the right-most column of this table provide the security team with an opportunity to contact a potentially suspicious user and investigate why that incident occurred. If the triggered analytic was unintentional, the team can report that the error was benign in the box labeled “**Was this analytic triggered in Error?**” If needed, a button at the lower right can disable the particular analytic for the user.

## Annotate Concurrent Resource Sessions Analytic

Analytic Title	User	Analytic Expired	Expired At	Timestamp
Concurrent Resource Sessions	super	Expired	May 11, 2022 5:56 PM	May 11, 2022 5:55 PM

Concurrent active Resource Sessions detected  
User - super has more than one active Resource Session initiated from Service - CA PAM

**Was this analytic triggered in Error?**

User reported that in logging on he had very slow network access and mistakenly opened another session.

Update

☒ Concurrent Resource Sessions is enabled for this User  
 Disable this analytic from triggering for this User in the future.

Disable Analytic

The entire set of 58 analytics is included in the default Threat Analytics Console. Users can also go to the admin console to disable some analytics, modify others, or create analytics as needed. The analytics fall into four categories: **Location**, **Activity**, **Sensitivity**, and **Integrity**

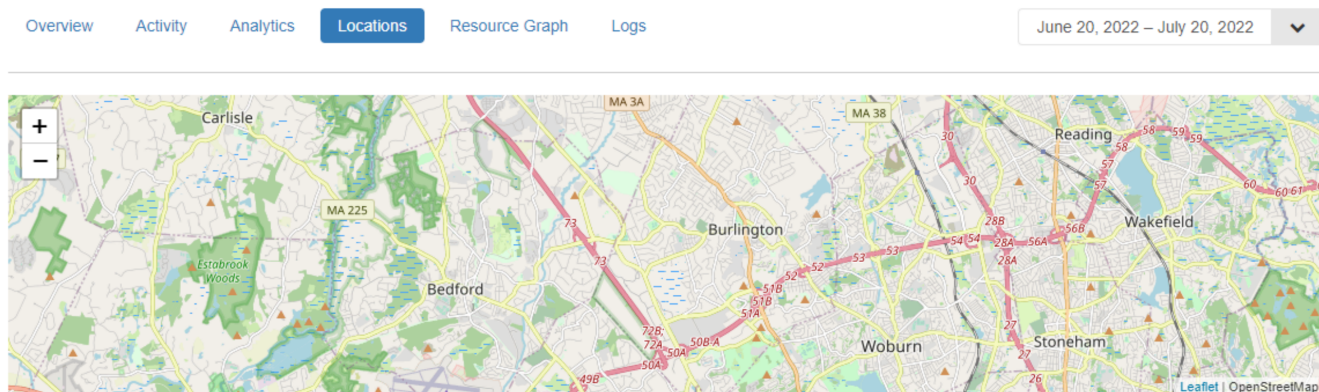

- There are 12 **Location** analytics that are based on the locations of the user or devices. These flag events such as the usage of blacklisted locations, changes of country, and unusual distances traveled. Users operating outside their normal location or outside the location of their organization can also be flagged. So can “impossible” transfers in which a user changes locations at speeds and distances that are implausible or unlikely.
- There are 17 **Activity** analytics that are triggered by potentially risky behavior. Some examples are abnormal resource session rates, overlong service sessions, and access denials. Others are concurrent resources or service sessions, and excessive data downloads. Analytics can detect multiple active VPN “tunnels,” overlong times, and the lack of activity for a preset time period that automatically turns “active” users into “dormant” ones.
- There are four **Sensitivity** analytics that detect access of a sensitive resource or user and that check for excessive group counts over a preconfigured hard limit or statistical/population-based limits.
- There are 25 **Integrity** analytics that flag the appearance of deactivated users or “bad” risk subjects, new users, new devices or shared devices, operating systems, risk subjects, user agents, device families, or outside subnets. They also warn of suspicious users, clients or IP addresses, and excessive network population and device families. An excessive number of operating systems in use or suspicious users and clients are also flagged. Not all of these conditions are necessarily dangerous (such as a new user or device), but they provide protection against a broad range of potential integrity threats.

Based on the triggering of these 58 analytics, the Threat Analytics Console can make decisions about when the behavior of a **Normal** user's has become **Suspect** (or “suspicious”). The console flags certain activities and users with the yellow-orange color in the dashboard and forces PAM to start a recording of that session. These preventative measures begin regardless of how the user set up the access policy. Threat Analytics then continues to monitor that user for all subsequent sessions, devices, and resources accessed to determine whether the risk level of a user must be further escalated.

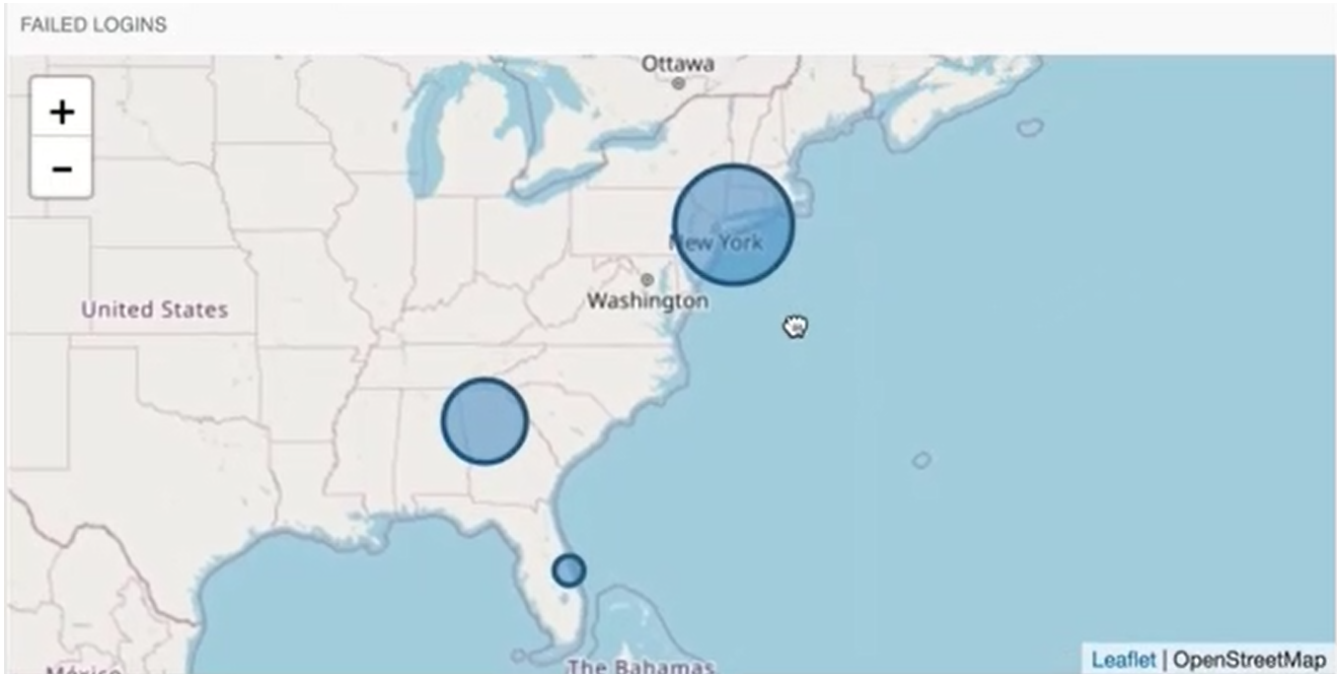

If so, the user goes from **Suspect** to **Bad** and the Threat Analytics Console then locks every session. The console then makes that user reauthenticate with name, password, and (optionally) a multi-factor sign-in to prove who they say they are. If they cannot, it terminates the session. This policy can, for example, help suppress someone who was able to intercept a one-time password to get into that initial session. If this user were to begin doing things that a normal user wouldn't do, the console can recognize the activity and require another set of authentications.

## Map User Locations

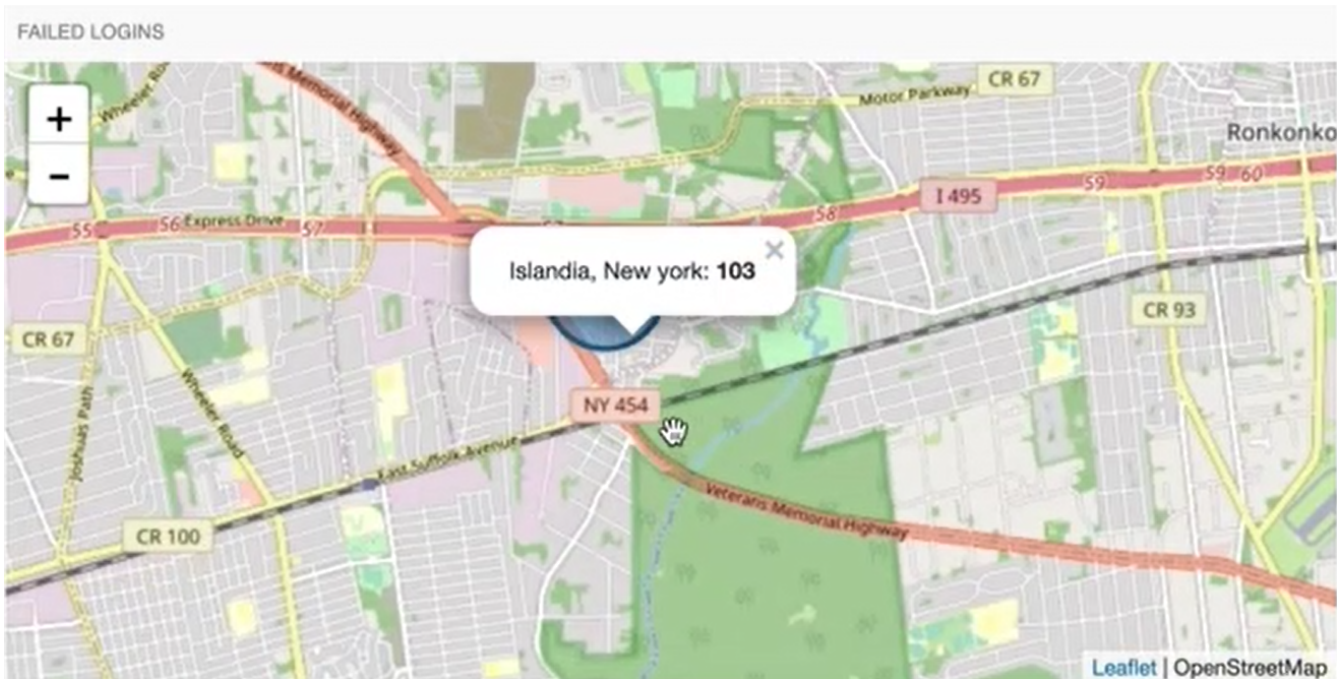

The **Locations** tab on the **Home** page provides a geolocation view of the PAM network that is based on IP addresses.

In the example below, you can see clusters of suspect users in Florida and Georgia, but the largest number of users are from Islandia, New York.

You can select locations on the map to get a closer view of suspect user locations going all the way down to the street-level detail. This one is a view of Islandia:

## Graph Network Resources

In addition to the graph of users presented on the **Overview** pane, you can use the **Resource Graph** tab to create a map of the resources inside PAM that are being utilized on the network. The following graph is an example:

Overview Activity Analytics Locations **Resource Graph** Logs

April 29, 2020 – October 29, 2020

Good Normal A Labels  
Suspect Sensitive  
Bad Disconnected

This view includes **Normal** and **Good** resources but also resources that are **Sensitive** and may require further examination. If you select a user in the graph, it opens a **User Quick View** that shows the name of the user, the latest IP address, changes in status, and a list of all the devices used.

 **User Quick View** 

 **super**

If you select the blue “Download as .csv” text block at the top of the left column in the table, the filtered list view can be saved as a \*.csv Excel file for a subsequent reference.

## Investigate Basic Components of the Network

The menu tabs in the bar at the top of the Threat Analytics display provide information about five functional components of the PAM environment:

- **Users:** [Examine Users and Risk Levels](#)
- **Devices:** [Track Analytics for All Devices](#)
- **Analytics:** [View All Analytics and Status Decisions](#)
- **Services:** [Track Activity across All Services](#)
- **Resources:** [Monitor Activity Across All Resources](#)

Two more tabs summarize and interpret this raw data to provide a deeper analysis of potential threats to the network, making them especially useful.

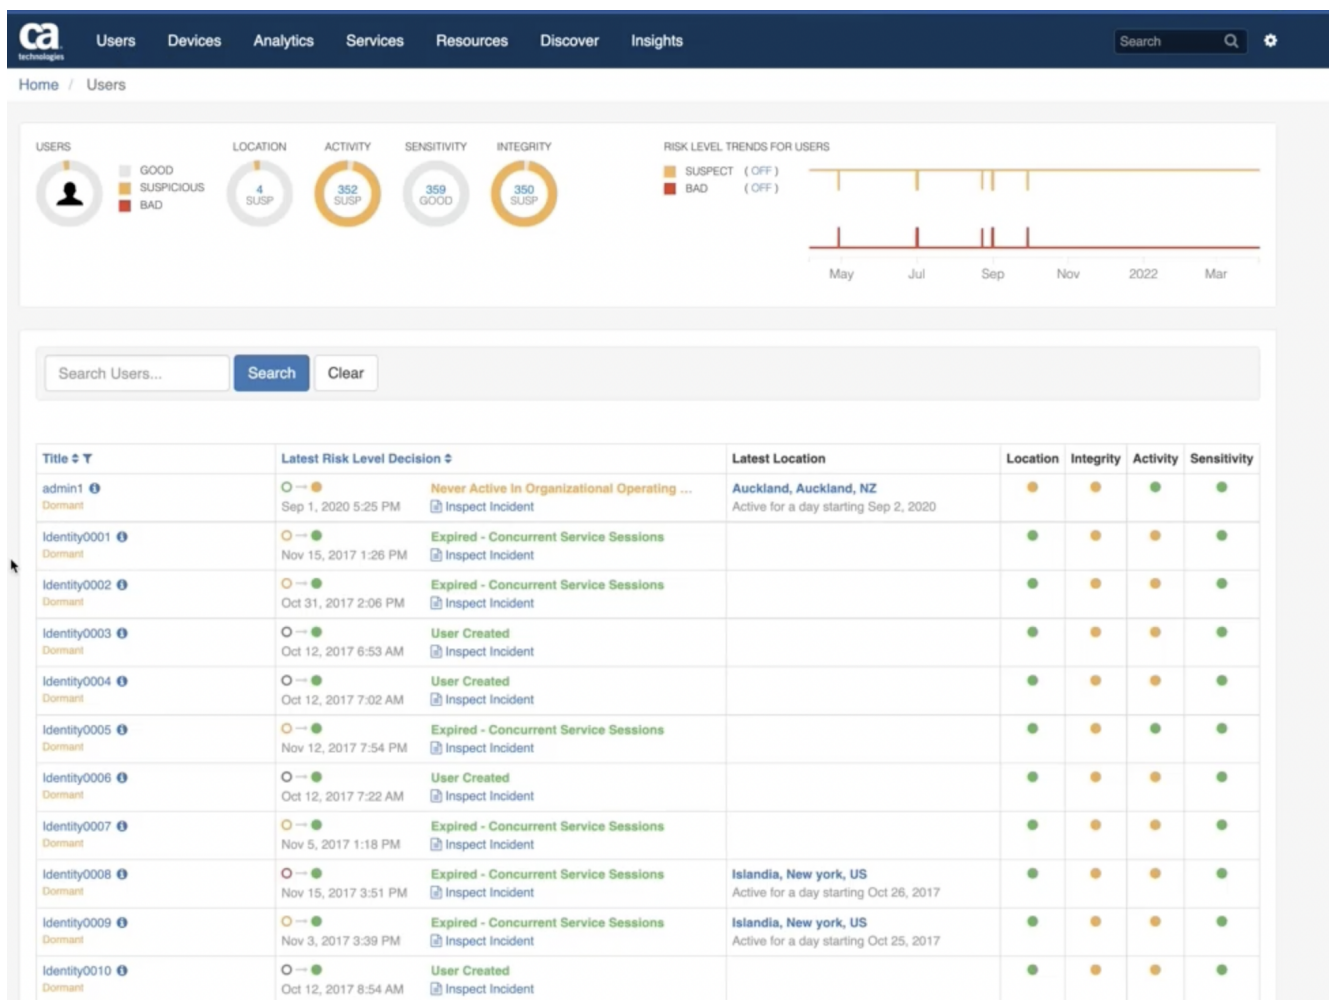

- **Discover:** [Interpret Threats Using the Discover Tab](#)
- **Insights:** [View Data Insights on Network Activity](#)

The first five menu tabs focus on lists of the users, devices, analytics, services, and resources detected as a starting point for analysis. Much of the raw data available on the six **Home** tabs also can be accessed from the seven top-line tabs. Generally the differences between the two sets of tabs are complementary methods of viewing and analyzing potential threats in the PAM environment, rather than separate sets of data.

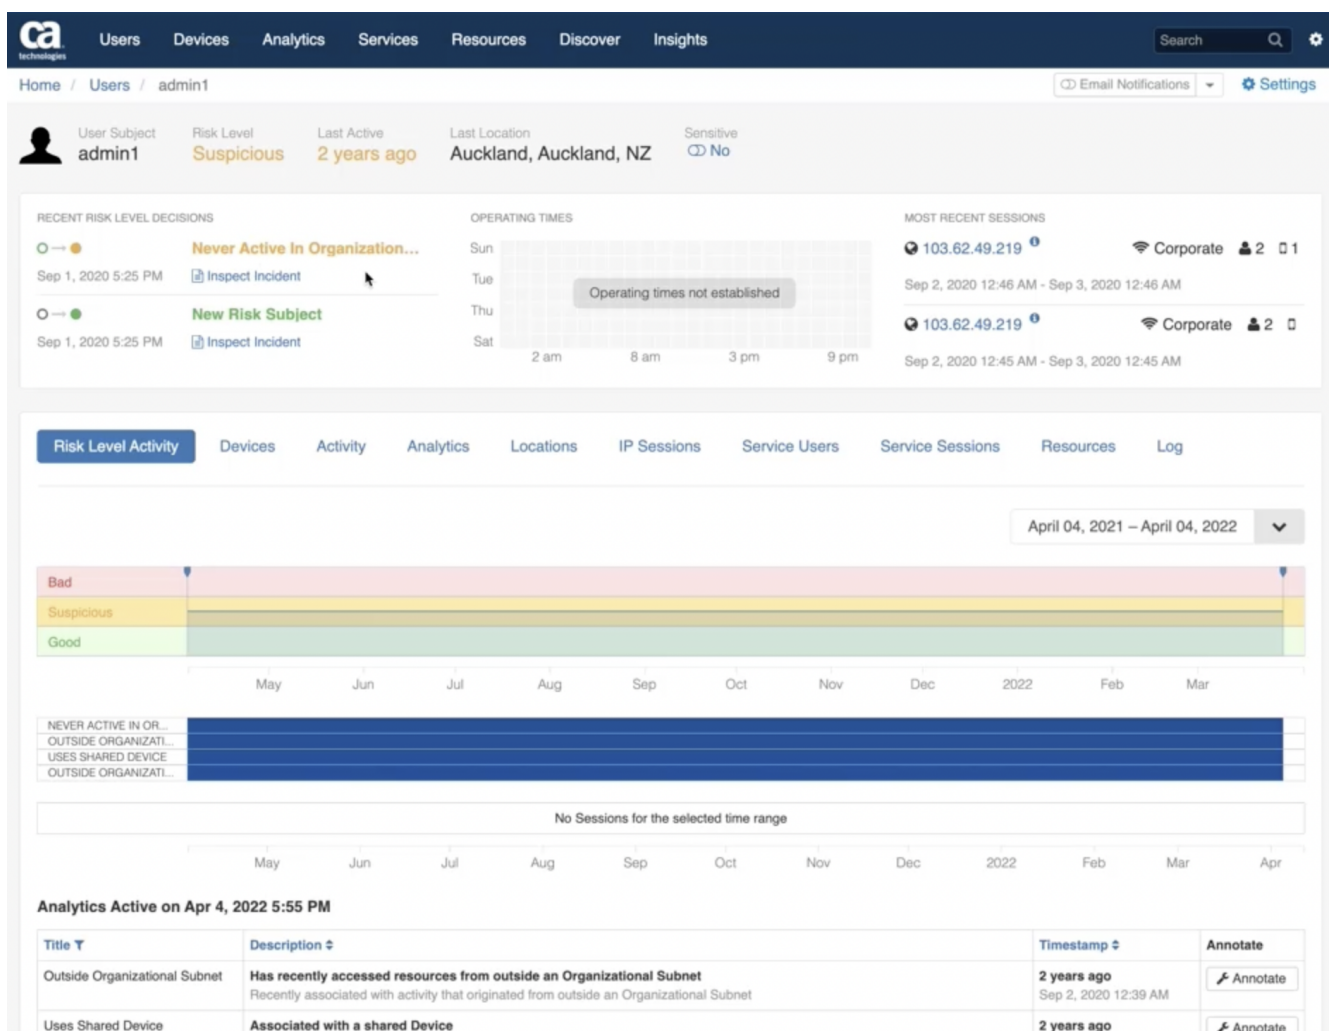

## Examine Users and Risk Levels

The **Users** tab lists all the active users in the PAM environment, their current risk level, their most recent locations, and the current status of the four categories of analytics: **Location**, **Integrity**, **Activity**, and **Sensitivity**. The same status circles seen on the **Overview** tab are reproduced here, and a time line tracks when instances of **Suspect** (yellow-orange) and **Bad** (red) activity have occurred.

Selecting an individual user in the **Title** column, you can view all incidents and analytics on the **Risk Level Activity** pane.

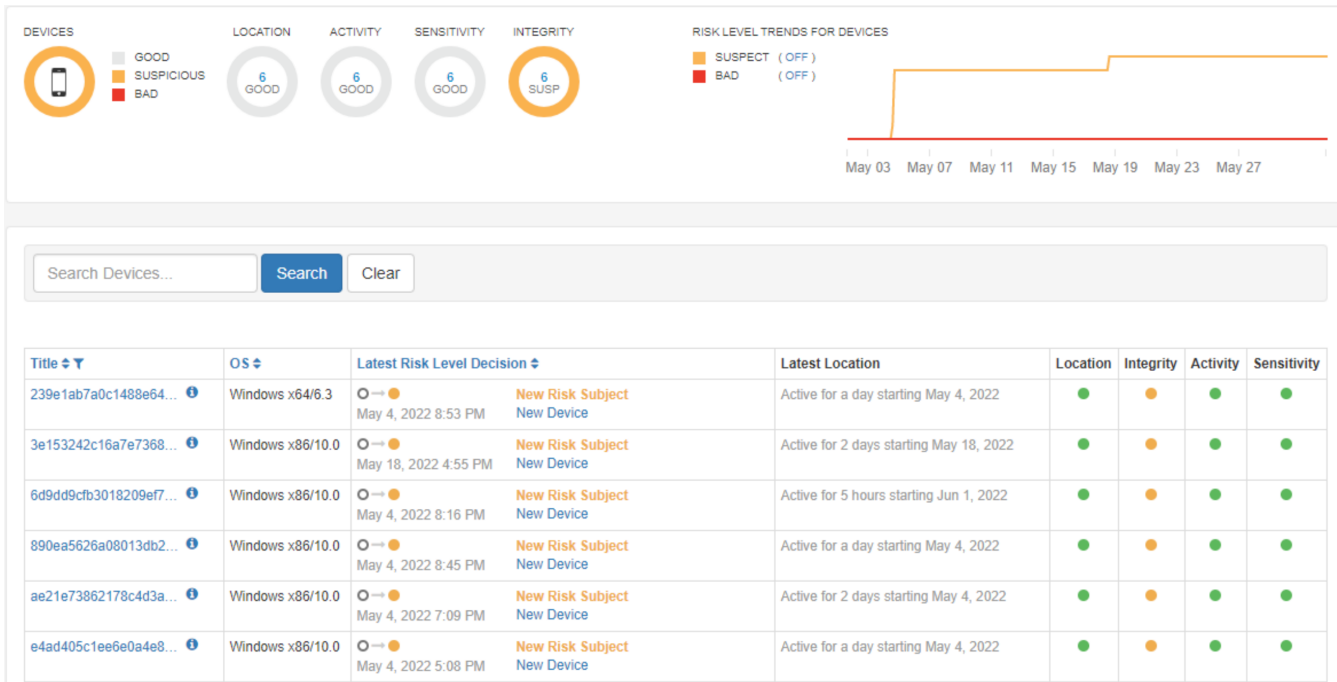

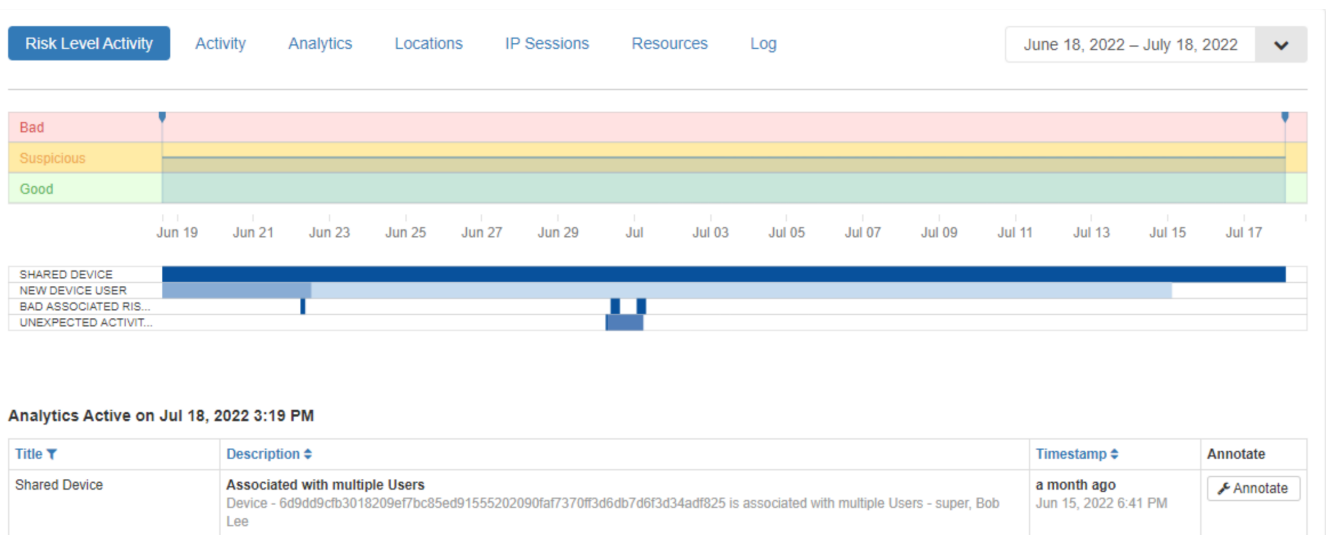

The particular user named “admin1,” shown in the example above has never been active in the organization and has become a new risk suspect. In addition, this user has logged in from an unusual location: Auckland, New Zealand, which has not been previously used. This user has also recently accessed resources that are not part of the organization’s subnet and has also been associated with a shared device. The triggering of these analytics has raised the risk level for this user to **Suspicious**.

## Track Analytics for All Devices

The **Devices** tab lists all the devices that connect to the PAM Appliance through a browser or the PAM client, along with the operating systems they use, latest risk level decisions, locations, and status in each of the four analytic categories. The following example shows six devices being used in the same session. An excessive number of devices could mean that the user is that trying to test multiple addresses to break into the network, which elevates the risk level of the user to **Suspect**.

Selecting a device name displays its risk level in the **Risk Level Activity** window, with a heat map over a time line and all the analytics that caused this risk level escalation. In this case, the device that is used has been associated with multiple users.

For more details about the **Risk Level Activity** window, see [Track Risk Level Activity for all Users and Devices](#).

## View All Analytics and Status Decisions

The **Analytics** tab in the top of the screen lists all 58 analytics that are used by the Threat Analytics Console, reporting the following information:

- The category of the risk factor (**Activity**, **Sensitivity**, **Integrity**, or **Location**)
- The name of the analytic
- Whether the analytic has been triggered, and if so when
- Whether each one was applied and enabled for the user or device
- How many times the analytic has been triggered.

In contrast, the **Analytics** tab on the **Overview** menu only shows the analytics that were triggered during a specific session.

You can select each analytic to see more information. This example displays four instances of the “Concurrent Service Sessions” analytic in the past month, revealing that a user was detected using more than one active service session simultaneously.

The **Annotate** buttons in the right-most column that can be used to report any relevant information that is uncovered after the incident, similar to what was previously described in the **Risk Level Activity** table for the analytic.

The **Analytics** menu tab also has a **Decisions** tab. This tab reports more details of all the analytics that are triggered within a specified time period. The user and device names appear in the **Object** column, as is the date when a triggered analytic occurred. You can select the analytic decisions that are listed on the left of the heat map timeline to discover all the details of that particular analytic decision.

Similarly, if you select a device in the **Object** column of the main **Analytic** table, you can see an assessment of **Risk Level Activity** for devices that have questionable status.

## Track Activity across All Services

The **Services** tab records the activity of all services that were used over a specified time period, showing your connections to the Privileged Access Manager. The only service in use for this example is the CA PAM client application. This tab is most often used to set up an environment and is not typically accessed daily.

## Interpret Threats Using the Discover Tab

The **Discover** tab in the top row of menus provides an overview of network activity. This tab displays the following features:

- A visual map of traffic over a timeline with **Suspect** and **Bad** activity color-coded (top left)
- A sortable and exportable filtered list of identities (bottom left)
- A set of ten **Quick filters** that display the age of an account, its weekly activity, weekly failures, and days since the last activity. They also include graphs of the resource count, the device count, and the session count, as well as the longest session (in hours), the longest resource session, and the overall risk level.

When you open the **Discover** page for the first time, you see data based on all the users on the network. The main graph on this page is entitled **Risk Exploration** and it shows the risk activity for all selected records. The four tabs on the upper right side toggle the **Quick Filters** through four types of users:

- **Dormant** (no recent activity)
- **Failures** (users with the most weekly failures)
- **New Users**
- **Risky Users**

Each of the 10 graphs and the map change for each user group selected. You can save and then print the list of identities table for reports by selecting the "Download as .csv" link in the top row.

The following example graph displays a resource count, showing how many targets the users are connecting to versus the age of their account. The yellow-orange area at the left of the time line reveals some suspicious activity. This user has only had the account for a short period but has connected with a high number of resources. You can select that area to bring up the particular user and get more insight into why the analytics were triggered.

### Quick filters

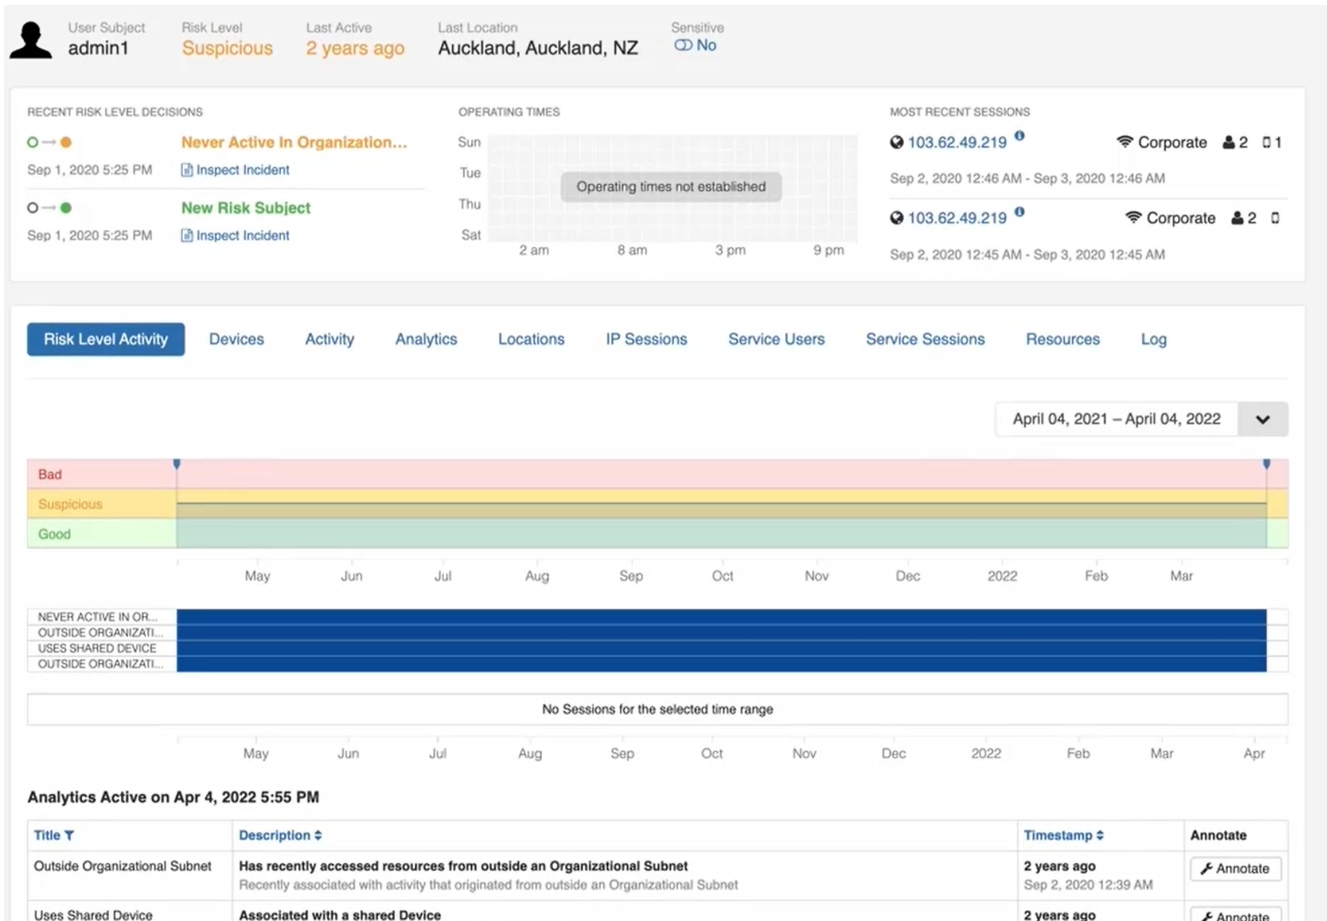

Explore your user population with these predefined filters.

[Dormant](#) [Failures](#) [New users](#) [Risky users](#)

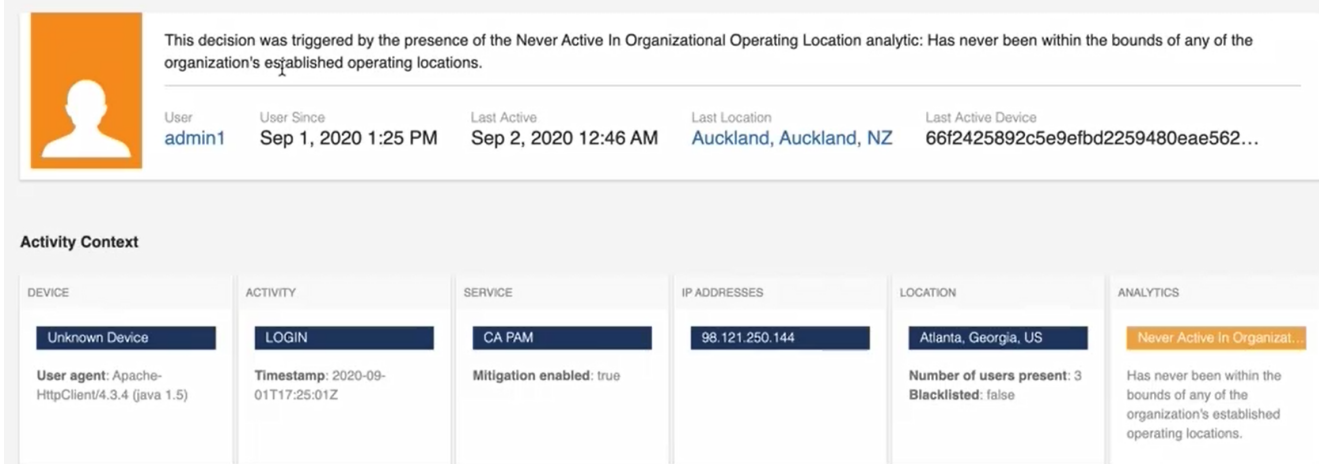

The **Quick Filters** on the right side also show more-specific graphs of the suspect user activity. This analysis might correspond to a server admin logging into many different servers to perform installations or patches, and may not be a threat. But it could be evidence of a breached account that is being used to steal data. Selecting one of the four **Quick Filters** tabs updates all the tables on the page, revealing statistics for dormant users, users with login failures, new users, and risky users. To return to the opening page of the **Discover** tab, select **Reset All** under the **Risk Exploration** title.

To view the **Risk Level Activity** page for the suspect user in this example, select the yellow-orange circle in the lower left portion of the **Risk Exploration** graph.

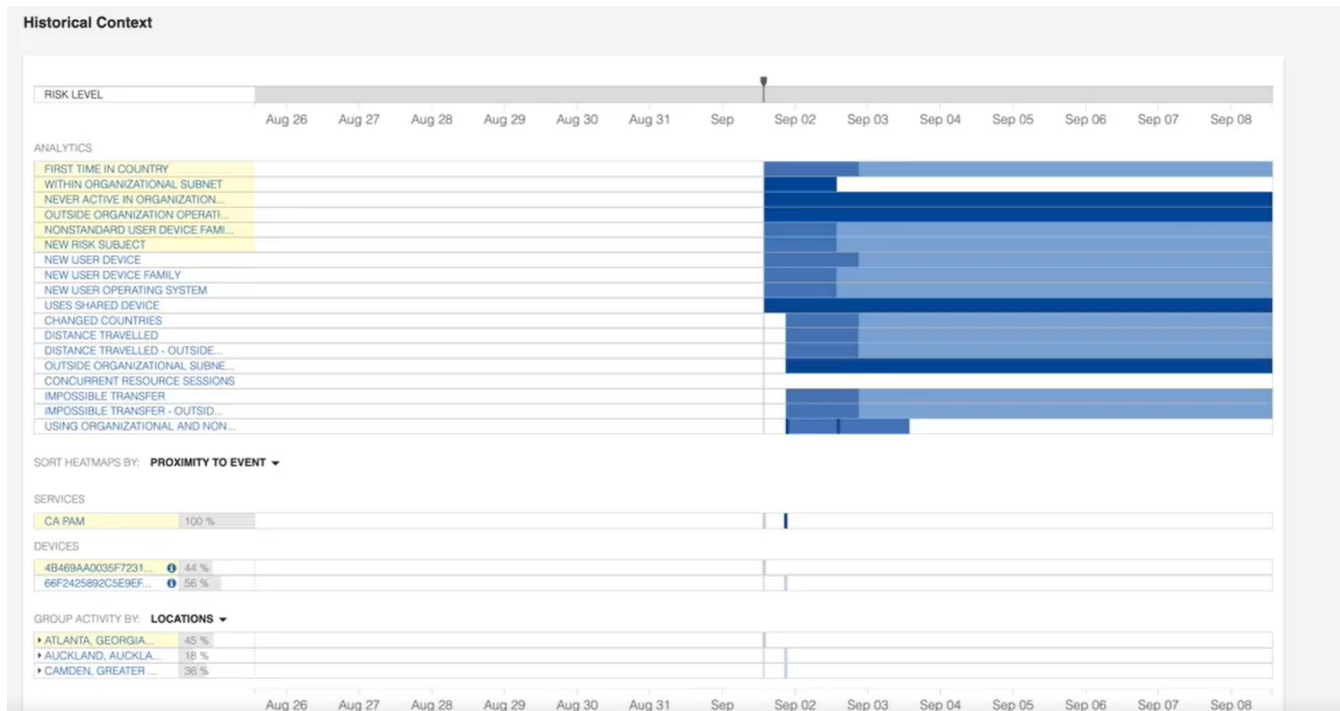

In this example, you can see in the summary pane that the "Never Active in Organization" analytic was triggered for the entire time line. Select the blue **Inspect Incident** link under the "Never Active in Organizational Operating Location" analytic at the top of the screen to display a report on that particular analytic decision:

### User admin1 changed from Good to Suspicious on Sep 1, 2020 5:25 PM

The **Risk Level Activity** page also displays a **Historical Context** table that provides information on past activity by the suspected "admin1" user. This table can be used in different ways:

- To help verify that the user has traveled to remote locations
- To determine when the analytics kicked in
- To obtain the different IP addresses used
- What services, devices, and locations were involve

If you need to share these insights with other team members or managers, select the blue “Export to PDF” link in the header of the **Inspect Incident** report (on the main **Risk Level Activity** page). The Threat Analytics Console allows you to collect and correlate all the data without having to contact other sources.

## View Data Insights on Network Activity

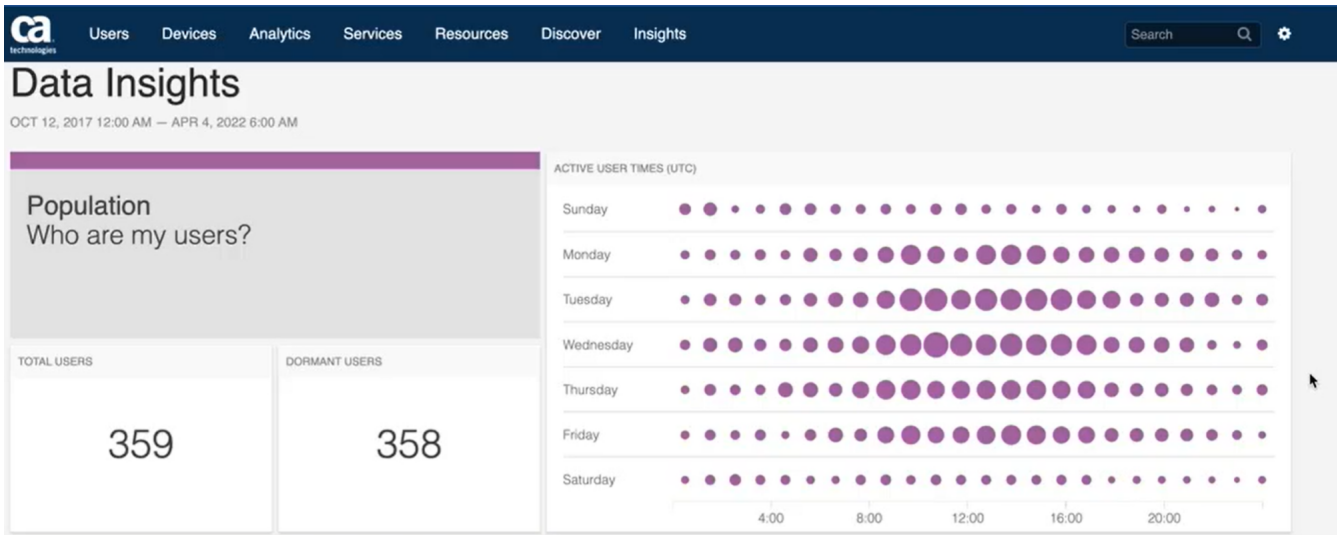

The **Data Insights** menu tab assembles key summary data for all PAM operations by deploying an array of statistics, maps, and graphs. This tab is divided into the following five sections:

- [Population: Who Are My Users?](#)
- [Location: Where Are My Users?](#)
- [Activity: How Are the Users Operating?](#)
- [Risk: How Risky Are my Users?](#)
- [Devices: Which Devices Are Being Used?](#)

### Population: Who Are My Users?

The **Population** section totals up all current and dormant users and provides a graph showing active user time, the busiest days of the week, and the busiest times of day. The larger the circles, the more traffic has been detected. The **Population** section also shows how many dormant users there are on the network. In the following example, there is a large percentage of dormant users, and you should examine them for possible decommission.

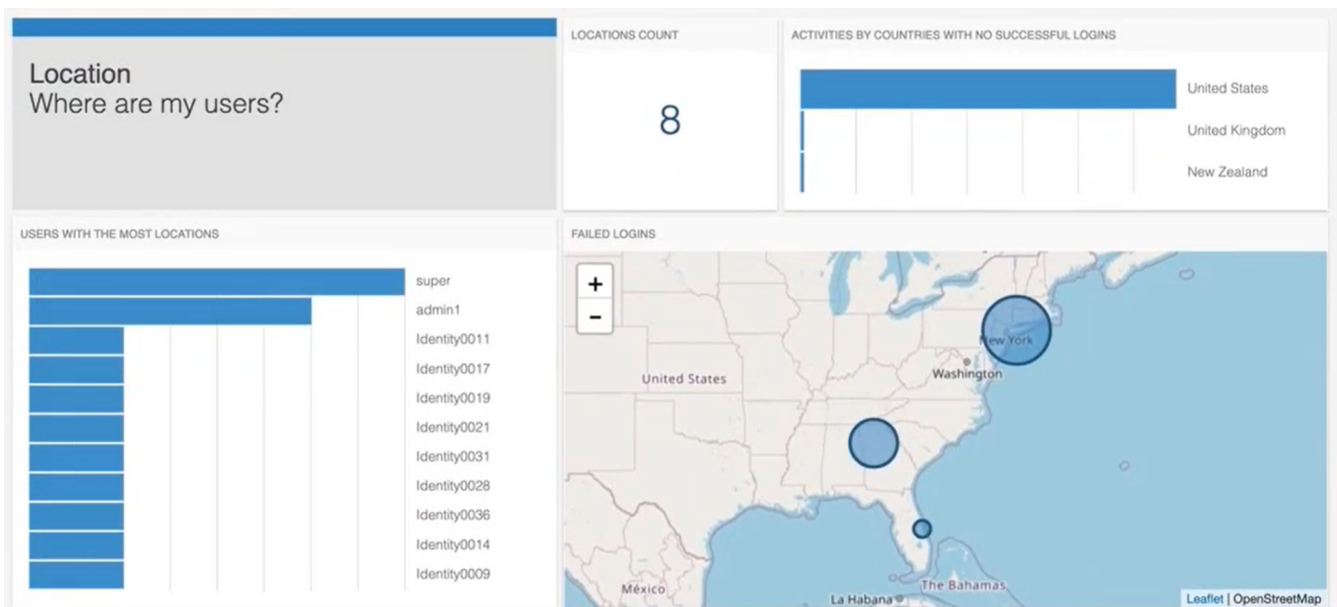

### Location: Where Are My Users?

The **Location** section helps answer the question, “Where are my users?” The section provides these statistics:

- The total number of locations in the network
- All activities from countries with no successful logins
- A list of users with the most locations
- A map of all these detected locations

A user with an unusually high number of locations could be a compromised account that has been sold many times on the dark web. But this high number could also be someone who frequently travels to different company sites.

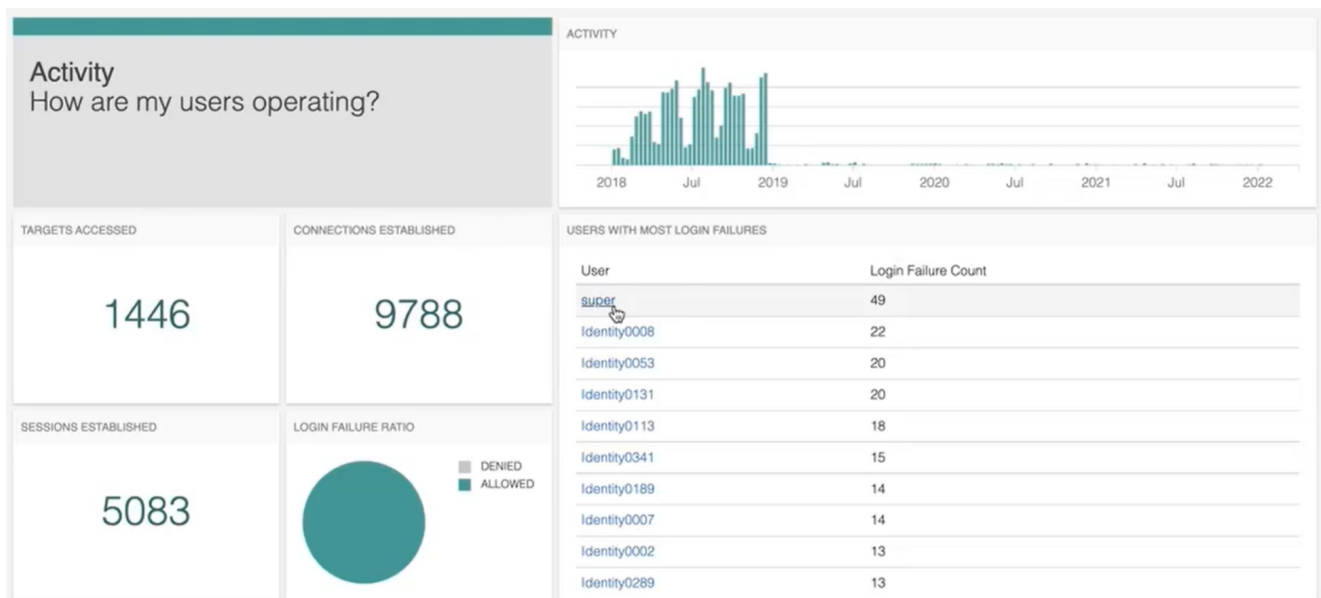

### Activity: How Are the Users Operating?

The **Activity** section of the **Insights** tab analyzes how users are operating. In the following example graphic, we see a network with 1446 different accessed devices, but with 9,788 device connections established. These numbers result in an

average of 6.77 devices per user, which is high. Some of these non-accessed devices could possibly become a source of potential attacks and you may want to consider decommissioning them.

The **Activity** section also lists the PAM network users with the most login failures. Typically these users should be rare because PAM manages logins. The following example shows a user with 49 login failures, and these failures could correlate to someone trying to brute-force an account. You can look for other alerts of this kind of activity and what IP addresses the account is trying log into.

The **Activity** section also lists users with the most resources. The following example shows a user who is associated with 123 resources. This user may be a server admin using PAM to log into servers to patch software or a help desk that is connected to the endpoints of many users. But it could also be a compromised account being used to undertake a lateral move to attack other devices on the network.

USERS WITH MOST RESOURCES		USERS WITH LONGEST SESSIONS	
User	Resources	User	Session Length
Identity0175	123	Identity0036	19:10:47
Identity0066	121	Identity0088	17:52:20
Identity0111	99	Identity0183	16:32:00
Identity0068	87	Identity0086	16:21:04
Identity0003	86	Identity0042	15:38:20
Identity0001	84	Identity0026	15:36:43
Identity0041	83	Identity0003	15:17:02
Identity0167	82	Identity0096	14:53:08
Identity0054	82	Identity0076	14:51:53
Identity0067	81	Identity0010	14:28:31

The **Activity** section also tracks the users with the longest sessions. Typically, PAM console sessions are set to time out and should not be taking 14 through 19 hours like the 10 users who are shown in this example. This activity could warrant further examination about what systems the users have logged into and whether someone has bypassed the time-out restrictions.

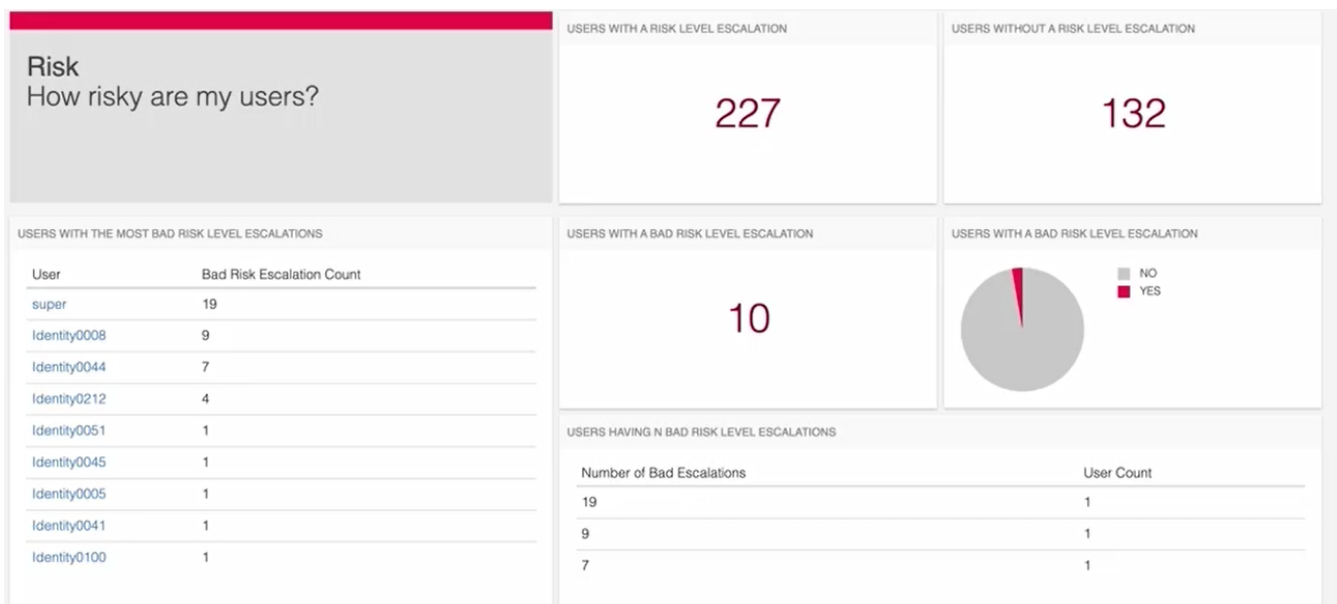

Two graphs complete the **Activity** section. One is **Users with New Device Type per Day**, valuable for networks that allow users to use their own personal devices (BYOD). Typically new device types spike after holiday periods, when users get a new phone or tablet device. Generally, new device activity should trend down after such periods.

The second graph is for **Login Failures (Bad User Name) per Day**, relatively rare incidents because PAM manages access to the network, but it can be valuable to know when and how often such activity occurs.

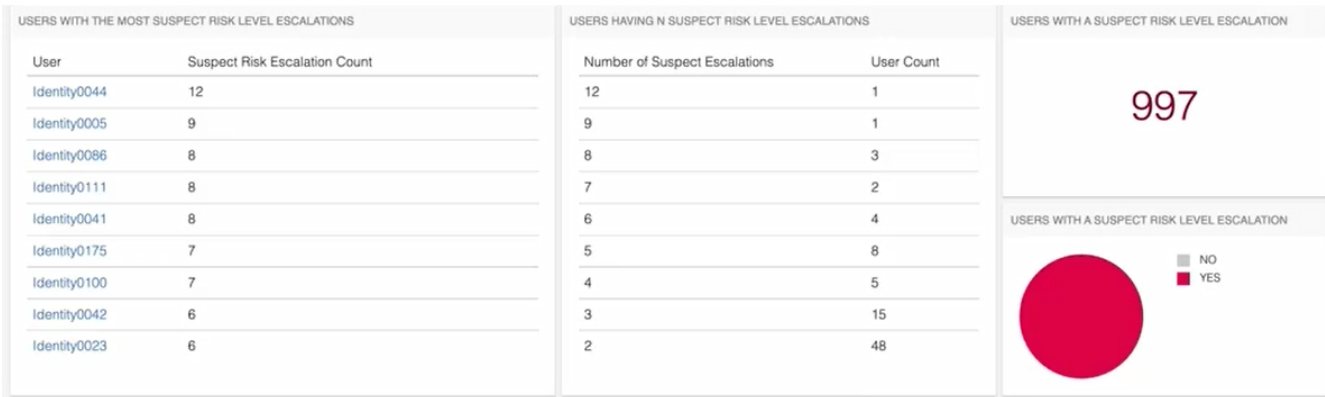

### **Risk: How Risky Are my Users?**

The **Risk** section of the **Data Insights** page provides counts of users with and without new risk level escalations and the number of users with both **Bad** and **Suspect** risk-level escalations. Pie charts help highlight the percentage of risky users on the network.

The **Risk** section also lists users with the following characteristics:

- The most suspect risk level activity escalations
- The number of suspect escalations
- The user count
- The count of users with a suspect risk level escalation
- A pie chart of users with a suspect risk level escalation

### Devices: Which Devices Are Being Used?

The **Devices** section provides the following information:

- The average number of device families and device operating systems per user
- A bar chart of users per device family
- A bar chart of users per device operating systems

## Track Risk Level Activity for All Users and Devices

The **Risk Level Activity** panel that was described earlier can be a useful tool to explore all kinds of risky behavior that is linked to users, devices, activities, analytics, locations, IP sessions, service users, service sessions, resources, and logs. From this one screen, you can examine all phases of risky network activity on your network. The **Risk Level Activity** panel has two separate sets of menus, one for users (with 10 submenus) and one for devices (with seven submenus).

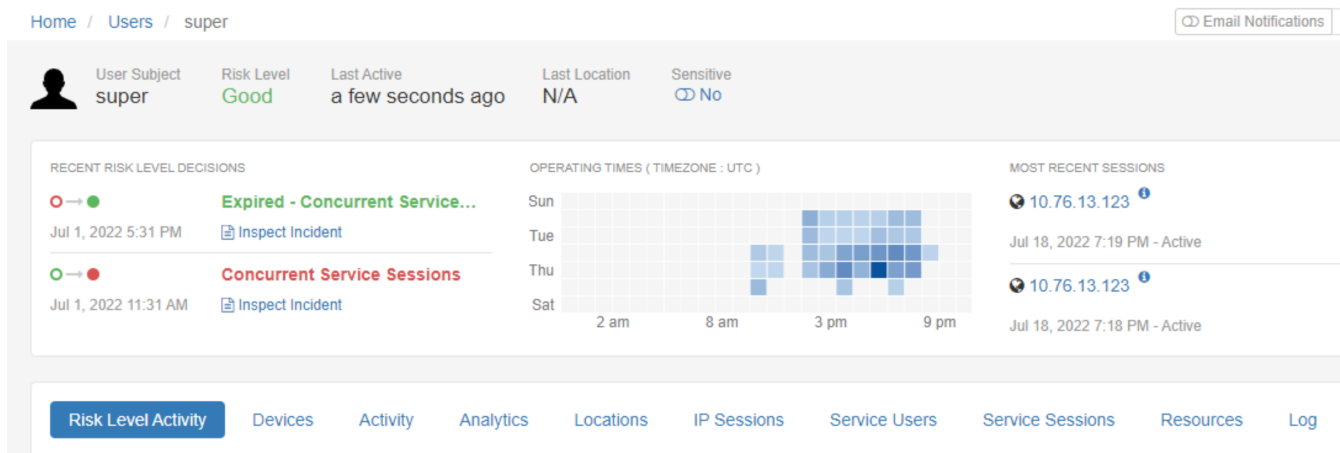

### View a Summary of User and Device Risk Level Activity

Typically users enter the **Risk Level Activity** panel by selecting a user or device. The label at the top of the screen provides the following features:

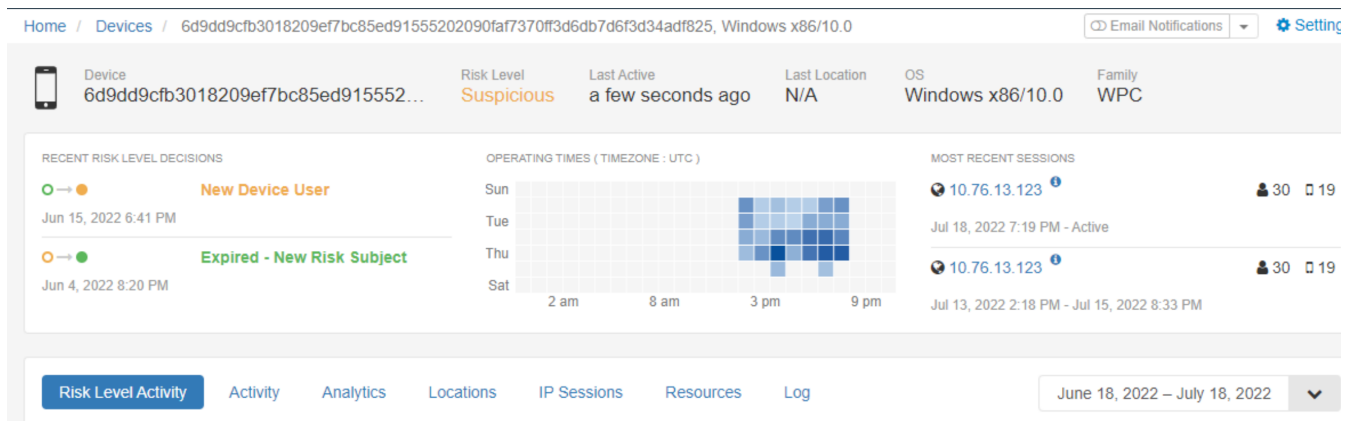

- A list of the most recently triggered analytics
- A heat map over a specified period of operating times
- The IP address and connection method for the most recent sessions
- The dates and times of those sessions

The view then scrolls down to the line of menus. This user or device header remains above the timeline, readily accessible at any time as you open each submenu.

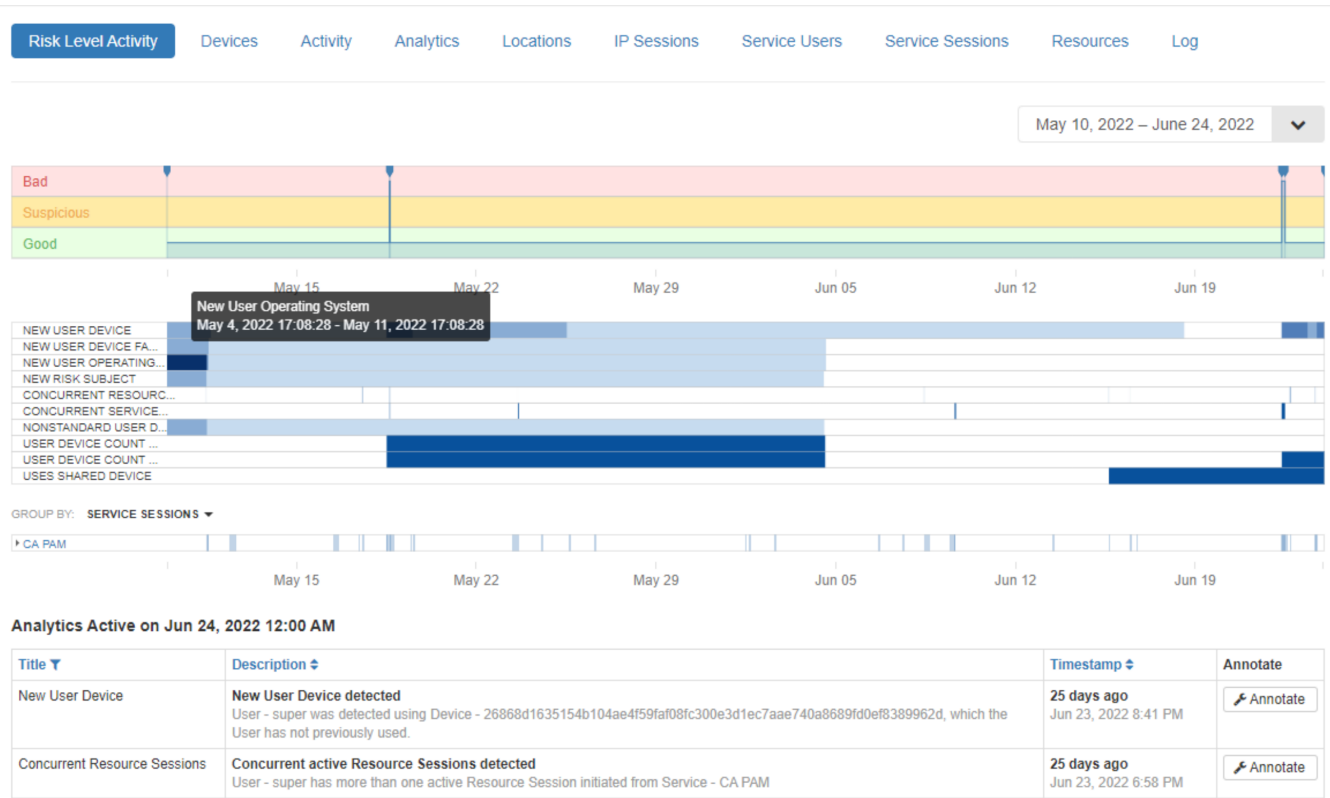

The **Risk Level Activity** header for a user appears similar to the following graphic:

The **Risk Level Activity** header for a device appears similar to the following graphic:

A bar-graph time line of risk level activities starts below the row of menu tabs, along with heat maps similar to the **Overview** screen. The active analytics appear below the heat maps. The timeline has three zones that record **Normal**, **Suspicious**, and **Bad** activity and vertical lines show when a triggered analytic appears on the timeline.

The three bands in the time line bar graph help you determine when and how long an analytic was active, and when it became **Suspicious** or **Bad**, or when it returned to **Normal**.

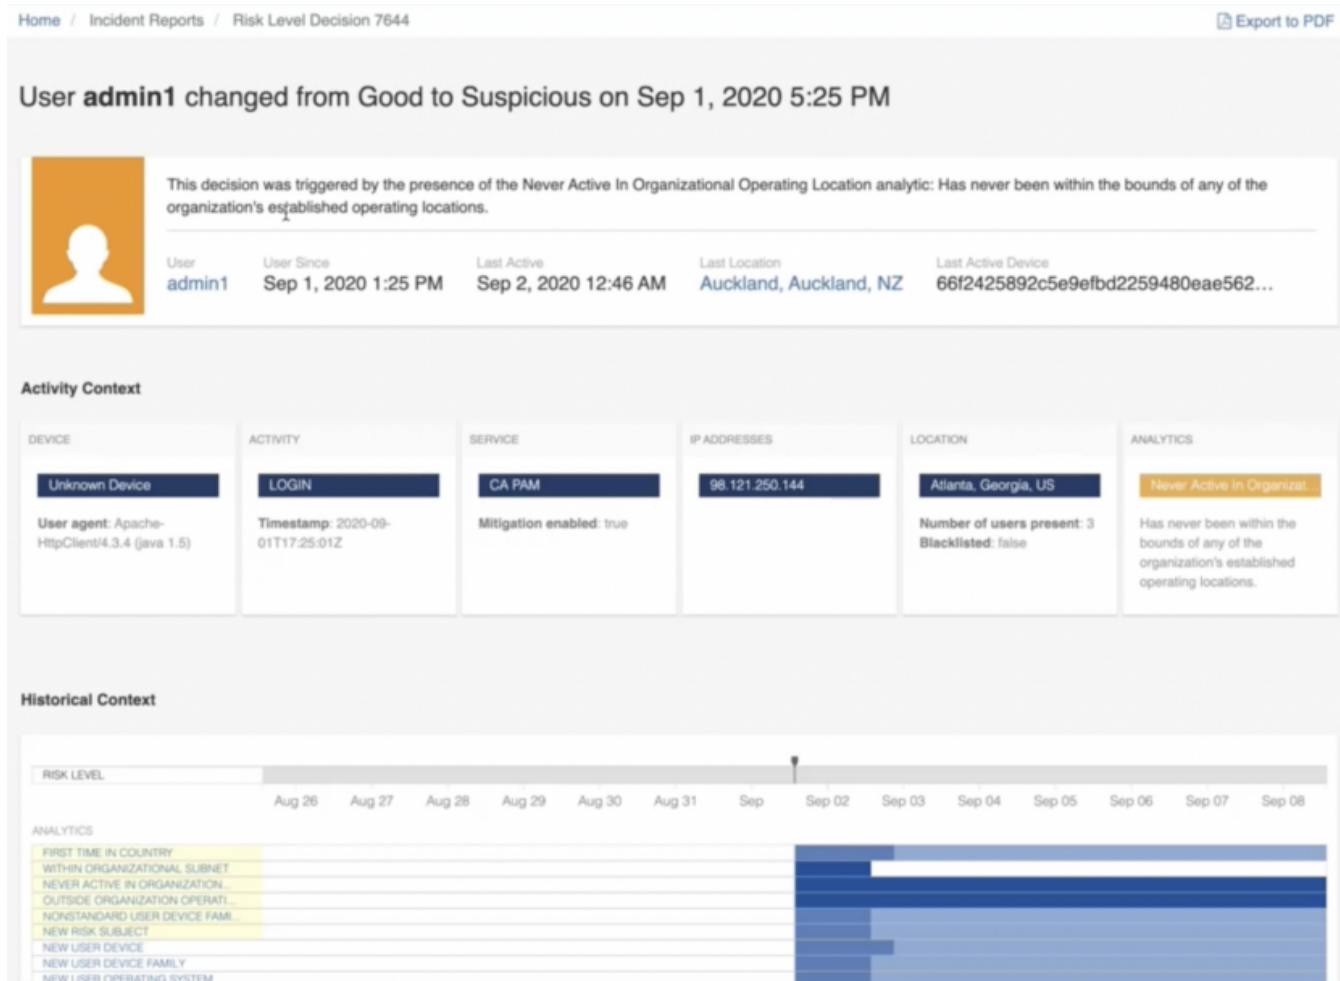

A one-line heat map of all service sessions or resources appears below the heat map. You can select the “Group By” entry to toggle between service sessions and resources.

You can drag the cursor through portions of the bar graph to isolate a portion of the graph. If you select the “Zoom to Selected Range” button, only the activity in the selected range displays on the time line and heat map.

Selecting the “Inspect Incident” links right below each analytic message in the **Recent Risk Level Decisions** list of the user header displays more details about the risk level changes and a heat map of previous problematic analytics is generated.

The risk level graph pane also shows separate heat maps for the services, devices, and locations used in the past.

A comprehensive activity log similar to the following one appears after the heat maps:

## Activity Log

Timestamp (UTC)	Device	Action - Resource	IP	Location	Client
May 12, 2022 6:47 PM	6d9dd9cfb3018209ef7bc...	SSO - tap.ca.com	10.76.13.123		Java
May 12, 2022 8:31 PM	6d9dd9cfb3018209ef7bc...	LOGOUT - CA PAM	10.76.13.123		Java
May 16, 2022 3:07 PM	Windows PC (Personal ...)	LOGIN - CA PAM	10.76.13.123		Mozilla/5.0 (Windows NT 10.0; WOW64; Trident/7.0; rv:11.0) like Gecko
May 16, 2022 3:18 PM	6d9dd9cfb3018209ef7bc...	SSO - tap.ca.com	10.76.13.123		Java
May 16, 2022 3:54 PM	6d9dd9cfb3018209ef7bc...	LOGOUT - CA PAM	10.76.13.123		Java

The links to the devices, resources, and IPs used are all active, so that every detail can be investigated more deeply.

### Get More Details about Risk Level Activity

All the **Risk Level Activity** menu tabs retain the same user or device header section. The **Devices** menu tab takes you to a list of devices used with the operating systems, the latest risk level decisions and locations, and the status of all four categories of analytics. This display is similar to what the **Devices** menu on the top row of the main window generates, but also includes an extra list of “device templates” with their respective operating systems and clients.

The **Activity** menu tab on the **Risk Level Activity** panel shows the same table as the **Activity** tab on the **Overview** home page. The **Locations** tab also duplicates the **Location** menu on the **Overview** panel.

The **IP Sessions** tab produces the following details:

- A location map
- A table with the city or region
- The session start and end times
- The connection type
- Users sessions
- Devices sessions

You can specify the start and end dates for the data to display. This particular data view is not duplicated anywhere else on the Threat Analytics console.

## Configure Threat Analytics Console Settings

As a user with administrative privileges, you can configure the properties of the Threat Analytics Console from the **Settings** panel.

### NOTE

If you do not have administrative privileges, see [Enable Admin Privileges for Users](#).

To access the **Settings** panel, select the gear icon at the top-right corner of the console and select **Settings** from the menu that opens.

Use the following tabs on the menu at the top of the **Settings** panel to access controls for configuring corresponding properties of the Threat Analytics Console:

- **User Accounts:** A list of user accounts with administration capabilities and status (see [Manage Threat Analytics Users](#))
- **Device Analytics:** A list of all *device* analytics that allows you to disable or enable each one (see [Select which Device Analytics Are Enabled or Disabled](#))
- **User Analytics:** A list of all user analytics that allows you to disable or enable each one (see [Select which User Analytics Are Enabled or Disabled](#))
- **Locations:** Allow or refuse access based on what country users are operating in (see [Whitelist or Blacklist Users from Network Locations Based on Country](#))
- **Operating Locations:** Map User Locations based on IP Address (see [Manually Identify Device Locations](#))
- **Subnets:** Maintains lists of subnetworks, their individual IP addresses, and their netmasks (see [Manage Subnets](#))
- **SMTP:** Set Up Simple Mail Transfer Protocol for Email (see [Set Up SMTP for Email](#))
- **Syslog:** Set up Syslog and SIEM (see [Configure Syslog/SIEM Logging](#))
- **Advanced:** Create more complex analytic configurations and operations (see [Modify Analytic Configurations, Jobs, and Mixing Functions](#))

## Manage Threat Analytics Users

Select the **User Account** tab from the **Settings** panel menu to open the **Manage User Accounts** pane from which you can do the following tasks:

- Add Threat Analytics user accounts
- Manage existing Threat Analytics accounts (for example, assign administrative privileges, lock, and delete)

[Home](#) / [Settings](#)

Login	Email	Admin	Enabled	Locked	Source	Last Login Time	Last Login IP	Actions
admin	admin@localhost.local	✓	✓		interlock	Jul 1, 2022 11:14 AM	127.0.0.1	<a href="#">Edit</a> <a href="#">Delete</a>
super	super@pam.local	✓	✓		saml	Jul 5, 2022 6:35 PM	127.0.0.1	<a href="#">Edit</a>

### Add a User

Complete this procedure to create a Threat Analytics user account.

#### Follow these steps:

1. Select the **+ Add User** button. The **Create User** pane opens.
2. Complete the following fields and options, as required:

- **Login:** The login name of the new user.
- **Email:** The email address of the new user
- **Password:** The password for the new user; this password is evaluated and if accepted a green “Strong Password” message appears.
- **Confirm Password:** Enter the same password to verify all characters
- **Enabled:** Set this option to enable the user account.
- **Admin:** Set this option to assign administrative privileges to the user account
- **SMTP Settings:** (Informational)  
Shows the current SMTP status (whether email is enabled or disabled). To change the setting, select the
- **Alerts:** Specify the frequency of **System Alerts**, **Service Alerts**, and **Risk Escalation Alerts** by selecting one of the following values from the associated drop-down menu:
  - **Inactive**
  - **Immediately**
  - **Hourly**
  - **Daily**
  - **Weekly**

3. Select the **Save** button. The user is created and added to the user account table.

### **Manage Existing Users**

The user account table displays static and manageable properties of existing users and allows you to:

- **Login:** The login name of the user.
- **Email:** The email address of the user.
- **Admin:** Specifies whether the user has administrative privileges. If yes, a checkmark icon is present. If no, an empty checkbox is present. Select the checkmark icon or checkbox to toggle the setting.
- **Enabled:** Specifies whether the user is enabled. If yes, a checkmark icon is present. If no, an empty checkbox is present. Select the checkmark icon or checkbox to toggle the setting.
- **Locked:** Specifies whether the user account is locked out. If yes, a checkmark icon is present. If no, an empty checkbox is present. Select the checkmark icon or checkbox to toggle the setting.
- **Source:** The access method of the user (for example, SAML)
- **Last Login Time:** The last time the user logged in.
- **Last Login IP:** The IP address from which the user logged in.
- **Actions:** Provides the following options:
  - **Edit:** Open the account for editing in the **Edit User** pane (which is similar to the **Create User** pane).
  - **Delete:** Delete the user account.

## **Select which Device Analytics Are Enabled or Disabled**

Access the **Device Analytics** tab from the **Settings** panel menu to enable or disable any of the 58 available risk level analytics for all *devices* on the network. All analytics are enabled by default.

In the following example, the "Bad Associated Risk Subject" and "Crossed Organizational Subnet Boundary" options are not set. Those analytics are therefore disabled for all devices.

## Whitelist or Blacklist Users from Network Locations Based on Country

Select the **Locations** tab from the **Settings** panel to allow or refuse network access to all users based on the country in which they are located using a *whitelist* **or** a *blacklist*.

A whitelist explicitly specifies the countries from which use users *are* accepted on the network. A blacklist explicitly specifies the countries from which users are *not* accepted on the network. (Whitelists and blacklists are therefore mutually exclusive.)

Use the **Whitelist** tab to configure a whitelist. Select the **Blacklist** tab to configure a blacklist. Both tabs are similar, each displaying a list of countries in alphabetical order and a **Search** field to quickly locate a specific country.

### Configure a Whitelist

Use this procedure to configure a whitelist.

#### Follow these steps:

1. Select the **Whitelist** tab.
2. Do the following steps to *add* a country to the whitelist:
  - a. Select the target country by scrolling down the list of locations on the left or by using the **Search** field.
  - b. Select the **Add** button in the **Action** column. The country is added to the list of **Whitelisted Locations** on the right.
3. To remove a country from the whitelist, select the red **Remove** button beside the list of **Whitelisted Locations** on the right.

### Configure a Blacklist

Use this procedure to configure a blacklist.

**Follow these steps:**

1. Select the **Blacklist** tab.
2. Do the following steps to *add* a country to the blacklist:
  - a. Select the target country by scrolling down the list of locations on the left or by using the **Search** field.
  - b. Select the **Add** button in the **Action** column. The country is added to the list of **Blacklisted Locations** on the right.
3. To remove a country from the blacklist, select the red **Remove** button beside the list of **Whitelisted Locations** on the right.

## Manually Identify Device Locations

If the physical location of a site cannot be determined from its IP address, you can manually identify its location using one of the following techniques:

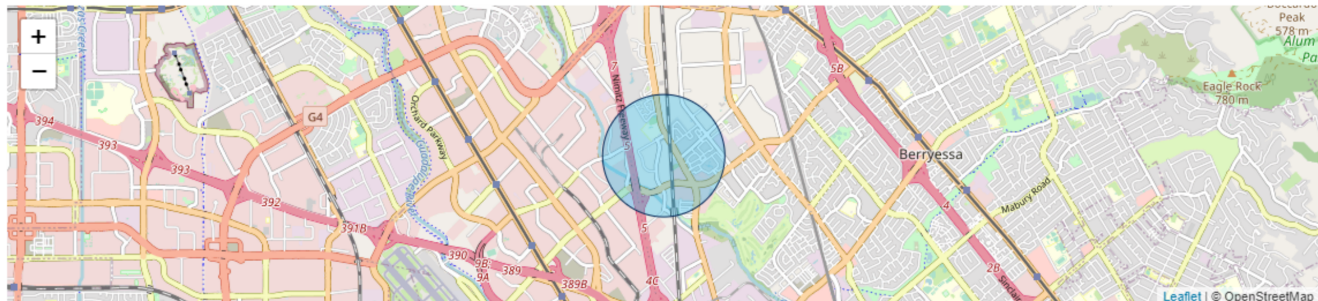

- Specify the coordinates of the site using its latitude and longitude
- Navigate to the site location using the map

**Follow these steps:**

1. Select the **Operating Locations** tab from the **Settings** panel. The **Managing Operating Locations** pane opens as shown in the following example:

User Accounts   Device Analytics   User Analytics   Locations   **Operating Locations**   Subnets   SMTP   Syslog   Advanced

### Manage Operating Locations

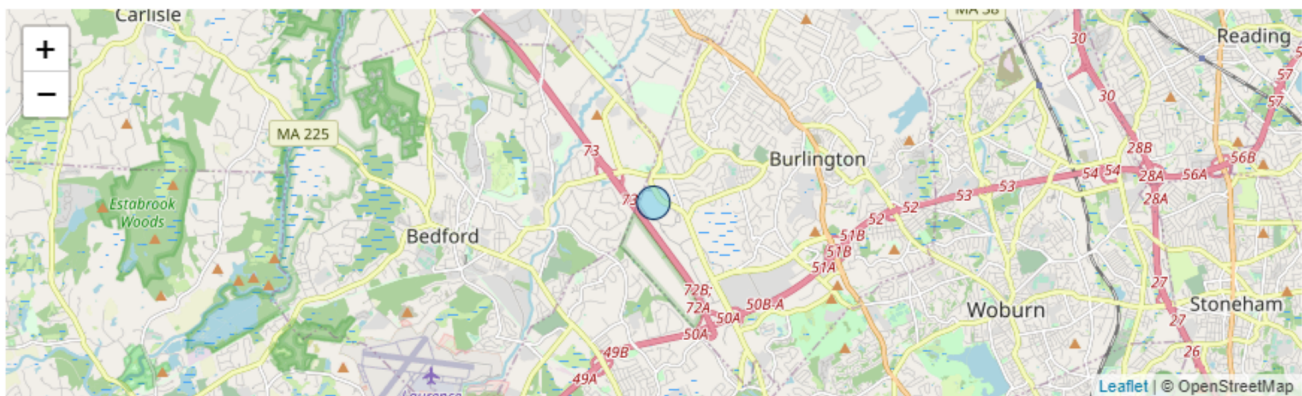

**+ Add Operating Location**

Title	Timezone	Radius (miles)	Created	Actions
Operating location at 37.3861, -121.9003 <a href="#">Focus Map</a>		1 mi	Jul 11, 2022 4:10 PM	<a href="#">Delete</a>

2. Select the **Add Operating Location** button. The **Add Operating Location** pane opens as shown in the following example:

## Add Operating Location

Click to add a point. Click the point to change the radius. Click the map to release the radius.

✖ Clear Map

Latitude	Longitude	Radius (miles)	
42.49728891992472	-71.23337745666505	0.2	<a href="#">+ Add Location</a>

### 3. Do one of the following actions:

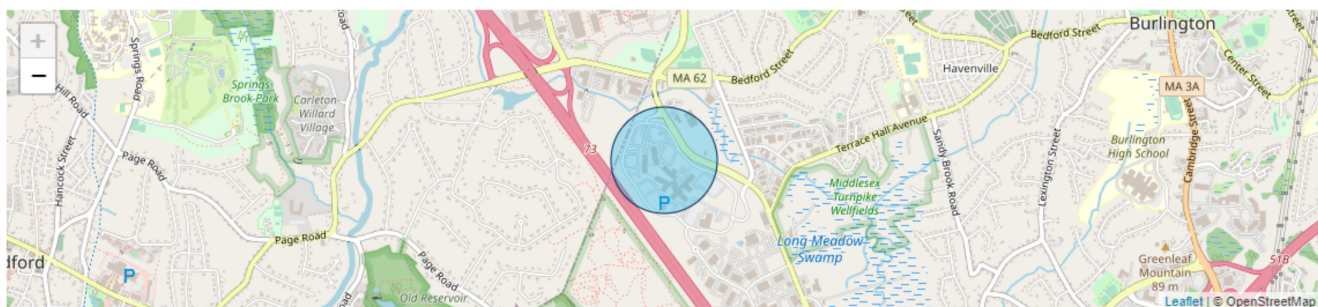

- Enter the site coordinates in the **Latitude** and **Longitude** fields. Use positive coordinates for northern latitudes and eastern longitudes and use negative coordinates for southern latitudes and western longitudes.
- Manipulate the map until the site location is centered.

### 4. Enter the margin of error for the site location in the **Radius** field.

The location that you entered is added to the operating locations list. The **Focus Map** text under each operating location takes you to a view of that particular location, as shown in the following example:

[User Accounts](#) [Device Analytics](#) [User Analytics](#) [Locations](#) [Operating Locations](#) [Subnets](#) [SMTP](#) [Syslog](#) [Advanced](#)

## Manage Operating Locations

[+ Add Operating Location](#)

Title	Timezone	Radius (miles)	Created	Actions
Operating location at 37.3861, -121.9003 <a href="#">Focus Map</a>		1 mi	Jul 11, 2022 4:10 PM	<a href="#">Delete</a>
Operating location at 42.49728891992473, -71.23337745666504 <a href="#">Focus Map</a>		0 mi	Jul 11, 2022 3:55 PM	<a href="#">Delete</a>

To delete a site, select the **Delete** button in the **Action** column of its entry in the operating locations list.

## Manage Subnets

A subnet is a segmented piece of a larger network, partitioned into multiple smaller network segments to help minimize the traffic. This segmenting splits a large network into groups of smaller interconnected networks, increasing transmission speeds.

To view and add subnets, select the **Subnets** tab from the **Settings** panel. The **Manage Subnets** pane that opens displays a list of each active subnet together with the following associated properties:

- **Title** (a numerical value)
- **IP Address**
- **Netmask** address
- The date and time that it was **Created**
- Whether the subnet is **Suspicious**
- Whether the subnet is part of the **Organization**
- The **Subnet Group** category of each subnet. (One of Amazon Web Services (AWS), RSLynx (RS), Google, or WA).

The following screenshot shows an example **Manage Subnets** pane.

To add a subnet, select the **Add Subnet** button and supply the required properties.

### NOTE

You cannot delete a subnet from the Threat Analytics Console.

## Set Up SMTP for Email

Simple Mail Transfer Protocol (SMTP), is an email protocol for sending emails between clients and accounts. To manage SMTP settings, select the **SMTP** tab from the **Settings** panel menu.

To configure the SMTP settings for Threat Analytics, configure the following settings as appropriate:

- **Enable System Emails:** Set this option to enable system emails.
- **Default From Address:** Specifies the email address of the user account from which messages are sent. Select the **Save** button to save the address. Select the **Send Test Mail** button to send a test message.
- **Host:** The host address to use.
- **Port Number:** The port number to use.
- **Domain:** The domain to use.
- **Use SSL :** Set this option to use SSL.
- **Authentication** (Optional): Specify the type of authentication to use; the options are Plain, Login, and CRAM-MD5. If an authentication method is specified, the following fields appear:
  - **Username:** The username of the account to use for authentication.
  - **Password:** The password of the account to use for authentication.

Select the **Save** button to commit your changes.

The following screenshot shows an example of a typical configuration:

User Accounts Device Analytics User Analytics Locations Operating Locations Subnets **SMTP** Syslog Advanced

## Configure Syslog/SIEM Logging

Syslog is a message logging protocol that handles the event data management and security. Syslog also monitors informational, analysis, and debugging messages. Syslog is essentially a mechanism for network devices to send event messages to a logging server, but it provides no analysis of the log data.

SIEM ([Security Information and Event Management](#)) goes further, combining event logs with contextual information about users and their vulnerabilities. SIEM also uses algorithms, rules, and statistics to compare the devices.

You configure Syslog and SIEM logging from the **Syslog** tab on the **Settings** panel menu.

### **Configure Syslog/SIEM Server Definitions**

Do this procedure to configure Syslog/SIEM server definitions.

**Follow these steps for each Syslog/SIEM server that you want to configure:**

1. Select the **Create Server Config** button.
2. Complete the following fields:
  - **IP**: The server IP address.
  - **Port**: The server port number.
  - **Protocol**: The server communication protocol (TCP or UDP).
3. Select the **Save** button to commit your changes.

The new server definition is listed at the top of the pane, as shown in the following screenshot:

IP	Port	Protocol	Created At	Actions
10.17.40.159	25	tcp	Jul 13, 2022 2:56 PM	<a href="#">Edit</a> <a href="#">Delete</a>

Alert me on: Risk Level Changes Transition: All Changes

[Save Filter Config](#)

**To edit a server definition:** Select the **Edit** button in the **Actions** column of the corresponding entry in the server list.

**To remove a server definition:** Select the **Delete** button in the **Actions** column of the corresponding entry in the server list.

### **Configure Filters to Limit the Events That Trigger an Alert**

By default, all events trigger an alert. This procedure describes how to configure filters that limit the changes that trigger an alert.

**Follow these steps for each filter that you want to create:**

1. Select one of the following options from the **Alert me on** drop-down.

- **All Changes** (Default): All events trigger an alert.
  - **Risk Level Changes**: All risk level changes trigger an alert.
  - **Analytic Triggers**: Only the analytics that you specify in the following step trigger alerts.
2. If you selected **Analytic Triggers**, select one of the following options from the **Transition** drop-down list that appears:
- **All Analytics**
  - **All Location Analytics**
  - **All Activity Analytics**
  - **All Sensitivity Analytics**
  - **All Integrity Analytics**
  - **Specific Analytics**
3. Select the **Save Filter Config** button.

The filter is added to the **Current Syslog/SIEM Filters** list.

**To remove a filter:** Select the **Delete** button in the **Actions** column of the corresponding entry in the filters list.

## Modify Analytic Configurations, Jobs, and Mixing Functions

Select the **Advanced** tab from the **Settings** panel to access the advanced threat analytics configuration options.

### CAUTION

Change these settings with caution, preferably with the assistance of Broadcom Support.

The **Risk Analysis** section lets you modify the threshold for how many possibly suspicious incidents should be shown. This section does not enable or disable individual analytics, but instead specifies whether you want to view more incidents or fewer incidents overall. There is also a **Reset to defaults** button to return to the original settings.

[User Accounts](#)[Device Analytics](#)[User Analytics](#)[Locations](#)[Operating Locations](#)[Subnets](#)[SMTP](#)[Syslog](#)[Advanced](#)

## Advanced

### Risk Analysis

These controls modify how the system evaluates risk. Be cautious about using them! Setting the value too low may cause the system to show no incidents, while setting it too high may generate too many incidents to deal with.

[+ Show me \*\*more\*\* incidents](#)
[- Show me \*\*fewer\*\* incidents](#)
[✕ Reset to defaults](#)

Update Mixing Function  No file chosen

The **Analytic Baseline Configurations** section lets you specify values for five specific analytic keys that govern the number of days with no activity before a user goes dormant, how many devices or device families a user has, how many operating systems associated with, and the number of groups a user can belong to. If a value is not set, the analytic is set to the default value. For example, the “default\_dormant\_days” threshold is 30 days with no activity, but you can make the threshold higher or lower as needed by selecting **Edit**.

#### CA Threat Analytics Configuration

**Warning!** Editing these settings may result in unexpected behavior. Please do not make changes **unless directed to do so by support staff**.

Key	Description	Value	
default_dormant_days Type: Integer	The default number of days with no Activity that must pass before a user is considered Dormant	-- Defaults to 30 when not set	<a href="#">✎ Edit</a>
user_device_count_limit Type: Integer	The hard limit on the number of devices a user can be associated with before being flagged. A value of null indicates no limit.	5 Defaults to Null when not set	<a href="#">✎ Edit</a>
user_device_family_count_limit Type: Integer	The hard limit on the number of device families a user can be associated with before being flagged. A value of null indicates no limit.	3 Defaults to Null when not set	<a href="#">✎ Edit</a>
user_device_os_count_limit Type: Integer	The hard limit on the number of device OSes a user can be associated with before being flagged. A value of null indicates no limit.	3 Defaults to Null when not set	<a href="#">✎ Edit</a>
user_group_count_limit Type: Integer	The hard limit on the number of Groups an identity can belong to before being flagged. A value of null indicates no limit.	-- Defaults to Null when not set	<a href="#">✎ Edit</a>

The **Advanced Configuration Values** section allows you to change the default values for 78 different analytic keys using the **Edit** button. This section is similar to the **Analytic Baseline Configuration** panel.

## CA Threat Analytics Configuration

**Warning!** Editing these settings may result in unexpected behavior. Please do not make changes **unless directed to do so by support staff**.

Key	Description	Value	
api_available Type: Boolean	Is the API Available to process requests? If false, API will return a 503.	-- Defaults to true when not set	<a href="#">Edit</a>
api_documentation_dynamic Type: Boolean	Indicates whether the API Documentation will be dynamically generated	-- Defaults to false when not set	<a href="#">Edit</a>
batch_loading Type: Boolean	Flag indicating whether the system is in a batch loading state, and thus that the jobs should treat time differently.	-- Defaults to false when not set	<a href="#">Edit</a>
cache_data_enabled Type: Boolean	Indicates whether Data/Resources should be cached from remote services, systemwide.	-- Defaults to true when not set	<a href="#">Edit</a>
cache_devices_enabled Type: Boolean	Indicates whether Devices should be cached from remote services, systemwide.	-- Defaults to true	<a href="#">Edit</a>
cache_group_subjects_enabled Type: Boolean	Indicates whether GroupSubjects should be cached from remote services, systemwide.	-- Defaults to true	<a href="#">Edit</a>
cache_ip_mappings_enabled Type: Boolean	Indicates whether IpMappings should be cached from remote services, systemwide.	-- Defaults to true when not set	<a href="#">Edit</a>
cache_user_subject_mappings_enabled Type: Boolean	Indicates whether UserSubjectMappings should be cached from remote services, systemwide.	-- Defaults to true when not set	<a href="#">Edit</a>
cache_user_subjects_enabled Type: Boolean	Indicates whether UserSubjects should be cached from remote services, systemwide.	-- Defaults to true when not set	<a href="#">Edit</a>
default_dormant_days Type: Integer	The default number of days with no Activity that must pass before a user is considered Dormant	-- Defaults to 30 when not set	<a href="#">Edit</a>
demo_mode Type: Boolean	Flag indicating whether the system is in demo mode.	-- Defaults to false when not set	<a href="#">Edit</a>
demo_user_id Type: String		-- Defaults to when not set	<a href="#">Edit</a>

The **Jobs** link on the **Advanced** tab shows the status of the thirty tasks being monitored by the network, presented in alphabetical order.

## CA Threat Analytics Jobs

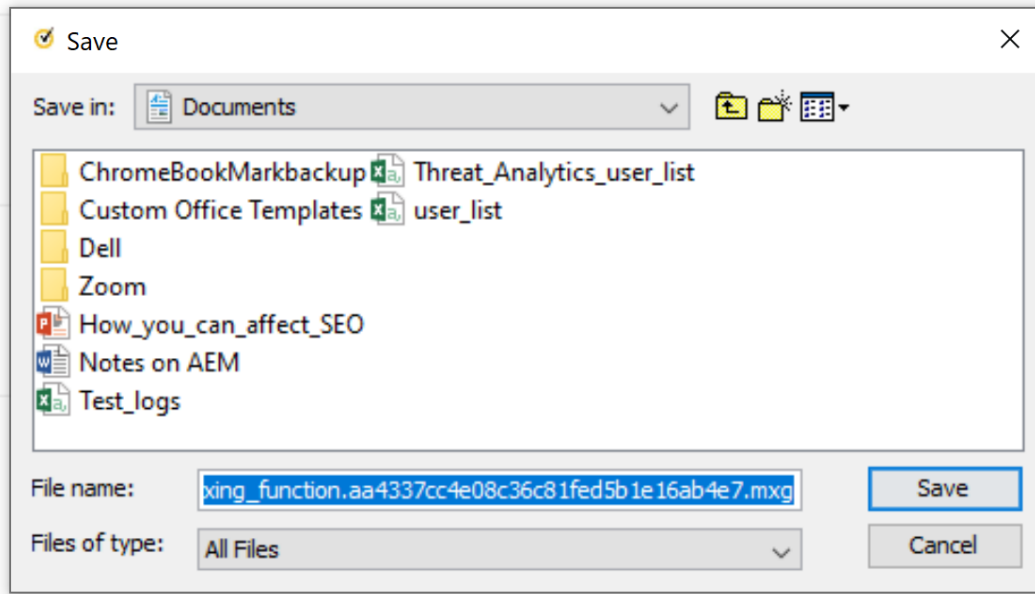

**Warning!** Manually manipulating Jobs may result in unexpected behavior. Please do not make changes **unless directed to do so by support staff**.

The **Jobs** link provides the following information:

- The job title
- The name of the \*.job file
- Whether it has been enabled
- Its status
- The statistics for a scheduled job or task in UNIX, known as a "cron" job
- How long it has been timed out (when applicable)
- The last start and end times (where relevant)
- Two **Stop** and **Run** buttons to stop or restart the job as needed

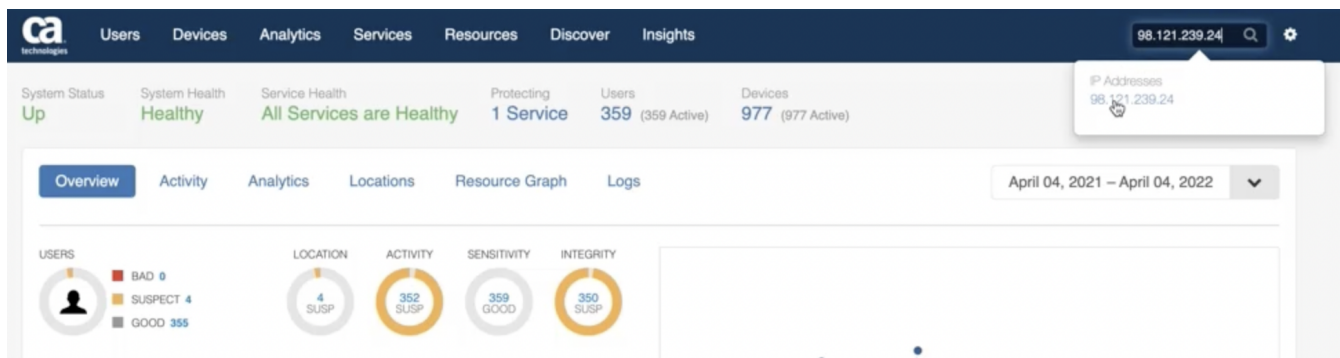

The **Mixing Function** section of the **Advanced** menu allows you to save a copy of the current mixing file to your system. The default location is the Documents folder of the user.

The file that is saved in this example is named `mixing_function.aa4337cc4e08c36c81fed5b1e16ab4e7.mxg`, and its content is not readable to most users. But the file does allow you to save and restore different mixing schemes using the **Update Mixing Function** button.

## Access User Activity Using IP Search

The search field at the upper right corner of the screen can be used to search on IP addresses. Enter the IP address, press the enter key, and then select the blue link that drops down.

You see a list of activity from this IP address that includes the following elements:

- A location map
- The user name
- The devices used
- The start and ending date and times of all IP sessions

At the top of the **IP Sessions** page are fields that monitor the following characteristics:

- The IP address
- The connection type
- The location
- The date of the first appearance on the network for the period specified
- The state of the user
- Counts of the number of sessions, users, and devices in the session

You can specify the start and end dates for the list in the search field at the top-right of the page.

The screenshot shows the Symantec Privileged Access Manager interface. At the top, there is a navigation bar with tabs: Users, Devices, Analytics, Services, Resources, Discover, and Insights. A search bar is located on the right. Below the navigation bar, a summary row displays the following information: IP Address: 10.76.13.123, Connection Type: N/A, Location: N/A, First Seen: May 4, 2022 8:28 PM, State: Active, Session Count: 41, Users Count: 3, and Devices Count: 3. Below this, there is a tabbed interface with 'IP Sessions' selected. A date range filter is set to 'June 20, 2022 – July 20, 2022'. The main content area displays a table of sessions.

If you select a user or device from the **IP Sessions** tab, it takes you to the **Risk Level Activity** page for that user or device.

The **Activity** tab from the IP Address page lists every session from the specified period of time. This list provides the following characteristics:

- The timestamp of the session
- The user
- The device
- The action that is taken and the resource that is used
- The IP address
- The client

This pane is similar to the **Activity** tab on the **Home** menu, but without the bar graphs.

# Administrating

---

The content in this section describes administrative procedures.

**Use the table of contents to access the topics in this section**

## Account Types

### 'super' (root account)

Privileged Access Manager has two preconfigured user accounts: 'super' and 'config'. The 'super' is a superuser (or root) account that has access to all Privileged Access Manager settings (and thus the config account settings). As with the config account, super cannot be deleted.

1. Point your browser to the Privileged Access Manager URL.
2. When you log in for the first time, accept the license agreement. Select **I Agree** to continue.
3. Enter your default "root" credentials (**User:** super / **Password:** super) and select **ENTER**.
4. The first time that you log in:
  - a. You see at least two requests to accept Java. If your Java console has been set on, you see the Java console startup too.
  - b. You see the **User Information** dialog. Several fields are available for edit, but you are required to change at least the default password ("super").
5. Change the password by using the fields **Old Password**, **New Password**, and **Confirm Password**.  
The strength of the new password must conform to Security Level 2, which requires that the updated password:
  - a. Differ from the previous password
  - b. Have a length between the Global Settings values for **Min Length** (default: 6) and **Max Length** (default: 14)
  - c. Have at least one (Latin) alphabet character
  - d. Have at least one numerical digit character
6. Change any other fields that are desired, and select **OK**.  
A warning message appears: "Configuration Password is still the default value." Address this warning now, as described in **'config' (root account)**.
7. Select **Logout** at the upper right-hand corner.

### 'config' (root account)

We recommend that you use this configuration account only for initial setup. Change the password from default using the Change Password button in the Toolbar Menu. Consider also changing the "config" Login Id in addition to the Password using the Change Password menu. Store the password in a safe place and use it only for emergencies when other authentication methods are not available.

This account is used only for Privileged Access Manager configuration. For information about resetting its name or password, see [Change Login for Config or Super User](#).

### Provisioned Users

All other Users that you create, regardless of their roles, are initially presented with the My Info page for password change. After they change their passwords, they land on the default page suitable to their roles.

- Global Administrators (including the 'super' account), Operational Administrators or Server Control Administrator roles land on the Dashboard Overview Tab.
- Most End Users (with the "Standard User" role) land on the **Access** page (whether it is populated with any access links). They do not see the rest of the dark gray menu bar.
- Other Users with various combinations of roles land on the **Access** page, but also see a customized administration menu bar.
- The 'config' account has access only to the **Configuration** menu, and cannot access the rest of the administration menu.

## Dashboards

Learn about the PAM Overview, System, and Cluster Dashboards.

PAM provides the following dashboards to monitor different aspects of your environment:

- The [Overview Dashboard](#) provides a centralized view of your PAM Environment.
- The [System Dashboard](#) shows current and historical system data about a single PAM node that allows you to visualize system performance and identify trends over time.
- The [Management Console Cluster Dashboard](#) shows current and historical system data about a cluster that allows you to visualize cluster performance and identify trends over time.

## Overview Dashboard

Learn how to use the Overview Dashboard (formerly known simply as the Dashboard) to monitor functional information about your PAM environment.

### Introduction

PAM provides Overview and System dashboards to monitor the functional information about your environment.

The Overview dashboard provides a centralized view of your PAM Environment. This dashboard shows a summary of key managed elements and counts newly added items, breakdown of logins and sessions currently in progress, list of violation log events, appliance and cluster health.

The Overview dashboard provides a centralized view of your PAM Environment, including:

- Access requests: View counts of approved access requests.
- Security alerts: View and respond to security alerts, such as suspicious login attempts and unauthorized access.
- System health: Monitor the performance and health of your PAM environment.
- At-a-glance view of privileged access activity: The dashboard provides a summary of all privileged access activity, including the number of active sessions and applications used.
- Threat Analytics Console that identifies anomalies in PAM user behavior and implementing policies to dynamically mitigate potential insider threats or breaches by external threat actors.

### **NOTE**

The Overview Dashboard is only present in the PAM UI if you are logged in with an account with Global Administrator, Operational Administrator, or Server Control Administrator roles.

To access the Overview Dashboard, select **Dashboard** in the menu bar and then select the **Overview** tab that appears below the menu bar, as shown in the following screen capture:

Symantec PAM Manager

Dashboard Sessions ▾ Users ▾

Overview System Metrics

## Dashboard

### Overview Dashboard Panel Components

#### **Messages**

Privileged Access Manager puts information for the user under the Dashboard heading.

#### **Elements Under Management**

This panel displays the current quantities of various managed elements, highlighting recent additions. Selecting an icon navigates to the respective view of the elements.

- **Devices** – Target Devices in use (all types)
- **Device Groups** – Device Groups in use
- **SC Policies** – Server Control Policies in use
- **SC Devices** – Server Control Devices in use
- **Privileged Accounts** – Privileged user target accounts registered and recently added account total
- **A2A Accounts** - A2A target accounts registered and recently added account total.
- **Users** – User accounts registered
- **A2A** – Accounts
- **Target Applications** – Target applications registered and recently added application total.
- **Vaults** – Vaults in use
- **Secrets** – Secrets in use
- **Credential and Vault Management** – For password and vault management target account use

#### **Session Management**

- **Logins** shows the number of currently active User login sessions. This number includes multiple logins of the same User (when applicable).
- **Sessions** shows the number of currently active connection sessions. This number includes multiple connections from the same User to the same Device (when applicable).

#### **Credential Management**

Credential Management shows the top four counts from Credential Manager Activities Reports. These reports are configured at **Credentials, Reports, Activities**. Any four of these report values might be reported here:

- Passwords used in last 30 days
- Password requests pending
- Passwords not verified
- Clients requiring activation
- Proxies requiring activation
- Passwords changed today
- Failed A2A client requests in last 30 days
- Successful A2A client requests in last 30 days
- All A2A client requests in last 30 days
- Unverified compound accounts
- Synchronized accounts with expired passwords
- Unsynchronized accounts with expired passwords

### ***Appliance Status (or Cluster Status)***

Per Hardware Appliance. The order of the appliances is the same as that in **Configuration, Clustering**.

- **CPU:** CPU capacity in use during the selected time period
- **RAM:** Memory in use during the selected time period
- **HDD:** Disk storage in use during the selected time period
- **Network Share:** Network share in use; only visible if a network share has been added for session recording or database backups
- **Hostname:** Hostname assigned
- **IP:** IP Address that is assigned
- **MAC:** Address assigned
- **Machine Type:** for example, Standard
- **Status indicator :** Displays current status

### ***License Usage***

**Quantities currently:** (In Use) / (Licensed)

- **Session Management** – For device access use
- **Credential Management** – For password management target use
- **A2A Management** – For A2A request server use
- **Server Control Management** – For Server Control device use

### ***Recent Events***

Time and Details of messages for recent connection and violation log events. The most recent events are listed first.

### ***Server Control Administrator Dashboard***

When a user with the Server Control Administrator role logs in, the Dashboard displays the following components:

- **Elements Under Management:** Devices, Device Groups, SC Policies, SC Devices, Users
- **Appliance Status:** CPU, RAM, HDD, Hostname, IP, MAC, Machine type, Status Indicator
- **License Usage:** Server Control Management
- **Recent Events**

### ***Analytics***

When the Threat Analytics component is enabled, the Analytics panel appears in the center/bottom of the Dashboard. Selecting the icon launches the **Threat Analytics** console that identifies anomalies in PAM user behavior. Selecting the **Threat Analytics** icon also implements policies to dynamically mitigate potential insider threats or breaches by external threat actors.

## Analytics

### Threat Analytics

To enable the Threat Analytics component, see [Implementing Threat Analytics](#) for more information.

## System Dashboard (Single Node)

Learn how to use the System Dashboard data visualization tool to view and interpret information about a single PAM node.

### Introduction

The System Dashboard is a visualization tool that shows current and historical system data that dynamically updates with time, allowing you to monitor system performance and identify trends. The System Dashboard shows system data about a single PAM instance.

The following screenshot shows some sample System Dashboard output:

## PAM Details ⓘ

```
Cluster:
Site:
PAM:PAM_INSTANCE1
CPU: 8
RAM: 8 GB
Disk: 9.70 GB
```

## CPU History ⓘ

## Disk Utilizati... ⓘ

### PAM OS Disk Utilization History

### Session Recording Storage History ⓘ

### Backup Session Recording Storage History ⓘ

No data

### Disk IO History

### Network IO History

## Access the System Dashboard

You can access the System Dashboard for a PAM instance from the PAM Client or a supported web browser.

### NOTE

Microsoft Edge running in Internet Explorer mode does not support the System Dashboard.

To access the System Dashboard, use one of the following options:

- Log in to a PAM instance using an account with either the Global Administrator or Operational Administrator role. The Overview Dashboard opens. Select **Dashboard, System** to open the System Dashboard.  
To return to the System Dashboard after navigating elsewhere in the UI, select **Dashboard** in the menu bar. If you have used the Overview Dashboard, select the **System** tab to open the System Dashboard.
- Log in to the Management Console using an account with either the Global Administrator or Operational Administrator role. The console lists all the clusters in your environment. To open the System Dashboard with the Management Console instance information, follow these steps:
  - Select **Administration**. The Overview Dashboard opens.
  - Select **Dashboard, System**.

## Refresh the Dashboard Data

By default, the dashboard does not update automatically to preserve system resources.

To update the data manually, select the **Refresh** icon () near the right end of the menu bar.

To configure the dashboard to refresh the data automatically, select the **Auto/Manual Refresh** icon () at the far right of the menu bar, and then choose **Auto** from the drop-down menu. The refresh time adjusts based on the time duration that is selected in the time option. The **Refresh** icon is updated to reflect the change (.

## Modify the Displayed Time Range

By default, the dashboard visualizations show data from the last 24 hours. PAM purges data older than 30 days.

Use either of the following methods to modify the range of time displayed:

- Click and drag over an activity timeline to zoom in.
- Select the **Time Range** button () in the menu bar and choose from a list of preset ranges or specify an absolute range on the **Time Range** dialog that opens.
- If a time range is displayed in the menu bar beside the **Time Range Zoom** button, use the lesser than (<) and greater than (>) buttons to shift the timeline forward and backward. The duration between the selected times remains constant.
- Select the **Time Range Zoom** button () in the menu bar to zoom out.

The selected time range is applied to the activity timelines and all other data on the dashboard shifts to reflect the same time period.

### IMPORTANT

Current status elements (for example, meters) also shift with the timeline but display the data applicable at the end of the selected time range (if that is not the current time).

## System Dashboard Components

This section describes all the data that the system dashboard provides about the current PAM instance, separated into functional groups.

### System Dashboard Visualization Elements

The dashboard presents system data using one or both of the following visualization elements:

- **Current status:** A meter or text box that describes current status as shown in the following example screenshots:

Example status meter:

Example status text box:

- **Activity Timeline:** A chart that shows status over time, as shown in the following example screenshot:

## System Health

The dashboard provides the following usage metrics for standard indicators of server system health.

### NOTE

**RAM, CPU, and Disk** charts select the line color to reflect the most-recent value. For example: if a line peaks above the threshold but the last data point (based on the given timeline) is below the threshold, the entire line appears green.

- **RAM:** Memory in use during the selected time period
- **CPU:** CPU capacity in use during the selected time period
- **Disk:** Current status within the activity timeline
- **Session Recording Storage** (primary NFS/CIFS mount) status: Activity timeline only.
- **Backup Session Recording Storage** (secondary NFS/CIFS mount) status: Activity timeline only.
- **Disk IO** status: Activity timeline only.
- **Network IO** status: Activity timeline only.

## Operational Health

The dashboard provides the following usage metrics about indicators of PAM operational health:

- **Mode** (Online or Maintenance): Current status and activity timeline.
- **Sync Status** (Online, Not Clustered, or Not Replicating): Current status and activity timeline. Not Clustered appears for PAM instances that are not part of a cluster.

## Access Activity

The dashboard provides the following usage metrics about PAM access activity:

- **PAM Logins** (users logged in): Activity timeline only.
- **PAM Sessions** (active access sessions): Activity timeline only.

## Interpret the Dashboard Data

Resource utilization on PAM appliances can exhibit short bursts or drops in activity levels, affecting both OS metrics like RAM and CPU usage, as well as physical resources like disk and network I/O.

In virtualized environments such as VMWare, KVM, and cloud platforms, the underlying physical infrastructure is shared among multiple VMs. PAM reflects the availability and allocation of resources to individual VMs, essentially scheduling and allocating resource capacity slots for their operation.

Under conditions of infrastructure strain, heavy load, or operations like snapshots, the overall performance of VMs may be impacted. While the effect is typically minimal, there may be instances where VM processing is completely paused or allotted resources are reclaimed to accommodate higher-priority activities.

**To avoid unnecessary concerns when evaluating PAM dashboard activity timelines, consider the following important factors:**

- **Magnitude of changes:** Assess the extent of resource utilization fluctuations. Consider orders of magnitude differences.
- **Episode duration:** Determine the duration of these fluctuations, distinguishing between quick blips and sustained periods of abnormal resource usage.

## What to look for in the dashboard:

- **Activity timeline chart time range:**
  - Examine the charts. Even if a chart appears to have a significant spike, if the time range is low or has a very narrow range, the visualized spike may not be a cause for concern.
  - However, if the scale is large and the meter remains high over an extended period, it is worth investigating. Keep in mind that while PAM may be busy, overall performance and response times may still function normally without degradation.
- **Interpret short spikes:**
  - Brief spikes are normal day-to-day behavior for VMs, appliances, and operating systems. Therefore, an infrequent spike in a chart does not necessarily indicate a problem.
  - However, long durations of elevated activity should warrant further investigation.
- **Identify performance issues:**

- When PAM performance issues occur, use the dashboard to identify when health and performance issues began and time windows when intermittent issues reoccur.
- Use the dashboard to highlight unexpected changes or changes that occur slowly over time.

## Management Console Cluster Dashboard

Learn how to use the Management Console Cluster Dashboard data visualization tool to view and interpret information about your cluster.

### Introduction

The Cluster Dashboard is a visualization tool that shows current and historical system data about a PAM cluster that dynamically updates at specified intervals. The Cluster Dashboard is a valuable tool for monitoring cluster performance and identifying trends over time. The following screenshot shows some sample Cluster Dashboard output:

Cluster Name PAM\_CLUSTER1 PAM Site Name All PAM Instance Name All

### Cluster Details

## Cluster Information ⓘ

## Access the Cluster Dashboard

To access the **Cluster Dashboard**, do the following steps:

1. Log in to the Management Console from the PAM client or a supported web browser using an account with either the Global Administrator or Management Console Administrator role.

### NOTE

Microsoft Edge running in Internet Explorer mode does not support the System Dashboard.

2. Select the cluster whose data that you want to visualize from the list of clusters that appear.
3. Either select the **View Dashboard** button, or choose **View Dashboard** from the **Actions** column.

## Refresh the Dashboard Data

By default, the dashboard does not update automatically to preserve system resources.

To update the data manually, select the **Refresh** icon () near the right end of the menu bar.

To configure the dashboard to refresh automatically, select the **Auto/Manual Refresh** icon () at the far right of the menu bar, and then choose **Auto** from the drop-down menu. The refresh time adjusts based on the time duration that is

selected in the time option. The **Refresh** icon is updated to reflect the change ()

## Modify the Displayed Time Range

By default, the dashboard visualizations show data from the past 24 hours. PAM purges data older than 30 days.

Use either of the following methods to modify the range of time displayed:

- Click and drag over an activity timeline to zoom in.
- Select the **Time Range** button () in the menu bar and choose from a list of preset ranges or specify an absolute range on the **Time Range** dialog that opens.
- If a time range is displayed in the menu bar beside the **Time Range Zoom** button, use the lesser than (<) and greater than (>) buttons to shift the timeline forward and backward. The duration between the selected times remains constant.
- Select the **Time Range Zoom** button () in the menu bar to zoom out.

The selected time range is applied to the activity timelines and all other data on the dashboard shifts to reflect the same time period.

### IMPORTANT

Current status elements (for example, meters) also shift with the timeline but display the data applicable at the end of the selected time range (if that is not the current time).

## Cluster Dashboard Components

The **Cluster Dashboard** provides the following data about the selected PAM cluster:

### Cluster Dashboard Visualization Elements

The dashboard presents system data using one or both of the following visualization elements:

- **Current status:** A meter or text box that describes current status as shown in the following example screenshots:

Example status meter :

- **Activity Timeline:** A chart that shows status over time, as shown in the following example screenshot:

- **Access Activity:** Aggregated usage metrics about PAM access activity across the cluster:
  - **PAM Logins:** The number of currently active user login sessions. This value includes multiple logins of the same user (when applicable).
  - **PAM Sessions:** The number of currently active connection sessions. This value includes multiple connections from the same User to the same Device(when applicable).
- **PAM Licenses Utilization:** Overall license usage at the latest data point within the selected time range:
  - **Session Management**
  - **Vaults / Credentials:** Vaults in use
  - **A2A:** The accounts in use
  - **Server Control:** Server Control license use
- **Cluster Node Details:** Health and access information for each node in the cluster:

- **Cluster Name:** the name of the cluster
- **Site:** the name of the site
- **Node:** The name of the node. Select the name to view the System Dashboard for the individual node.
- **Rec. Primary Disk:** Session Recording disk in use
- **Logins:** The number of currently active user login sessions.
- **Sessions:** The number of currently active connection sessions.
- **Maintenance:** Online or Maintenance.
- **Synchronization:** This detail reflects the replication status.
- **Network IO:** The network input/output
- **RAM:** Memory in use during the selected time period.
- **CPU:** CPU capacity in use during the selected time period.
- **PAM OS Disk:** OS in use
- **Sync Status Over Time:** Activity timelines showing the synchronization status for each node.
- **PAM Statistics:** A bar of status boxes that show the current usage of a number of managed

PAM Statistics ⓘ									
Devices	Device Groups	SC Policies	Target Applications	Users	Privileged Accounts	A2A Devices	SC Devices	Secret Vaults	Secrets

elements:

- **Licenses Over Time:** Meters showing license usage at the latest data point within the selected time range and Activity timelines showing usage over time:
  - **Sessions:** The number of currently active connection sessions.
  - **Vaults / Credentials:** The password and vault management target accounts in use
  - **A2A:** Accounts
  - **Server Control:** Server Control device licenses use

### Interpret the Dashboard Data

Resource utilization on PAM appliances can exhibit short bursts or drops in activity levels, affecting both OS metrics like RAM and CPU usage, as well as physical resources like disk and network I/O.

In virtualized environments such as VMware, KVM, and cloud platforms, the underlying physical infrastructure is shared among multiple VMs. PAM reflects the availability and allocation of resources to individual VMs, essentially scheduling and allocating resource capacity slots for their operation.

Under conditions of infrastructure strain, heavy load, or operations like snapshots, the overall performance of VMs may be impacted. While the effect is typically minimal, there may be instances where VM processing is completely paused or allotted resources are reclaimed to accommodate higher-priority activities.

**To avoid unnecessary concerns when evaluating PAM dashboard activity timelines, consider the following important factors:**

- **Magnitude of changes:** Assess the extent of resource utilization fluctuations. Consider orders of magnitude differences.
- **Episode duration:** Determine the duration of these fluctuations, distinguishing between quick blips and sustained periods of abnormal resource usage.

### **What to look for in the dashboard:**

- Activity timeline chart time range:

- Examine the charts. Even if a chart appears to have a significant spike, if the time range is low or has a narrow range, the visualized spike may not be a cause for concern.
- However, if the scale is large and the meter remains high over an extended period, it is worth investigating. Keep in mind that while PAM may be busy, overall performance and response times may still function normally without degradation.
- Interpret Short spikes:
  - Brief spikes are normal day-to-day behavior for VMs, appliances, and operating systems. Therefore, an infrequent spike in a chart does not necessarily indicate a problem.
  - However, long durations of elevated activity should warrant further investigation.
- Identify performance issues:
  - When PAM performance issues occur, use the dashboard to identify when health and performance issues began and time windows when intermittent issues reoccur.
  - Use the dashboard to highlight unexpected changes or changes that occur slowly over time.

## Session Management

The **Sessions** option on the menu bar allows several production-stage administrative activities:

- **Manage Sessions** – View and control (authenticate/terminate/record) user login and connection sessions.
- **Logs** – View the session log entries, which show user session activity.
- **Session Recordings** – View a list of recordings, and optionally view any recording (in a separate viewer application).

### View the List of Managed Sessions

The **Manage Sessions** page shows a list of the current user sessions. The columns in the table include:

- **User:** Shows the login session for a specific user.
- **Duration:** Indicates a single instance of a connection to a device within a login session. A single line-item within a User login item represents a session. Each user login can independently establish a session with a device. As with similar lists throughout the Administration menus, the list can be ordered on any user login column.
- **Timeout:** Indicates the time remaining until the login session times out. After the session expires, the user is automatically logged out.
- **Type** - Describes the session type, such as Access.
- **Authentication Type** - Indicates whether authentication is local or remote.
- **Connections** - Shows the number of connections that are made by a user.

Idle time is the duration in which there is no communication between the client UI and Privileged Access Manager.

Do not confuse the Timeout setting for the user session with the Login Timeout global setting. If Login Timeout is set to zero at the time the user session is established, the Timeout value for the session is always "NEVER".

When the corresponding Login Session begins an active Connection Session, the Timeout countdown is suspended. In place of the current Timeout value, there is a **UNDVC** placeholder. When every active session closes, the Timeout countdown resets to the global Login Timeout value, and a new countdown begins. When the Timeout value is changed while a Login Session is active, that Login Session continues to use the previous Timeout value.

### Manage Individual User Sessions

From the **Manage Sessions** page, you can select a currently logged-in user from the list and take the following actions:

- **View**— Select View to display information about the user, such as name, email,
- **Logout** – Select Logout to terminate the session for the user.
- **Re-authenticate** - Select Reauthenticate to force the user to log in again. Forcing users to reauthenticate suspends any active applets. This setting also stops the ability to perform administrative function until you give your password. After you provide your password, your session resumes where you left off.

### **Manage Sessions Using Selected Criteria**

The **I WOULD LIKE TO** button on the Sessions page lets you control user and device connection sessions for one or more sessions. For instructions about using this control, go to [Manage Sessions Based on Specific Criteria](#).

## **View Session Logs and Reports**

Use the session log to monitor user behavior and to prevent suspicious activity. You can then view log data in reports that are included with the product or in reports you create.

### **Unfiltered Log Records**

When you select **Sessions, Logs**, you see an unfiltered listing of all recent activity. The unfiltered log entries show a subset of all fields and wrapped-line field data. To display the full set of field data for a log entry, select once on a log entry to open it. To modify the display of the unfiltered log, select in the heading, then the resulting triangle to select **Columns**. Select the boxes that you want to display.

When you exit the Logs page, the column settings are saved.

### **Filter Logs to Focus Entries**

View a more focused list by filtering the display of entries.

#### **Follow these steps:**

1. Verify that you are looking at the unfiltered list.
2. At the top of the list, select a column type then enter a relevant value in the **Value** field.  
For some column types, a new window opens, from which you can select an available value.
3. Optionally, add more criteria by selecting **Add Filter**.
4. Select **Filter**.  
The list is updated with only the records matching the filter selections.

### **View Predefined Reports**

You can view logs in various report formats. These formats include:

- Payment Card Industry (PCI) Data Security Standard (DSS) reports included with the product.
- Reports that you create.

#### **Follow these steps to see a specific report:**

1. Select **Sessions, Logs**.
2. Under the **Reports** drop-down list, a list of existing reports (and, for custom reports, their owner) displays.  
Pre-configured PCI reports are in the list.
3. Select a pre-defined report to view.

To see the unfiltered list again, select **Unfiltered Logs**.

### **Create, Update, and View Custom Reports**

Use this procedure to create, update, or view custom reports that contain your choice of log data.

**NOTE**

Any user with privileges to view logs can create a custom report. Custom report names are appended with the user ID of their author for easy identification.

**Follow these steps:**

1. Select **Sessions, Logs**.
2. From the **Reports** drop-down list, select one of the following options:
  - To create a new custom report, select **Save As**.
  - To modify a report that you created, select that report from the list and select **Save**.
  - To view, update and manage existing reports, select **Manage Reports**. A dialog opens displaying a list of reports that you can view, update, or delete depending on their type (custom or preconfigured), your privileges, and ownership.

**NOTE**

Only the user that created a custom report (its owner) or the Global Administrator can update or delete that report. To quickly locate reports that were created by a particular user, filter the report list by "Owner User Id".

Preconfigured reports show no owner and can only be viewed.

3. If you chose to create or update a report, use the following tabs on the dialog that appears to design the report:
  - **Basic Info:** Enter a Name (required) for the report. Enter other fields as appropriate. Most of the tabs are self-explanatory.
  - **Date Range:** Enter specific dates or select **Relative**. The Relative range produces a report for your specified number of days, weeks, or months *before* the time of the report.
  - **Transactions:** Select from the list of available transactions the activities you want in the report.
  - **Users/Groups:** Select from the list of available users and groups those people whose activity you want in the report.
  - **Devices/Groups:** Select from the list of configured devices and device groups those systems that you want to in the report.
  - **Applets:** Select from the list of available service applets the ones you want in the report.
  - **Columns:** **Select all the columns that contain the type of information you want in the report.**
  - **Email:** To replicate the report at a regular interval and send it by email to specific individuals, select **Send Emails**. More fields display.
    - a. Enter email addresses in **Emails**, comma-delimited
    - b. Specify the intervals to send emails.
4. Select **OK** to save the report.

**Download a Report**

You can download any report as a comma-separated value (CSV) file. Use the report in spreadsheets or other applications.

**View Session Recordings**

This content describes how to view recorded sessions in the Session Recording Viewer.

**Open a Recording in the Session Recording Viewer**

Use this procedure to open a recording in the Session Recording Viewer.

**NOTE**

If you attempt to open a recording and receive a PAM-UI-2106 error message, the recording may be on a different share to which another PAM appliance is pointing. To view this recording, login to the PAM appliance that handled the access session and view the recording there.

**Follow these steps:**

1. Select **Sessions, Session Recording**
2. Select **View Recording** in the right-hand column of the file of interest.  
The Session Recording Viewer opens loaded with the selected recording.

**Session Recording Viewer Fields and Controls**

Within the Session Recording Viewer, you see the following information:

- **Session info** In the top segment of the upper-left panel, information about the session and its recording is displayed:
  - **Server:** target hostname or IP Address
  - **Security Layer:** NLA (TLS 1.2) | TLS (1.1) | TLS (1.0) | TLS (TLS 1.0) | TLS (1. 1) | TLS (1.2) | RDP
  - **Encryption Level:** High | Client Compatible | Low | FIPS Compliant | Not Applicable  
If Security Layer is SSL, then Encryption Level is shown as Not Applicable, regardless of FIPS status.
  - **Source IP** client hostname or IP Address
  - **Resolution:** pixels x pixels (graphical recordings only)
  - **Quality:** High | Medium | Low (web session recordings only). This setting is for web recording bit depth. Locate the setting from Settings, Global Settings, Applet Customization, Web Recording Bit Depth.
  - **Duration:** HH:MM:SS Start time, using the PAM server time zone. This setting is not used for CLI recordings. For the recording date, see the timestamp of recording.
  - **Start:** Start time, including Time Zone (not used for CLI recordings).
  - **End:** End time, including Time Zone (not used for CLI recordings).
- **User info** In the middle segment of the upper-left panel, information about the Privileged Access Manager and target users is displayed:
  - **User:** target user login ID (*when applicable*).
  - **Domain:** target user domain (*when applicable*)
  - **PAM ID:** appliance name (if available) or address.
  - **PAM User ID:** login ID
- **Recording info** In the bottom segment of the upper-left panel, information about the recording itself is displayed:
  - **Recording type:** ssh | RDP | TELNET | TN3270 | TN5250 | VNC | Web
  - **Size:** Filesize (KB)
  - **SHA verification** status for recording file: In progress... | Valid | FAILED
- **Events** In the lower-left panel, any violations that occurred are listed under **Events**:
  - **Type:** Violation or Text (icons)
  - **Time of Event:** HH:MM:SS
  - **Description:** Brief generic description of violation or text activity

Use the following controls to move through the session:

- Use the play buttons at the bottom center-right portion of the panel. (Play buttons are not available on CLI recordings.)

- **Step Backward** – Causes a 5 second jump backward
- **Play/Pause**
- **Stop** – upon re-Play, returns to beginning
- **Fast Forward** – Switch to run at 2x, 4x, or 6x actual speed (normal)
- **Step Forward** – causes a 5-second jump forward
- Drag the progress cursor across the timeline.
- Near the lower-left corner, enter figures in the **Jump to time** field to skip to any point in the session. The time of the position in the recording shows in the lower right corner, with the duration and the current progress.

### **Resize the Viewer Output for GUI Recordings**

When Initially opened in the Session Recording Viewer window, the recorded GUI fits against the inside border of the presentation area. Use the following options to resize the output:

- Activate the dynamic resizer option by selecting **Operation, Auto Scale** (or by typing Ctrl-A).
  - While *selected*, the GUI expands or contracts against the inner frame of the window as you resize the viewer. Meanwhile, it displays the new linear dimension (width or height) as a percentage of the original GUI length. After you stop resizing the viewer, this linear dimension box fades away.
  - When *unselected*, the viewer freezes the GUI to the size of the current inner frame. The frame no longer changes size as you expand or contract the viewer.
- A reset option, **Operation, Original Size (1:1)** (Ctrl-R), to resize the recorded GUI to its original dimensions immediately
- Keyboard shortcuts
  - Use **Ctrl +** to zoom in and expand the recorded window in 5 percent increments
  - Use **Ctrl -** to zoom out and contract the recorded window in 5 percent decrements
- Keyboard-mouse shortcuts
  - Press **Ctrl** while moving the mouse (scroll) wheel up to zoom in and expand the recorded window
  - Press **Ctrl** while moving the mouse (scroll) wheel down to zoom out and contract the recorded window
- Mouse panning:
  - If the recorded window is larger than the viewing window (not completely in view), you can pan with the mouse. Hold the mouse wheel down to grab and move the recorded window, so that the viewing window pans across the recorded window.
- Zoom control: When you select the magnifying glass icon to the left of the navigation buttons, a zoom control slider is available. This widget provides you fine-tuned control of the size of the recorded GUI:
  - When you move the slider button up or down, you can resize the recorded window in a continuous motion.
  - By selecting the plus or minus of the zoom control, you can increase or decrease the recorded window in 1 percent increments.
  - The *maximum* size of the recorded window is 200 percent of its original linear size. The *minimum* size is 180 pixels on the shorter of the two dimensions (height or width).  
For example: You can zoom in (expand) a 640 x 480 pixel window so that you view 1280 x 960 pixels. Zoom out (reduce) the window to see an actual viewing size of 240 x 180 pixels.

### **Search Text Within a CLI Recording**

Within a CLI Access Method applet recording, you can perform text string searches.

#### **Follow these steps:**

1. From the recording viewer menu bar, select **Operation, Find** to open a text-search panel above the display.
2. To the right of **Find what**, enter a string into the text box. Optionally, select checkboxes to restrict the search to **Match case** or to match only a **Whole word**.

3. Select the arrows next to the text box to reposition the window to the next instance of the search term on the top line.
4. Continue selecting the arrow to continue locating matches.

At the end of the recording file, the search returns to the top. You are also notified with a pop-up message.

### **Disrupted Audit Session Recordings**

If a mount is unavailable, session recording terminates. The recording file is deleted during post processing and an error like the following text is written to the session logs:

```
Recording file contains only file header packet. Possibly the remote server is powered
off
or security settings are too high. Deleting the file:
gk72-0000001518-20130322092630268_RDP
```

### **View Policy Violations in Session Recordings**

Use *one* of the following methods to two ways to view a recorded applet or web portal session:

- **Use the Session Recording list**  
Select **View Recording** at the right of the **red violation line** record in the **Session Recording** list. The Session Recording Viewer window launches, and starts playing from the beginning of the session.
- **Search the logs**  
To search the logs, following these steps:
  - a. Select **Sessions, Logs**.
  - b. In the upper-right hand corner of list, select **Search**.  
The Advanced Search pop-up window appears.
  - c. Set the Transactions to Violations, and select Search (at bottom of pop-up).  
If a policy violation has occurred in an RDP applet session, a **View Recording** button appears in its record.
  - d. Select the **View Recording** button to bring up the RDP Session Recording Viewer. The recording begins a moment before the time of the violation.

## **Manage Sessions By Specific Criteria**

You can control an ongoing individual session or group of sessions according to a set of actions and criteria.

**To manage sessions in progress, follow these steps:**

1. Navigate to **Sessions, Manage Sessions**.
2. Select the **I WOULD LIKE TO** button.
3. Select the action that you want to perform on a session or sessions from the **Action** drop-down list. The following actions are available:
  - Logout
  - Re-Authenticate
  - Disconnect
  - Record
  - Stop

See the table at the end for details about each action.

### **NOTE**

Do not select the Record or Stop action for a session that uses VNC access to a Windows system. You can manage session recordings using these actions only for new sessions that have not yet started.

4. Select the criterion to specify which *type* of session or sessions to control from the **Criteria** drop-down list. The **Criteria** drop-down list is context-sensitive based on the specified action.  
If you select the **Logout** or **Re-Authenticate** actions, the following criteria are available:
  - All
  - User
  - Group
  - Auth. Type
 If you select **Disconnect**, **Record**, or **Stop** actions, the following criteria are available:
  - All
  - Device
  - Group
  - Location
  - Address
  - Port
5. If you did not select **All** in the **Criteria** field, specify which session or sessions to control from the **Value** drop-down list. The Value drop-down list is context-sensitive. For example, if the specified criteria is **User**, a list of current login sessions displays. If the specified criteria is **Disconnect**, a list of current connection sessions to target devices displays.
6. Select **APPLY** to perform the selected action on the applicable users or devices.

### **Applying Actions**

The following table shows what happens when each action is applied.

Action	Behavior
Log out	<ol style="list-style-type: none"> <li>1. Request acknowledgment from administrator.</li> <li>2. Disconnect Users from PAM.</li> <li>3. Display message to Users (over login page).</li> </ol>
Re-Authenticate	<ol style="list-style-type: none"> <li>1. Request acknowledgment from administrator.</li> <li>2. Suspend User sessions.</li> <li>3. Display login request to Users (over login page).</li> <li>4. If authentication succeeds, restore suspended User session. If authentication fails, end session.</li> </ol>
Disconnect	<ol style="list-style-type: none"> <li>1. Request acknowledgment from administrator.</li> <li>2. Disconnect Users from target Device.</li> <li>3. Display message to Users.</li> </ol>
Record	<ol style="list-style-type: none"> <li>1. Request acknowledgment from administrator.</li> <li>2. Interrupt User sessions and start recording.</li> <li>3. Resume session to Users.</li> </ol>
Stop	<ol style="list-style-type: none"> <li>1. Request acknowledgment from administrator.</li> <li>2. Interrupt User sessions and stop recording.</li> <li>3. Resume session to Users.</li> </ol>

## **Display a Message to Users at Login**

This procedure describes how to configure a message containing important information to display in a dialog when a user logs in to the PAM UI. Examples of the type of information you might want to present in these messages include notifications about planned maintenance, availability of training for new available features, or process changes.

**Follow these steps:**

1. Log into the PAM UI.
2. Navigate to **Settings, Global Settings**.
3. Select the **Alerts** tab.
4. Set the **Show Informational User Message** option.
5. Use the text box and other related controls that appear to define your message and related settings.
  - Enter the message that you want to display in the text box. Limit: 64,000 characters.
  - Optionally, schedule when the message should be displayed using the following fields:
    - **Start Date:** The date when the message should start being displayed.
    - **Start Time (UTC):** The time when the message should start being displayed.
    - **End Date:** The date when the message should stop being displayed.
    - **End Time (UTC):** The time when the message should stop being displayed.
6. Select the **Save** button to commit your changes.

The following screenshot shows how to configure a message to warn users who log in on April 6 and 7 that PAM will be down for maintenance on the weekend:

☐ Show License Warning
 ☐ Show Recording Warning
 ☒ Show Informational User Message

PAM will be down for maintenance the weekend of April 8/9.

It will be available again on Monday April 10.

Start Date: 2023/04/06

End Date: 2023/04/07

Start Time (UTC): 00:00:00

End Time (UTC): 23:45:00

Reset Message Acknowledgement

**Reset Message Acknowledgments**

Once they have seen a message, users can select an option to acknowledge it so that it is not displayed on future logins. To reset user acknowledgments so the message is presented to *all* users when they next login, select the **Reset Message Acknowledgment** button.

**NOTE**

For information about the user experience, see [Accessing PAM](#).

## Maintenance

As an administrator, you can perform the Privileged Access Manager maintenance activities described in this section. This list of activities is not exhaustive. Some activities can be delegated to other administrators.

Use the table of contents to access the topics in this section.

## Configuration and Database Backups

To restore Privileged Access Manager instances for any reason, back up the configuration and database data. Backups are managed from the **Configuration, Database** UI page.

This topic explains:

### TIP

Schedule the database backups as soon and as frequently as practical. The backup is then available in case emergency recovery is needed.

### Types of Backups

As of version 3.3, database backups are performed in one step. Instead of copying the file and then compressing it, the file is compressed as it is copied. This method requires less disk space.

- **Configuration backup:** A configuration backup generates a file that contains all the unique settings and configuration information for each Privileged Access Manager instance. Use configuration files to roll back the configuration settings for a PAM instance. Use these files only on the server instance where they were created. This configuration file cannot be restored to or from another instance. The backup file includes the network context, globals, and settings such as "Disable Config User."

File-name format: gkyyyymmddhmmss.cfg

- **Database backup:** A database backup generates a compressed file that contains all the provisioning data, including:
  - Users and user groups
  - Devices and device groups
  - Socket and command filter configurations
  - Policies
  - Access data
  - Credential Manager data, with any A2A data

File-name format: gkdatabaseyyyymmddhmmss.gz; when downloaded, the *bin* extension is added

### Encryption of Configuration and Database Backup Files

The following information lists the encryption of configuration and database backup files.

### NOTE

Certificates, RSA authentication credentials, and cleartext passwords are not backed up.

- Scheduled configuration and database backup files are encrypted using AES-256-CBC, which is compliant with FIPS 140-2.
- Manual configuration backups are stored locally and encrypted using 3DES.
- Manual database backups are stored locally and not encrypted.
- Downloaded manual configuration backups are encrypted using 3DES.
- Downloaded manual database backups are encrypted using AES-256-CBC.

### NOTE

Beginning in version 3.0.1, only the appliance that performed the database backup can restore the database and function properly. Another appliance can restore the database, but it cannot decrypt the password data, so any functionality involving that data fails. To create a duplicate appliance for disaster recovery or migration purposes, see [Restore the Database to a New Appliance](#).

## Manual Backups

From the **Configuration, Database** window, a backup can be done manually. Select the **Save Database and Configuration** option. Separate files are created for the database and configuration data, and are stored on server hard drive.

File Type	File Name
Config	gk20170515211717.cfg
Database	gkdatabase20170515211715.gz

You can perform the following operations on these files:

- **Delete** - Delete the selected file from the hard drive.

### WARNING

**Warning!** This operation cannot be undone. Any deleted files are removed permanently.

- **Restore** - Restore the database or configuration file using the selected file. Restoring a file from a previously saved version overwrites any changes from the previous selected backup.
- **Download** - Copy the selected file from to your local hard drive. Downloaded files can be saved offline for long-term storage and retrieval.

## Scheduled Backups

You can schedule backups to occur automatically by selecting the **Backup Scheduler** option. Scheduled backups are offloaded to a specified external server. When you select this operation, the Backup Scheduler panel displays. If a backup schedule currently exists, the current schedule displays the month, day, weekday, and time of that scheduled backup.

For instructions on scheduling a database backup, see [Schedule a Backup of the Database](#).

## Export Backup Files

You can export backup files to an external location, protecting them in case you must restore a configuration.

Use one of the following methods to export a backup file:

- **Manually** - from the Database page, select the file from the list and select **Download**. If no files are listed, select **Save Database and Configuration**.
- **Automatically** - use the Backup Scheduler and specify the location for the backup file in the **Share Path** field.

### NOTE

- [Restore the Database from a Backup File](#)
- [Reset the Database to the Factory Defaults](#)
- [Compact the Database to Regain Storage Space](#)

## Schedule a Backup of the Database

You can schedule backups to occur automatically by selecting the **Backup Scheduler** option. Scheduled backups are offloaded to a specified external server. When you select this operation, the Backup Scheduler panel displays. If a backup schedule currently exists, the current schedule displays the month, day, weekday, and time of that scheduled backup.

This page contains the following sections:

- [Configure a Backup Schedule](#)
- [Use Your Own Public Keys for SCP and SFTP File Transfers \(Optional\)](#)
  - [Create the Target Application.](#)
  - [Create the Backup Target Account.](#)
  - [Schedule a Backup Using the Backup Target Account.](#)

## **Configure a Backup Schedule**

To schedule a database backup, follow these steps:

1. Select **Configuration, Database.**
2. Select the **Backup Scheduler** tab.  
In the scheduler, the current schedule is displayed. If a scheduled is already configured, the pane displays the schedule entries.
3. Populate the schedule fields. Most fields are self-explanatory. For the **Protocol** field, SCP and SFTP send files using these SSH-based protocols. NFS, CIFS, and Amazon S3 write to file mounts. Select **Mount** at the bottom of the page to mount the file.
  - **SCP** and **SFTP**: Set the **Share Path** in the form `/path` . Enter a **Port**, and select a **Backup Target Account**. See [Use Your Own Public Keys for SCP and SFTP File Transfers](#) for instructions on setting up a Backup Target Account.

### **NOTE**

(SCP and SFTP only). In clustered implementations of 2.x versions of the product, you could specify different backup servers for each node. In 3.x implementations, you specify a single backup server for the entire cluster. However, you can specify a different *directory* in the share path for each node. For example, `Server1/backupNode1` and `Server1/backupNode2` .

- **NFS**: Set the **Share Path** in the form `/<path_on_server>` . Enter a **Hostname** as FQDN or IP address. (Optional) Enter a non-default **Request Timeout** value (in tenths of a second). If no value is specified, the default is determined by the NFS server, typically 600.

### **WARNING**

Do not use the same NFS mount point that you are using for [session recordings](#). The session recording and scheduled database backup processes create and delete a file with the same name to check the remote storage status. If you specify the same NFS mount point, file locking can occur as both processes attempt to create or delete the same file.

- **CIFS**: Set the Share Path in the form `\\<hostname>\<share>` . Enter a **User Name** and **Password** to access the share account. Enter the **Domain**. Select the **SMB Version** (Server Message Block) used by the target system. Newer versions of SMB are more secure. If you do not support older file shares (like Windows 2003), use SMB2 or SMB3, provided the CIFS system supports it.
  - **Amazon S3**: Select the AWS S3 **Bucket** and the **AWS Provision**, as set in **Configuration, 3rd Party, AWS, AWS Configured Connections, Access Key Alias** – Region combination.
4. Complete the additional fields for the option that you select.
  5. (For SCP or SFTP protocols only.) Establish a secure communication that does not require an interactive login:
    - a. Download the key files from the public key file.
    - b. Copy these key files to the destination server, into the home directory of the user who represents Privileged Access Manager for authentication.
    - c. In the `.ssh` directory of the destination server, import or append the contents of the key files into the **authorized\_keys** file. If an `authorized_keys` file does not exist, create one.
    - d. Verify that the following directory and file permissions are applied or the backup fails:

- **.ssh directory**: owner has read (r), write (w) and execute (x) permissions
  - **authorized\_keys** file: owner has read (r) and write (w)
6. (Optional) Select **Delete After Successful Send** to remove the backup files from local storage on the PAM server.
  7. Set the **Maximum Files to Keep Locally** to specify the number of backup files that are stored locally on the server. Scheduled backup files are available for download in the file operations area. This field refers only to the local storage of backup files. The backups on an external storage device must be managed outside of Privileged Access Manager.
  8. Select **Save Schedule** to set the backup

### **Use Your Own Public Keys for SCP and SFTP File Transfers (Optional)**

You can use your own generated public keys for backup file transfers over SCP and SFTP connections, using the following process:

1. [Create the Target Application.](#)
2. [Create the Backup Target Account.](#)
3. [Schedule a Backup Using the Backup Target Account.](#)

Complete these steps in the UI.

#### **Create the Target Application**

To create a **CAPAM\_DatabaseBackup** target application, perform the following steps:

1. Select **Credentials, Manage Targets, Applications**.  
The Target Applications list appears.
2. Select **Add**.  
The Add Target Application window appears.
3. Select the magnifying glass next to the **Host Name** field and pick the host system to which your database files are to be backed up.
4. In the Application Name field, enter **CAPAM\_DatabaseBackup**. If the Target Application name is anything else, the Scheduled Backup does not work.
5. Select the "UNIX" **Application Type**.
6. Select **OK** to save the Application.

#### **Create the Backup Target Account**

To create a backup target account that uses the target application, complete the following steps:

1. Select **Credentials, Manage Targets, Accounts**.  
The Target Accounts list appears.
2. Select **Add**.  
The Add Target Account window appears.
3. Select the magnifying glass next to the **Application Name** field and select **CAPAM\_DatabaseBackup** from the Target Applications list that appears.
4. Specify a unique name for the target account in the **Account Name** field.
5. Select the "SSH-2 Public Key Authentication" **Protocol** option.
6. Do one of the following steps to specify a public key to use:
  - Select the key icon next to the **Private Key** field to generate a key pair.
  - Copy your own key pair into the **Public Key** and **Private Key** fields.
7. Select **OK** to save the Account.

#### **Schedule a Backup Using the Backup Target Account**

To schedule a backup on the target database backup system, use the backup target account and perform the following steps:

1. Select **Configuration, Database**.
2. Select **Backup Scheduler**.
3. Configure the Schedule and Protocol options according to [Configure a Backup Schedule](#).
4. Select your backup target account: next to the **Backup Target Account** field, choose the **Select** button (icon of a magnifying glass) to display the **Database Backup Target Account** selection panel. Use this panel to select your backup target account.

After you select a target account, the **Backup Target Account Device** field displays the name of the device that is associated with the target account you selected.

#### NOTE

If you no longer want to use the **Backup Target Account** for your backup, select the **Clear** button (icon of a circle with a line) to remove the account from the field.

5. Select the **Download** button to download the public key file to the home directory of the user account that represents Privileged Access Manager for authentication.
6. Navigate to the `.ssh` directory. Append the contents of the public key file into the `authorized_keys` file. If the `authorized_keys` file does not exist, create one.
7. Select **Save** to save the schedule.

## Restore the Database from a Backup File

You can restore the server configuration or database from existing backup files.

Restoring these files has the following consequences:

- The instance reverts to an earlier state, including passwords.
- The server overwrites all session logs. However:
  - Immediately before recovering or restoring, you can save and download the logs.
  - Before a recovery/restoration is required, you can use the external log server option.

Restoring the configuration does not interfere with session recordings. Session Recordings are saved externally, so access to this data is maintained.

The red highlighted text indicating a violation within recordings is lost for the interval after the database was last saved. (This highlight is not available for RDP graphical session recordings.)

During the restoration process, the PAM server compares the existing database size to the size of the backup file.

- If the existing database size is greater than the size of the backup file, the restoration completes.
- If the backup file is larger than the existing database, the server determines whether 100 MB exists within the file system. If not, the restoration fails.
- The next calculation determines whether the size of the backup file is more than half the available disk space. If it is less than half the available disk space, the restoration succeeds. If it is greater than half the available disk space, the restoration fails.

To restore the entire system, see [Recover the Hardware Appliance](#).

#### NOTE

Beginning in version 3.0.1, only the appliance that performed the database backup can restore the database and function properly. Another appliance can restore the database, but it cannot decrypt the password data, so any functionality involving that data fails. To create a duplicate appliance for disaster recovery or migration purposes, see [Restore the Database to a New Appliance](#).

## **Restore the Database**

1. Navigate to **Configuration, Database**.
2. In the **Database** tab, select the file and select **Restore**. (See [Configuration and Database Backups](#) for file descriptions.)  
If the configuration or database file does not appear in the list, upload a saved backup. On the **Upload File** tab, select **Choose File** to select the database file, select the file, then select **Upload**. A copy of the backup is now available.
3. Select **Restore**, then select **OK** in the confirmation pop-up window to begin restoration.
4. After restoration completes, the server automatically reboots.
5. Close your browser, then restart it, and log in as *super*.

## **Reset the Database to the Factory Defaults**

1. Navigate to the **Configuration, Database** screen.
2. From the Database tab, select **Reset** to reset configuration to the factory default values.
3. After reset completes, the server automatically reboots.
4. Close your browser, then restart it, and log in.

## **Compact the PAM Database to Improve Startup Time**

Compact the PAM database to increase available storage space and improve startup time by purging space that is allocated to entries that have since been deleted. If you need to compact the database frequently, you should consider adding more storage space.

### **NOTE**

Users cannot log on while the database is compacting. To avoid this disruption in service, compact the database only during a planned maintenance window.

### **NOTE**

The procedures in this content assume that you are running a PAM cluster. If you have a single-server deployment, ignore cluster-specific directions.

## **Prepare to Compact the Database**

To prevent activity against the database during compaction, complete the following steps:

1. Turn on Maintenance Mode on each node in the cluster to prevent new logins.
  - a. Navigate to **Configuration, Diagnostic, System**.
  - b. Set the **Maintenance Mode** option to **On**.
2. Turn clustering off.  
On the primary master node, navigate to **Configuration, Synchronization**. In the **Cluster Settings**, select **Turn Cluster Off**.
3. (Optional) Log out current user sessions. Although Maintenance Mode prevents new logins, it does not disconnect current user sessions. You can force disconnections using the **Manage Sessions** screen:
  - a. Navigate to **Sessions, Manage Sessions**.
  - b. Select any entry in the table and select **LOGOUT** above the table. You can log out any users (except yourself).
4. If the Credential Manager External CLI is enabled, follow these steps on the primary master to disable it.
  - a. Select **Settings, Credential Manager** to access the Credential Manager settings.
  - b. Clear the **Enable External CLI** checkbox.
  - c. Select **Save**.
  - d. Restart the instance

## Compact the Database

After user activity has ceased on the master node of the primary cluster site, compact the database.

**Follow these steps on the primary master:**

1. Go to **Configuration, Database**.
2. From the **Database** tab, select **Compact**.

### NOTE

The **Compact** button is only active when Maintenance Mode is on and clustering is inactive.

A dialog stating that database compaction can take a long time appears.

3. Select **YES** to continue. The duration of the process and the amount of space that is freed depend on the number of entries deleted. To stop the process, select **Cancel**.

## Restore Your Environment After Compacting the Database

To bring your environment back up after compacting the database, complete the following steps:

1. Turn off Maintenance Mode on each node in the cluster to allow new logins.
  - a. Navigate to **Configuration, Diagnostic, System**.
  - b. Set the **Maintenance Mode** option to **Off**.
2. If applicable, follow these steps on the primary master to enable the Credential Manager External CLI.
  - a. Select **Settings, Credential Manager** to access the Credential Manager settings.
  - b. Set the **Enable External CLI** option.
  - c. Select **Save**.
  - d. Restart the instance
3. Turn clustering on.

On the primary master, navigate to **Configuration, Synchronization**. In the **Cluster Settings**, select **Turn Cluster On**.

### NOTE

Once the cluster is back up, the compacted database is propagated to all other cluster members.

## Restore the Database to a New Appliance

Beginning in version 3.0.1, only the appliance that performed the database backup can restore the database and function properly. Another appliance can restore the database, but it cannot decrypt the password data, so any functionality involving that data fails. The backup requires the key encryption key from the original appliance for restoration. This requirement prevents a bad actor from getting access to a database backup so that the passwords can then be decrypted and compromised.

To create a duplicate appliance for disaster recovery or migration purposes, follow these steps:

1. Deploy a Privileged Access Manager appliance. See [Deploying](#) for instructions.
2. Join the original appliance in a cluster with the new appliance, configuring the new appliance as a member of a secondary site. See [Set Up a Cluster](#) for details on how to configure clustering.  
You now have a "live" backup of the data from the original appliance because all cluster data is replicated to all nodes in the cluster. For disaster recovery, this new appliance should be in a different data center
3. If you want a new, independent appliance, the new appliance can [Cluster Synchronization, Promotion, and Recovery](#) for details. The new appliance and the original appliance can then move forward in separate, distinct, environments.

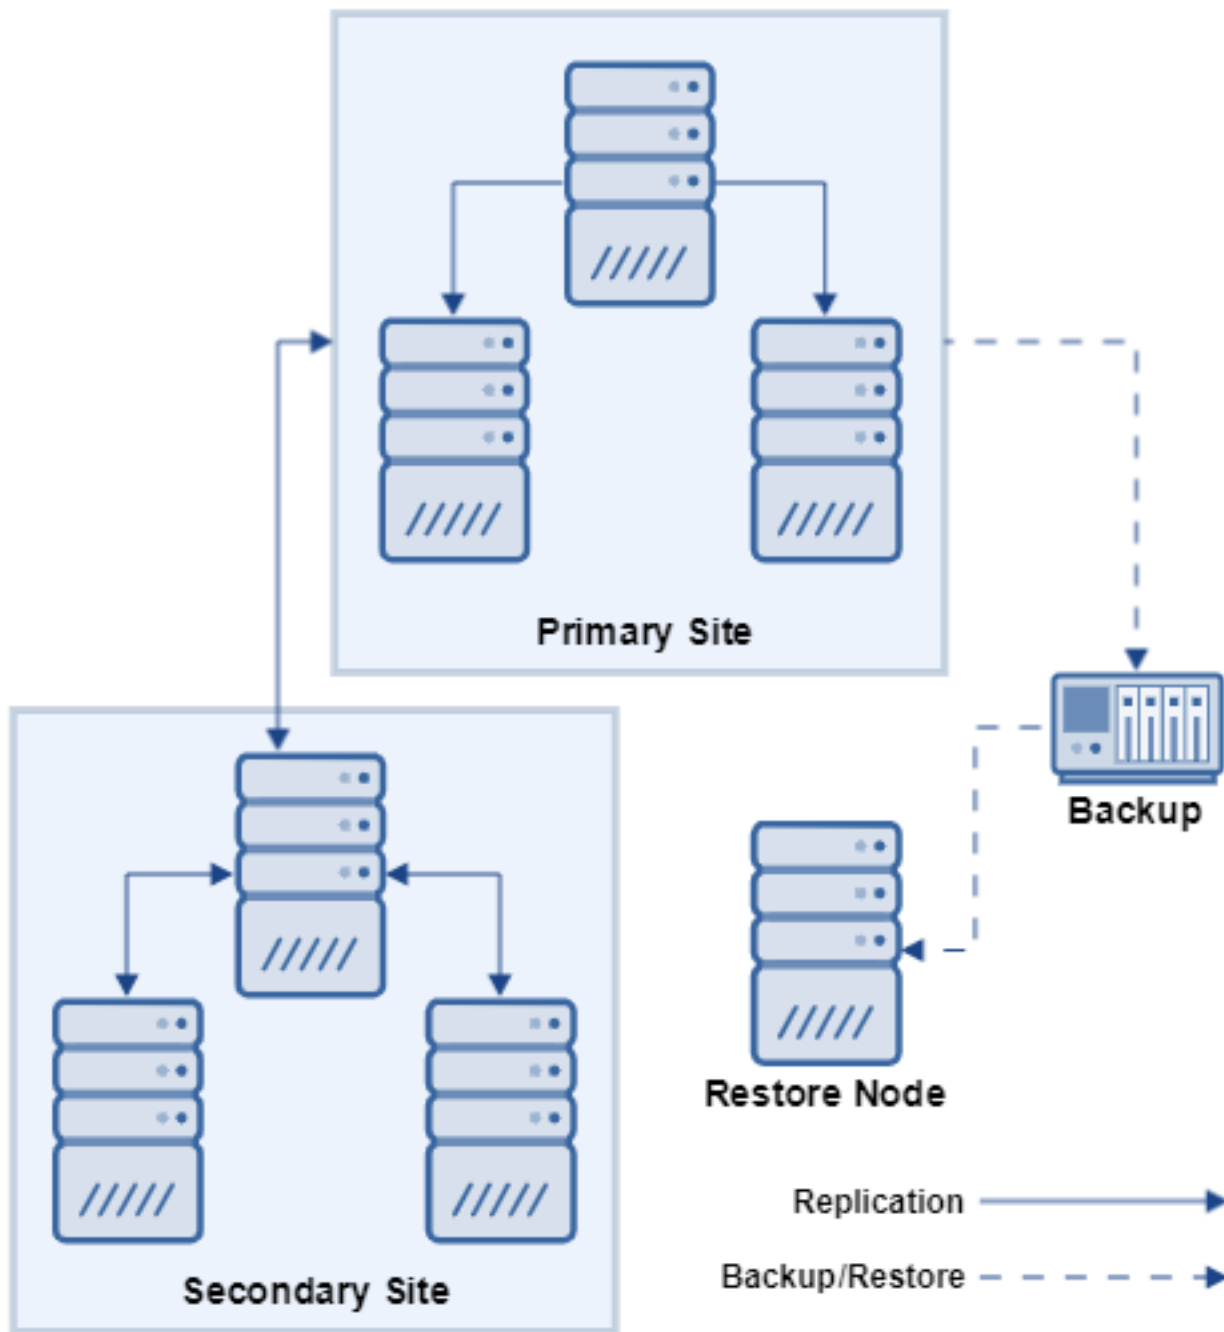

### NOTE

- [Cluster Backup and Disaster Recovery Process](#)

## Cluster Backup and Disaster Recovery Process

Beginning in version 3.0.1, only the appliance that performs a database backup can restore the database and function properly. Another appliance can restore the database, but it cannot decrypt the data unless it uses the same key encryption key (KEK) that was used when the backup was taken. PAM members all begin with a unique KEK. When members are joined to a non-HSM cluster, they inherit the KEK of the cluster leader. If you do not have the latest KEK, then any functionality involving data decryption fails and your appliance may become unusable. The backup requires the latest KEK for restoration. This requirement prevents a bad actor from getting access to a database backup to decrypt and compromise passwords.

A cluster is effectively a living backup of the database. Each member of a multi-master or primary site has the entire database. If you have secondary sites, they can be promoted to primary sites. But what happens if the entire cluster is lost in a disaster? The secure backups that you make can only be restored to a member of the cluster. One way to protect against this scenario is to create a stand-alone cluster member to restore the database in an emergency.

**Figure 62: Cluster Restore Member**

**To set up a stand-alone member backup, follow these steps:**

1. During the initial setup of a PAM cluster, add an extra member to the cluster. If the cluster already exists, you can subscribe a new PAM instance to join it.
2. After all members of the cluster are in sync, log in to the extra member and remove it from the cluster.
3. 1. Go to **Configuration, Clustering**, and select **Leave Cluster**.

This member is now a stand-alone PAM instance and has the same encryption key sets as the other cluster members. If all members of the cluster are unavailable, this “restore node” can restore a backup of a cluster database.

2. Remove this member from the network.
  4. Select a member of the Primary Site to perform a daily backup.
    - a. Go to **Configuration, Database, Backup Scheduler**. See [Schedule a Backup of the Database](#) for details.
    - b. **Save** the database backup schedule.
- The DB and configuration are backed up to external storage.

**To recover the backup using a stand-alone member, follow these steps:**

1. Access the “restore node.”
2. Load the latest database and configuration backup from the external storage. See [Restore the Database from a Backup](#) for instructions.
3. Use this node as the first member of a new Primary Site to set up a new cluster.

## Hardware Appliance Backup and Recovery

A backup of the PAM hardware appliance copies the OS, the software, and the configuration data. The backup also copies the provisioning data of managed users and devices. Use a backup to protect against software loss and to roll back the system to a known good state.

You can perform the following tasks:

### NOTE

Backups of the PAM databases and configurations are not covered in this topic. For information about database backups, see [Configuration and Database Backups](#).

You can perform a system backup only for the hardware appliance, not for an OVA or an AWS AMI instance. For information about AWS AMI backups, see [AWS AMI Backup and Recovery](#)

### Appliance Backup

An appliance backup copies system data from the primary drive to the backup (secondary) drive. During a backup, the previous version is written over with the new one so that only the most recent backup is ever in storage. This backup cannot be exported. To protect settings and data, export configuration and database backups.

You can complete a backup using the following methods:

- Manually, when you use the feature **Backup Appliance**.
- Scheduled, which results in automatic backups. Use a scheduled backup for every hotfix installation that requires a reboot, and every upgrade. You do not have to perform a backup manually in advance.

### Appliance Recovery

An appliance recovery restores the appliance from a backup of the appliance. The recovery returns the system back to the previously saved state.

Perform a recovery when:

- The system or firmware malfunctions or fails.
- A firmware upgrade appears to initiate problems.

### NOTE

If the PAM Server software fails to boot, you can reset the appliance back to its factory default state. For more information, see [Reset the Appliance to Factory Default State](#).

Hardware appliance backup and recovery are performed from the **Configuration, Upgrade** page.

Use the table of contents to access the topics in this section.

## Backup the Hardware Appliance

A backup of the hardware appliance creates a single copy of the current state of the appliance. The last saved software is copied from the primary drive onto the backup solid-state drive (SSD) to the last saved version. If the system malfunctions or fails, use the backup to recover the system. You can also use the backup to restore the system after the installation of a firmware package, such as a release upgrade or hotfix.

### TIP

The best practice is to perform system backups only during an installation or maintenance window.

These characteristics apply to system backups:

- A single backup is maintained – The secondary drive stores up to an entire primary drive capacity. The drive can contain only the most recently executed backup.
- Upgrades are done in the background – As part of any hotfix that requires a reboot or any upgrade, Privileged Access Manager performs the backup process automatically and silently.
- A full copy of the primary drive is made – During the backup process, the secondary drive makes a complete copy of the primary drive.
- Reboots the system automatically – After copying the primary drive, the system automatically reboots.

### Follow these steps:

1. Log in to the UI.
2. If this appliance is part of a synchronized cluster, turn off the synchronization.
3. Navigate to **Configuration, Upgrade**.
4. Select the **Backup & Recovery** tab.
5. From the **Backup & Recovery** tab, select **Perform Full Appliance Backup**.
6. At the confirmation prompt, select **Proceed**.  
A red text message displays asking you to wait.  
When the backup completes, the appliance automatically reboots.
7. At the login page, log in and navigate back to the Upgrade page.  
A successful backup generates a message in the Backup Appliance panel identifying the date and time of the backup.

The backup is complete.

## Recover a 404L Hardware Appliance

Learn how to recover a 404L hardware appliance from the last backup you performed to return it to its previous state. This topic describes how to recover the hardware appliance from the user interface or a serial cable.

### WARNING

Perform a system recovery only when recommended by Broadcom Support.

### Recover the Appliance Using the User Interface

If the appliance becomes inaccessible from the network, recovery is also possible from the Console in coordination with Support.

### NOTE

After this procedure, the appliance automatically reboots. To avoid impacting a production environment, perform this action only during an installation or maintenance window.

**Follow these steps:**

1. Log in to the UI.
2. If the appliance is part of a synchronized cluster, do the following steps to turn off the cluster:
  - a. Select **Configuration, Clustering**.
  - b. In the Cluster Settings, select **Turn Cluster Off**.
3. Navigate to **Configuration, Upgrade**.
4. Select the **Backup & Recovery** tab.
5. Select **Recover Appliance from Latest Backup** to start the process.
6. When you see the confirmation prompt, select **Proceed**.  
A red text message displays asking you to wait.  
When the recovery completes, the system reboots automatically, eventually refreshing with the login page.
7. Log in, and navigate to the **Upgrade** page to confirm recovery.  
If the recovery succeeded, the previous backup message no longer appears in the **Backup Appliance** panel.

**Recover the Appliance Using a Serial Cable**

PAM physical appliances have two solid-state drives (SSDs):

- A **Primary** drive that contains the current, operational PAM image.
- A **Secondary** drive that contains one or more backup images. (Any installation patch that requires a reboot writes a new backup image.)

**CAUTION**

PAM can only revert to an image on the secondary drive. Be careful not to overwrite a recovery image that you want to maintain.

Before you begin, locate an RS232 to RJ45 serial cable, and connect one side to the PAM console and the other side to your laptop. You should have one console cable that was shipped with the physical appliance, such as the one shown in the following image:

**Figure 63: RS232 to RJ45 serial cable**

**Follow these steps:**

1. Power down the unit.
2. Connect the serial cable to the RJ45 socket marked **Console** to a computer where you have a console-viewing client.

3. Launch putty (or other terminal emulator program) and configure the following settings:
  - **Connection speed:** 115; 200
  - **Data bits:** 8
  - **Stop bits:** 1
  - **Parity:** None
4. Start the appliance.
5. During the boot process, press and hold the **Esc** key within 5 seconds to open the boot loader menu.
6. Use the **^** and **v** keys to select the last entry in the GRUB menu (the latest PAM backup image, of the form "CA PAM x.x.x.x Backup as of Date Time").
7. Press **Enter**.

The boot loader initiates the recovery operation, performing the following steps without further intervention:

1. Boots PAM from the secondary drive.
2. Copies the selected PAM backup image from the secondary drive to the primary drive, replacing the corrupted image.
3. Boots PAM from the restored image on the primary drive.

#### NOTE

The recovery operation may take a considerable amount of time.

## Reset the Appliance to Factory Default State

This topic describes how to reset the PAM 404 hardware appliance to its factory default state if the PAM application repeatedly fails to operate effectively after you have attempted all other recovery methods.

#### CAUTION

The factory reset function wipes all database entries and any upgrade patches applied since the PAM version originally installed on the appliance. For this reason, we recommend that you only use the factory reset function if advised to do so by Broadcom Support.

Topics in this content:

### Reset the Appliance to Factory Default Settings

This section describes how to reset the appliance to its factory default settings.

#### Follow these steps:

1. Locate the hole indicated by the red arrow in the following photograph of the PAM 404 appliance.

**Figure 64: Photograph of the appliance showing the recessed Factory Reset button.**

#### NOTE

Not all PAM 404 hardware appliances have the "Reset" label printed beside the hole for the recessed **Reset** button. In either case, the recessed button provides the same factory reset action.

2. Straighten a paperclip or locate another object of similar dimensions.
3. Insert the straightened paperclip (or alternative object) into the indicated hole and press and *hold* the recessed Factory Reset button for at least 3 seconds.

The appliance resets to its factory settings and the display shows the following message "System is booting... LOM card not existed".

### **Restore the Appliance to Its Previous State**

Do the following procedures to restore the appliance to the state it was in when the last good backup was taken:

1. **Configure Network Connections for the Appliance:**

After the appliance comes back up after the factory reset, configure the IP network interfaces so the appliance can access a network. You can set up your network connections using the LCD panel, the CA PAM UI, or a Console port. The appliance is inaccessible to the network until its IP address is assigned. For more information, see [Configure Network Connections for the Appliance](#).

2. **Reinstall Service Packs and Hotfixes:**

To restore the appliance to its previous release state, reinstall all service packs and hotfixes that were previously installed when the database was last backed up.

3. **Restore the Database from a Backup File:**

To restore the configuration and database data to your appliance, restore the database from a backup file. For more information, see [Restore the Database from a Backup File](#).

## **AWS AMI Backup and Recovery**

To protect from software loss, backup Privileged Access Manager deployed on an AWS AMI instance. The procedure backs up the entire instance, allowing you to roll back all software to a known good state.

### **Back Up the AMI Instance to a Volume**

The AWS AMI backup process creates a snapshot of the state of the current instance. It stores the snapshot in the designated S3 bucket for later use in recovery.

#### **TIP**

This procedure can be automated by using the AWS API.

#### **Follow these steps to backup the instance:**

1. Navigate to your AWS Management Console EC2 view.
2. From the **Navigation** panel, select **INSTANCES, Instances**.  
If needed, search for the instance Name or instance number (labeled "Instance").
3. From the Instance list, select the checkbox of the instance you want to back up.
4. From the **Instance Actions** menu, select **Stop** to stop the instance to freeze its state.

#### **NOTE**

When in a production environment, stopping the instance might not be practical.

5. Record the **Instance ID**.
6. From the Navigation panel, select **ELASTIC BLOCK STORE, Volumes**.
7. Identify the volume that is attached to the instance you want to back up.  
To more easily find the volume, select the arrow in the **Attachment Information** column heading to reorder the entries alphabetically to find the Instance ID.
8. Select the checkbox of this volume.

9. From the **More** drop-down list, select **Create Snapshot**. In the pop-up that opens, enter a **Name** and optionally, a **Description**.
10. Select **Yes, Create**. Ensure that this snapshot is created in the same instance zone.
11. Go back to the Navigation panel, and select **ELASTIC BLOCK STORE, Snapshots**.  
You see an entry for your snapshot, which might still be generating. This snapshot is your full system backup for this point in time.
12. Make a note of the **Snapshot ID**, especially if your snapshot Name or Description does not provide identifiable information as to when and why the snapshot was created.  
You might also want to create extra snapshots at other points in time. You are not limited in the number of snapshots.
13. Create a volume from the snapshot.

### **Create the Volume from the Snapshot**

Use the snapshot to restore the instance to this state. Privileged Access Manager cloud instances are available in the AWS environment. Within this environment, you can create a snapshot of an instance at a specific time, and then recreate it if an instance failure occurs.

Recover a volume from a snapshot of a previous machine state that is stored in a designated S3 bucket. This volume can then be substituted for the non-functioning volume.

#### **Follow these steps:**

1. Navigate to your AWS Management Console EC2 view.
2. From the **Navigation** panel, select **INSTANCES, Instances**.
3. Find the correct instance and record the **Instance ID**. If necessary, stop the instance.
4. Return to the **Navigation** panel and select **ELASTIC BLOCK STORE , Snapshots**.
5. Locate and select the checkbox of the correct snapshot. Record the snapshot ID for later use.
6. From the top-level buttons in this panel, select **Create Volume** and give the recovered volume a **Size** that is equal or larger than the original.

### **Restore the AMI Instance from the New Volume**

After you complete the following procedure, the machine ID changes. A license update that reflects that change is required.

1. Return to the **Navigation** panel and select **ELASTIC BLOCK STORE, Volumes**.
2. Confirm that the recovery volume exists by checking for the snapshot ID in the generated Volumes list. To locate the volume instance easily, reorder the Snapshot list alphabetically for the correct **snap-xxxxxxx** number.  
It is not attached to a machine instance at this point. You can tell because the **Attachment Information** field is blank.
3. Find the old volume that you want to replace. This volume *is* attached to the machine Instance ID and is in the **Attachment Information** column.  
To more easily locate the attached volume, reorder the **Attachment Information** list and scan according to the instance number.
4. Select the checkbox of this old volume that you want to remove.
5. From the **More option**, select **Detach Volume**.  
This can take a few minutes. Select **Refresh** to confirm completion.
6. Select the checkbox of the volume you want to use for recovery.
7. Select **Attach Volume**. In the Attach Volume page, select the Privileged Access Manager **Instance**. In the Device field, enter **/dev/sda**.
8. If necessary, restart the instance. From the **Navigation** panel, select **INSTANCES, Instances**.

## Mitigate Host Header Attacks

Privileged Access Manager can mitigate host header attacks by denying any X-Forwarded-Host values that are not specified in a whitelist. This feature then protects against arbitrary and invalid hosts headers.

**To configure this defense, perform these steps:**

1. Go to **Configuration, Exceptions**.
2. Add the Whitelist Hosts to the text box under PAM Exception Rules. Separate the entries with commas or put them on new lines.
3. Select **Save**.
4. Go to **Configuration, Security, Access**.
5. On the **X Forwarded Host Check** line, select **Enabled**.

The X-Forwarded-Host Check is now enabled. Only **X-Forwarded-Host** HTTP headers that are specified on the Exceptions page are accepted by Privileged Access Manager.

## Memory Management

PAM appliances allocate memory according to their amount of available RAM. Two new configuration files (one each for primary and secondary site members) control the allocation. If you are experiencing “Out of Memory” errors or performance issues, contact Broadcom Support.

### Memory Management

This chart shows the default memory allocation to major processes in the PAM appliance according to its total amount of RAM:

Appliance memory in GB	Tomcat memory in MB	JBoss memory in MB	PHP memory in MB	MySQL buffer pool in MB	Hazelcast thread count
4 or less	1536	1024	512	128	1
8	1638	1092	546	1024	53
12	2457	1638	819	1536	79
16	3276	2184	1092	2048	106
20	4096	2730	1365	2560	133
32	6552	4368	2184	4096	213
48	9828	6552	3276	6144	326
64	13104	8736	4368	8192	426

## View System Information

The **System Info** pane provides administrators with system status and version information on five tabs.

### Basic Info Tab

The **Basic Info** tab includes your version, and several status indicators:

- **Version** indicates the detailed version number of your appliance or instance.
- **FIPS Mode** indicates whether you are running in FIPS mode.
- **HSM** indicates the status of a hardware security module (HSM). The following values are possible

- SafeNet LUNA Network HSM
- SafeNet LUNA PCI-E
- Entrust nShield Connect
- None
- Licensed, not Configured

For more information about HSMs, see the [Hardware Security Modules \(HSMs\) for Credential Manager](#) section.

- **TLS v1.0/1.1** indicates whether these communication protocols are enabled or disabled through the **TLS v1.0/1.1 Connection Allowed** option.
- **RDRAND** indicates whether the RDRAND hardware random number generator is available.
- **Cryptographic Provider** indicates whether HSM, OpenSSL, WolfSSL, or Bouncy Castle is being used.

### System Resources Tab

The **System Resources** tab displays current CPU usage; total, used, and free disk storage; and total, used, and available memory.

#### NOTE

If you resize your disk in VMware, AWS, or Azure, it is reflected here and in the Appliance Status on the **Dashboard Overview Tab**. Follow the resizing procedure for your platform, then reboot your instance. Go to **Configuration, Power**, and select **Reboot Instance**. For information about resizing VMware or AWS disks, see [Deploy a VHD on Azure](#).

### System Activity Tab

The **System Activity** tab displays information about general system activity and status information about session recording reconciliation processes on the *current node*:

- **General System Activity**
  - **Uptime**: The amount of time that the server has been up since the last appliance boot,
  - **Active Logins**: The number of users that are currently logged in
  - **Active Sessions**: The number of active connection sessions.
- **Session Recording Reconciliation Process Status**:
  - **Most Recent Recordings**: Status of the job that reconciles recent session recordings.
  - **Restored Recordings**: Status of the job that reconciles session recordings that are recovered from archives.
  - **All Other Recordings**: Status of the job that reconciles all other recordings.

If reconciliation is operational, the status of each reconciliation job is one of following values:

- **Available**: The reconciliation process is idle.
- **Running**: The reconciliation process is in progress.

If reconciliation is not operational, all reconciliation jobs report the same one of the following failure reasons:

- **Unmounted**: The reconciliation process cannot run because the session recording share is not mounted.
- **Mount Not Available**: The reconciliation process cannot run because, although the session recording share is mounted it is not reachable, probably because of a network outage.
- **Maintenance Mode**: The reconciliation process cannot run because the node is in maintenance mode.
- **Health Check Failed**: The reconciliation process cannot run because the node failed a [health check](#).

#### NOTE

For more information about session recording reconciliation, see [Configure and Manage Session Recording](#).

### **Licensing Tab**

The **Licensing** tab lists the number of devices that are allowed with your license, and the number in use, in the form of Devices used/Devices licensed. Each type of license, such as Password Management and A2A are listed. Licensed capabilities are also listed, such as Mainframe, Threat Analytics, and External API.

### **Hardware Identifiers Tab**

The **Hardware Identifiers** tab displays the Hardware ID and the Hardware Serial Number (if assigned).

### **Hotfixes Tab**

The **Hotfixes** tab identifies any hotfixes that are applied to this installation of Privileged Access Manager.

### **General Tasks**

You can perform the following tasks from any tab:

- To refresh the data in the **System Info** pane, select the Refresh circular arrow icon in the upper right of the pane.
- To download a text file of the data in the **System Info** pane, select the Download checkmark icon in the upper right of the pane.

## **Cluster Maintenance**

This content describes best practices for maintaining your cluster.

### **Routine Cluster Maintenance**

Administrators should regularly log into the appliance to monitor the various health information available on the **Dashboard Overview Tab**. A summary of conditions of which you should be aware, including the following information appear at the top of the page:

- Health alerts on the cluster members
- Configuration warnings (configuration password has not been changed, users are being monitored by the TAP server, and so on.)
- Operational warnings (maintenance mode is on, primary or secondary session recording mounts are down, insufficient disk space for network backups, and so on).

The **Dashboard Overview Tab** also reports CPU usage and disk usage for each node in the cluster. Causes of high disk utilization include the following issues:

- Many locally stored database backups
- Failure to prune the metrics or logs tables in the database.
- Leaving logging levels elevated for a prolonged interval

### **Best practices for Backups**

You can perform database and configuration backups at any time. They can be run manually or invoked on a fixed schedule. Backups can be stored on the appliance or remotely. Remote copies can be made manually or automatically. For more information, see [Configuration and Database Backups](#) for details.

#### **NOTE**

Restoring a backup to an appliance that was not part of the original cluster results in scrambled passwords. This situation is caused by a security enhancement that specifies to which appliances a backup can be restored. To address this issue, follow these steps:

1. Subscribe the target appliance to the cluster as a secondary site while in maintenance mode.
2. Unsubscribe the appliance.

3. Restore the database.

### **Best Practices for Live Migration and Live Snapshots of Sites Running on VMware vSphere**

You can take a live snapshot of secondary nodes at any time.

#### **WARNING**

Do not take a live snapshot of the primary node while the cluster is live. Doing so may drive the nodes out of sync.

#### ***VMware vMotion Support For Live Migration***

PAM supports VMware vMotion for live migration of both primary and secondary cluster members running on VMware vSphere.

#### **NOTE**

Do not attempt to simultaneously move all or most primary members, which may result in a cluster warning, a potential quorum loss, or both. PAM attempts to self-heal all warnings. However, if they do not heal successfully, you may need to perform a manual sync. PAM continuously evaluates quorum and automatically attempts to recover from a quorum loss.

#### ***VMware DRS or Live Snapshotting Support***

PAM does not support the use of VMware DRS, or other functionality relying on live snapshotting on a PAM VM that is a *member of a live cluster*. However, you can perform live snapshotting with the cluster up and running using the following procedure.

#### **Follow these steps:**

1. Remove a single PAM VM from the cluster, typically a secondary node.
2. Snapshot the PAM VM that you removed from the cluster.
3. Resubscribe the PAM VM back into the cluster.

### **Save the State of a Physical Appliance**

To save the entire state of a physical appliance, use the **Perform Full Appliance Backup** operation. A full appliance backup is distinct from a database backup; it writes the entire contents of the primary drive onto the secondary drive. Only one full appliance backup can be kept on the secondary drive so each full appliance backup wipes out any previous backup. You cannot download a full appliance backup from the physical appliance.

#### **NOTE**

This operation forces a reboot, throwing all users off the system. Perform it only during scheduled downtime.

#### **Follow these steps:**

1. Turn off the cluster.
2. Put the first node of the primary site into maintenance mode.
3. Open the **Configuration, Upgrade** page **Backup & Recovery** tab and select **Perform Full Appliance Backup**. The current state of the primary drive is copied onto the secondary drive and the appliance reboots.
4. Sign back on and turn off maintenance mode.
5. Turn on the cluster.

#### **Follow these steps to restore the appliance to the backed-up state:**

1. Turn off the cluster.
2. Turn on Maintenance Mode.
3. Open the **Configuration, Upgrade** page **Backup & Recovery** tab and select **Recover Appliance From Latest Backup** button.

4. Turn on the cluster.

The contents of the secondary drive are restored to the primary drive and the appliance reboots.

## Credential Manager Reports

You can generate reports from Credential Manager data. Credential Manager stores audit, metric, and event data in the database. Using this data, Credential Manager can produce four types of reports: activity, metric, SQL, or command.

- **Activity:** Pulls data from the auditlog table in the Credential Manager database. These reports are not customizable. An example is the Administrative Activities report.
- **Metrics:** Pulls data from XML blocks within entries in the metrics table of the Credential Manager database. All entries are available to the report. These reports can be customized. An example is the Account Request report.
- **SQL:** Generates reports by executing SQL queries on the database. These reports can be customized. An example is the Orphaned Request Server report.
- **Command:** Pulls data from CLI search command responses.

Credential Manager can produce a defined set of reports using these report types. The reports reflect the time zone that the user selects or UTC. All reports are based on Coordinated Universal Time (UTC). You can customize metrics and SQL reports to produce more reports.

### NOTE

Credential Manager uses pop-ups to display reports. Some web browsers might block pop-ups. We recommend that you configure your browser to allow all pop-ups.

Use the table of contents to access the topics in this section.

## Available Credential Manager Reports

The following list describes the available Credential Manager reports. The maximum number of report entries defaults to 5000. For information about changing this setting, see Maximum Number of Report Entries on [Set Up Credential Manager Operation Settings](#). The setting can be changed at **Settings, Credential Manager, General Settings**.

You can refine the output of most reports by date and other filterable parameters by entering values in the available fields or selecting values using the calendar or magnifying glass icons beside them as is seen in the following screenshot:

**Figure 65: Credential Manager report filters**

**Report: Account Passwords Update Attempts**

Description: Lists accounts where an attempt to change the password was made

Time Zone: UTC

Quick Dates:

Start Date:

End Date:

Target Account Name:

Changes By: dax axelrod

Target Server Host Name:

Target Application Name:

Account Access Type:

Password View Policy ID:

Attempts: ☒ All ☐ Changes ☐ Failures

Output Format: ☒ HTML ☐ CSV ☐ PDF

OK CANCEL

The following content lists the data returned by all the available reports and indicates which values can be filtered when requesting the report:

### ***Account Password Update Attempts***

This report lists accounts where an attempt was made to change the password. This report returns the following information:

- **Date:** Select a **Quick Date** (such as This Month) or the **Start** and **End Date** of the update. (Filterable)
- **Target Account Name:** The name of the target account. (Filterable)
- **Changes By:** The User who initiated the password update attempt. (Filterable)
- **Target Server Host Name:** The name of the target server host. (Filterable)
- **Target Application Name:** The name of the target application. (Filterable)
- **Account Access Type:** The type of account access. (Filterable, **but not included in the report**)
- **Password View Policy ID:** Use the magnifying glass to filter by Password View Policy. (Filterable, **but not included in the report**)
- **Changed:** This value displays TRUE if the password update attempt succeeded, or an error code if the update failed.
- **Gen'd:** Displays whether the password update attempt was automatically initiated by PAM. This value displays TRUE if PAM initiated this password update attempt automatically, for example due to a Password Composition Policy's

Maximum Password Age or a recurring Scheduled Job. This value displays FALSE if the password update was the result of a direct user action, for example if a user manually generated a new password for a Target Account.

- **Duration:** The duration of the password update attempt.
- **User:** The user that initiates the password update attempt. For example, such a user might be a PAM admin who updates a target account from the user interface, a scheduled job to update target account passwords, or the user could be the expired password processor.

### ***Account Requests***

This report lists A2A account password retrieval requests. This report returns the following information:

- **Date:** Select a **Quick Date** (such as This Month) or **Start** and **End Date** of the update. (Filterable)
- **Target Alias Name:** The name of the target alias. (Filterable)
- **Execution User ID:** The ID of the execution user. (Filterable)
- **Request Server Host Name:** The name of the request server host. (Filterable)
- **Request Server IP Address:** The IP address of the request server. (Filterable)
- **Account Access Type:** The type of account access. (Filterable)
- **Script Name:** The name of the script.
- **Execution:** The user who executed this request.
- **Error code:** The error code generated, if any.
- **Error Description:** A description of the error code.

### ***Accounts***

This report lists target accounts. This report returns the following information:

- **Account Type:** Synchronized or Unsynchronized. (Filterable)
- **Password State:** Expired or Not Expired (Filterable)
- **Account:** Displays the target account name
- **Target Application:** The name of the target application.
- **Target Server:** Displays the target server.
- **Password Composition Policy:** Displays the Password Composition Policy.
- **Password Created:** Displays the date and time the password was created.
- **Max Pwd Age:** Displays the maximum password age, in days.
- **Password Expiry:** Displays the date and time the password expires.
- **Synchronized:** Displays whether the account is synchronized (true) or not (false).

### ***Accounts with Expired Passwords***

This report lists accounts with expired passwords. This report returns the following information:

- **Account:** Displays the account name
- **Target Application:** The name of the target application. If "unknown", the account referenced application information that was not found. Contact Technical Support for assistance with resolving this issue.
- **Target Server:** Displays the target server.
- **Password Composition Policy:** Displays the Password Composition Policy.
- **Password Created:** Displays the date and time the password was created.
- **Max Pwd Age:** Displays the maximum password age, in days.
- **Password Expiry:** Displays the date and time the password expires.
- **Synchronized:** Displays whether the account is synchronized (true) or not (false).

#### **NOTE**

You cannot filter any parameters for this report.

### ***Accounts with Incorrect Passwords***

This report lists accounts whose passwords have not verified. This report returns the following information:

- **Target Server:** The name of the target server.
- **Target Application:** The name of the target application. If "unknown", the account referenced application information that was not found. Contact Technical Support for assistance with resolving this issue.
- **Target Account:** The name of the target account.
- **Last Used:** The date and time the account was last used.

#### NOTE

You cannot filter any parameters for this report.

### **Administrative Activities**

This report lists administrative activities. This report returns the following information:

- **Date:** Select a **Quick Date** (such as This Month) or **Start** and **End Date** of the update. (Filterable)
- **User:** The user initiating the activity, such as a PAM administrator user name.
- **Activity:** List of administrative activity, such as Add, Update, or Delete.
- **Type:** The type of object that is involved in the activity, such as Target Server, Account, or User.
- **User Name:** Name of the object that is involved, such as Server IP address, account name, or user name. (Filterable)
- **Details:** Clarifying details, such as, for example, "Synchronized=true, Device Name=WinServer, Owner User ID=1"
- **Date:** Select a **Quick Date** (such as This Month) or **Start** and **End Date** of the update.
- **User Name:** The name of the user.
- **Activity:** The administrative activities, including Add, Update, or Delete. (Filterable)
- **Type of Object:** The type of object, including All, A2A Authorization, A2A Request Script or Application, A2A Request Server Default, A2A Request Server, Account History, Password Composition Policy, Password View Policy, Role, Scheduled Job, Server Key, SSH Certificate Policy, SSH Key Pair Policy, System Property, Target Account, Target Alias, Target Application, Target Server, Target or Request Group, User (Group), or User. (Filterable)

### **Authorization Mappings**

This report lists all authorization mappings. This report returns the following information:

- **Alias/(Group):** The target alias/group, such as AWS API Proxy Access Accounts,
- **Target Server:** Displays the target server.
- **Application:** The name of the target application.
- **Account:** The name of the account.
- **Request Server (Group)** The request server and its group, such as AWS API Proxy Clients.
- **Script:** The script used in the mapping.

#### NOTE

You cannot filter any parameters for this report.

### **Automatically Updated Expired Passwords**

This report lists target accounts that are updated to comply with applicable Maximum Age policy. This report returns the following information:

- **Date:** Select a **Quick Date** (such as This Month) or **Start** and **End Date** of the update. (Filterable)
- **Pass:** Displays whether the password update was successful.
- **Account** The corresponding expired account.
- **Target Application:** The name of the target application. If "unknown", the account referenced application information that was not found. Contact Technical Support for assistance with resolving this issue.
- **Target Server:** Displays the target server
- **Password Composition Policy:** Displays the Password Composition Policy.
- **Password Updated:** Displays whether the password is updated.

- **Max Password Age:** Displays the maximum password age, in days.
- **Password Expiry:** Displays the date and time the password expires.

### **Cluster State**

This report lists cluster state changes. This report returns the following information:

- **Date:** Select a **Quick Date** (such as This Month) or **Start** and **End Date** of the update. (Filterable)
- **Hostname:** The name of the cluster host.
- **Activity:** Lists cluster activity, such as "application cluster started".
- **Members:** The members of the cluster.
- **Origin Host Name:** The name of the origin host. (Filterable)

### **Event Processing Status**

This report lists event status for A2A request servers. This report returns the following information:

- **ID:** The identification of the event, expressed as an integer.
- **Host:** The name of the host
- **Delete:** true or false
- **Type:** Displays the type, such as master or client.
- **Status:** Display the status, where 1 is successful.
- **Site:** Displays the site, such as Primary, or the Site ID integer.
- **Oldest:** Displays the oldest event.
- **Newest:** Displays the newest event.
- **Last:** Displays the most recent event
- **New:** Displays the number of new events.
- **Success:** Displays the number of successful events.
- **Failed** Displays the number of failed events.

#### **NOTE**

You cannot filter any parameters for this report.

### **Failed Password Updates**

Lists failed attempts to change an account password. This report returns the following information:

- **Date:** Select a **Quick Date** (such as This Month) or **Start** and **End Date** of the update. (Filterable)
- **Target Account Name:** The name of the target account. (Filterable)
- **Changes By:** The User who initiated the password update attempt. (Filterable)
- **Target Server Host Name:** The name of the target server host. (Filterable)
- **Target Application Name:** The name of the target application. (Filterable)
- **Account Access Type:** The type of account access. (Filterable)
- **Password View Policy ID:** Use the magnifying glass to filter by Password View Policy. (Filterable)
- **Error Code:** The error code generated, if any.
- **Duration:** The duration of the password update attempt.
- **Gen'd:** Displays whether the password update attempt was automatically initiated by PAM. This value displays TRUE if PAM initiated this password update attempt automatically, for example due to a Password Composition Policy's Maximum Password Age or a recurring Scheduled Job. This value displays FALSE if the password update was the result of a direct user action, for example if a user manually generated a new password for a Target Account.

### **List all Target Accounts in a Target Group**

Lists all target accounts in the target group specified in the **Target Group Name** field. This report returns the following information:

- **Hostname:** The hostname of the target account.
- **Application:** The name of the target application.
- **Account Name:** The name of the account.

#### **List all Target Applications in a Target Group**

Lists all target applications in the target group specified in the **Target Group Name** field. This report returns the following information:

- **Hostname:** The hostname of the target application.
- **Application Name:** The name of the target application.
- **Application Type:** The type of target application.

#### **List all Target Servers in a Target Group**

Lists all target servers in the target group specified in the **Target Group Name** field. This report returns the following information:

- **Hostname:** The hostname of the target server.
- **IP Address:** The IP address of the target server.
- **Device Name:** The device name of the target server.

#### **Orphaned Request Servers**

Lists all A2A request servers with no activity for one year. This report returns the following information:

- **Request Server:** The name of the request server
- **IP Address:** The IP address of the request server
- **Active:** Indicates whether the request server is active (true) or not active (false).
- **Client Type:** The type of client.
- **OS:** The operating system of the request server.
- **Date Registered:** The date of registration.

##### **NOTE**

You cannot filter any parameters for this report.

#### **Privileged Accounts**

This report lists privileged accounts. This report returns the following information:

- **Server Hostname:** Displays the server hostname or IP address.
- **Application:** The name of the target application.
- **Account:** Displays the account.
- **Access Type:** Displays the access type.
- **Date Registered:** Displays the date the registration.

##### **NOTE**

You cannot filter any parameters for this report.

#### **Requests for Invalid Aliases**

This report lists requests for aliases.

- **Date:** Select a **Quick Date** (such as This Month) or **Start** and **End Date** of the update. (Filterable)
- **Request Server:** The name of the request server
- **Alias:** The name of the invalid alias.
- **Script Name:** The name of the script.
- **Execution:** The user who executed this request

### ***Scheduled Jobs***

This report lists scheduled job results. This report returns the following information:

- **Date:** Select a **Quick Date** (such as This Month) or **Start** and **End Date** of the update.
- **Job Name:** The name of the job.
- **Successful:** Whether the job was successful (true) or not successful (false).
- **Command** Displays the command involved, such as scheduleReport
- **Repeats** Displays the job count.
- **Error Message:** Displays the error message, if any, such as "PAM-CMN-0680: E-mail server/account has not been set."

### ***View Password Requests***

This report lists view account password requests from the admin UI. This report returns the following information:

- **Date:** Select a **Quick Date** (such as This Month) or **Start** and **End Date** of the update. (Filterable)
- **Hostname:** Displays the hostname for the password request.
- **Application:** The name of the target application.
- **Account:** The account making the password requesting the password.
- **Reason:** Generally displays the reason for the password view entered by the requesting user, if they are required to supply one (because the **Reason Required for View** option is set in the password view policy). When integrated with a service desk solution (for example, ServiceNow), shows a predefined reason for the password view request provided by the service desk solution.
- **Workflow** (Returns Retrospective Approval, if selected.)
- **Details:** Generally displays an additional description of the reason for a password view (optionally supplied by the requesting user if they are required to supply a reason for the password view), "Not Required", or "Password Viewed". When integrated with a service desk solution, it shows details about why the target account is required.
- **Code:** Generally displays the reason code for a password view (optionally supplied by the requesting user if they are required to supply a reason for the password view). When integrated with a service desk solution, it shows the service desk ticket number.
- **Requestor:** User who executed this request.

## **Credential Manager Roles and Privileges for Running Reports**

You require a Credential Manager role with sufficient privileges to run Credential Manager Reports. The preconfigured Credential Manager ViewReports role has the following default privileges:

- Event Processing Status
- Generate Report
- List Reports
- Schedule Report

A user with the preconfigured ViewReports role can run the following set of Credential Manager reports:

- Accounts
- Accounts with Expired Passwords
- Accounts with Incorrect Passwords
- Authorization Mappings
- Automatically Updated Expired Passwords
- Event Processing Status
- Orphaned Request Servers
- Privileged Accounts
- Request for Invalid Aliases
- Scheduled Jobs
- View Password Requests

To run the other reports, a user requires a role with the default ViewReports privileges *and* the following permissions, as applicable:

Report Name	Required Additional Privileges
Account Passwords Update Attempts	<ul style="list-style-type: none"> <li>• Search Target Account</li> <li>• Search Target Server</li> <li>• Search Target Application</li> <li>• Search Password View Policy</li> </ul>
Account Requests	<ul style="list-style-type: none"> <li>• List Target Aliases</li> <li>• List A2A Clients</li> </ul>
Administrative Activities	<ul style="list-style-type: none"> <li>• Search Role</li> </ul>
Cluster State	<ul style="list-style-type: none"> <li>• Search Target Server</li> </ul>
Failed Passwords Updates	<ul style="list-style-type: none"> <li>• Search Target Account</li> <li>• Search Target Server</li> <li>• Search Target Application</li> <li>• Search Password View Policy</li> </ul>
List all target accounts in a target group	<ul style="list-style-type: none"> <li>• List Target Groups</li> </ul>
List all target applications in a target group	<ul style="list-style-type: none"> <li>• List Target Groups</li> </ul>
List all target servers in a target group	<ul style="list-style-type: none"> <li>• List Target Groups</li> </ul>

To configure a role with additional privileges, create a role (or roles) with the default ViewReports privileges *and* the new privileges. For details on how to add a new role, see [Add or Modify Credential Manager Roles](#).

For example, the following screenshot shows a new custom "ViewAllReports" role that has privileges to run all reports.

### Add Credential Manager Role

Name: \*

Description:

Available Privileges

<input type="checkbox"/> Name
<input type="checkbox"/> Reconcile Discovered Accounts
<input type="checkbox"/> Rename User
<input type="checkbox"/> Reset Client Cache
<input type="checkbox"/> Reset DB Hash
<input type="checkbox"/> Reset Group Cache
<input type="checkbox"/> Search A2A Client
<input type="checkbox"/> Search A2A Script
<input type="checkbox"/> Search Agent
<input type="checkbox"/> Search Audit Log
<input type="checkbox"/> Search Authorization
<input type="checkbox"/> Search Filter
<input type="checkbox"/> Search Group
<input type="checkbox"/> Search Password Policy
<input type="checkbox"/> Search Password View Request
<input type="checkbox"/> Search Password View Request By Approver

Selected Privileges

<input checked="" type="checkbox"/> Name
<input checked="" type="checkbox"/> Event Processing Status
<input checked="" type="checkbox"/> Generate Report
<input checked="" type="checkbox"/> List Reports
<input checked="" type="checkbox"/> List A2A Clients
<input checked="" type="checkbox"/> List Target Aliases
<input checked="" type="checkbox"/> List Target Groups
<input checked="" type="checkbox"/> Schedule Report
<input checked="" type="checkbox"/> Search Password View Policy
<input checked="" type="checkbox"/> Search Role
<input checked="" type="checkbox"/> Search Target Account
<input checked="" type="checkbox"/> Search Target Application
<input checked="" type="checkbox"/> Search Target Server

OK CANCEL

**NOTE**

If you also want a user with this role to be able to view passwords on the **Access** screen, also add the following privileges:

- Get Password View Policy
- View Account Password
- Get Target Account

## Generate Credential Manager Reports

You can generate various reports on demand on the Reports page. Audit, metric, and event data can be archived through the CLI.

**NOTE**

The size of a report is governed by a Credential Manager setting. To set the size limit, see [Schedule Credential Manager Reports](#).

**NOTE**

To view Credential Manager PDF format reports in Japanese, install the Adobe Acrobat Reader DC FontPack1900820071\_XtdAlf\_Lang\_DC fontpack.

**Follow these steps:**

1. Select **Credentials, Reports, Run**.  
The Reports page appears.
2. Select the report to generate, for example, Administrative Activities, and select **Update**. For descriptions of the reports, see [Available Credential Manager Reports](#).  
The relevant Report window appears.
3. If applicable, select a Quick Date range, or enter the Start and End Dates for the report. Reports cover the period from 00:00:00 (midnight) of the start day to 23:59:59 of the end day.
4. Specify any additional parameters, including filters, that are specific for your report.
5. Select the Output Format type (HTML, CSV, or PDF).
6. Select **OK** to run the report.  
The report displays in a new browser window.

**NOTE**

Your Web browser might first ask you to allow the report to be displayed, or might notify you that pop-ups are blocked.

## Schedule Credential Manager Reports

Credential Manager allows you to schedule jobs that run the selected report and emails the output to the selected recipients. Recipients can be selected from all Credential Manager users with a valid email address.

You can schedule report jobs with the following recurrence: daily, weekly, monthly, yearly, or after an arbitrary number of days. Alternatively, you can schedule the report to occur only once at a specified time.

Scheduled reports do not support filtering.

To view the status of scheduled jobs, generate the Scheduled Jobs Report. See [Generate Credential Manager Reports](#).

**Follow these steps:**

1. Select **Credentials, Reports, Scheduled Jobs**.  
The Scheduled Report Jobs screen appears.
2. Select **ADD**.  
The Add Scheduled Report Job dialog appears.
3. Enter the **Job Name**, which is a text description for the job, up to 80 characters long.
4. In the **Recurrence** field, select the frequency. You can select **Run Once**, **Daily**, **Weekly**, **Monthly**, **Yearly**, and **Every N Days**.
5. The **Date/Time** option changes to correspond with your **Recurrence** selection:
  1. For **Run Once**, use the **Date/Time** option to select the date and time to run one instance.
  2. For **Daily**, use the **Time** option to select the time to run a daily instance. The **Repeat Only On Weekdays** option excludes a daily run on any weekend day (Saturday and Sunday).
  3. For **Weekly**, use the **Time** option to select the time and the days of the week to run the instance.
  4. For **Monthly**, you have two options:

- **Run on day <number> of the selected month(s):** Select a date (1 to 31), or **Last** for the last day of the month to run the job. You can select one or more months to run the job using the corresponding checkbox beneath this option.
  - **Run on the <number><day> of the selected month(s):** Select First, Second, Third, Fourth, or Last day to run the job. This option allows you to specify a particular day instead of a particular date. You can select one or more days and months to run the job.
5. For **Yearly**, use the **Date/Time** option to select the date and time to run the annual instance.
  6. For **Every N Days**, use the **Date/Time** option to select the start date and time, and then how long to wait before running another instance. For example, you could select a start date, and set the time to 1 AM every four days, by setting the **Time** to 01:00:00 and the **Days** to 4.
  6. On the **Report Details** tab, in the **Report Name** field, select the type of report you want to generate.
  7. Select the **Quick Dates** for the timeframe that you want the report to cover. Reports cover the period from 00:00:00 (midnight) of the start day to 23:59:59 of the end day. The Start Date and End Date fields update automatically, and are recalculated each time that the report is run.
  8. Select one of the following Output Format options:
    - **HTML** (on the current page)
    - **CSV** (export file)
    - **PDF** (generated document)
  9. Move the desired email recipients from the **Available Recipients** list to the **Selected Recipients** list. As a default, the logged-in user is saved in the Selected Recipients list.
  10. Select **OK**.

### **Limit the Size of the Report Email Attachment**

You can configure the maximum size of a report email attachment through the system property `reportAttachmentLimit`. This system property limits the maximum size of a report email attachment. When the report exceeds the configured size set through this property, the email is not sent.

You can configure an email attachment size through the `reportAttachmentLimit` system property as shown in the following example:

Windows:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty ^
propertyName=reportAttachmentLimit propertyValues=5cspmserver_admin -u admin ^
cmdName=setSystemProperty propertyName=reportAttachmentLimit propertyValues=5
```

Linux:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty \
propertyName=reportAttachmentLimit propertyValues=5cspmserver_admin -u admin \
cmdName=setSystemProperty propertyName=reportAttachmentLimit propertyValues=5
```

The following table shows the details of the `reportAttachmentLimit` system property:

Property Name	Value	Required	Notes	encryptValue
<code>reportAttachmentLimit</code>	Maximum size of a report email attachment (for example, 1)	N/A	Set an integer value in MB. The default value is 5 MB.	False

## **Credential Manager Activities List**

The Credential Manager Activities page provides a set of predefined metrics to monitor system activity. Administrators with appropriate permissions can change [Configure Credential Manager Settings](#) and can apply those changes globally. Global changes affect all users of the product. Individual users can configure their own Activities list [here](#).

**Follow these steps:**

1. Select **Credential, Reports, Activities**.  
The Credential Manager Activities page appears. If you have not changed them, the default items from the Settings, Credential Manager page are listed.
2. Select the **Configure** button to change the items that are listed.  
The Credential Manager Activities Settings window appears.
3. To add a new item to the Credential Manager Activities Settings list, follow these steps:
  - a. Select the Plus icon. The Item Name window appears.
  - b. Select one or more entries from the list of available activity items.
  - c. Select **OK**. The Item Name windows closes.
4. To remove an entry from the Activities list, select the **X** icon.
5. To reposition a list item, select the item and use the Up or the Down arrow.
6. To set a threshold limit that activates a warning icon in the Activities list, enter a value in the Threshold field. For example, a threshold value of 5 for Passwords Not Verified causes a warning icon to appear in the Activities List page when the number of unverified passwords reaches 5.
7. Select **OK** to save.

## Management Console

The Privileged Access Manager Management Console is a solution for administering large cluster deployments or sets of clusters.

The Management Console helps alleviate the management burden of large installations for Managed Service Providers and other distributed deployments. The Management Console performs the following functions:

- Gathering of the site endpoints into a single location for easy navigation, similar to a launch pad
- Holding and distributing patches that can then be staged onto sites
- Gathering of basic health information from sites to present a consolidated status of the health of the clusters

Three key personas can benefit from using the Management Console:

- **Management Console Auditor:** An auditor has read-only access to the console. The auditor can evaluate patch levels and cluster health, but cannot set up clusters and cannot configure patch tasks. An auditor does not have access to the Administration function of Privileged Access Manager.
- **Management Console Operator:** An operator is able to configure the console, including staging patches. An operator cannot set up Clusters, does not have access to the Administration pages, and cannot alter Service settings.
- **Management Console Administrator** has full access to configure the console, to the Administration pages, and to launch Privileged Access Manager on managed clusters. The administrator uses the Management Console to:
  - Set up a new customer cluster.
  - Determine the health of clusters.
  - Manage patches that are available from the console.
  - Stage patches onto sites in a cluster.
  - [Approve Smart Card users to allow logins](#)
  - [Configure Active Directory for user authentication](#)

### NOTE

After the **Management Console Admin** or **Global Admin** approves the Smart Card user, make sure that the appropriate Management Console Role is assigned to these new users so they can access the **Management Console** UI. See [User Roles](#) for more information about assigning roles.

## **Initial Setup and Security**

### ***Prerequisites***

- Port 443 must be open bidirectionally within each managed cluster.
- Port 443 from each managed cluster to the MC.
- Port 443 must be open from the MC to the VIP of each managed cluster.
  - If port 443 is not open to the cluster, the Console can still monitor health and distribute patches. However, the Console operator cannot launch a session to the cluster.

### **NOTE**

The Management Console, regardless of whether it is a hardware or virtual appliance, can manage both hardware and virtual appliances.

### ***Setup***

The Management Console requires a different license, and a separate appliance (or virtual instance) on which to run the Management Console. If the Management Console is already licensed, your login defaults to the Management Console interface. If you are in the normal Administration interface, you see a Management Console link to the right of the Configuration menu. The Administration interface is limited, having some of the Configuration options, but missing most of the Provisioning settings. A Management Console appliance cannot be used as a regular Privileged Access Manager appliance.

### ***Security***

The Management Console cannot manage a cluster until its integration is configured in that cluster using information from a specific Management Console. Only one "aggregator" member of a cluster has contact with the Management Console. See [Integrate with the Management Console](#) for details.

Once configured, communication is initiated by the managed cluster. ("Launching" from **Clusters, Actions, Launch PAM** simply opens the target login page in a browser. You still have to log in.)

The managed cluster does not need to enable the external REST API.

### ***Aggregated Data***

There are two types of aggregated data: Legacy Cluster information and Time Series based meters

#### **Legacy Cluster Information**

No client-specific data is collected and transmitted outside of any managed cluster or instance. The aggregator typically sends a short status message, but sends a full report when it detects changes, or when the Management Console requests one. Status information is organized in several sections, each containing one item for each cluster member:

- Cluster Structure
  - FQDN
  - IP address
  - Master node (Boolean flag)
  - Node position (internal)
  - Record type (internal)
  - Site name
  - Site type (standalone/primary/secondary)
  - Site version (PAM version)
  - Hardware ID
- Database Status

- DB cluster status
  - DB replication role
  - Hardware ID
- License Usage (counts)
  - A2A, A2A Max
  - Access, Access Max
  - AWS Proxy, AWS Proxy Max
  - Azure Proxy, Azure Proxy Max
  - NSX Proxy, NSX Proxy Max
  - Password, Password Max (Credential Management usage count)
  - Hardware ID
- Member Performance
  - Disk free space
  - Disk total space
  - DB access status
  - Site active member flag
  - Hardware ID
- Member Staging
  - Staged patches
  - Staging status
  - Version
  - Hardware ID
- Patch Deployment
  - Patch ID
  - Status

### **Time Series-Based Meters**

To better understand overall system health, sets of meters are scraped from each VM and stored into a time series-based database. Each PAM instance has the meters for its own instance. However, after configuring the Management Console for the cluster, the meters then also aggregate to the Management Console.

This interface provides a single location to visualize the cluster activity and health from all of the cluster members.

This data is then visualized in dashboards that allows users to filter the data in various ways, including over specific time windows.

Health data includes the following information:

- CPU Utilization
- Disk, Disk I/O Utilization for PAM storage and attached Session recording storage
- Network I/O Utilization

Activity data includes the following information:

- Current users actively logged in over time
- Current active access session over time
- Current License Utilization and Utilization over time
- Cluster health status

### ***Monitoring the Management Console***

The Management Console can be set up to monitor itself. See [Integrate with the Management Console](#) for information about integrating the cluster into the Management Console.

## **Patch Delivery**

### **Prerequisite**

Patch delivery works with a firewall in place, as long as the firewall is not blocking access from the cluster to the Management Console.

## **Estimate Management Console Disk Requirements**

The Management Console retains at least 31 days of data but may temporarily maintain older data for a short period. Visualizations within the Management Console display all available data.

Internally, data is purged once a month. Therefore, for planning purposes, consider that data may accumulate for up to 62 days.

For example, if data is captured from October 1 through November 30. On December 1, the October data is removed.

### **Calculate Expected Disk Requirements:**

To estimate the disk space required for the Management Console, follow these steps:

1. Determine the total number of PAM instances across all connected clusters.
2. Add 1 for the Management Console data.
3. Use the estimated data per-node, per-day: 11 MB.
4. Apply the expected maximum retention period: 62 days.

### **Example 1:**

A single cluster with three sites, each site having three nodes (nine PAM instances in total).

**Result:** (9 PAM instances + 1 Management Console) × 11 MB × 62 days = 6.4 GB of disk space

### **Example 2:**

Two clusters:

- First cluster (production) has three sites, each site having three nodes (9 PAM instances total)
- Second cluster (UAT) has two sites with two nodes each (4 PAM instances total)

**Result:** (9 PAM instances + 4 PAM instances + 1 Management Console) × 11 MB × 62 days = 8.9 GB of disk space.

### **NOTE**

#### **Next Steps:**

- [Add a Cluster to the Console](#)
- [Integrate with the Management Console](#)
- [Enable Console Services](#)
- [Upload Patches to the Console](#)
- [View the Status of Tasks](#)

## **Add a Cluster to the Console**

The Management Console Clusters page displays the status and other properties of the clusters under management by the console. To add a cluster to the console for management, a Management Console Administrator follows these steps:

1. Go to the Management Console.
2. On the Clusters page, select **Add**.
3. On the **Basic Info** tab, create a **Name** for the cluster, and an optional Description.

4. The **Active** checkbox defaults to selected. Clear this box to add the cluster without activating it in your list.
5. The Primary Contact tab is optional, to save notes for the Management Console operator.
6. On the **Onboarding Info** tab, copy the **Cluster cookie**. You need this cookie to configure the Management Console integration on the target clusters. The Cluster VIP is read-only, and is populated when the target cluster contacts the Management Console.
7. Select **OK** to save.

To activate the cluster on the console, an administrator logs in to the target cluster to [integrate it with the console](#).

An administrator can update the optional information or can delete these clusters from the list using the Update and Delete buttons on the Cluster list. The **View Dashboard** button navigates the user to the graphical dashboard showing data meters over time for the selected cluster. **View Dashboard** is not available if you are using Internet Explorer 11.

For each cluster under management, these attributes are displayed on the Clusters page:

- **Name:** The cluster is named by the console operator.
- **Active:** If the **Active** check box is selected when you add a cluster, a check mark appears in its row. If the check box is cleared, this column reads "Inactive", and the data for that cluster row ceases to update.
  - "Not Registered" appears after the cluster has been added, but has not yet been integrated, or has not been called in yet.
  - "Pending" appears after a status refresh has been requested.
- **Last Comm:** If the most recent communication is less than a minute, a check mark appears. After one minute, it displays a warning icon with the number of elapsed minutes. After 5 minutes, it displays an error icon with the number of elapsed minutes (m), hours (h), or days (d).
- **On:** If the cluster is turned on, a check mark appears. If two or more members are sending information, a "CONFLICT" message appears.
- **Online:** If all the members in a cluster are active (in the cluster), a check mark appears.
- **Synced:** If the cluster is synced, a check mark appears. An error icon appears if the cluster is out of sync.
- **Min. Disk Free:** This column displays the disk space available in a cluster member with the least free disk space in that cluster. Any patch that is staged needs to fit on all members.
- **Version:** The Privileged Access Manager version of the reporting member is shown. All members in a cluster require the same version.
- **Members:** The total number of members in all the sites in the cluster is shown.
- **Sites:** The number of sites in the cluster is shown.
- **Licenses:** A slider graphic displays, from left to right, green, yellow, or red, to show the percent of licenses used. From 0 percent to 50 percent, the indicator is green. From 50 percent to 90 percent, the indicator is yellow. At 90 percent and above, the indicator is red.
- **Actions:** Select the arrow icon to select from these actions:
  - **View Dashboard:** Navigates the user to the graphical dashboard showing data meters over time for the selected cluster. **View Dashboard** is not available if you are using Internet Explorer 11.
  - **Launch PAM:** Open a session on the cluster.
  - **Details:** Open a page with detailed information about the cluster:
    - Number of total and used licenses for each license type, such as Session Manager
    - Information about each site, including its site membership, IP address, and status
    - Aggregator identification
    - You can stage a patch from this page, using the **Stage Patch** button. See [View the Status of Tasks](#) for more information.

Selecting the Cluster Name on the Clusters page opens this same page.

- **Refresh Status:** Select this option to request a status update from the selected cluster.
- **Send email to Contact:** Open an email that is addressed to the Email of the Primary Contact that is defined for this cluster. The email address is defined on the Primary Contact tab of the Add Cluster window. You can also access it with the Update button.

**NOTE****Next Steps:**

- [Integrate with the Management Console](#)
- [Enable Console Services](#)

## Integrate with the Management Console

To integrate your Privileged Access Manager clusters with the Management Console, a Management Console Administrator configures each cluster. You enter integration settings on one member of the Primary Site of the managed cluster, and the settings are replicated to all cluster members. An election algorithm running on the managed cluster determines which member is the aggregator who uploads information to the Management Console.

To integrate your clusters with the Management Console, you need information from the Management Console to enter into each managed cluster. Follow these steps:

1. Go to the **Administration** interface on the target cluster.
2. Go to **Configuration, Management Console, Integration**.
3. Wait to enable Integration until *after* you have tested the connection and API.
4. Enter the **Console Host Name** or **IP** address of the Management Console.
5. Enter the **Port**, such as 443, for the Management Console.
6. Select **Use SSL** if you are using SSL.
7. Enter the **API Key** and **Password** from the Management Console. Get the API Key and Password from the built-in Management Console account:
  - a. On the Management Console, go to **Administration, Credentials, Manage Targets, Accounts**.
  - b. On the Target Accounts page, find the Account Name similar to *MCApiKey-x*.
  - c. Select the View eye icon in the Action column to see the password for the API Key.
  - d. Copy the Password from the Show Password window.
  - e. Return to the target cluster and paste the password into the **Password** field of the cluster Management Console Integration page.
8. Paste the **Cluster cookie** from the Management Console for this cluster into the target cluster **Cluster cookie** field. Each cluster has its own Cluster cookie. See [Add a Cluster to the Console](#) for more information.
9. Select an **Info Upload Interval**, in minutes. We recommend that you use one minute to avoid raising warnings and alarms on the Management Console.
10. Select to **Save** the settings.
11. Select **Ping** to ensure that the cluster can communicate with the Management Console.
12. Select **Test Integration API** to ensure that the API Key, Password, and Cluster Cookie are accurate, and that the cluster can connect to the Management Console. The Management Console Services have to be running on the Management Console to succeed. If the Management Console itself is clustered, clustering must be turned on to activate the REST API.
13. Select **Enable Integration** if you are ready to report data to the Management Console.
14. Select to **Save** the settings and start reporting to the Management Console.
15. Select **Test Reporting API** to ensure that this cluster member can connect to the Aggregator member of the cluster. The managed cluster has to be on for this test to succeed.

**NOTE****Next Step:**

- [Enable Console Services](#)

## Enable Console Services

### Apply the Management Console License

Before you configure Services, apply your Privileged Access Manager license for Management Console. A license file is prepared by Broadcom Support and installed with your appliance. You update the existing license by following these steps:

1. Go to **Configuration, Licensing**.
2. Select the **Install New License** tab.
3. Use **Choose File** to locate the license file on your system. The license file is of type XCDLIC.
4. Select the **Upload License File** button.  
The **Verify New License** window appears.
5. Verify that the capabilities that are listed are expected and appropriate.
6. Select **Save New License**.
7. Log out and log back in to refresh your capabilities.

For more information about licensing, see [Apply Software and Feature Licenses](#).

### Configure Management Console Services

To configure Management Console Services, follow these steps:

1. Select the **Administration** link on the console menu.
2. Go to **Configuration, Management Console, Services**.
3. Select **Enable Services** to activate the Management Console Services, including patch distribution, and internal tasks.
4. The remaining options govern the delivery of patches to the clusters:
  - **Task Check Interval** sets the number of seconds between internal maintenance tasks. Do not change this setting unless directed by Broadcom Support.
  - **Enable Downloads** is the default mode. Clear this check box to stop distribution of any patches to any cluster.
  - **Max Number of Connections** limits the number of simultaneous connections while sending patches.
  - **Max Number of Retries** defines the number of unsuccessful attempts to download a patch before deeming it a failure.
  - **Enable Download Throttling** to keep downloading from affecting the console performance, and possibly saturating the network with Management Console traffic.
  - **Allowed Bandwidth** is in effect only if Download Throttling is selected. This setting limits cumulative bandwidth that is consumed by simultaneous patch downloads.
5. Select **Save** to save your settings.

## Upload Patches to the Console

The Management Console enables you to manage the upgrading of remote clusters and instances of Privileged Access Manager. On the Patches page, you upload patches and upgrades to the Management Console for later distribution to your managed clusters for staging.

To upload a patch, locate the Privileged Access Manager patch (for example, on the CA website) and download it to your local computer. Follow these steps to upload the patch:

1. On the **Patches** page, select the **Add** button.
2. Select **Choose File** to browse to the file, and select **Upload** to upload it. The **Archive** is the patch name.  
When a patch is uploaded to the Management Console inventory, its checksum is validated.
3. Metadata is read from the uploaded archive, and its display is read-only. These properties appear once a patch is uploaded:

- **Patch ID** identifies the patch, and can include the precise version number.
  - **Patch File** is the file name of the patch.
  - **Checksum** is presented for your validation. The hash is validated upon uploading it.
  - **Size** is specified by rounding up to the next MB.
  - **Min Level** is the lowest version number that accepts this patch.
  - **Max Level** is the highest version number that accepts this patch.
  - **Patch Type:** Upgrade or Hotfix is indicated.
  - **Reboot Type:** Member or Cluster, both, or neither are shown.
4. The optional **Information** section is intended for the Management Console operator to record how long the patch takes to execute, and any notes.
- **Duration** (in minutes)
  - **Notes**
  - **Archived:** Select the Archived checkbox to prevent the patch from being listed as a Compatible Patch in the Stage Patch Task window. Archiving allows current tasks to continue without the risks of deleting the patch, while preventing further distribution. You can return an archived patch to active duty by clearing this checkbox.
5. Click **OK** to save.

The **Update** button allows you to edit the Duration, Notes, and Archived attributes. All other Patch information is read-only. Select the row of the patch to edit, and select **Update**.

The **Patches** page lists each uploaded patch with its required information and any optional information that was provided. The following columns are displayed for each uploaded patch. This information is the same that is available during Add or Update. The Requires column combines the Min Level and Max Level fields. The Outage column displays the same information as Reboot Type.

- Patch ID
- Upload Date
- Size
- Requires
- Outage
- Duration
- Notes
- Archived

#### **NOTE**

#### **Next Step:**

- [View the Status of Tasks](#)

## Cluster Details

To see the details for an individual Cluster from the **Clusters** page, select the Cluster Name, or select **Details** from the **Actions** column.

### Cluster

The Cluster section provides cluster level details about available licenses.

### **Licenses**

License information is reported for each of the License Types that are purchased by quantity:

- Session Manager (also known as Access Devices)
- Credential Manager (also known as Password Devices)
- App to App Manager (also known as A2A Devices)
- AWS API Proxy (Users)
- NSX API Proxy (also known as VMware NSX API Proxy Users)

For each License Type, the licensed quantity is shown as Total, and the quantity being used is shown as Used. The Status graphic displays, from left to right, green, yellow, or red, to show the percent of licenses used. From 0 percent to 50 percent, the indicator is green. From 50 percent to 90 percent, the indicator is yellow. At 90 percent and above, the indicator is red.

## **Sites**

The Sites section lists each member of each site in the cluster, including the following information:

- **Site Name** displays Site Name as set in the Configuration section of that site.
- **Site Type** is either Primary or Secondary.
- **Member** displays the IP address or host name of the site (or instance).
- **Aggregator**: A check mark indicates that this member sends cluster information to the Management Console.
- **Online**: A check mark indicates that this member is online.
- **Replication**: A check mark indicates that the database is synchronized. A red exclamation mark indicates that it is not synchronized or has timed out. Mouse over the field to see the underlying status value. This field can also display "Unknown."
- **Disk Free** displays the amount of free disk space for each member. In contrast, the "Min Disk Free" column on the Clusters page shows the least amount available among all cluster members. Any patch that is staged must fit on all members.
- **Version** displays the current Privileged Access Manager version.
- **Staged** displays the patches which are staged on each member.

## **Actions**

The buttons in the Sites section allow the following actions:

**View Dashboard** Opens the *Cluster Dashboard*, an advanced visualization tool that shows current and historical system data about the selected cluster that updates over time. For more information, see [Management Console Cluster Dashboard](#).

### **NOTE**

**View Dashboard** is not available if using Microsoft Edge in Internet Explorer mode.

**Launch PAM** launches a login screen for a specific member if a site is selected, or to the cluster VIP if none is selected.

**Delete** allows you to delete a site entry from the cluster listing. The site itself is not affected and reappears at the next information upload.

The **Stage Patch** button launches the [Stage Patch Task window](#), which allows you to stage patches to the cluster. A Management Console Administrator or Operator can stage a patch.

## **Visualize Cluster Data Using the System Dashboard**

After logging into the Management Console, users see a list of configured Clusters. There are several ways to reach the visual dashboard for a particular cluster:

- Using the **Action** icon found on each of the Cluster's row, select **View Dashboard** from the menu.
- While in the Cluster details page, select the **View Dashboard** button.

Both will navigate the user to that Cluster's dashboard.

**NOTE**

When the Dashboard first loads, the Site and Instance filters will be pre-selected to include all sites and instances.

The Cluster dashboard page aggregates information from across all sites into a succinct layout, providing both current levels of key, cluster-wide data. Key data includes items such as license count and access activity, as well as changes over time.

Within the Cluster dashboard page is a table listing its PAM instances. Selecting one of those instances navigates to the PAM Single instance dashboard page. This dashboard page is the same page found on that instance of PAM.

**NOTE****Next Steps:**

- [Stage a Patch Task](#)
- [View the Status of Tasks](#)

## Stage a Patch Task

The Management Console allows you to stage tasks, such as delivering patches to your configured Privileged Access Manager clusters.

To stage a patch, follow these steps:

1. Go to the **Clusters** page.
2. Open the details for an individual Cluster by clicking the Cluster Name, or selecting **Details** from the **Actions** column.
3. The Cluster page appears, with details about available licenses, individual site members, IP addresses, and status. The Sites section of the Details page displays the current Privileged Access Manager version.
4. Select the **Stage Patch** button in the Sites section.  
The Stage Patch Task window appears, with a list of previous staging tasks, and compatible patches.  
See [Upload Patches to the Console](#) for more information about patch properties.
5. Select the appropriate Compatible Patch, and select **OK**.  
The staged patch now appears on the Tasks page.
6. To follow the status of the staged patch, you can go to the [View the Status of Tasks](#). You can reorder the rows by Cluster to help find a staged patch. The Task also appears in the Previous Staging Tasks list in the Stage Patch Task window.  
Each staged patch row displays the following information:
  - **Patch ID**
  - **Cluster** name (on the Staging Tasks page)
  - **Command** shows the most recent command, such as Recall, Retry, or Stage.
  - **Status** includes Assigned, Notified, Sending, Send Failed, Sent, Received, Dispatching, Staging, Staged, Stage Failed, Deploying, Deployed, Deploy Failed, Recalling, Recalled, and Recall Failed.
  - **Updated** shows the time that the status was last updated.
  - **Created** shows the time that the task was initiated.
  - **Attempts** displays a count of the attempts. The number of attempts is limited by the settings on the [Enable Console Services](#) configuration page.
  - **Delivered** shows the size of the patch file that is delivered.
  - **Target** cluster (only in the Stage Patch Task window)

To see details about a task in the **Previous Staging Tasks** list, select its row, and select the **Events** button. The resulting page lists each step in the staging process, with the following attributes:

- **Command** shows the type of command, such as Stage and Recall.
- **Created By** lists the User who initiated the Task.
- **Creation Time** is when the particular event was recorded.
- **Status** specifies which step in the staging flow is listed, such as Assigned, Notified, Sending, Send Failed, Sent, Received, Dispatching, Staging, Staged, Stage Failed, Deploying, Deployed, Deploy Failed, Recalling, Recalled, and Recall Failed.
- **Attempts** shows the number of attempts for the listed event.

Select **Refresh** to update the information in the Previous Staging Tasks window.

For a selected row on the Previous Staging Tasks list, you can **Retry** or **Recall** the task.

## View the Status of Tasks

To follow the status of a staged patch in the Management Console, go to the **Tasks** page. You can reorder the rows by Cluster to help find a staged patch.

Each staged patch row displays the following information:

- **Patch ID**
- **Cluster** name
- **Command** shows the most recent command, such as Recall, Retry, or Stage.
- **Status** shows the status of the task, such as Assigned, Notified, Sending, Send Failed, Sent, Received, Dispatching, Staging, Staged, Stage Failed, Deploying, Deployed, Deploy Failed, Recalling, Recalled, and Recall Failed.
- **Updated** shows the time that the status was last updated.
- **Created** shows the time that the task was initiated.
- **Attempts** displays a count of the attempts. The number of attempts is limited by the settings on the [Console Services](#) configuration page.
- **Delivered** shows the size of the patch file that is delivered.

To see details about a task in the **Staging Tasks** list, select its row, and select the **Events** button. The resulting page lists each step in the staging process, with the following attributes:

- **Command** shows the type of command, such as Stage and Recall.
- **Created By** lists the User who initiated the Task.
- **Creation Time** is when the particular event was recorded.
- **Status** specifies which step in the staging flow is listed, such as Assigned, Notified, Sending, Send Failed, Sent, Received, Dispatching, Staging, Staged, Stage Failed, Deploying, Deployed, Deploy Failed, Recalling, Recalled, and Recall Failed.
- **Attempts** shows the number of attempts for the listed event.

For a selected row on the main **Staging Tasks** page, you can **Launch PAM** on the target Cluster, and **Retry** or **Recall** the task.

## Integrating

---

The contents of this section describe how to configure the product so that it can co-operate with external, third-party devices and servers.

Use the table of contents to access the topics in this section.

### Configure Login Options for Windows Target Devices

You can configure the following options for Windows target devices:

#### Network Level Authentication Login for RDP Access

RDP sessions to a Windows server can be subject to denial-of-service (DoS) attacks. To lower the risk of DoS attacks, Windows server administrators can configure Network Level Authentication (NLA). NLA prompts a user to authenticate before a session is established with the server. PAM accommodates NLA so that connections to a Windows target server can complete successfully.

No specific configuration is required for the appliance to handle the NLA requirement. Simply add users to the Windows target device record. In the Device configuration, only the **Device Name**, **Address**, and the **Access Method** (RDP) are mandatory.

If you configure the RDP-TCP access method with the setting: **Allow connections only from computers running Remote Desktop with Network Level Authentication**, the appliance handles the NLA requirement properly. To configure the RDP-TCP access method, select the **General** tab of the **RDP-TCP Properties** dialog.

#### *User Experience with NLA*

When a user selects the RDP access method, the RDP page appears, and then a security dialog prompts for the NLA-based credentials. After the user enters the credentials, the appliance submits them to the Windows target device to complete the login operation.

#### **NOTE**

If you [enable a password push](#) for the Windows target device, this login prompt is overridden.

#### Enable a Password Push for RDP Password Enforcement

The Windows Remote Desktop Services interface has an option that is labeled **Always prompt for password**. This option allows the Windows administrator to force a password prompt even when the client workstation is configured to connect automatically.

#### **NOTE**

If NLA is enabled on an RDP server using the TLS security layer, the server ignores the **Always prompt for password** option. Users are not prompted for passwords. To enforce the password option, the Windows administrator must configure the server with the RDP security Layer.

You can configure a device group to populate the password prompt automatically, with the password obfuscated.

The following procedure assumes that you have set up the following components:

- Users
- Devices
- Target accounts
- Associated policies for auto-connection for those target accounts

**Follow these steps:**

1. Log in to the UI as an administrator with configuration privileges.
2. Navigate to **Devices, Manage Device Groups**.
3. Select an existing device group, or select **ADD** to create a group.
4. From the **Devices** tab, select the target devices that require a password push for an auto-connection policy.
5. Select the **Enable** tab, and set the **Provide Credentials for 'Always Prompt for Password'** option. This setting forces an auto-connection at the device level for any device in the device group.

**NOTE**

If the target RDP server is running 32-bit Windows 2008, you can set the **Handle 'Legal Notice' on Logon Screen** option to automatically accept the Windows legal notice that appears during login. On every other Windows version, the user must manually accept the legal notice.

6. Navigate to **Policies, Manage Policies**.
7. Prepare a policy for the user/user group and the device group that you previously configured. Select RDP as the access method for the policy.
8. Select **OK**.

**NOTE**

Windows generally presents a legal notice that the user must manually dismiss within a specified timeout period to start the session.

Password push is now enabled.

***User Experience with Password Push Configured***

When a user logs in using the RDP access method, the following actions occur:

1. The RDP Access Method splash page appears.
2. The RDP window displays the Windows login screen.
3. The appliance immediately overrides the login prompt. A brief delay occurs, during which the user sees a countdown screen until auto-connection is complete.

**NOTE**

If presented with a Windows legal notice, the user must manually dismiss that notice to start the session. If the legal notice is not dismissed within a timeout period that is defined on the server, the login session fails.

The remote user is logged in.

## Configure Kerberos PIV/CAC Authentication for Windows Targets

As an administrator, you can implement Kerberos authentication with PIV/CAC smart cards to log in to LDAP-imported Windows target devices. For Kerberos authentication, you configure connections to one or more Kerberos Key Distribution Center (KDC) servers. You then associate each applicable device group or device with a KDC.

This topic describes prerequisites for using Kerberos PIV/CAC, configuring connections to Kerberos KDC servers, associating a device group or device with a Kerberos KDC server, and logging in to a Windows target device with a smart card.

**Prerequisites for Using Kerberos PIV/CAC**

Verify the following prerequisites:

- The applicable client workstations have the approved PIV/CAC hardware and software. Up to two smart card readers can be used on each workstation.
- Network Level Authentication (NLA) is enabled on the applicable Windows RDP target devices. For more information about NLA, see [Configure Windows Target Device Options](#).
- One or more Kerberos KDC servers are available

## **Configure Connections to Kerberos KDC Servers**

Configure connections to one or more KDC servers.

### **Follow these steps:**

1. Navigate to **Configuration, 3rd Party, KDC**.
2. Select **Add** to add a KDC Server.  
The Add KDC Server Configuration window appears.
3. Enter the Kerberos KDC Server IP address and Port (typically 88).
4. Select **OK**.
5. Repeat these steps to add other KDC servers.

## **Associate a Device Group or Device with a Kerberos KDC Server**

Associate a device group or device with a Kerberos KDC server.

### **Follow these steps:**

1. Navigate to **Devices, Manage Devices**, or **Manage Device Groups**.
2. Select **Add** or **Update** to create or edit a Device or Group.
3. On the **KDC Server** tab, select the KDC Server from the drop-down list.
4. Select **OK** to save your changes.

### **NOTE**

If you specify a Kerberos KDC server at the device level, that device-level setting overrides any KDC server configuration for a device group. If a device does not have a KDC Server that is specified, only then is the KDC server for the device group used.

## **Log in to a Windows Target Device with a Smart Card**

If you are a PIV/CAC smart card user, you can log in to a destination Windows system automatically.

### **Follow these steps:**

1. Log in to the UI.
2. Select **Access** from the menu bar.
3. On the Access page, select the RDP link for the desired device to launch a connection.
4. Select **Smart Card**.
5. Complete the following steps:
  - a. Select a credential from the **Choose a smart card credential (Kerberos authentication)** drop-down list.
  - b. If your environment supports mapping one smart card certificate to multiple accounts, select **Add Hint** and enter a **Username Hint** in the field that appears.
  - c. Enter your smart card **PIN**.
6. Select **Login** to access the target Windows device.

### **NOTE**

If Kerberos is not being used, select **Login Form** to access the device.

7. (Optional) To identify the authentication protocol, select the lock icon in the top toolbar of the RDP window. A pop-up window confirms that the identity of the remote computer was verified using Kerberos.

If your credentials are correct, you are logged in to the target device.

## Kerberos Authentication Support in RDP Proxy Service

This content provides information about Kerberos functionality.

**To configure Kerberos support in RDP Proxy service, follow these steps:**

1. Navigate to **Configuration, RDP Proxy**.
2. Select **Add** to add a Kerberos Realm and KDC servers to that realm. The **Add RDP Proxy Kerberos Configuration** window appears.
3. Add the Kerberos Realm Name.
4. Enter the KDC server (IP address/FQDN) with an optional port number.
5. Select **OK**.

**Note:** You can add only one realm. Multiple Kerberos realms are not currently supported.

**Prerequisites:** The target device must be a fully qualified domain name. Defining a device with an IP address does not work for Kerberos authentication. Please ensure that PAM is able to successfully resolve all FQDNs. Also, ensure that PAM is able to ping remote desktop servers and KDC servers using their FQDNs. If using the PAM agent, ensure that the client machine, (the machine on which PAM agent is installed), is able to resolve FQDNs for remote desktop servers.

### Credential Collector for RDP Proxy service:

If no auto-login has been configured for the RDP Proxy service, then you are prompted for the credentials to log into the remote desktop server. A credential collector is displayed. Enter the following information:

- **Username:** Example: **user01**
- **Password:** Example: **mypassword**
- **(Optional) Domain:** Example: **mydomain**. If specified, this value is only used during NTLM authentication. For Kerberos authentication, the domain value is ignored. Kerberos authentication uses the realm as the domain name

**Note:** The realm value is supplied while configuring Kerberos authentication for RDP Proxy. Once you provide all required information, click Login to log into the remote desktop server. Click Cancel to cancel the login.

Once you provide all required information, click **Login** to log into the remote desktop server.

Click **Cancel** to cancel the login.

## VMware vCenter and NSX Integration

You can configure Privileged Access Manager to coordinate with a VMware installation to import virtual machines into Privileged Access Manager and apply the VMware security settings.

The Privileged Access Manager coordination with an NSX installation engages the following objects. See [Configuration tasks](#) for detailed instructions.

### VMware Requirements

Verify that you have installed NSX 6.2 or later and that it is available to Privileged Access Manager on the network.

### Privileged Access Manager Requirements

#### **Restrictions**

When VMware NSX coordination is activated in Privileged Access Manager, the following cluster synchronization features are **not** supported:

- Clustering over a WAN
- Hybrid clusters, using two or more of the three form types for Privileged Access Manager (hardware, AWS AMI instance, and VMware VMs)
- The [Access Restrictor](#) does not operate on A2A transactions.

### **Prerequisites**

- Configuration of VMware objects in Privileged Access Manager:
  - **Device:** a target vCenter
    - a Target Application for this Device
    - a Target Account for this Target Application that is an administrator account
  - **Device:** the affiliated NSX Manager
    - a Target Application for this Device
    - a Target Account for this Target Application that is an administrator account
- Configuration in of parent vCenter (**Config uration, Add VMware vCenter**)
- Configuration and activation of NSX administrator access ( **Configuration, VMware NSX**)

Following configuration and registration, the NSX and Privileged Access Manager effects include:

*In Privileged Access Manager:*

- **Device imports** – vCenter virtual machines are imported (a Device record is created for each VM)
- **Security controls** – Existing NSX Security Tag, Security Group, and Security Policy restrictions are imposed on vCenter devices that are imported into Privileged Access Manager.

*In NSX:*

- **Privileged Access Manager Service** – A new NSX partner service named "Privileged Access Manager Service" is created, with Profile Configurations for these functions:
  - **Session Recording**
  - **Terminate Sessions**
  - **Privileged Access Manager Re-Authentication**
- **Dynamic effects** – As NSX Security Tag, Security Group, and Security Policy definitions are altered over time, the effects are propagated from NSX to Privileged Access Manager.
- **Access restrictor** – Privileged Access Manager dynamically pushes its access policies for mirroring as NSX distributed firewall exceptions. Thus these rules are created as connections open, and are destroyed when those connections close.

### **Coordination with NSX**

When you configure Privileged Access Manager to coordinate with an NSX installation, Privileged Access Manager begins sharing objects that are managed in NSX. Following registration, you can (manually) specify controls on VMs by applying VMware Security Tags to VMs directly. You can use the NSX Service Composer to define Security Groups and impose Security Policies on those groups, which affect imported Privileged Access Manager devices. This process applies two features that are illustrated here:

- Service Composer integration with Privileged Access Manager Service
- Dynamic transfer of NSX Security Groups and Security Tag assignment to Privileged Access Manager

### **Access Restrictor**

When Privileged Access Manager is registered in NSX, and before it connects to a managed VM, it pushes its access policy for that connection into NSX as a distributed firewall *exception*. It instructs NSX to temporarily "poke a hole" through the firewall managing the VM to allow the Privileged Access Manager-authorized connection.

### **Permitted Connections Tracked**

You can impose a highly restrictive but distributed NSX firewall without concern about it interfering with Privileged Access Manager-managed access to targets. NSX auditing is aided in this manner, because now the logging and recording capabilities of Privileged Access Manager are explicitly imposed on any connections making it through the otherwise broadly imposed firewall.

### ***Verifiable in NSX Manager***

In the NSX Manager **Firewall** panel, you see the Access Restrictor rule being applied for the active connection. This rule automatically occupies highest precedence order over other rules and thus is applicable to the connection. When the Privileged Access Manager-managed connection is closed, this exception rule is deactivated and removed.

### **NSX Service Composer Security Controls**

Three pre-defined NSX Service Profile Configuration controls are provided in the product Service that is registered when you configure the product to work with a vCenter and an NSX installation that is associated with that vCenter.

Any of those Profile Configurations can be specified in an NSX Security Policy. That policy is applied to an NSX Security Group of VMs. The members of that Security Group might consist of, for example, those VMs with certain Security Tags or labels, such as "Surveillance\_Target", that can be applied at any time deemed necessary by the administrator.

### ***Dynamic Event Infrastructure***

The following NSX callbacks that are built in to the Privileged Access Manager Service are created in NSX when a Privileged Access Manager registers to an NSX installation. When any of the following Service Profiles have been activated in NSX Security Policy applied to Devices imported from VMware, Privileged Access Manager imposes the described actions to the active Privileged Access Manager connection sessions:

- **Terminate Sessions** – Prevent any future session attempt from consummating.
  - User receives a pop-up message during a current session or session attempt.
  - Terminate Sessions works for all connection types. Event is logged and is captured in session recordings.
- **Session Recording** – Switch session recording on or off.
  - NSX policy overrides Privileged Access Manager Policy setting.
  - Works for RDP, SSH, and Telnet Access Method applets; RDP Applications; all native SSH or Telnet Services; CA PAM Browser (HTTP and HTTPS)
  - Event is logged and is captured in session recordings.
- **Privileged Access Manager Re-Authentication** – One-time (non-recurring) application to force Users to re-authenticate to Privileged Access Manager.
  - User receives an interactive pop-up message to submit credentials.

### ***Provisioning in Following NSX Tagging***

Privileged Access Manager imports the Security Tags and Security Groups of VMs into Device records to manage the connection to these VMs. Basic device characteristics (name, address, OS, VMware directory) populate the Device records. Unassigned, user-defined Security Groups and Security Tags are always imported because you can provision policies before tags are assigned. For example, if the policies to be used are complex.

Changes in the NSX environment are propagated each time a Privileged Access Manager User loads their Access page. Changes to NSX Security objects are dynamically applied in Privileged Access Manager. NSX Manager executes callbacks to the product whenever its Security Groups or Security Tags are updated. The product can make the corresponding adjustments and can propagate any policy effects.

### **NOTE**

Assign the same name to a Security Group and associated Security Tag when the Security Group contains only items with a single Security Tag.

These imported tags can then be assigned to Device Groups to impose the desired controls.

When Security Groups or Security Tags are created in an NSX installation running a Privileged Access Manager Service, or they are newly assigned to NSX devices, these changes propagate to Privileged Access Manager in several ways:

- When a tag (either local, or VMware-imported Security Group or Security Tag) is assigned to a Device Group, the Devices that the tag specifies are identified as members of the Device Group.
- If you apply an unused tag to a Device Group and you use that group in an active Privileged Access Manager policy, and then later assign the tag to a device in NSX, the corresponding Privileged Access Manager Device and corresponding policy is dynamically activated. The policy becomes available on the User Access page.

You can prepare compact Privileged Access Manager policies that are also complex and powerful.

## **Configuration Tasks**

Perform the following tasks to activate coordination of an NSX installation with your Privileged Access Manager.

### ***Preparation***

You must have the following applied:

- VMware vCenter applicable with NSX 6.2.
- Privileged Access Manager licensing applied: **VMware Capability**

### **Register Privileged Access Manager in NSX Manager**

VMware configuration has been expanded to allow use of multiple vCenter deployments, and now (for a single vCenter) allows synchronization of an NSX deployment. The VMware configuration panel set on the **Configuration, 3rd Party** page has been expanded with a new **VMware** page.

### ***Prerequisites***

- Registration with NSX requires that a single vCenter is configured in Privileged Access Manager. Multiple vCenter configurations, although permitted, cannot be used while there is an active NSX registration.

### ***Procedure***

To provision preliminary Devices and Accounts, and configure vCenter and NSX, follow these steps:

1. Prepare VMware target Device records:
  - a. In Privileged Access Manager, navigate to **Devices, Manage Devices**.
  - b. Add a Device record for vCenter with **Address=Your-vCenter-portal-address**
  - c. Add a Device record for NSX with **Address=Your-NSX-Manager-portal-address**
2. Prepare corresponding target accounts to access:
  - a. Navigate to **Credentials, Manage Targets, Applications**:
    - a. **Add** a new target application for vCenter.
    - b. **Add** a new target application for NSX.
  - b. Navigate to **Credentials, Manage Targets, Accounts**:
    - a. **Add** a new target account for the vCenter target application you created.
    - b. **Add** a new target account for the NSX Manager target application you created.
3. Navigate to the **Configuration, 3rd Party, VMware** page.
4. **Add** a previously **Configured VMware vCenter**:
  - a. In the **vCenter Authentication Device** field, select from the drop-down list the vCenter Device you prepared earlier.
  - b. In the **vCenter User** field, select from the drop-down list the vCenter access target account you prepared earlier.
  - c. In the **URL** field, enter the URL address of the vCenter. Include the port and any subdirectory path.
  - d. Select **Device Sync** to attempt to import from this account immediately following an **Add**. Syncs then continue according to the Global VMware vCenter Sync period.
  - e. Click **OK**.

5. On the **VMware NSX** tab:
  - a. In the **NSX Authentication Device** field, select from the drop-down list the NSX Manager Device you prepared earlier.  
In the **NSX User** field, select from the drop-down list the NSX access target account you prepared earlier.
  - b. In the **URL** field, enter the URL address of the NSX installation. Include the port and any subdirectory path.
6. On the **Refresh Interval** tab:
  - a. Select a Refresh Interval from the drop-down list. The interval begins on the next multiple according to the system clock. For example, "5 Minutes" causes a sync to start at the next multiple of 5 minutes, such as 12:25.
  - b. Select **Update**.
  - c. You can force all vCenter Account combinations to import newly active provisions at the next fixed refresh interval.  
On the **Configured VMware vCenter** tab, select **Global VMware Sync**.

### **Confirm Registration**

You can confirm that NSX has created "Xsuite Service" by inspecting the Networking & Security Service Definitions in a vSphere client.

## **Additional Privileged Access Manager Registration Options**

### **Re-register NSX Manager**

When your NSX Manager registration fails, the VMware NSX fields remain, but Status changes from "Not Configured" to "Not Registered".

- After you correct the issue, you can again attempt registration using the staged settings by clicking **Save**.
- Otherwise, you can remove all settings by clicking **Disable**.

### **Unregister NSX Manager**

To unregister Privileged Access Manager in NSX:

1. Take care to back out of all corresponding settings you had applied in Privileged Access Manager and NSX.
2. When that is completed, select **Unregister** in the **VMware NSX** panel.
3. The currently registered Privileged Access Manager Service is removed from NSX, and the NSX Manager is unregistered in Privileged Access Manager.

### **Options for Updates**

- **Access page runtime updates**  
NSX synchronization with Privileged Access Manager is initiated whenever the Access page is loaded. **Note:** This feature increases Access page load time.
- **Background updates**  
Privileged Access Manager updates are initiated after NSX settings are updated, and after each vCenter Refresh Interval.

#### **NOTE**

- [NSX Provisioning Examples](#)

## **NSX Provisioning Examples**

You can configure Privileged Access Manager to coordinate with a VMware installation to import virtual machines into Privileged Access Manager and apply the VMware security settings. We include two examples of NSX provisioning to assist with your VMware integration.

### Example 1: Preparation of an NSX Security Policy for Privileged Access Manager Use

You can impose any of the above three controls on Devices managed by Privileged Access Manager from within NSX features. The following procedure shows how this process works by completing the following steps:

- Creating Security Policies that specify access controls
- Creating Security Groups that dynamically specify a set of devices
- Applying those policies to those groups to activate their controls on their devices. These controls are propagated to Privileged Access Manager, and then imposed when Users access VMware-imported Devices.

Following registration of Privileged Access Manager with NSX, open your vSphere Client or Web Client:

1. From the vSphere home, select the **Networking & Security** item from the left menu.
2. From the new left menu items, select the **Service Composer** item, and then in the Service Composer body select the **Security Policies** tab to display the (currently empty) policies list.
3. Above the item list in the far left, select the Create Security Policy icon to open a policy editing window.
4. Specify a policy that imposes Privileged Access Manager session recording, and call it "Session Recording SP":
  - a. Select the **1 Name and description** tab, and enter in the **Name** field "Session Recording SP".
  - b. In **2 Guest Introspection Services**, select the icon further right to open an editing window. In it:
    - a. For **Service Name**, select "Privileged Access Manager Service"
    - b. For **Service Profile**, Select "Session Recording (Data Collection)"
    - c. Leave the other fields and buttons as is, and select **OK**.
 The editing window now disappears, and you see the new service specification as a line item.
  - c. In **4 Network Introspection Services**, perform the same previous steps for (b), except that here you edit the **Profile** field rather than the **Service Profile**.
  - d. In the lower right corner, select the **Finish** button to activate the Security Policy.

With procedures parallel to the preceding procedures for the other two Service Profiles, you can prepare corresponding policies. The following table lists the three Service Profile options currently made available through Privileged Access Manager Service registration.

#### Privileged Access Manager Service: Service Profiles

Privileged Access Manager Service: Service Profiles	Description
Session Recording (Data Collection, Vulnerability Management)	Toggles the Privileged Access Manager-based session recording policy: Where Privileged Access Manager policy for a connection has recording off, NSX turns it on, and vice versa.
Terminate Sessions (Vulnerability Management, Data Collection)	Terminates current connection sessions and prevents new sessions from being initiated.
Privileged Access Manager Re-Authentication (Data Collection, Vulnerability Management)	Suspends current Privileged Access Manager User login sessions and forces the Users to reauthenticate. Where reauthentication succeeds, the login session resumes and the previous session state is restored. Where re authentication fails, the login session is terminated.

After preparing Security Policies for all three Service Profiles, you will see three Security Policies listed.

## Example 2: Dynamic Application of an NSX Security Policy for Privileged Access Manager Session Recording

With an NSX Security Policy in place to switch Privileged Access Manager session recording, you can prepare an example of that Service Profile in action:

1. From the same location in your vCenter client as you used when preparing Security Policies ([Example 1](#)), select the **Security Groups** tab to open its pane.  
(The list might be empty except for Activity Monitoring Data Collection.)
2. To record all current and future connection sessions to certain devices, create a Security Group named "Capture Sessions SG":
  - a. Select the **1 Name and description** tab, and enter in the **Name** field "Capture Sessions SG".
  - b. In **2 Define dynamic membership**, and in the pane at the right named **Membership criteria 1**:
    - a. In the lower left drop-down list, select "Security Tag" to specify that the VMs with a Security Tag are included in this group.
    - b. In the lower center drop-down list, select "Equals to".
    - c. In the field to the lower right, enter "Capture Sessions ST".
  - c. In the lower right corner, select the **Finish** button to activate the Security Group, as we have provided the definition that we need for this group.
3. Apply the Security Policy that you created earlier to this Security Group:
  - a. Select again the Security Policies tab to open its pane.
  - b. Select the Rank number for the **Session Recording SP** policy so that the line item is selected, then right click and select **Apply Policy** from the pop-up menu.
  - c. Select the **Capture Sessions SG** group and select **OK**.
4. Apply a Security Tag to a VM device. This illustrates how the Security Group picks up the tagged device for imposition of the policy, and the effect of that policy for Privileged Access Manager.
5. Navigate from the vSphere home:
  - a. Select the **vCenter** item from the left menu.
  - b. From the new left menu items, select the **Hosts and Clusters** item.
  - c. In the left panel (with left tab at top selected), open the tree until you find an (existing) VM to which you would like to apply this Security Group. In this example, the device is named "BEE".
6. The VM device ("BEE") has a number of specification panels. Apply the tag that is specified when you created the "Capture Sessions SG" Security Group. That is, "Capture Sessions ST":
7. Select the "BEE" line item. Then in the device specification section to the right, in the **Security Tags** pane:
  - a. Select the **Manage** link in the lower right corner of the pane.
  - b. In the **Assign Security tag** pop-up window, select the icon to create the new "Capture Sessions ST" tag.
  - c. When created, scroll to the location of the new tag, and select it.
  - d. Select **OK** to close the pop-up.  
The "Capture Sessions ST" tag is listed in the **Security Tags** pane. The "Capture Sessions SG" that uses that tag is also specified in the **Security Groups** pane.  
Because that group has the "Capture Sessions SP" Security Policy applied against it, then when a Privileged Access Manager User attempts a connection session to BEE – whether the Privileged Access Manager policy itself specifies session recording – Privileged Access Manager activates recording.
8. Navigate Privileged Access Manager to the **Devices, Manage Devices** page.
  - a. Open the Device record for "BEE".  
**Note:** You can also continue instead with a Privileged Access Manager-based Device Group that includes this Device. In place of a fixed, imported tag, manually apply the imported Security Tag as described in the following steps.

There is an editable "Privileged Access Manager-assigned-tag-3". There are also two tags which are not editable in Privileged Access Manager: "NSX-SG-Capture Sessions SG" and "NSX-TAG-Capture Sessions ST".

These reflect the Security Group and Security Tag that were imported from VMware.

9. Navigate to the **Policies, Manage Policies** page.
  - a. Create (or open) a policy for BEE (and you, the current administrator User).  
Do *not* assign a recording policy.
10. Navigate to the **Access** page, and open a connection session to BEE.
11. Navigate to the **Sessions, Session Recordings** page.  
You see near the top of the line items that a session recording has begun to BEE.  
The VMware Security Policy overruled the (empty) Privileged Access Manager recording policy, dynamically imposing session recording.

## VMware NSX API Proxy Integration

### WARNING

**Warning:** VMware NSX API support is deprecated and will be removed in a subsequent version of PAM.

VMware NSX API Proxy requires licensing from CA Technologies for a specific number of proxy users. The proxy is available for deployment in VMware OVA file format.

### NOTE

If your Privileged Access Manager installation allows use of both VMware NSX API Proxy and AWS API Proxy, these proxies must be on different subnets.

The use case flow is:

1. A user sends a REST API request (intended for NSX Manager) to the new CA Technologies VMware NSX API Proxy. The request uses credentials from Privileged Access Manager, which are valid only for use with this proxy. (They differ from the credentials that are used by NSX Manager).
2. The proxy validates the request, obtains the actual (and persistent) NSX Manager credentials that have been vaulted on Privileged Access Manager. The proxy then uses those credentials to forward the request to NSX Manager.
3. The NSX Manager response is passed directly to the user. Audit and request syslog entries are stored in vCenter Log Insight. If configured, Privileged Access Manager rotates the NSX Manager credential.

A VMware NSX API Proxy User role has the accessAll and manageAll privileges, and a **VmwareNsxApiProxy** role allows use of the proxy.

### Auto-Activation Whitelist

Only NSX API Proxies which are within specified subnets are permitted to receive NSX Manager credentials automatically from Privileged Access Manager. Such subnets are called "whitelisted subnets." Specify these whitelists as follows:

1. Navigate to the **Configuration, 3rd Party, VMware NSX API Proxy** page.
2. In the **NSX API Proxy Auto-Activation Whitelist** tab, select **Add**.  
The **Add NSX Subnet** window appears.
3. Enter a private subnet that contains the NSX API Proxy instances. Use CIDR form (for example, 10.21.1.0/24), and select **OK**.  
You receive a green confirmation message at the top of the page: "NSX API Proxy Auto-Activation Whitelist successfully updated."

# Managing Java on Your Client Workstation

This content describes how to manage Java on your client workstation.

## Clear the Java Cache (Windows)

To help prevent mismatched Java cache contents during or after upgrading a Windows client workstation, clear the Oracle Java cache.

To clear the Java cache, open the Java control panel (**Control Panel, Java**) and remove all "Temporary Files".

## Update the Java Heap Setting

We recommend that you adjust your Java heap so that with 4 GB of total memory, 1024 MB is allocated to it. An example of the adjustment mechanism would be to Assign the Java maximum heap size value in **Runtime Parameters**:

```
-Xmx1024m -Xms1024m
```

### **NOTE**

Do not copy-and-paste the string into a word processor (such as Microsoft Word) before pasting into the Java Control Panel. This action might alter the characters. Instead, if you want to store the string, use a plain-text application such as Notepad.

To confirm that the heap adjustment has taken effect: When your mouse is in focus in the Java console, press: m to display the memory values. If successful, the results are close to the settings.

## Applet JAR File Signing

By default, Privileged Access Manager JARs are signed and are validated against a public Certificate Authority (CA). For many customers, this arrangement is sufficient and no further action is required. However, if your users do not have access to the public Internet, this feature provides an alternative.

If you are considering self-signing, we suggest you discuss this strategy first with Broadcom Support.

## **Certificate Configuration**

You can sign JAR files using certificates that are issued from any CA, including one located in an isolated internal network. Use this procedure to set the signing certificate.

### **To use a certificate from a CA, follow these steps:**

1. Have your organization CA administrator prepare a code-signing certificate.  
You receive the public certificate and private key for signing the JARs. You also receive the public key of the CA that issues this certificate with its CRL.
2. Log in as Privileged Access Manager User "config", or as another account with at least a role of Configuration Manager. For example, you can also use "super".
3. Navigate to **Configuration, Security, Certificates**.
4. On the **Upload** tab, **Browse** to your certificate files and **Upload** them.  
Upload at least the public certificate and private key, and these files must have the same root name. The public and private key files should end with the ".crt" and ".key" extensions respectively; for example, you might have "ExampleCorp1.crt" and "ExampleCorp1.key".
5. On the **Sign Applets** tab, enter the node IP address as the **Domain**. For a cluster, use the primary VIP.
6. Select the **Certificate** with the bundle root name you uploaded, or the Default Applet Certificate.
7. To confirm the certificate integrity, select **Verify**, and note the confirmation message at the top of the page.

8. After the certificate passes verification, select **Sign Applets**. Wait a few moments for the Privileged Access Manager applets to be signed, and confirmed at the top of the page.
9. Clear your Java cache.
10. Log out from Privileged Access Manager, and then log back in.

**To use the Default Applet Certificate, follow these steps:**

1. On the **Sign Applets** tab, enter the appliance IP address as the **Domain**. For a cluster, use the primary VIP.
2. Select Default Applet Certificate as the **Certificate**.
3. To confirm the certificate integrity, select **Verify**, and note the confirmation message at the top of the page.
4. After the certificate passes verification, select **Sign Applets**. Wait a few moments for the Privileged Access Manager applets to be signed and confirmed at the top of the page.  
To ensure that you access the signed JAR files, follow these steps:
5. Clear your Java cache.
6. Log out from Privileged Access Manager, and then log back in.

### **Client Configuration**

To configure a client to trust the certificate that is used to sign the applet JARs, add the certificate to one of the following locations:

#### **Your Java JRE installation**

To add the certificate to your client Java installation, follow these steps:

1. Open the Java Control Panel.
  - In Windows, open `c:\Program Files\Java\jreX.X.X_X\bin\javacpl.exe`.
  - On a Mac, select System Preferences, Java, Java Control Panel.
2. In the Java Control Panel, select the **Security** tab, and the **Manage Certificates** button.
3. Select the **Certificate Type** "Signer CA".
4. On the **User** tab, select the certificate, and select **Import**.
5. Browse to the location of the certificate and select **Open**.
6. Select **Close** and **OK**.

#### **Your browser certificate store**

To add the certificate to Internet Explorer, follow these steps:

1. Select the **Tools** icon or the Tools menu, then select **Internet Options**.
2. Select the **Content** tab, then select the **Certificates** button.
3. In the Certificates windows, select the **Import** button.
4. Select **Next**, then the **Browse** button to locate the certificate file. Select **Open**.
5. Select **Next**, then "Automatically select the certificate store based on the type of certificate."
6. Select **Next**, then inspect the settings summary. If you approve, select **Finish**.  
A status message appears.

## **Juniper Integration**

You can allow use of manual login to access a Privileged Access Manager appliance behind a Juniper Networks SSL VPN, rather than configuring Privileged Access Manager auto-connection access.

### **User experience**

While logged in to Juniper, open the login page through a Juniper bookmark, and manually log in.

## Juniper setup

1. Log in to Juniper.
2. Set up a bookmark to the Privileged Access Manager login page:  
For the **URL** string for that bookmark, append the following tag:

?XSUITE\_VPN\_LOGIN=1

**Example:** `https://xsuite.example.com/?XSUITE_VPN_LOGIN=1`

### NOTE

Remember to add a trailing slash "/" to the Privileged Access Manager address/path.

## User experience (after configuration)

1. Log in to Juniper.
2. Select the Juniper bookmark you created earlier, and open the Privileged Access Manager login page.
3. Log in to Privileged Access Manager.

# Integrate a Java Application or Application Server

The following method has been tested with a WebLogic version 12.2.1 application server.

## Setup

To modify a Java application or application server (such as Weblogic, JBoss, or Tomcat) into a requestor, modify them to use the Privileged Access Manager JARs and native code libraries:

- The JAR files must be in the class path of the requestor. The JAR files are `cspmclient.jar` and `cwjcafips.jar`. They are located in the `$CSPM_CLIENT_HOME/cspmclient/lib` directory.
- If the requestor uses the Privileged Access Manager JDBC proxy, the `cloakwareJdbc.jar` file must be in the class path of the requestor. It is located in the `$CSPM_CLIENT_HOME/cspmclient/tools` directory.
- The library path of the requestor must include `$CSPM_CLIENT_HOME/cspmclient/lib`.

Setting the class path can be done in the standard Java manner or might be application-specific. The latter is a common requirement of application servers. See your application documentation for details.

The library path can be set:

- As part of the requestor Java invocation using the `-Djava.library.path` syntax
- Using the OS-specific environment variable. The possible environment variables are `PATH` for Windows, `LD_LIBRARY_PATH` for Solaris and Linux, and `LIBPATH` for AIX.

## Using the Privileged Access Manager JDBC Proxy Driver

The Privileged Access Manager JDBC driver is a proxy for the original Database Management System (DBMS) JDBC driver. Without A2A, the requestor has a JDBC connection to a DBMS. The requestor is configured with the following information:

- The class of the JDBC driver, which must be in the class path of the requestor
- Information about where it is connecting (the DBMS' hostname, and so on)
- Extra driver parameters, such as the username and password to log in as, the driver buffer sizes, and so on.

To use Privileged Access Manager JDBC driver:

1. Change the driver reference from the original DBMS-specific one to the Privileged Access Manager JDBC driver. The driver class name becomes `com.ca.pam.a2a.client.jdbc.JdbcDriver`.

2. Change the JDBC connection string to add information specifying the Privileged Access Manager JDBC driver name, the target alias that identifies the target account, and the class name of the original DBMS JDBC driver as follows:
3. 1. Prefix the JDBC connection string with `capam`.
2. Suffix the JDBC connection string with `;CSPMDriver=targetDriverClassName;CSPMAlias=alias` where:
  - `targetDriverClassName` is the class name of the original DBMS JDBC driver (such as `oracle.jdbc.driver.OracleDriver` for Oracle, `com.microsoft.sqlserver.jdbc.SQLServerDriver` for Microsoft SQL Server, `com.mysql.jdbc.Driver` for MySQL, `org.postgresql.Driver` for Postgres, or `com.ibm.db2.jcc.DB2Driver` for DB2)
  - `alias` is the target alias that is associated with the target account the requestor uses to log in to the DBMS

CA Technologies also recommends that the username and password fields be cleared out. They are overwritten by the Privileged Access Manager JDBC proxy driver.

The following example shows a modified connection string to an Oracle database:

- **Before:** `jdbc:oracle:thin:@//dbHost:1521/myService`
- **After:** `capam:jdbc:oracle:thin:@//dbHost:1521/myService;CSPMDriver=oracle.jdbc.OracleDriver;CSPMAlias=myAlias`

## Integrate with Your Service Desk Solution

As a system administrator, you can configure Privileged Access Manager to provision privileged account access to your service desk solution.

### Password View and Update

Administrators create password view policies for target service desk accounts. The policy can dictate the interaction between a user password request and the application. When a user asks to view a privileged account password, the service desk application prompts for a service desk ticket number. The application uses the ticket number to validate the user.

The following IT service management products have password update or view capabilities:

- BMC Remedy version 8.1 and 9.1
- CA Service Desk Manager r14.1 and r17.0
- HP Service Manager version 9.32 and 9.41
- ServiceNow Jakarta and Istanbul
- Salesforce Service Cloud Winter 2015 release (supports password viewing, but not updating)

### Auto-Connect to an Application

To log in automatically to the service desk application, configure a password view policy to the privileged user account. This policy can use a service desk ticket number to connect automatically to the application.

### Service Desk Logs

If you have to troubleshoot your service desk integration, you can download CA NIM logs. Use this option only with the aid of Broadcom Support. For more information, see [Configure Diagnostic Logs](#).

### Integration Instructions for Your Service Desk Solutions

To obtain specific integration procedures for your service desk application, select the corresponding entry from the table of contents.

## CA NIM UM and SM Integrations

CA Normalized Integration Management User Management (CA NIM UM) and Service Management (CA NIM SM) let PAM integrate with various third-party service desk solutions. These solutions provide a normalized generic API to create Incidents in service desk products.

The product includes the following CA NIM pre-existing components:

- Device (Target Server) – displayed on the Manage Devices page, cannot be edited.
- Two target applications – one for User Management (CA NIM UM), one for Service Management (CA NIM SM)
- Two accounts – one for each application type. Both accounts are named **nimadmin**.

The only configuration task for CA NIM accounts is to change the default passwords for the two nimadmin accounts. The default password is nimadmin.

### Follow these steps to change the default passwords:

1. Log in to the UI and select **Credentials, Manage Targets, Accounts**.
2. Select the checkbox for one of the nimadmin accounts and select **Update**.
3. Enter a new password in the Password field.
4. Select **OK**.
5. Repeat the procedure for the other nimadmin account.

## Clarity Service Desk Manager Integration

As a system administrator, you can configure Privileged Access Manager to provision privileged account access to Clarity Service Desk Manager (formerly CA Service Desk Manager).

### Prerequisites

Before you configure the settings for Clarity Service Desk Manager, verify that you have an appropriate version. To enable password updates by Privileged Access Manager, ensure that Clarity Service Desk Manager is configured for PIN-based authentication.

### **Supported Versions**

- Clarity Service Desk Manager r14.1 and r17.0
- Clarity Service Desk Manager REST Services are installed and deployed. REST Services are not deployed by default. To deploy them, use the following command:

```
pdm_rest_util -deploy
```

For more information, see your Clarity Service Desk Manager documentation.

### ***PIN-Based Authentication***

Clarity Service Desk Manager contact records do not have a "password" field, but another field is used for the password. A Clarity Service Desk Manager administrator can specify a contact record field such as contact\_num or email\_address to be used for passwords. Therefore, updating a password through Privileged Access Manager updates that same field.

### **To enable PIN-based authentication, follow these steps:**

1. On the Clarity Service Desk Manager system, navigate to Administration, Security and Role Management, Access Types.
2. Select the Access Type for which you are enabling PIN-based authentication.
3. On the Web Authentication tab, select PIN from the Validation Type drop-down list.
4. Select Save.

For more information, see the following topics in the Clarity Service Manager documentation at [techdocs.broadcom.com](http://techdocs.broadcom.com):

- Configuring User Accounts
- Create an Access Type
- User Authentication

### **Device Configuration**

To integrate with Clarity Service Desk Manager, create a target server device.

#### **Follow these steps:**

1. Navigate to **Manage Devices** under the **Devices** menu. Select the **Add** button.
2. Enter the **Name** and **Address**.
3. Enter a description. The description displays on the Devices panel as Description.
4. Select the **Operating System**.
5. Select the **Device Type**.
6. The remaining values are optional, and are described in [Device Setup](#).
7. Select **OK**.

### **Application Configuration**

Next, set up an Application for Clarity Service Desk Manager.

#### **Follow these steps:**

1. Go to **Credentials, Manage Targets, Applications**.
2. Select the **Add** button.  
The Add Target Application window appears.
3. Select the Select magnifying glass icon to select the SDM device you created.
4. The **Host Name** and **Device Name** are populated.
5. Enter "SDM" or similar into the **Application Name** field.
6. Select "SDM" from the **Application Type** drop-down list.  
A details box is added to the Application Details panel. Each ITSM solution has its own detail fields.
7. Select a Password Composition Policy if you have created one.
8. Add Descriptor 1 and 2, optionally.
9. Enter the SOAP Protocol, SOAP Port, REST Protocol, and REST Port.
10. Enter the `DefaultAttachmentRepositoryName`.
11. Enter the PIN Field (such as `contact_num` or `email_address`) that Clarity Service Desk Manager is using as password.
12. Select **OK**.

### **Account Configuration**

Set up the Account using the Device and Application you have already set up.

1. Go to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.  
The Add Target Account window appears.
3. Select the Find Server magnifying glass icon to select the SDM device you created.  
The **Host Name** and **Device Name** are populated.
4. Select the Select magnifying glass icon to select the SDM application you created.  
The SDM Account Details box is added to the Account window, with the Change Process selection.
5. Enter a name into the **Account Name** field.
6. Leave the Password View Policy as Default unless you already have one to use.

7. Enter a password or select the Generate Password icon. Generating a password disables the Show Password check box.  
**Note:** The remaining password-related fields are read-only. The maximum age and expiration fields are determined by the Password Composition Policy, if any. See [Construct Password Composition Policies](#) for more information.
8. Select a Synchronized option. The default is to change only the Password Authority Server. To change the password on the target server also, select "Update both."
9. In the SDM Account Details box, select the Change Process. Select whether the Account can change its own password, or can indicate another account. If the user does not have permission to change passwords, use another account. Selecting "Use the following account to change password" displays a list of existing accounts.
10. You can optionally select an Owner User Name from the list of users on the CA Privileged Account Manager system.
11. Select **OK**.  
 The Message "The account was saved successfully" appears.

### **Password View Policy Configuration**

Each target account is associated with a password view policy, either the default policy or a policy that you create. See [Establish Password View Policies](#) for more information. Using Service Desk Integration in a Password View Policy requires the user to enter a service desk ticket number.

#### **Follow these steps:**

1. Go to **Credentials, Workflow, Password View Policies**.
2. Select the Add button. The Add Password View Policy window appears.
3. On the **Service Desk** tab, select CA Service Desk Manager from the **Service Desk Integration** drop-down list. Specific SDM configuration fields appear.
4. Enter the **SDM Server** name, the **SDM Application** name, and the **Account** name.
5. You can be more specific in your ticket number request: limit the type of ticket, or use a query filter. **Ticket Type** defaults to All. Incident, Problem, and Request are also available. See [Query Filter](#) for details about Query Filters. On the **Basic Info** tab, Reason Required For View and Reason Required For Auto-Connect are checked. These options are required for service desk integration. A warning appears if you try to clear either checkbox.
6. You can use more credential workflows methods, such as dual authorization and re-authentication. See [Establish Password View Policies](#) for more information.
7. Select **OK**.  
 A message appears: "The Password View Policy Has Been Saved Successfully"

### **Query Filter**

Create Queries with the Query Filter field. Use combinations of values that are used to filter which service desk tickets are used for validation.

#### **Field Values**

- **Impact:** entireorganization, multiplegroups, none, oneperson, singlegroup, smallgroup
- **Priority:** highpriority, lowpriority, medium-highpriority, medium-lowpriority, mediumpriority, none
- **Severity:** allhandsescalation, escalated, hdmgrescalation, mgrescal, supervisorsescal
- **Status:** acknowledged, analysiscomplete, approvalinprogress, approved, avoided, awaitingenduserresponse, awaitingvendor, cancelled, closed, closedunresolved, closerequested, fixed, fixinprogress, hold, inprogress, knownerror, open, pendingchange, problem-closed, problem-fixed, problem-open, rejected, researching, resolved, sa-abandon, sa-resolved
- **Urgency:** immediate, quickly, soon, veryquickly, whenpossible

#### **Operators**

```

== (equals)
&& (and)
|| (or)
!= (not equals)

```

### Examples

```

status==acknowledged
status!=closed
status==open
(urgency==immediate&&priority==highpriority)||status==inprogress&&impact==none

```

## HP Service Manager Integration

Complete the following tasks to enable the appliance to work with HP Service Manager:

### Prerequisites

Before you configure the settings for HP Service Manager, ensure that HP Service Manager uses GMT as the time zone. If not, when you use the timestamp to search for users, the search fails. See your HP Service Manager documentation for more information.

To consume Service Manager tables, fields, and display actions, you must grant an operator the SOAP API or RESTful API capability word.

### Follow these steps in the HP Service Manager UI:

1. From the System Navigator, select **System Administration, Ongoing Maintenance, Operators**.
2. Enter or select your search criteria, and then select **Search**.
3. Select an operator from the record list to view the operator record.
4. Select the **Startup** tab.
5. Add `RESTful API` or `SOAP API` in the Execute Capabilities section.

### HP Service Manager Configuration

Configure the operator WSDL file from the HP Service Manager UI.

### Follow these steps:

1. Select **Tailoring, Web Services, Web Service Configuration**.
2. Enter the Name as **Operator**, select search, and select the **Operator** from the **Object Name**.
3. Select the **Fields** tab to enable **ContactName**, select the **contact.name** from the **Field list**, and give the **ContactName** against the **contact.name**, and select **Save**.
4. To delete, go to the **Allowed Actions** tab, select **Delete** from the **Allowed Action list**, and select **Save**.
5. To get **userName** in **Get users by filter** response:
  - a. Enter the Name as **Contacts**, select **Search**, and select the **Contact** from the **Object Name**.
  - b. Select the **Fields** tab, select the **operator.id** from the **Field list** and give the **Name** against the **operator.id**, and select **Save**.

### Add a Device

To integrate with HP Service Manager, create a target server device.

**Follow these steps:**

1. Navigate to **Manage Devices** under the **Devices** menu. Select the **Add** button.
2. Enter the **Name**, **Address**, and optionally, a description.
3. Select the **Operating System**.
4. For the **Device Type**, select all applicable options. To create a target application and account later, you must select **Password Management**.
5. The remaining values are optional, and are described in [Device Setup](#).
6. Select **OK**.

**Define a Password Composition Policy**

If you want to manage HP Service Manager passwords in the appliance, avoid certain special characters. The HP Service Manager web service that we use for integration does not accept these special characters in passwords:  `; ; ? / \ "`

Create a Password Composition Policy to configure the policy to avoid these characters.

**Follow these steps:**

1. Go to **Credentials, Manage Targets, Password Composition Policies**.
2. Select the **Add** button.  
The Add Password Composition Policy window appears.
3. Enter a **Name** and optionally, a **Description**.
4. In the **Must Not Contain** section, select **Characters To Exclude**. In the adjacent text field, enter  `; ; ? / \ "`
5. Ensure that these same characters do not appear in the text fields for **Must Contain** or **First Must Contain**. If characters exist in both "must contain" and "must not contain" conditions, the policy fails when you select **Test** or **OK**.
6. See [Construct Password Composition Policies](#) for more information about the remaining fields.
7. Select **Test** to test the policy. Select **OK** to save the policy.

**Add a Target Application**

Set up an Application for HP Service Manager.

**Follow these steps:**

1. Go to **Credentials, Manage Targets, Applications**.
2. Select the **Add** button.  
The Add Target Application window appears.
3. Select the Select magnifying glass icon to select the HP Service Manager device you created.  
The **Host Name** and **Device Name** are populated.
4. Enter "HP Service Manager" or similar into the **Application Name** field.
5. Select "HP Service Manager" from the **Application Type** drop-down list.  
An HP Service Manager Details box is added to the Application Details panel. Each ITSM solution has its own detail fields.
6. Select a **Password Composition Policy** if you have created one.
7. Add Descriptor 1 and 2, optionally.
8. On the **HP Service Manager** tab, enter the Port or accept the default of 13080.
9. Enter the **HP SM Client URL**. The initial field value suggests the correct format for the URL (`http://hpsm-host-name:port-number/webtier-9.41`).
10. Enter the **Enabled Protocol** or accept the default of `http`.
11. If HP Service Manager uses a proxy, enter the parameters as appropriate.
12. Select **OK** to save the application.

## Add a Target Account

Set up the Account using the Device and Application you have already set up.

### Follow these steps:

1. Go to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.  
The Add Target Account window appears.
3. Select the Find Server magnifying glass icon to select the HP Service Manager device you created.  
The **Host Name** and **Device Name** are populated.
4. Select the Select magnifying glass icon to select the HP Service Manager application you created.  
The HP Service Manager Account Details box is added to the Account window, with the Change Process selection.
5. Enter a name into the **Account Name** field.
6. Leave the **Password View Policy** as Default unless you already have one to use.
7. Enter a password or select the **Generate Password** icon. Generating a password disables the **Show Password** check box.
8. On the **Password** tab, select **Discovery Allowed** if you want to enable Account Discovery. See [Use Account Discovery to Add Target Accounts](#) for more information.
9. The remaining password-related fields are read-only. The maximum age and expiration fields are determined by the Password Composition Policy, if any. See [Construct Password Composition Policies](#) for more information about Password Composition Policies.
10. Select a Synchronized option. The default is to change only the Password Authority Server. To change the password on the target server also, select "Update both."
11. On the HP Service Manager tab, select the **Change Process**. Decide whether the account can change its own password. If not, select another account in the **Use the following account to change password** field. If the user does not have permission to change passwords, use another account.
12. Select **OK** to save the Account.  
The Message "Target account saved" appears.

## Establish a Password View Policy

Each target account is associated with a password view policy, either the default policy or a policy that you create. See [Establish Password View Policies](#) for more information. Using Service Desk Integration in a Password View Policy requires the user to enter a service desk ticket number.

### Follow these steps:

1. Go to **Credentials, Workflow, Password View Policies**.
2. Select the Add button. The Add Password View Policy window appears.
3. On the **Service Desk** tab, select HP Service Manager from the Service Desk Integration drop-down list.  
Specific HP Service Manager configuration fields appear.
4. Enter the **HP Service Manager Server** name, the **HP Service Manager Application** name, and the **Account** name.
5. You can be more specific in your ticket number request by limiting the type of ticket or by using a query filter. **Ticket Type** defaults to All. Incident, Problem, Change, and Request are also available. See [Query Filter](#) for details about Query Filters.
6. On the **Basic Info** tab, Reason Required For View and Reason Required For Auto-Connect are checked. These options are required for service desk integration. A warning appears if you try to clear either checkbox.
7. You can use more credential workflows methods, such as dual authorization and re-authentication. See [Establish Password View Policies](#) for more information.
8. Select **OK**.  
A message appears: "The Password View Policy Has Been Saved Successfully"

## **Specify a Query Filter for Validation**

The Query Filter field enables you to create queries that filter which service desk tickets are used for validation.

### ***Field Values***

- **Impact:** enterprise, multiple users, site/dept, user
- **Status:** accepted, closed, open, pending change, pending customer, pending other, pending vendor, referred, rejected, replaced problem, resolved, work in progress
- **Urgency:** average, critical, high, low

### ***Operators***

== (equals)

&& (and)

|| (or)

!= (not equals)

### ***Examples***

status==accepted

status!=closed

status==open

(urgency==critical&&impact==enterprise)||status==open&&urgency==high

## **BMC Remedy ITSM Integration**

To integrate with BMC Remedy service management platform, complete the prerequisites and the ITSM configuration.

### **Prerequisites**

Before you configure the settings for BMC Remedy ITSM, copy the SDK JAR files from the BMC Remedy System. These files enable communication between the appliance and the BMC Remedy Service Desk application.

### **Follow these steps:**

1. On the BMC Remedy system, go to the following directory:  
 \\bmc\Software\ARSystem\Arserver\api\lib
2. Copy the following SDK JAR files:
  - arapi\*.jar
  - arutil\*.jar
3. Save the copied JAR files to a location accessible to the appliance.
4. In the UI, select **Configuration, 3rd Party, Remedy Service Desk..**
5. On the **Upload File** tab, use the **Choose File** button to browse for the JAR files individually. Use the Upload button to upload each file, one at a time.
 

**Note:** If you are load balancing, you have to upload the JAR files to each server. The files are the same for Windows and Linux.
6. On the **Remedy Service Desk Files** tab, restart the app server by clicking the **Restart Tomcat** button. Wait until the process completes.  
 A message displays: "Tomcat restarted successfully."

## **Configure the Remedy Device**

To integrate with BMC Remedy ITSM, create a target server device.

### **Follow these steps:**

1. In the UI, navigate to **Manage Devices** under the **Devices** menu. Select the **Add** button.
2. Enter the **Name** and **Address** of the Remedy application server. If your Remedy web server is separate from your application server, ensure that this address is for the application server.
3. Enter a description. The description displays on the Devices panel as Description.
4. Select the **Operating System**.
5. Select the **Device Type**.
6. The remaining values are optional, and are described in [Device Setup](#).
7. Select **OK**.

## **Add the Target Application and Connector**

Next, set up a target application and target connector for BMC Remedy.

### **Follow these steps:**

1. Go to **Credentials, Manage Targets, Applications**.
2. Select the **Add** button.  
The Add Target Application window appears.
3. Use the Select magnifying glass icon to select the Remedy device you created.  
The **Host Name** and **Device Name** are populated.
4. Enter "Remedy" or similar into the **Application Name** field.
5. Select Remedy from the **Application Type** drop-down list.  
The **Remedy** tab appears.
6. On the Remedy tab, enter the **Port** or accept the default of 0.
7. Enter the **Remedy Client URL**, which is for the Remedy web server. If your Remedy web server is separate from your application server, ensure that this address is for the web server. The initial field value suggests the correct format for the URL:  
`(href="http://bmc-client-host-nameport-number" scope="external">http://bmc-client-host-name:port-number/arsys )`
8. Select a **Password Composition Policy** if you have created one, or you can leave the default "None."
9. Add Descriptor 1 and 2, optionally.
10. Select **OK**.

## **Specify the Target Account**

Set up the Account using the Device and Application you have already configured.

### **Follow these steps:**

1. Go to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.  
The Add Target Account window appears.
3. Select the Find Server magnifying glass icon to select the Remedy device you created.  
The **Host Name** and **Device Name** are populated.
4. Use the Select magnifying glass icon to select the Remedy application you created.  
The Remedy Account Details box is added to the Account window, with the Change Process selection.
5. Enter a name into the **Account Name** field.
6. Leave the Password View Policy as Default unless you already have one to use.

7. Enter a password or select the Generate Password icon. Generating a password disables the Show Password check box.  
**Note:** The remaining password-related fields are read-only. The maximum age and expiration fields are determined by the Password Composition Policy, if any. See [Password Composition Policies](#) for more information about Password Composition Policies.
8. Select a Synchronized option. The default is to change only the Password Authority Server. To change the password on the target server also, select "Update both."
9. In the Remedy Account Details box, select the Change Process. Decide whether the Account can change its own password, or you can indicate another account. If the user does not have permission to change passwords, use another account. Selecting "Use the following account to change password" displays a list of existing accounts.

#### NOTE

Remedy users with the "AR User Fixed" or "AR User Floating" license type can update their own password. For other users, select "Use other account", and specify a Remedy user with a fixed or floating license.

10. Optionally, select an Owner User Name from the list of users available to the appliance.
11. Select **OK**.

### Set Up a Password View Policy (Optional)

Each target account is associated with a password view policy, either the default policy or a policy that you create. See [Establish Password View Policies](#) for more information. Using Service Desk Integration in a Password View Policy requires the user to enter a service desk ticket number.

#### Follow these steps:

1. Go to **Credentials, Workflow, Password View Policies**.
2. Select the Add button. The **Add Password View Policy** window appears.
3. On the **Service Desk** tab, select Remedy from the Service Desk Integration drop-down list. Specific Remedy configuration fields appear.
4. Enter the **Remedy Server** name, the **Remedy Application** name, and the **Account** name.
5. In the **Ticket Type** field, specify the type of ticket record for the policy. The default is All but the options Incident, Problem, Change, and Request are also available. You can also use a [query filter](#) to narrow the tickets for validation.
6. On the **Basic Info** tab, Reason Required For View and Reason Required For Auto-Connect are checked. These options are required for service desk integration. A warning appears if you try to clear either checkbox.
7. You can use more credential workflows methods, such as dual authorization and re-authentication. See [Password View Policies](#) for more information.
8. Select **OK**.  
 A message appears: "The Password View Policy Has Been Saved Successfully"

### Filter Service Desk Tickets (Optional)

To filter which service desk tickets are used for validation, use the **Query Filter** field. Create queries with combinations of the following fields and operators:

#### Fields and Values

Field Name	Values
impact	high, low, medium, minor
priority	critical, high, low, medium
status	assigned, cancelled, closed, inprogress, new, pending, resolved
urgency	critical, high, low, medium

## Operators

Operator	Meaning
==	equals
&&	and
	or
!	not equals

### Example Query Filters

- `status==active`
- `status!=closed`
- `status==open`
- `(urgency==critical&&priority==high) || status==inprogress&&impact==high`

## ServiceNow Integration

Learn how to configure the ServiceNow target connector to enable PAM to communicate with ServiceNow service management software.

Complete the procedures in this topic to integrate PAM with ServiceNow. Before you begin, contact ServiceNow and confirm that the services are accessible so that PAM can integrate with ServiceNow applications.

### NOTE

The integration with ServiceNow only supports the following ticket types: **Incident**, **Request**, and **Change**.

Complete the following tasks to integrate PAM with ServiceNow:

### Prerequisites

This section describes prerequisites for integrating with a ServiceNow server.

#### ***Required ServiceNow Roles for the Connection API Type***

PAM can connect to ServiceNow using either of its API protocols:

- SOAP web service interface
- REST API

The ServiceNow account that you configure as the target account must be assigned the roles that are required for the chosen API type.

#### **ServiceNow SOAP API Roles:**

- SOAP-related roles: `soap`, `soap_query`, `soap_script`
- Web service admin role: `web_service_admin`
- For Get Incident & Request & Change: `odbc` role
- Roles that are assigned in the ACLs of tables: `incident`, `sys_db_obj`, `sys_user`, `sys_dictionary`, `sys_journal_field` and `task` tables for read permissions. (Contact your ServiceNow admin If you need help with ACL roles).

#### **ServiceNow REST API Roles:**

- personalize\_dictionary
- u\_journal\_entry\_user
- web\_service\_admin>
- catalog\_admin
- itil & itil\_admin

### **Configuration Prerequisites If Accessing ServiceNow Via a Proxy Server**

If you are accessing ServiceNow using a proxy server, configure a device for that server. If the proxy server requires a password, also configure a target application and target account for the proxy server.

#### **Follow these steps:**

1. Navigate to **Manage Devices** under the **Devices** menu. Select the **Add** button.
2. Complete the following fields:
  - Enter the **Name** and **Address** of the proxy server.
  - Enter a description. The description displays on the **Devices** panel as **Description**.
  - Select the **Operating System**.
  - Set the **Password Management** option under **Device Type**.
  - The remaining values are optional, and are described in [Device Setup](#).
3. Do one of the following steps:
  - If the proxy server has no password, select **OK** and proceed to [Configure an Access Device for the ServiceNow Server](#).
  - If the proxy server has a password, select the **Save and Add Target Applications** button and continue this procedure.
4. In the **Add Target Application** window that appears, complete the following fields:
  - Select the proxy device that you created.  
The **Host Name** and **Device Name** are populated.
  - Enter "ServiceNow Proxy" or similar into the **Application Name** field.
  - Select **Generic** in the **Application Type** field.
  - Leave all the other fields in their default state.
5. Select **OK**.
6. To create a target account, go to **Credentials, Manage Targets, Accounts**.
7. Select the **Add** button.  
The **Add Target Account** window appears.
8. Complete the following fields:
  - In the **Host Name** field, enter the host name or IP address of the device you created for the proxy server, or select the magnifying glass icon and select the proxy server from the list in the **Target Servers** dialog that appears.
  - Select the target **Application Name**.
  - Enter the proxy **Account Name**.
  - Leave the **Password View Policy** as Default.
  - Enter the proxy account **Password**.  
The remaining password-related fields are read-only. If you configure a password composition policy, the maximum age and expiration fields are determined by this policy. To configure a password policy, see [Password Composition Policies](#).
9. Select **OK**.

### **Configure an Access Device for the ServiceNow Server**

To integrate with ServiceNow, first create an access device.

**Follow these steps:**

1. Navigate to **Devices, Manage Devices** under the **Devices** menu. Select the **Add** button.
2. Enter the **Name** and **Address**.
3. Enter a description. The description displays on the Devices panel as Description.
4. Select the **Operating System**.
5. Set the **Password Management** option under **Device Type**.
6. The remaining values are optional, and are described in [Device Setup](#).
7. Select **OK**.

**Configure a Target Application for the ServiceNow Server**

Configure a target application for the ServiceNow server.

**Follow these steps:**

1. Go to **Credentials, Manage Targets, Applications**.
2. Select the **Add** button.  
The **Add Target Application** window appears.
3. Complete the following fields:
  - Select the ServiceNow device that you created.  
The **Host Name** and **Device Name** are populated.
  - Enter "ServiceNow" or similar into the **Application Name** field.
  - Select **ServiceNow** in the **Application Type** field. (The **ServiceNow** tab appears.)
4. Select the **ServiceNow** tab and complete the following ServiceNow-specific configuration fields:
  - Enter the ServiceNow **URL**. The initial field value suggests the correct format for the URL (`https://servicenow-host-name/`).
  - Enter the **ServiceNow Client URL**. The initial field value suggests the correct format for the URL (`https://servicenow-host-name/`).
  - If the ServiceNow instance uses a custom endpoint, enter "true" in the **Custom Endpoint** field. If not, leave the default setting of "false."
  - Specify the type of ServiceNow API to use:
    - **SOAP** (the default)
    - **REST**
  - If ServiceNow uses a proxy server, enter the following parameters:
    - **Proxy protocol**: Specify the protocol required to access the ServiceNow proxy server (HTTP or HTTPS).
    - **Proxy server**: Specify the hostname or IP address of the ServiceNow proxy server.
    - **Proxy application**: If the proxy server requires a password, specify the target application that you configured earlier.
    - **Proxy account**: If the proxy server requires a password, specify the target account that you configured earlier.
    - **Proxy port**: Specify the port number to access ServiceNow on the proxy server.
5. Select **OK**.

**Create a Target Account for the ServiceNow Server**

Now that you have a device and target connector, specify the target account.

**Follow these steps:**

1. Navigate to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.  
The **Add Target Account** dialog appears.

3. In the **Host Name** field, enter the host name or IP address of the device you created for the ServiceNow server, or select the magnifying glass icon and select the ServiceNow server from the list in the Target Servers dialog that appears.
4. Select the ServiceNow application in the **Application Name** field.  
The **ServiceNow** tab is added to the Account window, with the Change Process selection.
5. Enter the name of the ServiceNow user account designated for PAM integration in the **Account Name** field.  
**NOTE**  
Verify that the ServiceNow account is assigned the [roles that are required for the chosen API type](#) (SOAP or REST).
6. Leave the **Password View Policy** as Default unless you already have one to use.
7. Enter a **Password** or select the **Generate Credential** icon. Generating a password disables the Show Password check box.  
The remaining password-related fields are read-only. If you configure a password composition policy, the maximum age and expiration fields are determined by this policy. To configure a password policy, see [Password Composition Policies](#).
8. On the **Password** tab, select a **Synchronized** option. The default is to **Update only the Credential Manager Server**. To also change the password on the target server, select **Update both the Credential Manager Server and the target system**.
9. Also on the **Password** tab, optionally select an **Owner User Name** from the list of users on the appliance.
10. On the **ServiceNow** tab, optionally select the **Change Process**. Decide whether the Account can change its own password, or can indicate another account. If the user does not have permission to change passwords, use another account. Selecting "Use the following account to change password" displays a list of existing accounts.
11. Select **OK** to save your changes.

### **Define a ServiceNow Password View Policy**

Each target account is associated with a password view policy, either the default policy or a policy that you create. Using Service Desk Integration in a Password View Policy requires the user to enter a service desk ticket number.

For more information about view password policies and how to use them for credential workflows, see [Password View Policies](#)

#### **Follow these steps:**

1. Go to **Credentials, Workflow, Password View Policies**.
2. Select the **Add** button. The **Add Password View Policy** window appears.
3. Enter a **Name** (for example, "ServiceNow") for the password view policy.
4. On the **Service Desk** tab, select ServiceNow from the Service Desk Integration drop-down list.  
Specific ServiceNow configuration fields appear.
5. Enter the **ServiceNow Server** name, the **ServiceNow Application** name, and the **Account** name.
6. Use the **Ticket Type** drop-down to narrow the ticket number request. The default is **All**, but the options **Incident**, **Problem**, **Change**, and **Request** are individually selectable. You can also use a [query filter](#) to narrow the scope of service desk tickets for user validation.

#### **NOTE**

Although the **Problem** appears in the **Ticket Type** drop-down, the ServiceNow integration does not support it; do not select it or use it in a query filter.

7. On the **Basic Info** tab, Reason Required For View and Reason Required For Auto-Connect are checked. These options are required for Service Desk integration.
8. Select **OK**.

## Assign the New Password View Policy to Target Accounts

Assign the new ServiceNow password view policy to target accounts of users who require a valid ServiceNow

ticket to view their password. To do this, use the search icon (🔍) beside the **Password View Policy** to select your ServiceNow password view policy when [adding or modifying a target account](#).

## Filter Service Desk Tickets (Optional)

To narrow which service desk tickets are used for validation, use the **Query Filter** field. Create queries with combinations of the following fields and operators:

### Fields and Values

Field Name	Values
impact	high, medium, low
priority	critical, high, moderate, low, planning
status	Ticket type: <ul style="list-style-type: none"> <li>Incident: new, active, awaiting problem, awaiting user info, awaiting evidence, resolved, closed</li> <li>Change: pending, open, work in progress, closed complete, closed incomplete, closed skipped</li> <li>Request: pending approval, approved, closed complete, closed incomplete, closed cancelled, closed rejected</li> </ul>
urgency	high, medium, low

### Operators

Operator	Meaning
==	equals
&&	and
	or
!	not equals

### Example Query Filters

- `status==new`
- `status!=closed`
- `status==awaiting problem`
- `status==active|| (status==awaiting problem)`

## Salesforce Service Cloud Integration

### Device Configuration

To integrate with Salesforce Service Cloud, create a target server device.

#### Follow these steps:

1. Navigate to **Manage Devices** under the **Devices** menu. Select the **Add** button.
2. Enter the **Name** and **Address**.
3. Enter a description. The description displays on the Devices panel as Description.

4. Select the **Operating System**.
5. Select the **Device Type**.
6. The remaining values are optional, and are described in [Device Setup](#).
7. Click **OK**.

### **Application Configuration**

Next, set up an Application for Salesforce Service Cloud.

#### **Follow these steps:**

1. Go to **Credentials, Manage Targets, Applications**.
2. Select the **Add** button.  
The Add Target Application window appears.
3. Click the Select magnifying glass icon to select the Salesforce Service Cloud device you created.  
The **Host Name** and **Device Name** are populated.
4. Enter "Salesforce Service Cloud" or similar into the **Application Name** field.
5. Select "Generic" from the **Application Type** drop-down list.
6. Select a Password Composition Policy if you have created one, or leave the default "None."
7. Add Descriptor 1 and 2, optionally.
8. Click **OK**.

### **Account Configuration**

Set up the Account using the Device and Application you have already set up.

#### **Follow these steps:**

1. Go to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.  
The Add Target Account window appears.
3. Click the Find Server magnifying glass icon to select the Salesforce Service Cloud device you created.  
The **Host Name** and **Device Name** are populated.
4. Click the Select magnifying glass icon to select the Salesforce Service Cloud application you created.  
The Salesforce Service Cloud Account Details box is added to the Account window, with the Change Process selection.
5. Enter a name into the **Account Name** field.
6. Leave the Password View Policy as Default unless you already have one to use.
7. Enter a password or click the Generate Password icon. Generating a password disables the Show Password check box.  
**Note:** The remaining password-related fields are read-only. The maximum age and expiration fields are determined by the Password Composition Policy, if any. See [Password Composition Policies](#) for more information about Password Composition Policies.
8. You can optionally select an Owner User Name from the list of users on the CA Privileged Account Manager system.
9. Click **OK**.  
The Message "The account was saved successfully" appears.

### **Password View Policy Configuration**

Each target account is associated with a password view policy, either the default policy or a policy that you create. See [Password View Policies](#) for more information. Using Service Desk Integration in a Password View Policy requires the user to enter a service desk ticket number.

**Follow these steps:**

1. Go to **Credentials, Workflow, Password View Policies**.
2. Select the Add button. The Add Password View Policy window appears.
3. On the **Service Desk** tab, select Salesforce Service Cloud from the Service Desk Integration drop-down list. Specific Salesforce Service Cloud configuration fields appear.
4. Enter the **SFDC Server** name, the **SFDC Application** name, and the **SFDC Account** name.
5. Enter the **SFDC Login Endpoint** URL. The initial field value suggests the correct format for the URL ( `https://login.salesforce.com/services/Soap/u/32.0f` ).
6. Enter the **SFDC Service Cloud Client** URL. The initial field value suggests the correct format for the URL ( `https://sfdc-instance-name` ).
7. Enter the **Date Format** of Salesforce Service Cloud. The default is `yyyy-MM-dd'T'HH:mm:ss.SSS'Z'` .
8. Enter **Case Object**, **Case Comment Object**, and **Attachment Object** according to your Salesforce Service Cloud configuration.
9. See [Query Filter](#) for details about Query Filters.
10. If SFDC uses a proxy, enter the parameters as appropriate on the **SFDC Proxy** tab.
11. On the **Basic Info** tab, Reason Required For View and Reason Required For Auto-Connect are checked. These options are required for service desk integration. A warning appears if you try to clear either checkbox.
12. You can use more credential workflows methods, such as dual authorization. See [Password View Policies](#) for more information.
13. Click **OK**.  
A message appears: "The Password View Policy Has Been Saved Successfully"

**Query Filter**

The Query Filter enables you to create Queries with combinations of values to filter which service desk cases are used for validation.

***Field Values***

- **Status:** new, escalated, on hold, waiting on customer, working, researching, closed
- **Priority:** critical, high, medium, low

***Operators***

`==` (equals)

`&&` (and)

`||` (or)

`!=` (not equals)

***Examples***

```
status==new
```

```
status!=closed
```

```
(status==new&&priority==critical)||status==working&& priority=high
```

## Privileged Access Manager Server Control Login Integration

As a security administrator, you want to audit the actual user of your server, not the shared local privileged user name. Privileged Access Manager Server Control Login Integration allows Privileged Access Manager to integrate the login process and information with Server Control. When activated, it allows the use of the actual user name for auditing in Privileged Access Manager Server Control.

## Configure Server Control Login Settings

Integration of Server Control Login requires configuration of specific Server Control settings and the creation of the following endpoint definitions:

- Device
- Account
- Application
- Policy

### NOTE

To use server names instead of IP addresses, verify that DNS Servers are configured in the Network Configuration section. From the UI main page, select **Configuration, Network, Network Settings**. Verify that in the **DNS Servers** field, a DNS IP address is listed. If none is listed, add your DNS Servers. Select Update to save the changes.

## Enable Legacy Server Control Configuration

Set up ActiveMQ for Server Control on the Server Control. Some information from the Server Control setup is required.

1. Log in to the PAM UI.
2. Select **Configuration, Server Control**.
3. Set the **Enable Legacy Login Integration** option.
4. Enter the target server hostname or IP address in the **ENTM Host Name or IP** field.
5. Enter the **Port** number, or accept the default 61616.
6. Enter the **ActiveMQ Broker Account**. The default is "reportserver."
7. Enter the ActiveMQ Broker Account **Password** and **Confirm** it.
8. Optionally, specify a different **Message time-to-live** value (the default is 60 minutes).
9. Optionally, specify a different **Reply Timeout** (the default is 10 seconds).
10. Optionally, disable TLS (the default is enable).
11. Select **Ping AMQ Console** when complete.
12. Verify that your information is correct and select **Save**.

## Create a Device

Create a Device for the Privileged Access Manager Server Control endpoint.

1. Select **Devices, Manage Devices**.
2. Select **Add** to create a device.
3. Enter the host name in the **Name** field.
4. Enter the IP address in the **Address** field. To verify the IP address, select **Scan**.
5. Specify the target **Operating System**.

### IMPORTANT

Always specify the applicable operating system. Use of the "Other" setting causes access failure when a PAM user attempts to log into the specified device.

6. Set the **Password Management** option.
7. Select the **Access Methods** tab and select the plus sign (+) button to add an Access Method.
8. Select the access type (such as SSH or RDP) from the **Name** drop-down list.  
Specific access method details appear. Add or alter the information as necessary.
9. All other fields on all tabs are optional.
10. Select **OK** to save your changes.

## Create an Application

Create an Application for the Privileged Access Manager Server Control endpoint.

1. Select **Credentials, Manage Targets, Applications**.
2. Select the **Add** button to create an application.
3. Enter the host name in the **Host Name** field or use the magnifying glass icon to the right to select from existing Devices.
4. Enter the **Device Name**. (Selecting an existing device using the magnifying glass icon to the right of the **Host Name** field also populates this field.)
5. Enter the target **Application Name**.
6. Select the **Application Type**.

#### IMPORTANT

Do not select the "Generic" option; doing so can result in access issues.

Certain Application Types display more options when selected. For example, Windows Proxy allows selection of Local or Domain Account. Most fields are optional or show a default value.

7. Select **OK** to save your changes.

#### NOTE

Windows or Windows proxy applications using a local account require that you use the target device's machine name (netbois name) in the **Name** field of the target device.

### Create an Account

Create an Account for the Privileged Access Manager Server Control endpoint.

1. Select **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button to create an account.
3. Enter the host name in the **Host Name** field or use the Select magnifying glass icon to the right to select from existing Devices.
4. Enter the **Device Name**. (Selecting an existing device using the Select magnifying glass icon to the right of the **Host Name** field also populates this field.)
5. Use the magnifying glass icon to the right of the **Application Name** field to select from Applications that have already been created for the Device. Alternatively, use the Add Target Application plus sign (+) icon to add an application directly from this screen.
6. Enter the **Account Name** to use for connecting to the Server Control endpoint.
7. Enter the **Password** for the Account Name that you selected.
8. Other fields are optional. At this point, you may want to enable password management options. For more information, see [Protect Privileged Account Credentials](#).
9. Select **OK** to save your changes.

### Create a Policy

Create an Access Policy for the Server Control endpoint.

1. Select **Policies, Manage Policies**.
2. Select the **Add** button to create a policy.
3. Select the **User** to use for connecting to the Server Control device.
4. Select the Server Control **Device**.
5. On the **Access** tab, select one or more entries from the **Available Access** list and move them to the **Selected Access** list.
6. On the **CA PAM Server Control** tab, set the **Login Integration** option.
7. Other fields are optional.
8. Select **OK** to save your changes.

### Test the Login Integration

To test Privileged Access Manager Server Control Login Integration, connect through the Access link on the Access Management page. Verify the user name substitution.

1. Select **Access**  
A list of Device Names appears with corresponding Access Methods and Target Applications.
2. Select the Access Method link (such as RDP or SSH) for the Server Control Device you are integrating.  
An RDP or SSH session opens to the Device.
3. For Windows RDP, open PowerShell or the Command prompt. For Linux, use the SSH prompt.  
The prompt includes the local Server Control privileged user login, not the Privileged Access Manager user.
4. For Windows, enter "secons -whoami". For Linux, enter "/opt/CA/AccessControl/bin/sewhoami -a".  
Server Control secons utility writes several lines of text.
5. Find the "PUPM User". This should be the Privileged Access Manager user, not the local Server Control privileged user.

## Symantec SiteMinder Integration

As a security administrator, you can integrate Privileged Access Manager with Layer7 SiteMinder (formerly CA Single Sign-On). You can use Layer7 SiteMinder as a second layer of protection for Privileged Access Manager. First you authenticate to Privileged Access Manager, then to Layer7 SiteMinder, which is also auditing access to Privileged Access Manager.

### NOTE

Privileged Access Manager does not support integration with Layer7 SiteMinder for AWS instances in this version.

### Prerequisites

- Layer7 SiteMinder Policy Server requires manual set-up before setting up Privileged Access Manager. Depending on your environment, you configure many of the following objects on the Policy Server:  
Agent, Agent Configuration Object, Host Configuration Object, Directory Object, Authentication Scheme Object, and either an Application, Domain, or Realm Object.
- User Store supported by Layer7 SiteMinder (such as Active Directory)

### Layer7 SiteMinder Policy Server Configuration

Before you set up SiteMinder on Privileged Access Manager, configure these objects in the SiteMinder Administrative UI.

1. Create an Agent.
  - a. On the Infrastructure menu, select Agent, then Agents on its submenu. Select the Create Agent button on the right.  
Select OK to accept the option "Create a new object of type Agent."
  - b. For Name, enter the Fully Qualified Domain Name of the host Privileged Access Manager.
2. Create an Agent Configuration Object.
  - a. On the Agent menu, select Agent Configuration Objects. Select the Create Agent Configuration button.
  - b. Select the option "Create a copy of an object of type Agent Configuration." The `ApacheDefaultSettings` object is selected by default. Select OK.
  - c. Enter a Name for the agent configuration object.

### NOTE

Use the value of the Name field in the Privileged Access Manager SiteMinder configuration.

- d. Of the many Parameters that are displayed, only these parameters change:

- **AgentName:** Enter the Name of the Agent object that is created in Step 1. Select OK.
  - **DefaultAgentName:** Enter the Name of the Agent object that is created in Step 1. Select OK.
  - **HttpsPorts:** Enter the Privileged Access Manager HTTPS port, such as 443.
  - **GetPortFromHeaders:** Enter yes.
  - **LogoffUri:** Enter the Logoff page, such as "/logoff.php".
- e. Select **Submit**.
3. Create or modify an existing Host Configuration Object.
- a. Under the Hosts menu, select Host Configuration Objects.
  - b. Select Create Host Configuration to create one, or edit one by clicking the pencil opposite its Name field. For example, use `DefaultHostSettings`.

#### NOTE

Use the value of the Name field in the Privileged Access Manager SiteMinder configuration.

- c. Ensure that the Host address for the Policy Server field is the IP address of the Policy Server.
  - d. Select Submit.
4. Create a Directory Object.
- a. Under the Directory menu, select User Directories.
  - b. Select the Create User Directory button on the right.
  - c. Complete the following fields, according to your customer environment.
    - In the Name field, enter a name for the user directory.
    - In the Server field, enter the IP address and port.
    - In the Administrator Credentials section, select Require Credentials.
    - In the Username, enter a user DN who has at least read access to the user directory. For example: `CN=test,OU=Administrators,OU=IT,CN=doejo01`
    - Enter the password for this user in the Password and Confirm Password fields.
    - In the LDAP Settings section, set the LDAP Search Root, enter a DN. For example: `OU=Administrators,DC=company,DC=inc`
    - Under LDAP User DN Lookup, for Start, enter "(sAMAccountName=".
    - In the End field, enter ")".
    - Under User Attributes, set the Universal ID field as "sAMAccountName".
    - In the Disabled Flag field, enter "carLicense".
    - In the Password field, enter "unicodePwd".
    - In the Password Data field, enter "audio".
  - d. Select the Submit button.
5. Create an Authentication Scheme Object.
- a. Under the Authentication menu, select Authentication Schemes. Select the Create Authentication Scheme button on the right.
  - b. Select the option "Create a new object of type Authentication Scheme."
  - c. Complete the following fields:
    - In the Name field, enter `HTMLForm`.
    - In Authentication Scheme Type, select HTML Form Template.
    - In the Scheme Setup section, select Use Relative Target.
    - For Target, enter `/siteminderagent/forms/pamlogin.fcc`.
    - Accept the default values for the remaining fields.
  - d. Select submit.
6. Set up an Application, Domain, or Realm Object.

Depending upon how you want to protect your resources, select Application, Domain, or Realm. In this example, we demonstrate setting up an Application Object. We show how to set up protection for Privileged Access Manager. For more information about setting up these objects, see the Layer7 SiteMinder documentation.

- a. Under the Policies menu, select Application, Applications. Select the Create Application button on the right.
- b. Complete the following fields:
  - In the Name field, enter Privileged Access Manager.
  - In the Component Name field, enter Privileged Access Manager for our example.
  - In the Resource Filter field, enter **/cspm/home** for our example.
  - In the Default Resource Protection field, select Protected.
  - In the Authentication Scheme field, select **HTMLForm**.
  - Select Lookup Agent/Agent Group.
  - Select the Agent that you created in Step 1 (the Fully Qualified Domain Name of the host Privileged Access Manager). Select OK.
  - Select the Add/Remove button in the User Directories section.
  - Select the User Directory object that you created in Step 4. Select the arrow to move it to the Selected Members panel. Select OK.
  - Select the Resources tab, and select the Create button.
    - In the Name field, enter Privileged Access Manager for our example.
    - In the Resource field, enter **\***.
    - In the Action field, select Get and Post.
    - Select OK.
  - Select the Roles tab, and select the Create button.
    - Select "Create a new object of type Role." Select OK.
    - In the Name field, enter All Users.
    - For "Role applies to", select All Users.
    - Select OK.
  - Select Submit to create the Application object.
  - In the Applications panel, edit Privileged Access Manager by clicking the pencil icon.
  - Select the Policies tab.
    - Select the box for All Users under the Roles column, in the Privileged Access Manager row.
- c. Select submit.

## **Privileged Access Manager Configuration**

### **NOTE**

For a clustered environment, configure this on each cluster member.

Once the Layer7 SiteMinder Policy Server configuration steps are complete, follow these steps on Privileged Access Manager.

1. On the **Configuration** menu, select **Symantec Modules, SiteMinder**.
2. Add a Policy Server by clicking **+** under Policy Servers.
  - Enter the IP Address and Port. Use either IPv4 or IPv6 address.
3. Enter the **Policy Server Username**.
4. Enter the **Policy Server Password**.
5. Enter the **Host Configuration Object** from the SiteMinder setup, such as **DefaultHostSettings**.
6. Enter the **Agent Configuration Object** from SiteMinder setup.

**Note:** If this setting is incorrect, it causes the resource that is protected by this integration to become inaccessible. See [Use Console in Emergency](#) for more information.

7. Enter the **Trusted Host Name**. This name is used to register the SiteMinder Policy Server with Privileged Access Manager.
8. Select a **FIPS Mode**.  
This setting corresponds to one of the three Federal Information Processing Standard (FIPS) modes in which Layer7 SiteMinder operates:
  - **COMPAT**  
FIPS-compatibility mode uses algorithms existing in previous versions of Layer7 SiteMinder to encrypt sensitive data to maintain compatibility.
  - **MIGRATE**  
FIPS-migration mode enables you to transition from FIPS-compatibility mode to FIPS-only mode.
  - **ONLY**  
FIPS-only mode ensures that the Agent only accepts session keys, Agent Keys, and shared secrets that are encrypted using FIPS-compliant algorithms.
9. The read-only **SSO Enabled** checkbox indicates whether SiteMinder is enabled.
10. Select the **Save** button to save your configuration CA SiteMinder Web Agent and turn on Single Sign-On.
11. For the changes to take effect, select the **Restart Apache** button to restart the web server.
12. To test the SiteMinder feature, log in to Privileged Access Manager. Attempt to access the resource you are protecting. The SSO login screen appears. If the SSO login screen does not appear, the SSO integration has failed.
13. (Optional) **Disable**: If Layer7 SiteMinder integration is "Currently enabled," this button disables it.
14. The standard Layer7 SiteMinder login form has been modified for use with the main Privileged Access Manager frame. Select **Download Form** to download this form (pamlogin\_xx-XX.fcc). Alter it if necessary, and copy it to the desired location. Change the Target field value to the new form name and location.
15. To download the latest log file record of this instance of the Layer7 SiteMinder Web Agent, select **Download Log**. This file might be useful for troubleshooting if problems arise in the configuration of this CA module integration.

## **Troubleshooting**

### ***Use Console in Emergency***

If Privileged Access Manager is inaccessible, and you must disable SSO, use the Utility Console. If you have a VM, use an admin app such as vSphere to access the console. On the Console Main Menu, there is a new menu item for SSO. Select **Disable CA Single Sign-On**.

## **Known Issues**

### ***Agent Configuration Object Internal Server Error***

If an invalid Agent Configuration Object is specified, the web agent does not report an error. The user gets a success message and is prompted to restart. They do and then they cannot get back into Privileged Access Manager. They get this message:

#### **Internal Server Error**

The server encountered an internal error or misconfiguration and was unable to complete your request.

Please contact the server administrator, or support.ca.com and inform them of the time the error occurred,

and anything you might have done that may have caused the error.

More information about this error may be available in the server error log.

Additionally, a 500 Internal Server error was encountered while trying to use an ErrorDocument

to handle the request.

To enter Privileged Access Manager in this situation, disable SSO with the Utility Console. If you have a VM, use an admin such as vSphere to access the console. On the Console Main Menu, there is a new menu item for SSO. Select **Disable CA Single Sign-On**.

### **Client Failure**

When using the Privileged Access Manager Client to connect to your Privileged Access Manager instance, use the FQDN rather than the IP address. The Fully Qualified Domain Name succeeds, but the IP address fails without raising an error.

## **Integrate A2A Applications**

The concept of *request integration* refers to the process of replacing the hard-coded user names and passwords in an application with Credential Manager credential requests. This application is a “requesting application” or “requestor.”

The request integration process involves the following steps:

1. [Set up your Environment for Integration](#)
2. [Request Integration Algorithm](#)
3. Add your requestor to Credential Manager. See [Add A2A Requestors](#).
4. Adding an authorization mapping to Credential Manager. See [Add A2A Authorization Mappings](#).

### **Set Up Your Environment for Integration**

**Follow these steps:**

1. Install the A2A Client. See [Install an A2A Client for Credential Management](#).
2. Do the setup steps that are specific to your integration environment:
  - For a UNIX environment, source the **.cspmclicentrc** file or set up the environment variables that are contained within the file. The **.cspmclicentrc** file is located in: `$CSPM_CLIENT_HOME/cspmclicent/bin`.
  - For Microsoft Visual Studio, you do not need to register the DLL. It was done during A2A client installation.
  - For Eclipse, add the **capamclient.jar** file to the build path. This allows Eclipse to compile your application. See the procedure that is described in [Set Up Eclipse for A2A Integration](#).

### ***Set Up Eclipse for A2A Integration***

Use the following procedure to add the **capamclient.jar** file to the build path.

**Follow these steps:**

1. Open the project **Properties** dialog.
2. Select **Java Build Path**.
3. Select the **Libraries** tab.
4. Select **Add External JARs**.
5. Browse to the `$CSPM_CLIENT_HOME/cspmclicent/lib` folder and select the **capamclient.jar** file.
6. Close the **Properties** dialog.

### **Request Integration Algorithm**

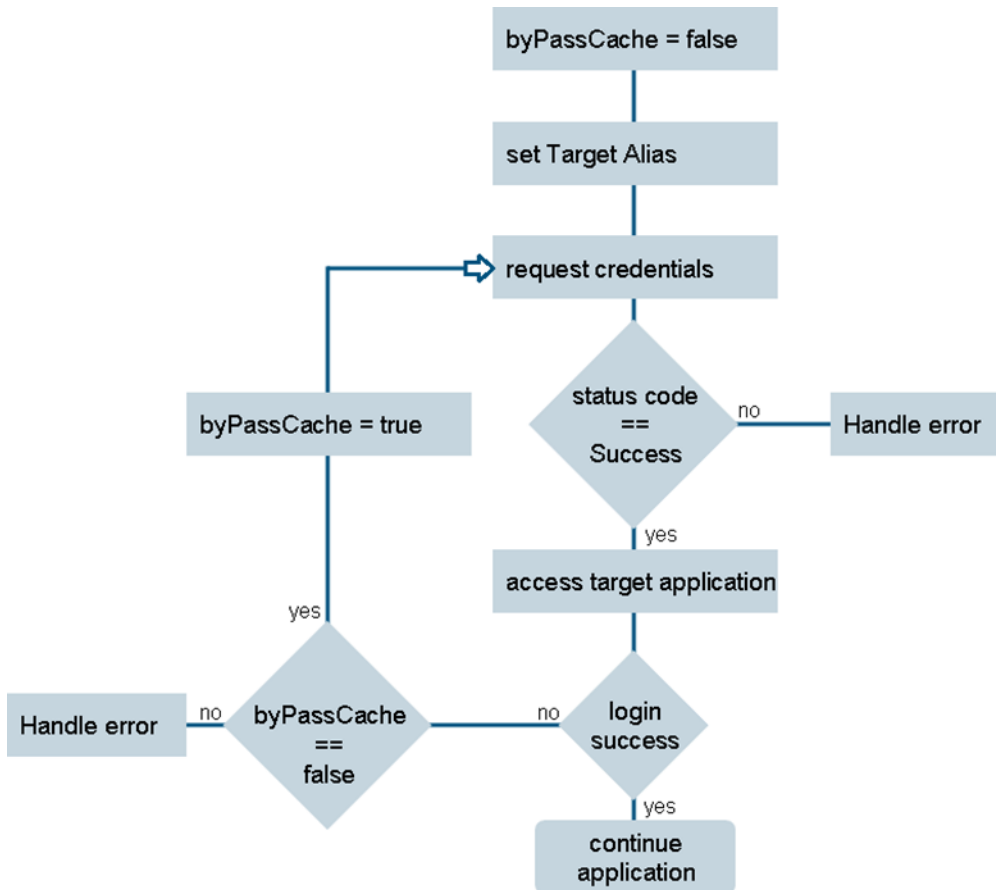

"Request integration" is the process of modifying your existing requestor to use Credential Manager to retrieve credential information instead of using hard-coded user names and passwords.

Integration methods for implementing the credential request are described in [Integrate Applications with the Credential Manager A2A Client](#).

Typically, when you integrate your application or script with the A2A client, you use the cached version of the credential. However, the supplied credentials only give the requestor access to the data if the A2A client cache is up-to-date. The following algorithm uses the cached credentials for the first login attempt. If the login fails the A2A client cache is

overridden, credentials are retrieved directly from the appliance, and a second login is attempted. By using the cached credentials for the first login attempt, you reduce the load on the appliance and improve performance. However, if the cached credential has gone stale, it can potentially incur a failed login attempt.

A failed login attempt can trigger an auditable security incident and possibly an account lockout condition if the number of failed login attempts exceeds the maximum that the policy allows.

## Integrate with SailPoint

- **SailPoint STI (Simple Table Integration)**  
STI is an extensive SailPoint-specific integration, with configuration required on both sides, resulting in automatic synchronization and workflow. This option requires an integration license option. See the following [STI Setup](#) section.
- **SCIM (System for Cross-domain Identity Management)**  
SCIM is an application-level REST protocol for managing user identity data between domains. The PAM REST API includes a SCIM section, including several undocumented SailPoint-specific extensions. For information about enabling the REST API, see [Connect with SCIM API](#). For information about the SCIM standard, see <http://www.simplecloud.info/>. For information about the SailPoint side of the integration, see the [SailPoint](#) documentation. The STI configuration is not necessary when using SCIM.

### Clustering

When Privileged Access Manager is clustered, users should connect to the cluster Primary Site VIP rather than an individual server. The VIP address provides availability in case the server that was originally configured for SailPoint is unavailable.

## STI Setup

Privileged Access Manager populates SailPoint integration tables with Privileged Access Manager Users (with current Role and User Group assignments), Roles, and User Groups. Privileged Access Manager Roles and User Groups are imported by SailPoint to be defined as Entitlements. Privileged Access Manager Users are imported and made into IdentityIQ Users in SailPoint. Whenever changes occur within Privileged Access Manager, these tables are updated on a configurable interval.

### Configuration

For the SailPoint configuration options to appear, the SailPoint integration option must be licensed. SailPoint STI uses port 3306 to communicate with PAM.

To configure SailPoint integration in Privileged Access Manager, follow these steps:

1. Go to **Configuration, 3rd Party, SailPoint**.
2. Enter the **Database User**, and **Database Password**. The password is used in SailPoint configuration, which follows.
3. Set the **Update Interval**, in seconds. This value determines how often Privileged Access Manager checks for incoming SailPoint requests, exports relevant data to SailPoint.
4. For **SailPoint Whitelist**, enter at least one SailPoint server address. These addresses are the only connections to allow for SailPoint integration. Valid entries are IP address, hostname, and FQDN values.
5. Select **Save** to save your settings.
6. Select **Install** to set up the SailPoint integration Tables. The installation is only done once. This button is enabled if SailPoint is licensed, and disabled again once the installation is complete.
7. Select **Download** to acquire a zip file of the Privileged Access Manager SailPoint application. Use this file during the configuration of the SailPoint side of the integration. Unzip this file and save CAPamConfiguration.xml in a location accessible by your SailPoint application.
8. The **Import** button is optional. You can manually direct Privileged Access Manager to read the provisioning queue. Import is also automatically done according to the Update Interval setting.
9. The **Export** button is optional. You can manually direct Privileged Access Manager to populate the SailPoint tables. Export is also automatically done according to the Update Interval setting.

### SailPoint Configuration

Before you configure the integration in SailPoint IdentityIQ, ensure that these prerequisites are met:

- Install the LCM (Lifecycle Manager) module for SailPoint
- Install the STI (Simple Table Integration) integration for SailPoint

To configure the integration in SailPoint, follow these steps:

1. In SailPoint IdentityIQ, select the configuration gear icon and select **Global Settings**. The Global Settings page appears.
2. Select the **Import from File** option in the lower right.
3. Select **Choose File** under **Import Objects**. Select CAPamConfiguration.xml, which you downloaded during the Privileged Access Manager configuration.
4. Select **Import**.
5. Under **Applications, Application Definitions**, select the **CAPam** application. The **Edit Application CAPam** page appears.
6. Select the Configuration tab.
7. Under **Settings**, enter the correct **Connection Password**, which was not provided in the configuration XML file. This password is the password that you entered in step 2 of [Privileged Access Manager Configuration](#).
8. Scroll down to **Object Type: usergroup**. Under **Settings**, enter the correct **Connection Password**.
9. Scroll down to **Object Type: role**. Under **Settings**, enter the correct **Connection Password**.
10. Scroll down to **Object Type: group**. Under **Settings**, enter the correct **Connection Password**.

11. Scroll to the bottom of the page and select **Test Connection**.  
"Test successful" appears. If not, edit the passwords.
12. Select **Save** to save your changes.

For your specific SailPoint IdentityIQ configuration, you can change the default provisioning policies that are provided by Privileged Access Manager. Inspect these settings to determine if you must change them.

1. Under **Configuration**, select **Provisioning Policies**.
2. Under **Object Type: account**, for the **Create** Type, select **User**.  
The **Attributes** for User appear.
3. Select an Attribute, such as **lastName**. See [Operations and Attributes](#) for a list of the supported operations and attributes.  
The **Edit Options** appear on the right.
4. Select **Value Settings**. The value for **lastName** can be a static Value, be Dependent, be determined by a Script, or be determined by a Rule.
5. If you want to save you changes, select **Save**.
6. On the **Edit Application CAPam, Password Policy** page, configure a default password policy that follows the default password policy set for Privileged Access Manager users.

### ***Operations and Attributes***

The following operations and attributes are supported for SailPoint integration. The listed attributes must be associated with a rule or value in a Provisioning Policy in the SailPoint **CAPam** application for attributes to sync. The **CAPam** application is configured with some default values, but clients might need to adjust these settings.

#### **Create a User**

To create a user with the "local " **authType**, all the listed attributes are required. To create a user with the "cac " **authType**, none of the listed attributes are required.

- **firstName**: User first name
- **lastName**: User last name
- **email**: User email address
- **password**: User password
- **authType**: supported values are **local** or **cac** (for smartcard users)
- **IIQDisabled**: **true** if user is disabled, or **false** if user is enabled
- **Roles** and **User Groups** are assigned as **Entitlements**.

#### **Modify a User**

To modify a user, all attributes are optional.

- **firstName**: User first name
- **lastName**: User last name
- **email**: User email address
- **password**: User password
- **authType**: supported values are **local** or **cac** (for smartcard users)
- **IIQDisabled**: **true** if user is disabled, or **false** if user is enabled
- **Roles** and **User Groups** are assigned or removed as **Entitlements**.

#### **Delete a User**

- No attributes

### ***Aggregation Tasks***

As part of the **CAPam** application setup in SailPoint, aggregation tasks are defined to SailPoint to collect the user and entitlement data from Privileged Access Manager. These tasks should be scheduled to execute regularly to keep this data in sync with Privileged Access Manager.

Follow these steps:

1. From the main SailPoint menu, select **Setup, Tasks**.  
Two Tasks are set up by the initial configuration:
  - **CAPam Account Aggregation** regularly reads the Privileged Access Manager User table to keep in sync with Users and their entitlements
  - **CAPam Group Aggregation** reads Privileged Access Manager User Roles and Groups and creates SailPoint Entitlements from them.
2. To schedule a task, right-click and select **Schedule** from the drop-down list to display the New Schedule dialog.
3. Select the **Scheduled Tasks** tab to edit schedules. You can select the **Run Now** box on the **Edit Schedule** tab to run the Task immediately.
4. To see a list of SailPoint entitlements, go to the main menu, **Applications, Entitlement Catalog**.

### **Workflow Example**

Once everything is configured in Privileged Access Manager and SailPoint IdentityIQ, the following example of the integration workflow is valid. This example shows a SailPoint user making a provisioning request for a Privileged Access Manager user.

1. In SailPoint, go to **Home**, and select **Manage User Access**.  
An IdentityIQ user list appears under the **Select Users** tab.
2. Select a User and select the **Manage Access** tab.
3. Select **Filters** on the right.  
The **Filter Access** panel appears.
4. From the **Entitlement Application** drop-down list, select **CAPam**, and **Apply**.  
The Roles and User Groups that are imported from Privileged Access Manager appear as Entitlements.
5. Select a User Group or Role as an Entitlement. Select the **Review** tab at the top of the page.
6. If the listed **Add Access** Entitlements are correct, select **Submit** at the bottom of the page.  
The Home page appears with a Success message at the top of the page.
7. SailPoint send this data to Privileged Access Manager as a provisioning request.
8. In Privileged Access Manager, go to **Users, Manage Users**, and find the new (or updated) User.  
The User should have the matching information, including Roles and Groups, as applicable.
9. The User should be able to log in to Privileged Access Manager with the appropriate entitlements.
10. An Aggregation Task runs in SailPoint, reading the information in the Privileged Access Manager integration tables,  
This Task closes the loop on the operation.

### **Activity Log**

The **Activity Log** displays information about every action pertaining to the SailPoint integration. Create, delete, and update actions, their source, time, and results are listed. To view the Activity Log, follow these steps:

1. Go to **Configuration, 3rd Party, SailPoint**.
2. Select the **Activity Log** tab.
3. The log table is sortable by clicking column headings. You can filter data using the controls above the headings.  
The **Info** column provides error messages, if applicable.

# Programming

The content in this section describes how to use the following APIs to create applications that interact with Privileged Access Manager:

- [External API](#) – A REST API that allows custom applications to configure and provision Privileged Access Manager.
- [Credential Manager CLI](#) – A command-line interface (CLI) that allows you to enter Credential Manager commands, or scripts of commands, from a command line.
- [Credential Manager Java API](#) – A Java API that provides access to Credential Manager capabilities from a Java program.

## PAM External REST API

The Privileged Access Manager External REST API provides programmatic control over most operations involving provisioning and granting access. These operations include managing users, devices, and policies.

External REST API access is over an HTTPS connection. Data is sent and received in the form of a JSON response. For more information about JSON, see <http://www.json.org/>.

This topic describes the following information:

### Deploying and Using the External REST API

Before programmers can use the External REST API, an administrator has to deploy and enable the API. After the API is enabled, programmers can implement API calls into their own programs.

Go to the appropriate procedures for your role in your organization:

- [Deploy the External REST API \(Administrators\)](#)
- [Use the External REST API \(Programmers\)](#)

### Use the API Explorer to View Dynamic External REST API Reference Information

Administrators and authorized users can explore the External REST API using the *API Explorer* that you access in the PAM UI by navigating to **Settings, API Doc**. The API Explorer allows you to view all API resources that are available for external use and the methods that are associated with them.

#### **NOTE**

The API Explorer is not available until the External REST API has been deployed.

### URIs for the External REST API

Each REST URI for the External REST API has *one* of the following formats:

- **CSPM URI:** `/cspm/ext/rest/resource_name/`  
Complete URL: `https://capam_hostname or ip_address/cspm/ext/rest/resource_name`
- **PHP URI:** `/api.php/v1/resource_name.json`  
`resource_name` represents an object or entity that you are managing through HTTP requests.

These URIs are only part of the REST URLs. To see the complete URLs, which include parameters and other values, see the **API Doc** in the UI.

**Example:** REST call to the `/cspm/ext/rest` endpoint. This call lists the global settings configuration properties:

```
GET https://111.12.32.1/cspm/ext/rest/configProperties
```

**Example:** REST call to the `/api.php/` endpoint. This call retrieves the user with an ID of 55.

```
GET https://111.12.32.1/api.php/v1/users.json/55
```

## Deploy the External REST API (Administrators)

Learn how to deploy the External REST API to provide programmatic control over most PAM functions.

As an administrator, use the procedures in this topic to enable the External REST API and configure who can use it.

### Enable the External REST API

External REST API capability is licensed by default. You cannot remove this capability. However, it is disabled by default.

Enable the External REST API to allow external calls to the appliance and to allow access to the online API Explorer documentation.

#### **Follow these steps:**

1. In the PAM UI, navigate to **Configuration, Security, Access**.
2. Next to the **External REST API** option, select **Enabled**.
3. Select **Save**.  
A confirmation message displays at the top of the page. Also, a message is written to the session logs.
4. Log out from the UI then log back in for all changes to take effect.

The External REST API methods are now available to calls from the battery the development of user applications and the **Try it out!** button of each method in the API Explorer documentation (**Settings, API Doc** in the UI):

### Grant External REST API Access to Users

To access the External REST API, a user requires a unique identifier that is called an *API key* that you assign and configure in its [account definition](#). The API key provides a password for authentication and role assignments that determine its privileges.

When the External API is invoked to execute a particular method, the API challenges for credentials using Basic authentication, requiring the assigned API key name and password in response. The API key is secured using HTTPS. When permissions are checked for the invoked method, the privileges that are associated with that particular API key are used.

To assign an API key to a user, follow *one* of these methods:

- [Add API Keys Using the UI](#)
- [Import API keys from a CSV file](#)

#### **Add API Keys Using the UI**

Add API keys in the PAM UI.

#### **Follow these steps:**

1. Log in to the UI and navigate to **Users, Manage Users**.
2. Open the user record of the user that you want that you want to authorize to make API method calls.
3. Select the **API Keys** tab.

4. Complete the following steps for each API key that you want to add:

- a. Select the **Add** icon () in the blue **API Keys** row at the top. A new entry opens, as shown in the following

example:

- b. Select the **Please Specify an API Key name** field and overwrite the text with a name for the API key. The name cannot contain whitespace. PAM appends a unique number. Consider the following information:
- A check symbol () in a checkbox across from the key name indicates that the key is active. To deactivate the key, select the box.
  - By default, the roles for the API key are the same roles that are assigned to the user account, including roles that are inherited from user groups of which the user is a member. Therefore, if you do not change the API Key role assignments (see Step C), the user can use the API to perform every function that they can do in the PAM UI.
  - To see roles inherited from user groups, select the **View inherited roles** icon (). The inherited roles are displayed in a dialog box.
- c. (Optionally) Do one or more of the following operations to modify existing roles:
- Select the **Add** icon () on the **Roles** line to add a role that is a subset of an existing role that is assigned to the user.  
For example, if the user is a Global Administrator, you can add any role that has privileges that the Global Administrator has. Similarly, if the user is a Delegated Administrator, only the roles that contain privileges that the Delegated Administrator has are available to add. If you select a role that requires permissions the user does not have, the API returns a warning that indicates that the API key has permissions that the user does not. If you receive this warning, remove the role.
- NOTE**  
You can assign roles to an API key that relies on privileges that are inherited from the groups of which the user is a member. However, if the user is removed from the group, the API key stops working.
- To remove an existing role, select the **Delete** icon () to the right of the role entry.
  - To remove roles that are inherited from a user group or groups, select the **Select User Group** icon () and deselect those groups in the dialog that opens.
- d. When you are finished modifying API keys, select **OK**.

### Import API Keys from a CSV File

You can prepare API keys in a comma-separated values (CSV) file and then import the file into the appliance database. If you do not have your own file, you can download a sample file. You can also import a CSV file exported from an existing PAM environment.

#### NOTE

Starting in PAM 4.1.6, the CSV definition for API keys includes a new `groupNames` attribute that allows you to specify from which user groups (of which the user is a member) an API key inherits roles.

In releases before 4.1.6, API keys inherited all roles from user groups of which the user was a member. When you import a CSV file that is exported from a release before 4.1.6, PAM reproduces the existing behavior by configuring all defined API keys to inherit from all user groups associated with the user.

#### Follow these steps:

1. Navigate to **Users, Manage Users**.
2. Select the **Import/Export** button.
3. To use the sample file as the starting point for preparing API key definitions, select **Download Sample File**, download the file (`UsersImportSample.csv`) and continue to Step 4.  
To import an existing CSV file, skip to Step 6.
4. Open the `UsersImportSample.csv` file, which contains a sample definition for a single API key:  
`"name=SampleApKey/;isActive=t/;description=Sample Api Key/;groupNames=DevMgrs|UserMgrs/;roles="`
5. Add values in the **API Keys** column, as required. Each entry must be represented by a concatenation of fields, as shown in the following excerpt. Bolded text highlights the parameters.

```
name=apikey1_name/;isActive=[t|
f]/;description=apiKey1_description/;groupNames=user_group1|user_group2/;roles=rolename=role_name1 roleUserGroups=[
f]/;description=apikey2_description/;groupNames=role_inheritance_groups/;roles=rolename=role_name1/;roleUserGroups=
rolename=role_name2
```

The delimiters for the API key entries are:

"	If multiple keys are assigned to one user, insert a double-quote character before and after the full string.
/;	Insert a forward slash and colon between each pair of fields for a key.
	Insert a pipe between user group names.
, rolename	If there are multiple roles for one key, insert a space followed by a comma between each pair of roles.
#&	Insert hash and ampersand between each pair of keys.

The following example shows two API key entries for a user:

```
name=apikey123/;isActive=t/;description=APIkey 123 description=Pre-poluated
API key/;groupNames=user_group1|user_group2/;roles=roleName=Service
Manager/;roleUserGroups=roleDeviceGroups=, roleName=Password Manager roleUserGroups=All
roleDeviceGroups=All#&name=apikey876/;isActive=t/; description=APIkey 876/; groupNames=Group1|
Group2/;roles=roleName=Service Manager roleUserGroups= roleDeviceGroups=, roleName=Password Manager
roleUserGroups= roleDeviceGroups="
```

6. Do the following steps to import a newly created or existing CSV file:
  - a. Select **Users, Manage Users, Import/Export**.
  - b. Select **Choose File** and browse to the CSV file.
  - c. Select **Import Users (User Groups)**.

#### View API Key Accounts and Policies

After you save a user record with newly added API keys, the appliance automatically creates the following objects:

- A target account. The name of the target account takes the format *API Key-UserID*. You can view the target accounts by navigating to **Credential Manager, Manage Targets, Accounts**. The following graphic shows an example:

<input type="checkbox"/>	Account Name	Application Nan	Application Type	Host Name	Device Name	Account Type	Owner User Na	Verified	Action
<input type="checkbox"/>	Test-API-3	ApiKey	Xsuite API Key	apikey.xceedium.com	apikey.xcee...	A2A			

**WARNING**

The Application Type **1.6Xsuite API Key** application type is only for use with the External REST API. Do not create any additional target applications of Application Type="Xsuite API Key".

- A policy for the user and the External REST API virtual device. The device has the default name [apikey.xceedium.com](http://apikey.xceedium.com). From the policy, you can view the password for the API key. A user can view the API Key name and password from the Access page in the UI. See [Obtain API keys](#).

**Deactivate or Delete an API Key**

To make an API key unavailable to its associated user, deactivate or delete the key. Navigate to **Users, Manage Users** then select the **API Keys** tab. Complete either of the following tasks:

**Deactivate:** To deactivate an API key for later use, clear the checkbox across from the API key name.

**Remove:** To remove an API key, select the **x** across from the API Key name.

**Disable the Test Button for API Methods (Optional)**

In the API Explorer, a button labeled **Try it out!** at the bottom of each API method description allows users to test API calls. The button is highlighted in the following example.

## roles

GET /api.php/v1/roles.json

### Implementation Notes

Retrieves the access roles defined in the system.

### Parameters

Parameter	Value	Description
fields	<input type="text" value="roleId,roleName,roleDescription,userFilter,deviceFilt"/>	The list of fields to return for each retrieved role data. Specify * to return all fields.
roleName	<input type="text"/>	Filter the returned roles by their names.

### Response Messages

HTTP Status Code	Reason	Response Model
200		

Try it out!

You can test an API after applying variable settings, and it returns output to the documentation interface. This test mechanism accesses actual data and can change data in the live Privileged Access Manager database.

If you do not want users to have this ability, you can hide the **Try it out!** Button (for all users).

#### To hide the button:

1. From the UI, go to the **Global Settings, Basic Settings**
2. Clear the **External REST API Buttons** checkbox. (**Enable** is checked by default.)

After you enable the API, permit users access to the API by assigning API keys.

## Use the External REST API (Programmers)

You can review and test the External REST API methods before using these methods with a production application.

Complete the following tasks to use the External REST API with your applications:

## Obtain an API Key

To perform any API operation, you must authenticate with the External REST API. The External REST API authenticates users with HTTP Basic authentication. When you are challenged for credentials, provide an API key and password that a PAM Administrator has assigned to you.

### NOTE

If an administrator deactivates your user account, the appliance deactivates the API key.

After your Administrator assigns you an API key, obtain your API key credentials so you can test API methods. Retrieve the credentials from one of two places:

- [Access page](#)
- [Target account](#)

### Follow these steps:

1. In the UI, navigate to the **Access** page.
2. For the `apikey.xceedium.com` device, select the pull-down menu from the icon under the **Target Applications** column. Select the key name, `Test-API-3` in this example screen, to display the account name and password.

Device Name	Address	Operati	Access Methods	Web Portal	RDP Applications
apikey.xceedium.com	apikey.xceedium.com	Other			

3. Note these values somewhere then select **Close**.

When you test an API method for the first time, you are prompted to enter credentials. Specify the API account name and password. You can now test the API methods in the API Explorer.

From a target account, follow these steps:

1. In the UI, navigate to the **Credentials, Manage Targets, Accounts**. The list of accounts displays.
2. For the API account, select the View icon under the **Action** column to view the account name and the password.

<input type="checkbox"/>	Account Name	Application Name	Application Type	Host Name	Device Name	Account Name
<input type="checkbox"/>	Test-API-3	ApiKey	Xsuite API Key	apikey.xceedium.com	apikey.xcee...	A2A

The **Show Password** screen displays.

3. Note these values somewhere then select **Close**.

When you test an API method for the first time, you are prompted to enter credentials. Specify the API account name and password. You can now test the API methods in the API Explorer.

### NOTE

The appliance appends a number to the API key name that matches the User ID. The number ensures that the key name is unique for each user. For example, if the API key name is `Test-API` and the User ID is `3`, the appliance appends `-3` to the name. The result is `Test-API-3`.

## Reset the Active API Key

To change which API keys are available to you, follow the action for the interface to the UI.

- Web browser: Clear the browser cache and execute a new API call.
- CA PAM Client: Log out and log back in. Execute a new API call.

When you execute the next API call, you are prompted for API key credentials.

### View API Methods in the API Explorer

You can view each External REST API method using the API Explorer. Each method is presented with a description and its syntax. You can also test an API method with varying parameters. API method test calls are executed against the Privileged Access Manager database. Messages and responses are returned only for the fields that are shown in the Explorer.

#### Follow these steps:

1. Select **Settings, API Doc**.
2. The **API Explorer** opens and lists all the API resources available. To the right of each resource, you can filter the display using the options:
  - **Show/Hide** – Toggles the display for that resource.
  - **List Operations** – Displays a list of the API methods in that category.
  - **Expand Operations** – Displays parameter details for all API methods in that category.

You can also select any resource to see the methods. The following sample shows the **/devices** resource with the **get /api.php/v1/devices.json/{id}** expanded. Open or close the methods by selecting the method name itself.

GET
/api.php/v1/devices.json/{id}
Retrieve the device with the specified id.

#### Implementation Notes

Retrieve the device with the specified id. GET {id}

#### Parameters

Parameter	Value	Description	Parameter Type	Data Type
id	(required)	The id of the device.	path	undefined
fields	deviceId,deviceName,domainName,description,os,t	The list of fields to return for the retrieved device. Specify * to return all fields.	query	string

#### Response Messages

HTTP Status Code	Reason	Response Model	Headers
200			

Try it out!

The display shows the following sections:

- Implementation Notes – Describes the API function.
- Parameters – Describes each input parameter. Populate required fields to test a response.
- Response Messages - Describes the HTTP response.

### Test API Requests

After you enter parameters for a method, select the **Try it out!** button at the bottom of the page to test the method call. Use any parameter inputs from the fields in the API Explorer. Most API methods accept standard parameters and API-specific parameters. The parameters can affect how a request is handled and how a response is formatted.

A response displays with the following information:

- Curl - Shows the URL request using cURL format.
- Request URL – Displays the URL submitted to for API method call processing.
- Response Body – Displays the JSON structure returned.
- Response Code – Displays the HTTP status codes returned.
- Response Headers – Displays the response fields of the HTTP transaction.

The full set of parameters and their descriptions is in the **API Doc** interface. All parameters are optional except where noted. To exclude an optional parameter, leave it out from the request or include it with an empty value.

#### TIP

If you have a user role with the necessary permissions, you can hide the **Try it out!** button so that no operations can be performed on active settings. See [Disable the test button](#).

#### *Example: Test attributes for a Single User*

##### Follow these steps:

1. Under the **users** resource, select the method **get api.php/v1/users.json{id}**. This method retrieves information about a specific user.
2. Populate the **id** field with the account name for the API key, such as Test-API-3. If you do not know the account name, see [Obtain API Keys](#).
3. Make any needed edits to the requested attributes list in the **fields** field.
4. Select **Try it out!**  
If this method is the first one you are trying in this session, the API prompts you for the API Key credentials.
5. Enter your credentials.
6. If your credentials are correct and the parameters are valid, you receive a successful response. If the request fails for some reason, you receive error feedback.

#### Use the External REST API in a Clustered Environment

In a clustered environment, use the primary VIP for bulk operations.

Load balancers can use health.php to determine the node status. If you are using external load balancers in a clustered environment, set the External REST API URLs to use the load balancers URLs. See [Configure Load Balancers to Determine the Availability of Cluster Nodes](#) for details.

#### External API Example Implementation

The following code excerpt shows a PHP example in curl using External API methods. The example provisions a user, a device, and the auto-connection policy between the two. You can work with CA Technologies Professional Services to prepare client software that can access Privileged Access Manager with API requests.

```
<?php
class APIConstants{
    const DEVICE_ENDPOINT_V1 = "/api.php/v1/devices.json";
    const DEVICE_GROUP_ENDPOINT_V1 = "/api.php/v1/devicegroups.json";
    const GET = "GET";
    const POLICIES_ENDPOINT_V1 = "/api.php/v1/policies.json";
    const ROLE_GLOBAL_ADMINISTRATOR = 1;
    const ROLE_STANDARD_USER = 2;
    const ROLE_OPERATIONAL_ADMINISTRATOR = 14;
```

---

```

const POST = "POST";
const PUT = "PUT";
const TWO_DAYS = 172800;
const USER_ENDPOINT_V1 = "/api.php/v1/users.json";
const USER_GROUP_ENDPOINT_V1 = "/api.php/v1/userGroups.json";
}
/**
 *
 * This function will make a single request to the API.
 * @param string $apiKey - api key name and password delimited by colon
 * @param string $url - the URL to reach the desired endpoint of the API.
 * For a get may include parameters
 * @param string $postData - JSON encoded set of parameters
 * @param string $httpOperation - GET, POST, PUT, or DELETE
 * @return string -1 for failure, otherwise results of request
 */
function makeAPIRequest($apiKey, $url, $postData = null, $httpOperation) {
    global $debug;
    $httpOperation = strtoupper($httpOperation);
    if(!in_array($httpOperation,array("GET","POST","PUT","DELETE"))){
        return -1;
    }

    /*
        In real code the url could be validated. This is left out as a distraction
        to the point of the cookbook.
    */

    if(!empty($postData) && is_null(json_decode($postData))){
        error_log("Invalid post data " . print_r($postData,true) .
            "\n Post data must be in JSON format.");
        return -1;
    }

    // apiKey must have at least one colon, and not in the first position
    if(strpos($apiKey,":") == 0){
        error_log("Incorrectly formatted api key. Key must consist of api key name, a
colon, and the api password");
    }

```

```

        return -1;
    }

    $ch = curl_init();
    curl_setopt($ch, CURLOPT_URL, $url);
    curl_setopt($ch, CURLOPT_SSL_VERIFYPEER, FALSE);
    curl_setopt($ch, CURLOPT_SSL_VERIFYHOST, FALSE);
    curl_setopt($ch, CURLOPT_RETURNTRANSFER, 1);
    curl_setopt($ch, CURLOPT_CONNECTTIMEOUT, 5);
    curl_setopt($ch, CURLOPT_TIMEOUT, 30);
    curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_ANY);
    curl_setopt($ch, CURLOPT_USERPWD, $apiKey);
    switch($httpOperation){
        case "GET":
            break;
        case "PUT":
            curl_setopt($ch, CURLOPT_CUSTOMREQUEST, "PUT");
            // absence of break is intentional
        case "POST":
            curl_setopt($ch, CURLOPT_POST, true);
            curl_setopt($ch, CURLOPT_POSTFIELDS, $postData);
            curl_setopt($ch, CURLOPT_HTTPHEADER,
                array('Content-Type: application/json', 'Content-Length: ' .
strlen($postData)));
            break;
        case "DELETE":
            curl_setopt($ch, CURLOPT_CUSTOMREQUEST, "DELETE");
    }
    /*
    * These are useful debug statements
    */
    if($debug){
        echo "XXX: URL = " . $url . PHP_EOL;
        echo "YYY: parameters = " . print_r($postData, true) . PHP_EOL;
        echo "ZZZ: httpOperation = " . $httpOperation . PHP_EOL;
    }
    $data = curl_exec($ch);
    if($debug){
        echo "AAA: return = " . print_r($data, true) . PHP_EOL;
    }

    $error = curl_error($ch);
    if(!empty($error)){
        error_log("CURL request to $url returned error: $error");
    }

```

```

        $data = -1;
    }

    curl_close($ch);
    return trim($data);
}

/* assume following parameters
 * argv[1] = URL component e.g, http://10.1.10.24/ port may be included
 * argv[2] = user name for REST API
 * argv[3] = password for REST API
 * argv[4] = first name of user to be provisioned
 * argv[5] = last name of user
 * argv[6] = email address of user
 * argv[7] = device name
 * argv[8] = domain name
 * argv[9] = operating system
 * argv[10] = user name for target account
 * argv[11] = debug 0 for false any positive for true
 */
if(count($argv) != 12){
    // in real code more information would be supplied
    echo " Missing required parameters. ". PHP_EOL;
    return ;
}
$baseUrl = $argv[1];

    $results = makeAPIRequest($apiKey, $url, json_encode($parameter),
    APIConstants::POST);
    if(is_numeric($results)){
        return $results;
    }
}
/**
 * Replace the existing access method for the policy with one that has a target account
 * for auto-connection.
 * @param array $policy
 * @param integer $accessMethodId
 * @param integer $targetAccountId
 */
function addSSOToPolicy($policy, $accessMethodId, $targetAccountId) {

```

```

global $apiKey, $baseUrl;
/**
 * Multiple target accounts could be assigned, so the accountIds are an array
 */
$putData = array(array("accessMethodId"=>
$accessMethodId,"accountIds"=>array($targetAccountId)));
$url = "https://" . $baseUrl . APIConstants::POLICIES_ENDPOINT_V1 . "/" .
$policy['id'] .
"/accessMethods";
$results = makeAPIRequest($apiKey, $url,json_encode($putData),APIConstants::PUT);
}

```

## Connect with SCIM API

SCIM is an application-level REST protocol for managing user identity data between domains. The PAM REST API includes a SCIM section. For information about enabling the PAM REST API, see [PAM External REST API](#). For information about the SCIM standard, see <http://www.simplecloud.info/>.

For information about SailPoint and SCIM, see [Integrate with SailPoint](#). SailPoint SCIM access with REST API uses port 443.

### SCIM Methods

A selection of supported SCIM 2.0 API methods follows. For complete documentation of the API, use the [API Doc](#).

#### Get

ResourceTypes	Retrieve all SCIM Resource Types or for a specific ID.
Schemas	Retrieve all SCIM schema or for a specific ID.
Groups	Retrieve all SCIM User Groups or for a specific ID.
Users	Retrieve all SCIM Users or for a specific ID.
ServiceProviderConfig	Retrieve SCIM Service Provider Configuration.

#### Post

Groups	Add new SCIM User Group.
Groups/.search	Search for a SCIM User Group.
Users	Add new SCIM User.
Users/.search	Search for a SCIM User.

#### Put

Groups/{id}	Update a SCIM User Group.
Users/{id}	Update a SCIM User.

**Delete**

Groups/{id}	Delete a SCIM User Group.
Users/{id}	Delete a SCIM User.

**LDAP External REST API Extensions**

The PAM LDAP update task is performed automatically by the LDAP periodic update daemon. The following REST API extensions give users more explicit control over the process of synchronizing PAM with the corresponding LDAP information.

The API Doc section of the PAM UI, which includes the REST API test facility, contains an abbreviated version of this content.

**NOTE**

See [Use the External API \(Programmers\)](#) for information about enabling the external API and accessing the API Doc.

LDAP import/update processing for all domains is performed on the first member of the primary site. Only one import/update process can be running at any time. To avoid API call conflicts and failures, follow this best practice procedure:

1. In a clustered environment, use the LDAP REST APIs:
  - Ensure that the cluster is on. Otherwise, HTTP Error 503 (Service Unavailable) is returned.
  - The APIs can be invoked only against the Primary site.
  - Secondary sites return this message in the JSON response: "PAM-CM-1786: This API operation is not available from a secondary site."
2. Disable the periodic update process for all configured LDAP domains using one of the following methods:
  - Make changes in the UI: Go to **Configuration, 3rd Party, LDAP, LDAP Domains, Update Domain, Disable Periodic Update**.
  - Invoke the REST API: [PUT /cspm/ext/rest/ldap/refresh](#)
3. Ensure that no other LDAP update job is running. This rule applies to both automatic and API-triggered updates. You can either:
  - Wait for the current job to complete
  - Use the REST APIs to test ([GET /cspm/ext/rest/ldap/refresh](#)) and abort ([DELETE /cspm/ext/rest/ldap/abort](#)) the current job.
4. Invoke REST APIs to perform the required updates of LDAP-imported groups. You can use either:
  - [PUT /cspm/ext/rest/ldap/userGroup](#)
  - [PUT /cspm/ext/rest/ldap/deviceGroup](#)
5. Enable the periodic update process for LDAP domains that you do not want to control using the REST API.
  - Once disabled, the update process is not automatically enabled by the system.
  - The periodic LDAP domain update is controlled separately for each configured LDAP domain.

**NOTE**

**NOTE:** The searches that are performed by this REST API are not case-sensitive.

**GET /cspm/ext/rest/ldap/refresh**

Test whether an LDAP job is running.

**URL:**

`https://<PAM>/cspm/ext/rest/ldap/refresh`

**Parameters:**

- none -

**Response:**

JSON, job is running:

```
{
  "data": null,
  "success": true,
  "total": 1,
  "message": null
}
```

JSON, job is not running:

```
{
  "data": null,
  "success": true,
  "total": 0,
  "message": "PAM-CM-1784: LDAP Refresh is not in progress."
}
```

**POST /cspm/ext/rest/ldap/userGroup**

Create a new PAM LDAP user group and import its users.

**URL:**

`https://<PAM>/cspm/ext/rest/ldap/userGroup`

**Parameters:**

Parameter	Required	Values	Description
groupDn	Yes		Domain name or common name for the LDAP group or Organizational Unit to be imported to PAM.
domainDn	Yes		Base domain name for the domain to which this group belongs.
authenticationType	Yes	ldap / ldap+rsa / ldap+radius / pki / radius / rsa / saml / tacacs+	Authentication method used by users in the group. The method must be configured on the PAM appliance.

**Response**

JSON:

```
{
  "data": null,
```

```

"success": true,
"total": 1,
"message": null
}

```

**success\_value:**

"true" if the LDAP creation process completed successfully,

"false" otherwise (For example, if interrupted, errors, warnings, and so on).

**Note:** Warnings and Errors in each data response set have to be inspected to make the determination of the overall operation outcome.

**total:**

Contains the number of groups processed (successfully or not).

**message:**

May contain error text indicating the source of failure.

**POST /cspm/ext/rest/ldap/deviceGroup**

Create a new PAM LDAP device group and import its devices.

**URL**

<https://<PAM>/cspm/ext/rest/ldap/deviceGroup>

This API has the same structure as [/cspm/ext/rest/ldap/userGroup](#) but applies to LDAP-imported devices.

**Parameters**

Parameter	Required	Values	Description
groupDn	Yes		Domain name or common name for the LDAP group or Organizational Unit to be imported to PAM.
domainDn	Yes		Base domain name for the domain to which this group belongs.

**Response**

JSON:

```

{
  "data": null,
  "success": true,
  "total": 1,
  "message": null
}

```

**success\_value:**

"true" if the LDAP refresh process completed successfully,

"false" otherwise (For example, if interrupted, errors, warnings, and so on).

**Note:** Warnings and Errors in each data response set have to be inspected to make the determination of the overall operation outcome.

***total:***

Contains the number of groups processed (successfully or not).

***message:***

May contain error text indicating the source of failure.

**PUT /cspm/ext/rest/ldap/refresh**

Enable or disable the LDAP periodic refresh process.

This API mimics the function of the UI switch in the **Configuration, LDAP, LDAP Domains, Update Domain, Disable Periodic Update** section of the UI.

**URL:**

`https://<PAM>/cspm/ext/rest/ldap/refresh?baseDN=dnValue&disableRefresh=drValue`

**Parameters:**

[required] `domainName` :

`dnValue` specifies the LDAP DN of the domain for which to set the switch controlling the refresh.

The refresh of each LDAP domain that is configured in Privileged Access Manager is controlled separately.

[required] `disableRefresh` :

`drValue` is either "true" to disable the periodic refresh process, or "false" to enable it.

**Response:**

JSON, success:

```
{
  "data": null,
  "success": true,
  "total": 1,
  "message": null
}
```

JSON, failure:

```
{
  "data": null,
  "success": true,
  "total": 0,
  "message": "PAM-CM-1785: No change. LDAP Disable Refresh switch is already in the requested state."
}
```

**PUT /cspm/ext/rest/ldap/userGroup**

Refresh the indicated LDAP-imported user groups.

**URL:**

<https://<PAM>/cspm/ext/rest/ldap/userGroup?groupNamesList=gnList>  
<https://<PAM>/cspm/ext/rest/ldap/userGroup?groupNamesLike=gnLike>  
<https://<PAM>/cspm/ext/rest/ldap/userGroup?groupNamesList=gnList&dryRun=drValue>  
<https://<PAM>/cspm/ext/rest/ldap/userGroup?domainName=dnValue&groupNamesList=gnList>  
<https://<PAM>/cspm/ext/rest/ldap/userGroup?domainName=dnValue&groupNamesLike=gnLike>

**Parameters:**

Parameter	Required	Values	Description
domainName	No		dnValue specifies the LDAP DN of the domain from which to select the user groups to refresh. If not provided, all available LDAP domains are checked for the specified groups to refresh.
groupNamesList	Yes*		A semicolon-separated list of DNs of user groups to refresh. For example: OU=ITC_OU2, DC=qapam, DC=local
groupNamesLike	Yes*		A SQL LIKE expression to use while selecting the DNs of the user groups to process. For example: %OU=Info %OU=Contract%
dryRun	No	true/false	If "true", the API prepares and verifies the user group names that are specified by other parameters, but it does not submit them to the Appliance for processing. This parameter can be used with any combination of the other parameters.

\*Either groupNamesList or groupNamesLike parameter is required.

**Response**

JSON:

```

{
  "data": [
    {
      "numberOfNewMembers": 0,
      "numberOfUpdatedMembers": 0,
      "groupDN": "group 1 name",
      "numberOfProcessedMembers": 2,
      "warnings": [],
      "connectionFailure": false,
    }
  ]
}
```

```

    "numberOfFailedAddMembers": 0,
    "numberOfFailedUpdateMembers": 0,
    "numberOfDeletedMembers": 0,
    "numberOfFailedDeleteMembers": 0,
    "errors": []
  },
  ...
],
"success": success_value,
"total": number-or-groups-processed,
"message": null
}

```

**data:**

Contains the array result sets, one set for each processed group.

Each set comprises properties describing the result of group update.

**NOTE**

If `connectionFailure` is "true", data set may not contain the usual complement of properties.

**success\_value:**

"true" if the LDAP refresh process completed successfully,

"false" otherwise (For example, if interrupted, errors, warnings, and so on).

**Note:** Warnings and Errors in each data response set have to be inspected to make the determination of the overall operation outcome.

**total:**

Contains the number of groups processed (successfully or not).

**message:**

May contain error text indicating the source of failure.

**PUT /cspm/ext/rest/ldap/deviceGroup**

Refresh the indicated LDAP-imported device groups.

**URL**

`https://<PAM>/cspm/ext/rest/ldap/deviceGroup?groupNamesList=gnList`

`https://<PAM>/cspm/ext/rest/ldap/deviceGroup?groupNamesLike=gnLike`

`https://<PAM>/cspm/ext/rest/ldap/deviceGroup?groupNamesList=gnList&dryRun=drValue`

`https://<PAM>/cspm/ext/rest/ldap/deviceGroup?domainName=dnValue&groupNamesList=gnList`

`https://<PAM>/cspm/ext/rest/ldap/deviceGroup?domainName=dnValue&groupNamesLike=gnLike`

This API has the same structure as `/cspm/ext/rest/ldap/userGroup` but applies to LDAP-imported devices.

## Parameters

Parameter	Required	Values	Description
domainName	No		dnValue specifies the LDAP DN of the domain from which to select the device groups to refresh. If not provided, all available LDAP domains are checked for the specified groups to refresh.
groupNamesList	Yes*		A semicolon-separated list of DNs of device groups to refresh. For example: OU=ITC_OU2, DC=qapam, DC=local
groupNamesLike	Yes*		A SQL LIKE expression to use while selecting the DNs of the device groups to process. For example: %OU=Info %OU=Contract%
dryRun	No	true/false	If "true", the API prepares and verifies the device group names that are specified by other parameters, but it does not submit them to the appliance for processing. This parameter can be used with any combination of the other parameters.

\*Either groupNamesList or groupNamesLike parameter is required.

## Response

JSON:

```
{
  "data": [
    {
      "numberOfNewMembers": 0,
      "numberOfUpdatedMembers": 0,
      "groupDN": "group 1 name",
      "numberOfProcessedMembers": 2,
      "warnings": [],
      "connectionFailure": false,
      "numberOfFailedAddMembers": 0,
      "numberOfFailedUpdateMembers": 0,
      "numberOfDeletedMembers": 0,
      "numberOfFailedDeleteMembers": 0,
      "errors": []
    },
    ...
  ]
}
```

```

],
"success": success_value,
"total": number-or-groups-processed,
"message": null
}

```

**data:**

Contains the array result sets, one set for each processed group.

Each set comprises properties describing the result of group update.

**NOTE**

If `connectionFailure` is "true", data set may not contain the usual complement of properties.

**success\_value:**

"true" if the LDAP refresh process completed successfully,

"false" otherwise (For example, if interrupted, errors, warnings, and so on).

**Note:** Warnings and Errors in each data response set have to be inspected to make the determination of the overall operation outcome.

**total:**

Contains the number of groups processed (successfully or not).

**message:**

May contain error text indicating the source of failure.

**DELETE /cspm/ext/rest/ldap/abort**

Abort the current LDAP group refresh.

Invoking this API aborts current LDAP refresh process, either periodic or triggered by the API.

**URL:**

```
https://<PAM>/cspm/ext/rest/ldap/abort
```

**Parameters:**

- none -

**Response:**

JSON, job canceled:

```

{
  "data": null,
  "success": true,
  "total": 0,
  "message": null
}

```

JSON, job not canceled:

```

{
  "data": null,

```

```

"success": false,
"total": 0,
"message": "PAM-CM-1784: LDAP Refresh is not in progress."
}

```

## Credential Manager CLI and Credential Manager Java API

Credential Manager has two programming interfaces that you can use for password management functions:

- **Command-line interface (CLI):** The Credential Manager CLI enables programmatic access to the password management functions of the Credential Manager. The CLI also provides access to a limited set of maintenance operations. You can issue a command, or a script of commands, from a Windows or UNIX/Linux command line. The [Credential Manager CLI Commands](#) describe all the available commands.
- **Java API:** The Java API gives access to Credential Manager capabilities from a Java program. The Java API provides you with a mechanism to integrate Credential Manager with your Java programs. The Java API is supported on the UNIX/LINUX and Windows platforms. The cliTool.jar file also contains the Javadocs that describe each available Java API command.

For each interface, the commands available to a user depend on the roles and groups that are assigned to the user in the PAM UI.

Install the CLI and the Java API on any client system, then connect this remote system to the Privileged Access Manager appliance across an HTTPS network connection. From the client system, issue CLI or Java API commands to administer the Credential Manager information programmatically.

### NOTE

The client must be able to establish a secure (HTTPS) connection to the appliance.

This section provides information about the Java API and the CLI.

**Use the table of contents to access the topics in this section.**

## Install and Set Up the Remote CLI and Java API

To use the remote CLI or the Java API, install and configure the software on a client system in your environment. The client system is remote to the PAM appliance, and it is the system that you plan to use to manage Credential Manager.

Complete the following procedures on the client system connecting to Privileged Access Manager.

### NOTE

Complete these instructions whether you plan to use the Remote CLI, the Java API, or both.

### Download and Deploy the Remote CLI Software

Follow this procedure to download and deploy the appropriate version of the Remote CLI software, which is packaged as a zip file, to your client system. The release version of the Remote CLI software should be the latest available version corresponding to the PAM release running on your appliance.

### **Follow these steps on the client system:**

1. Download the Windows Proxy software from the Broadcom Support site. For information on how to download the software, see [Download PAM Installation Media](#).
2. Create a directory on the local system and extract the contents of the zip file into it.  
The following files are extracted:

- **cliTool.jar**
  - **capam\_command.bat** (for CLI access from a Windows system)
  - **capam\_command** (for CLI access from a UNIX/Linux system)
3. (Optionally) For convenience, add the installation directory to your `PATH`.
  4. Do one of the following steps:
    - For UNIX/Linux systems, identify the installation directory by entering `export CAPAM_DIR =installation_directory`.
    - For Windows systems, add an Environment Variable named `CAPAM_CLI` with the value of the path to the installation directory. For example: `C:\CA\CAPAM\CLI_32`
  5. If it is not already installed, install the Java Runtime Environment (JRE) Version 8u-latest. Obtain the JRE from <https://adoptopenjdk.net>. If you are creating a Java application that uses the Java API, you also need the Java Version 8 SDK.

### **Enable the Credential Manager CLI**

**Follow these steps to enable the remote CLI:**

1. Connect to the PAM appliance using a browser or the CA PAM Client.
2. Navigate to **Configuration, Security, Access**
3. On the Access page, select the **Enabled** radio button that is associated with the **Credential Management CLI** entry.
4. Select **Save**.
5. Navigate to **Settings, Credential Manager**.
6. Verify that the **Enable External CLI** option is enabled. If not, enable it and restart the appliance.

### **Obtain a Certificate**

CLI and Java API commands must be executed over an HTTPS connection between your client system and the PAM appliance. To secure the connection, obtain a certificate that the client trusts.

Complete the following steps to obtain a certificate:

1. [Gather Information for the certificate](#)
2. [Generate a certificate or use an existing certificate](#)
3. [Apply the certificate](#)
4. [Create a keystore](#)

#### **NOTE**

To complete the steps for getting a certificate, connect to the appliance using a browser or the CA PAM Client.

### ***Gather Information for the Certificate***

Gather the following information for each PAM appliance before generating a certificate:

- IP address or the internal VIP for appliances in a cluster
- Fully qualified domain name (FQDN)
- FQDN short name: If the fully qualified domain name is `jdoe@ca.com`, the short name is `jdoe`.

### ***Generate a Certificate or Use an Existing Certificate***

Use a certificate from a Certificate Authority or use a self-signed certificate to secure the network connection. If the PAM appliance already has a certificate available, skip to [Generate a keystore](#).

#### **WARNING**

Do not use the default certificate, `gkcert.crt`, or a certificate that has no Alternate Subject Names.

**Follow these steps to obtain a certificate:**

1. From your client system, log in to the PAM UI from a web browser or using the CA PAM Client.
2. Select **Configuration, Security, Certificates, Create**.

The following screen shows the Certificates page:

**Certificates**

Create Upload Download Set CRL Options Sign Applets

Type ☒ Self-Signed Certificate ☐ CSR

Key Size: \* 2048 ▼

Common Name: \*

Country: \*

State:

City:

Organization: \*

Org. Unit:

Days: \* 365 ▲▼

Alternate Subject Names:

Filename: default

CREATE

3. Select the one of the appropriate options:
  - **Self-signed Certificate**
  - **CSR** to request a certificate from a Certificate Authority
4. Complete the fields in the form. Add the appliance information that you gathered to the **Alternate Subject Names** box. Add one name or IP address per line.
5. After the form is complete, select **Create**.  
If you completed a CSR, download the CSR and then send the request to a Certificate Authority. The Certificate Authority signs and returns a certificate, which you must upload to the appliance. Use the **Upload** tab on the Certificates page.
6. Set and accept the certificate:
  - a. Select the **Set** tab.
  - b. Pick the certificate in the **Filename** field.
  - c. Select **Verify Certificate**. A confirmation message displays at the top of the page.
  - d. Select **Accept Certificate**.

**WARNING**

Accepting the certificate forces the appliance to reboot.

7. After the reboot, apply the certificate.

## Apply the Certificate

If you are using a PAM-generated certificate, download it to your client system. If you are using a Certificate Authority-obtained certificate, upload it from your client system to the PAM appliance.

Complete *one* of the procedures for your certificate:

### If you obtained a certificate from the PAM appliance:

1. Select the **Download** tab.
2. In the **Filename** field, select the certificate from the pull-down list.  
A password for the certificate is not required.
3. Select **Download**.
4. When prompted, save the certificate to the directory where you installed the cliTool.jar file.

### If you obtained a certificate from a Certificate Authority:

1. Select the **Upload** tab.
2. For the Type option, select **Certificate**
3. In the **Filename** field, browse for the certificate on your client system.
4. **Fill in any other required fields.**
5. Select **Upload**.

Go to the next section to generate a keystore on your client system.

## Create a Keystore

Generate a keystore on the client system. This keystore must contain the certificate from the client system. You can generate a keystore in many ways. The following steps explain only *one* method, using the keytool utility.

### Follow these steps for the keytool utility:

1. Navigate to the directory where you put the cliTool.jar file.
2. Generate the keystore and import the certificate to this keystore. Use the following command but note the guidelines:
  - You can substitute capam.crt for another file name with the .crt extension.
  - Do not change the keystore name. It must be **capam.keystore**
  - You must place the **capam.keystore** file in the same folder as the cliTool.jar file. If keytool is executed directly in the Java bin directory, you must manually copy the resulting **capam.keystore** file to the same folder as cliTool.jar.

#### UNIX/Linux:

```
$JAVA_HOME/bin/keytool -import -trustcacerts -file capam.crt -alias capamserver -
keystore capam.keystore
```

**Note:** starting in JRE 1.8, **-import** is replaced by **-importcert**

#### Windows:

```
%JAVA_HOME%\bin\keytool -import -trustcacerts -file capam.crt -alias capamserver -
keystore capam.keystore
```

**Note:** starting in JRE 1.8, **-import** is replaced by **-importcert**

- After you execute the command, you are prompted for the keystore password. Enter a new password for the keystore you are creating. The following messages display:

```
Trust this certificate? [no]: yes
```

```
Certificate was added to keystore
```

- Verify that the import is successful by listing the keystore contents:  
UNIX/Linux:

```
$JAVA_HOME/bin/keytool -list -v -keystore capam.keystore
```

Windows:

```
%JAVA_HOME%\bin\keytool -list -v -keystore capam.keystore
```

### **Verify the Installation**

To verify that the installation works, execute a command. For example:

```
capam_command capam=forwardinc.com adminUserID=admin cmdName=getErrorCodes
```

If successful, a list of error codes displays. The host name (forwardinc.com) must match the server name in the certificate. If the certificate contains an IP address for the appliance, you can use the address in place of the server name.

Before the command executes, you are prompted for the Credential Manager administrator password. If the command executes successfully, it produces an XML string. For more information about the return values, see [Remote CLI Return Values](#).

## **Use the Credential Manager Java API**

To develop a program using the Java API, add the cliTool.jar file as a build path dependency. The resulting Java program also has a runtime dependency on the cliTool.jar file.

To run a program that uses the Java API, ensure that the cliTool.jar file is part of the classpath. You access the Java API from a Java program by including the cliTool.jar in your project classpath.

### **NOTE**

The cliTool.jar file also contains the Javadocs that describe each available Java API command.

Use the following procedure to use the Java API to run CLI commands from your Java program.

### **Follow these steps:**

- Import the necessary classes. At a minimum, you require:

```
com.cloakware.cspm.common.AdminAPICommandNames
com.cloakware.cspm.common.AdminAPIParameterNames
com.cloakware.cspm.server.ui.Request
```

```
com.cloakware.cspm.server.ui.AdminAPI com.cloakware.cspm.server.ui.Result
```

Base Model objects represent elements of the Credential Manager data model. They include all objects that are derived from the `BaseModel` class; such as `TargetAccount`, `TargetApplication`, `TargetServer`, `Role`, `Request`, `RequestScript`, and `RequestServer`.

```
import com.cloakware.cspm.common.AdminAPICommandNames; import
com.cloakware.cspm.common.AdminAPIParameterNames;

import com.cloakware.cspm.server.ui.Request; import
com.cloakware.cspm.server.ui.AdminAPI; import com.cloakware.cspm.server.ui.Result;
```

2. Instantiate the `AdminAPI` class by entering the following command:

```
AdminAPI adminAPI = new AdminAPI();
```

3. Log in to Privileged Access Manager using the following command. The Java API operates in a session-specific state, which requires you to log in to the appliance.

```
adminAPI.login(locationOfKeystore, userId, password);
```

The roles and groups that are assigned to a user determine which CLI commands a user can execute CLI. The user must have the password management role. The group Operational Administrator is sufficient to execute CLI commands, and group "System Admin Group" contains full privileges to execute password management CLI commands.

4. Perform your CLI commands. You can run CLI commands by:

- Creating a request object and applying the `AdminAPI execute` method, or
- If the command involves a Base Model object, you can create an instance of the Base Model object and can run the `AdminAPI add`, `update`, or `delete` method.

For example, to add a target server using the request object and the `AdminAPI execute` method, enter the following commands:

```
Request myRequest = new Request();
myRequest.setCommand(AdminAPICommandNames.ADD_TARGET_SERVER);

myRequest.setParameter(AdminAPIParameterNames.ADD_TARGET_SERVER_HOST_NAME,
    "myhost.mycompany.com");

myRequest.setParameter(AdminAPIParameterNames.ADD_TARGET_SERVER_IP_ADDRESS,
    "12.12.12.12");

Result myResult = adminAPI.execute(myRequest); System.out.println("result: "+
    myResult.getStatusMessage());
```

For example, to add a target server using the `TargetServer` object and the `AdminAPI add` method:

```
myTargetServer.setHostName("myhost.mydomain2.com");
myTargetServer.setIPAddress("10.12.13.14");
```

```
Result myResult = adminAPI.add(myTargetServer); System.out.println("result: "+
    myResult.getStatusMessage());
```

## 5. When you are finished using the CLI, log out from the appliance:

```
adminAPI.logout();
```

### NOTE

More information: [Credential Manager Java API Example](#).

## Credential Manager Java API Example

The `javaAPIExample.java` helps you learn how to use the Java API.

This example is an implementation of a Java API-based application for use with Credential Manager.

```
import java.util.ArrayList;
import java.util.List;

import com.cloakware.cspm.common.AdminAPICommandNames;
import com.cloakware.cspm.common.AdminAPIParameterNames;
import com.cloakware.cspm.server.bo.Agent;
import com.cloakware.cspm.server.bo.Authorization;
import com.cloakware.cspm.server.bo.Filter;
import com.cloakware.cspm.server.bo.Group;
import com.cloakware.cspm.server.bo.PasswordPolicy;
import com.cloakware.cspm.server.bo.PasswordViewPolicy;
import com.cloakware.cspm.server.bo.RequestScript;
import com.cloakware.cspm.server.bo.RequestServer;
import com.cloakware.cspm.server.bo.Role;
import com.cloakware.cspm.server.bo.TargetAccount;
import com.cloakware.cspm.server.bo.TargetAlias;
import com.cloakware.cspm.server.bo.TargetApplication;
import com.cloakware.cspm.server.bo.TargetServer;
import com.cloakware.cspm.server.bo.User;
import com.cloakware.cspm.server.bo.UserGroup;
import com.cloakware.cspm.server.ui.AdminAPI;
import com.cloakware.cspm.server.ui.AdminAPIFactory;
import com.cloakware.cspm.server.ui.Request;
import com.cloakware.cspm.server.ui.Result;

     * Deletes a User Group.
     */
    public void deleteUserGroup() {
        result = adminAPI.delete(userGroup);
        System.out.println("deleteUserGroup: "+ result.getStatusMessage());
    }

    /**
     * Deletes a Request Group.
     */
    public void deleteRequestGroup() {
```

```
//Delete a Group
result = adminAPI.delete(requestGroup);
System.out.println("deleteRequestGroup: "+ result.getStatusMessage());
}

/**
 * Deletes a Target Group.
 */
public void deleteTargetGroup() {
    //Delete a Group
    result = adminAPI.delete(targetGroup);
    System.out.println("deleteTargetGroup: "+ result.getStatusMessage());
}

/**
 * Deletes an Authorization.
 */
public void deleteAuthorization() {
    //Delete the Authorization
    result = adminAPI.delete(authorization);
    System.out.println("deleteAuthorization: "+ result.getStatusMessage());
}

/**
 * Deletes a Target Alias.
 */
public void deleteTargetAlias() {
    //Delete the Target Alias
    result = adminAPI.delete(targetAlias);
    System.out.println("deleteTargetAlias: "+ result.getStatusMessage());
}

/**
 * Deletes a Target Server. Deleting a Target Server will also delete
 * all associated Target Applications and Target Accounts.
 */
public void deleteTargetServer() {
    //Delete the Target Server
    result = adminAPI.delete(targetServer);
    System.out.println("deleteTargetServer: "+ result.getStatusMessage());
}

/**
 * Deletes a Request Script.
 */
public void deleteRequestScript() {
    //Delete the Request Script
    result = adminAPI.delete(requestScript);
    System.out.println("deleteRequestScript: "+ result.getStatusMessage());
}

/**
 * Deletes a Request Server.
 */
```

```

    */
    public void deleteRequestServer() {
        //Delete the Request Server
        result = adminAPI.delete(requestServer);
        System.out.println("deleteRequestServer: "+ result.getStatusMessage());
    }
}

```

## Use the Remote CLI

After the Remote CLI is set up, you can execute a command or scripts of commands to administer Credential Manager or Secrets Management functions. This content in this section explains how to execute these commands.

**Use the table of contents to access the topics in this section.**

Also see the following topics for a list of CLI commands available for each CLI:

- [Credential Manager CLI Commands](#)
- [Secrets Management CLI Commands](#)

## Remote CLI Command Syntax

UNIX/Linux and Windows platforms support the CLI. To authenticate with the CLI and run a command, use the following syntax:

```

capam_command capam=hostname adminUserID=user_name [adminPassword=password]
cmdName=command [<parameter>=<value>]

```

### NOTE

SAML users are not supported for Remote CLI authentication.

The commands a user can execute are determined by the roles that are assigned to that user. See [Add or Modify Credential Manager Roles](#), or [About Secrets Management and Roles](#), as appropriate.

On UNIX, traditional and GNU style aliases for some parameters exist:

- `capam=hostname` can also be specified as `-n <hostname>`

### NOTE

If you run a command that requires an IPv6 address, you must enclose the address in square brackets. For example:

```
capam=[fd6d:8d64:af0c:1:0:252: 44:114]
```

- `adminUserID=user_name` can also be specified as `-u user_name` or `--adminUserID=user_name`
- `adminPassword=password` can also be specified as `-p password` or `--adminPassword=password`

If you do not specify the password as an option, you are prompted for it before the command is processed.

### TIP

- The CLI often requires commands that are long. To allow commands to span multiple lines in UNIX, use the continuation character, which is a backslash (\).
- If a parameter value contains a space, enclose the entire value pair definition in quotes. For example, enter "[TargetApplication.name](#)=AWS Access Credential Accounts" rather than [TargetApplication.name](#)="AWS Access Credential Accounts".

## Execute Commands Individually or as a Batch Sequence

The CLI can process commands individually or as a batch sequence. In both cases, the commands and argument values are the same.

Due to restrictions in the number of arguments that the Windows batch utility permits, you cannot run all commands individually. To work around this limitation, use the `batchSequence` command. For more information about the `batchSequence` command, see [Batch CLI Command Execution](#).

## Remote CLI Return Values

The CLI returns an XML string for each command. The return string includes the following information:

- a status code
- a status description
- a result with every parameter that is associated with the command object. The following XML structure is an example:

```
<CommandResult>
  <cr.itemNumber>0</cr.itemNumber>
  <cr.statusCode>400</cr.statusCode>
  <cr.statusDescription>Success.</cr.statusDescription>
</CommandResult>
```

For improved readability of the output, direct the XML structure to a separate file and then open it with an XML editor.

## Command Example

This example shows the **getErrorCodes** command. This command takes no parameters. The command returns an XML structure listing each Credential Manager server error code and its description. The command also directs the output of the `getErrorCodes` CLI command to a file named `error_codes.xml`.

### Follow these steps:

1. Use the following command:

```
capam_command capam=hostname -u admin -p password capam=mycompany.com
cmdName=getErrorCodes > error_codes.xml
```

Where *password* is the password of the admin account  
Credential Manager produces an XML command string to the `error_codes.xml` file.

2. Open the `error_codes.xml` file with an XML editor, such as Notepad++.

## Batch CLI Command Execution

The **batchSequence** CLI command enables the execution of multiple CLI commands in a single transaction. The CLI commands are specified as a sequence of XML elements in an XML-formatted file. Batch processing is primarily intended for a batch import of data, such as adding many target accounts to Credential Manager or many secret users to Secrets Management. You can use batch processing more generally. You can also use batch processing as an interface between automated system and the CLI.

## Batch Command Example

### Follow these steps:

1. Create a batch processing XML file to use as input for the `batchSequence` command. Use the XML schema in [Remote CLI XML Schema for Batch Processing](#) to ensure that the file is well formatted.

For example, the following file is named `AddAll.xml`. The file encloses a CLI request specifying two Credential Manager commands and their arguments (CLI requests for Secrets Management are structured identically). The two commands add a target application and a target account within that application:

```
<?xml version="1.0" encoding="UTF-8"?>
<CLI_REQUEST
  xmlns="http://www.cloakware.com"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.cloakware.com/opt/cloakware/cspmserver/tools/cli/cspmcli.xsd">
  <COMMAND name="addTargetServer">
    <COMMAND_PARAMETERS>
      <PARAMETER>
        <NAME>TargetServer.hostName</NAME>
        <VALUE>Ottawa-Lab3.cloakware.com</VALUE>
      </PARAMETER>
      <PARAMETER>
        <NAME>TargetServer.ipAddress</NAME>
        <VALUE>10.5.0.3</VALUE>
      </PARAMETER>
      <PARAMETER>
        <NAME>Attribute.descriptor1</NAME>
        <VALUE>Ottawa</VALUE>
      </PARAMETER>
      <PARAMETER>
        <NAME>Attribute.descriptor2</NAME>
        <VALUE>Lab</VALUE>
      </PARAMETER>
    </COMMAND_PARAMETERS>
  </COMMAND>

  <COMMAND name="addTargetApplication">
    <COMMAND_PARAMETERS>
      <PARAMETER>
        <NAME>TargetServer.hostName</NAME>
        <VALUE>Ottawa-Lab3.cloakware.com</VALUE>
      </PARAMETER>
      <PARAMETER>
        <NAME>TargetApplication.type</NAME>
        <VALUE>Generic</VALUE>
      </PARAMETER>
      <PARAMETER>
        <NAME>TargetApplication.name</NAME>
        <VALUE>Generic account type</VALUE>
      </PARAMETER>
      <PARAMETER>
        <NAME>Attribute.descriptor1</NAME>
        <VALUE>Ottawa</VALUE>
      </PARAMETER>
      <PARAMETER>
        <NAME>Attribute.descriptor2</NAME>
        <VALUE>Lab</VALUE>
      </PARAMETER>
    </COMMAND_PARAMETERS>
  </COMMAND>
```

```
</CLI_REQUEST>
```

## 2. Run the batch processing command with your file as input.

```
capam_command capam=pam02.ca.com adminUserID=admin cmdName=batchSequence inputfile=AddAll.xml
outputfile=results.xml
```

## 3. Enter your password at the prompt. After a brief moment of processing, Credential Manager presents the batch results as follows:

```
<BatchCommandResult>
  <CommandResult>
    <cr.itemNumber>0</cr.itemNumber>
    <cr.commandName>addTargetServer</cr.commandName>
    <cr.statusCode>400</cr.statusCode>
    <cr.statusDescription>Success</cr.statusDescription>
    <cr.result>
      <TargetServer>
        <Attribute.descriptor2>Lab</Attribute.descriptor2>
        <Attribute.descriptor1>Ottawa</Attribute.descriptor1>
        <ID>3</ID>
        <createDate>Mon Nov 12 17:18:41 EST 2007</createDate>
        <updateDate>Mon Nov 12 17:18:41 EST 2007</updateDate>
        <createUser>admin</createUser>
        <updateUser>admin</updateUser>
        <hash>qn/wPB8BBtxfu7/cJMKc3Bn+vCE=</hash>
        <hostName>Ottawa-Lab3.cloakware.com</hostName>
        <IPAddress>10.5.0.3</IPAddress>
      </TargetServer>
    </cr.result>
  </CommandResult>

  <CommandResult>
    <cr.itemNumber>1</cr.itemNumber>
    <cr.commandName>addTargetApplication</cr.commandName>
    <cr.statusCode>400</cr.statusCode>
    <cr.statusDescription>Success</cr.statusDescription>
    <cr.result>
      <TargetApplication>
        <Attribute.descriptor2>Lab</Attribute.descriptor2>
        <Attribute.descriptor1>Ottawa</Attribute.descriptor1>
        <ID>3</ID>
        <createDate>Mon Nov 12 17:18:41 EST 2007</createDate>
        <updateDate>Mon Nov 12 17:18:41 EST 2007</updateDate>
        <createUser>admin</createUser>
        <updateUser>admin</updateUser>
        <hash>I8XvBL6zIT/mCaDwy/F58Q2Z9LI=</hash>
        <targetServerID>3</targetServerID>
        <type>Generic</type>
        <name>Generic account type</name>
        <policyID>0</policyID>
      </TargetApplication>
    </cr.result>
  </CommandResult>
</BatchCommandResult>
```

## Remote CLI XML Schema for Batch Processing

Use the Remote CLI XML schema for batch processing to ensure that your input file is appropriately formatted.

```
<?xml version="1.0" encoding="utf-8" ?>

<xs:schema      xmlns="http://www.cloakware.com"
                 xmlns:xs="http://www.w3.org/2001/XMLSchema"
                 targetNamespace="http://www.cloakware.com"
                 elementFormDefault="qualified">
  <xs:element name="PARAMETER">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="NAME" type="xs:string"
                     minOccurs="1" maxOccurs="1"/>
        <xs:element name="VALUE" type="xs:string"
                     minOccurs="1" maxOccurs="unbounded"/>
      </xs:sequence>
    </xs:complexType>
  </xs:element>

  <xs:element name="COMMAND_PARAMETERS">
    <xs:complexType>
      <xs:sequence>
        <xs:element ref="PARAMETER" minOccurs="1"
                     maxOccurs="unbounded" />
      </xs:sequence>
    </xs:complexType>
  </xs:element>

  <xs:element name="COMMAND">
    <xs:complexType>
      <xs:sequence>
        <xs:element ref="COMMAND_PARAMETERS"
                     minOccurs="0" maxOccurs="unbounded" />
      </xs:sequence>
      <xs:attribute name="name" type="xs:string" use="required" />
    </xs:complexType>
  </xs:element>

  <xs:element name="CLI_REQUEST" >
    <xs:complexType>
      <xs:sequence>
        <xs:element ref="COMMAND" minOccurs="1"
                     maxOccurs="unbounded" />
      </xs:sequence>
    </xs:complexType>
  </xs:element>
</xs:schema>
```

## Credential Manager CLI Commands

You can use the Remote CLI to control and configure Credential Manager. This command-line interface allows administrators to provide scripted functionality to complete management and integration tasks. The Remote CLI supports a limited subset of features that are available through the GUI. There are also some commands that are only available through the CLI.

### NOTE

String searches in CLI commands are case sensitive. That is, a search for `deviceName=server` returns "server1" and "server2", but not "Server3."

Use the table of contents to access the command descriptions.

### addAuthorization

Use the `addAuthorization` command to add an authorization mapping. This gives a requesting application, request server, or request group permission to query credentials for a target alias or target group. The Windows CLI allows up to nine parameters, including the mandatory `adminUserID` and `capam`. To enter the `addAuthorization` command with more than nine parameters, use the `batchSequence` command with an XML formatted input file.

#### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=addAuthorization
RequestServer.hostName=myhostname.mydomain.com

RequestScript.name=example.pl RequestScript.executionPath=/usr/tmp/examples
Authorization.checkExecutionID=true

Authorization.executionUser=auser Authorization.checkPath=true
TargetAlias.name=myaliasname Authorization.checkScriptHash=true
```

### Parameters

#### TargetAlias.name

Specifies the target alias name.

Required	Default Value	Valid Values
One of <code>TargetAlias.name</code> , <code>TargetAlias.ID</code> , <code>Authorization.targetGroupName</code> , or <code>Authorization.targetGroupId</code> is required.	N/A	This value must match the target alias name that is registered in Credential Manager.

#### TargetAlias.ID

Specifies the target alias ID.

Required	Default Value	Valid Values
One of <code>TargetAlias.name</code> , <code>TargetAlias.ID</code> , <code>Authorization.targetGroupName</code> , or <code>Authorization.targetGroupId</code> is required.	N/A	Use <code>searchTargetAlias</code> to retrieve the <code>TargetAlias.ID</code> .

**Authorization.targetGroupName**

Specifies the target group name.

Required	Default Value	Valid Values
One of TargetAlias.name, TargetAlias.ID, Authorization.targetGroupName, or Authorization.targetGroupId is required.	N/A	This value must match the target group name that is registered in Credential Manager.

**Authorization.targetGroupId**

Specifies the target group ID.

Required	Default Value	Valid Values
One of TargetAlias.name, TargetAlias.ID, Authorization.targetGroupName, or Authorization.targetGroupId is required.	N/A	Numeric.

**RequestServer.hostName**

Specifies the request server host name on which the requesting application resides.

Required	Default Value	Valid Values
One of RequestServer.hostName, RequestServer.ID, Authorization.requestGroupName, or Authorization.requestGroupId is required.	N/A	This value must match the request server name that is registered in Credential Manager.

**RequestServer.ID**

Specifies the request server ID on which the requesting application resides.

Required	Default Value	Valid Values
One of RequestServer.hostName, RequestServer.ID, Authorization.requestGroupName, or Authorization.requestGroupId is required.	N/A	Use searchRequestServer to retrieve the RequestServer.ID.

**Authorization.requestGroupName**

Specifies the request group name the requesting application is a member of resides.

Required	Default Value	Valid Values
One of RequestServer.hostName, RequestServer.ID, Authorization.requestGroupName, or Authorization.requestGroupId is required.	N/A	This value must match the request group name that is registered in Credential Manager.

**Authorization.requestGroupId**

Specifies the request group name the requesting application is a member of resides.

Required	Default Value	Valid Values
One of RequestServer.hostName, RequestServer.ID, Authorization.requestGroupName, or Authorization.requestGroupId is required.	N/A	Numeric.

### **RequestScript.name**

Specifies the requesting application name.

Required	Default Value	Valid Values
One of RequestScript.name or RequestScript.ID is required.	N/A	This value must match the script name that is registered in Credential Manager.

### **RequestScript.ID**

Specifies the requesting application ID. Set this value to -1 to specify All request scripts for the indicated request server. Setting this to -1 also sets Authorization.checkPath, Authorization.checkFilePath, and Authorization.checkScriptHash to false.

Required	Default Value	Valid Values
yes	N/A	-1 or use searchRequestScript to retrieve the RequestScript.ID.

### **RequestScript.executionPath**

Specifies the requesting application execution path, as registered in Credential Manager.

Required	Default Value	Valid Values
Required if RequestScript.name is used.	N/A	This value must match the script execution path that is registered in Credential Manager.

### **Authorization.checkExecutionID**

Set Authorization.checkExecutionID=true to indicate that the execution user ID be validated.

Required	Default Value	Valid Values
no	false	true, false

### **Authorization.executionUser**

A comma-delimited list of execution user IDs. The IDs are only validated if Authorization.checkExecutionID=true.

Required	Default Value	Valid Values
no	N/A	String.

### **Authorization.checkPath**

Set Authorization.checkPath=true to indicate that the script execution path be validated.

Required	Default Value	Valid Values
no	false	true, false

### **Authorization.checkFilePath**

Set Authorization.checkFilePath=true to indicate that the script file path be validated.

Required	Default Value	Valid Values
no	false	true, false

### **Authorization.checkScriptHash**

Set Authorization.checkScriptHash=true to indicate that script hash integrity verification be performed.

Required	Default Value	Valid Values
no	false	true, false

## **addFilter**

Use the addFilter command to add a filter to a target group or request group. The group must first be added using the addGroup command.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=addFilter Group.ID=3
  Filter.objectClassId=c.cw.m.ts

  Filter.attribute=hostName Filter.type=contains Filter.expression="mydomain"
```

## **Parameters**

### **Group.ID**

Specifies the ID of the request or target group. It must be an integer greater than or equal to 1.

Required	Default Value	Valid Values
yes	N/A	Integer

### **Filter.objectClassId**

Specifies the type of object to filter. Class IDs are specific to group type.

Required	Default Value	Valid Values
yes	N/A	c.cw.m.ts, c.cw.m.tp, c.cw.m.ac, c.cw.m.rs, c.cw.m.sc

### **Filter.attribute**

Specifies the filter attribute. If static, attribute must be ID. If dynamic, attributes are specific to objectClassId.

Required	Default Value	Valid Values
yes	N/A	String.

### **Filter.type**

Specifies the filter type. If group is static, only equals is valid.

Required	Default Value	Valid Values
yes	N/A	equals, beginswith, contains, endswith, notcontains

### **Filter.expression**

Specifies the filter expression. If group is static, expression can only be an integer greater than or equal to 1.

Required	Default Value	Valid Values
yes	N/A	String, Integer

## **addGroup**

Use the addGroup command to add either a target or request group to Privileged Access Manager. Use the addFilter command to add filters to the group.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=addGroup
  Group.name=TokyoTargets Group.description="Targets in Tokyo" Group.type=target
```

## **Parameters**

### **Group.name**

Specifies the name of the target or request group.

Required	Default Value	Valid Values
yes	N/A	String

### **Group.description**

Specifies the description of the group.

Required	Default Value	Valid Values
no	N/A	String

### **Group.type**

Set Group.type=requestor for Request groups. Set Group.type=target for Target groups.

Required	Default Value	Valid Values
yes	N/A	requestor, target

### **Group.dynamic**

Set Group.dynamic=true for dynamic Request/Target groups, false for static Request/Target groups.

Required	Default Value	Valid Values
no	true	true, false

### **Group.permissions**

ArrayList object of filters, or XML encoded ArrayList of filters. If not set, the filters are cleared.

Required	Default Value	Valid Values
no	N/A	XML

Required	Default Value	Valid Values
yes	N/A	String, Integer

## **addPasswordPolicy**

Use the addPasswordPolicy command to add a Password Composition Policy in Privileged Access Manager.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=addPasswordPolicy
  PasswordPolicy.name=passwordPolicyName

Attribute.composedOfUpperCaseCharacters=true
Attribute.firstCharacterUpperCase=true
```

### **Parameters**

#### **PasswordPolicy.name**

The name of the password policy.

Required	Default Value	Valid Values
Yes	None	String

#### **PasswordPolicy.description**

The description of the password policy.

Required	Default Value	Valid Values
No	Blank	String

**Attribute.passwordPrefix**

The prefix for all passwords that are mandated by your password policy.

Required	Default Value	Valid Values
No	None	Constrained by your other settings.

**Attribute.composedOfUpperCaseCharacters**

Set to true to mandate that your password policy requires uppercase characters.

Required	Default Value	Valid Values
No	false	true, false

**Attribute.composedOfLowerCaseCharacters**

Set to true to mandate that your password policy requires lowercase characters.

Required	Default Value	Valid Values
No	false	true, false

**Attribute.composedOfNumericCharacters**

Set to true to mandate that your password policy requires numeric characters.

Required	Default Value	Valid Values
No	false	true, false

**Attribute.composedOfSpecialCharacters**

Set to true to mandate that your password policy requires special characters.

Required	Default Value	Valid Values
No	false	true, false

**Attribute.specialCharacters**

The list of all special characters that are allowed by your password policy.

Required	Default Value	Valid Values
No	None	!#\$%()*+,-./:;=?@[\\]^_`{ }~

**Attribute.firstCharacterUpperCase**

Set to true to mandate that your password policy requires the first character to be uppercase. If you select more than one first character requirement, they are combined. For example, if both Attribute.firstCharacterUpperCase and Attribute.firstCharacterLowerCase are true, then the policy requires the first character to be either upper or lowercase.

Required	Default Value	Valid Values
No	false	true, false

**Attribute.firstCharacterLowerCase**

Set to true to mandate that your password policy requires the first character to be lowercase. If you select more than one first character requirement, they are combined. For example, if both `Attribute.firstCharacterUpperCase` and `Attribute.firstCharacterLowerCase` are true, then the policy requires the first character to be either upper or lowercase.

Required	Default Value	Valid Values
No	false	true, false

#### **Attribute.firstCharacterNumeric**

Set to true to mandate that your password policy requires the first character to be numeric. If you select more than one first character requirement, they are combined. For example, if both `Attribute.firstCharacterUpperCase` and `Attribute.firstCharacterNumeric` are true, then the policy requires the first character to be either uppercase or numeric.

Required	Default Value	Valid Values
No	false	true, false

#### **Attribute.firstCharacterSpecial**

Set to true to mandate that your password policy requires the first character to be a special character. If you select more than one first character requirement, they are combined. For example, if both `Attribute.firstCharacterUpperCase` and `Attribute.firstCharacterSpecial` are true, then the policy requires the first character to be either uppercase or a special character.

Required	Default Value	Valid Values
No	false	true, false

#### **Attribute.firstCharacterSpecials**

The list of all special characters that are allowed as a first character by your password policy.

Required	Default Value	Valid Values
No	None	!#\$%()*+,-./:;=?@[\\]^_`{ }~

#### **Attribute.mustNotContainConsecutiveDuplicateCharacters**

Set to true to mandate that your password policy does not allow any repeating characters.

Required	Default Value	Valid Values
No	false	true, false

#### **Attribute.mustNotContainAnyDuplicateCharacters**

Set to true to mandate that your password policy does not allow any duplicate characters.

Required	Default Value	Valid Values
No	false	true, false

#### **Attribute.mustNotContainCharacters**

Set to true to mandate that your password policy prohibits certain uppercase, lowercase, or numeric characters.

Required	Default Value	Valid Values
No	false	true, false

#### **Attribute.composedOfMustNotContainCharacters**

The list of all characters that your password policy does not allow. Do not prohibit characters that are allowed in other attributes.

Required	Default Value	Valid Values
No	Blank	ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz0123456789

#### **Attribute.minLength**

Set the minimum length of characters to mandate by your password policy.

Required	Default Value	Valid Values
No	4	1– 2048

#### **Attribute.maxLength**

Set the maximum length of characters to mandate by your password policy.

Required	Default Value	Valid Values
No	16	1– 2048

#### **NOTE**

Although PAM supports a maximum password length of 2048 characters, target systems may have lower limits. For example, the maximum password length on a Linux system is 511 characters. Therefore, if you want PAM to manage accounts on a Linux system as synchronized accounts, set the Attribute.maxLength value to no more than 511.

#### **Attribute.minIterationsBeforeReuse**

Set the minimum number of iterations before a password can be reused.

Required	Default Value	Valid Values
No	0	Numeric

#### **Attribute.minDaysBeforeReuse**

Set the minimum number of days before a password can be reused.

Required	Default Value	Valid Values
No	0	Numeric

#### **Attribute.enableMaxPasswordAge**

Set to true to enable maximum password age in your password policy.

Required	Default Value	Valid Values
No	false	true, false

### **Attribute.maxPasswordAge**

Set the maximum password age in days. After this many days, passwords will have to be changed.

Required	Default Value	Valid Values
Yes, if Attribute.enableMaxPasswordAge is set to true.	None	Numeric

### **PasswordViewPolicy.passwordViewRequestBanner**

The banner description for the Password View Policy.

Required	Default Value	Valid Values
No	None	String

## **addPasswordViewPolicy**

Use the addPasswordViewPolicy command to add a password view policy to Credential Manager.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=addPasswordViewPolicy
  PasswordViewPolicy.name=restrictedAccounts
```

```
PasswordViewPolicy.changePasswordOnView=true
PasswordViewPolicy.checkinCheckoutRequired=true
PasswordViewPolicy.checkinCheckoutInterval=240
```

## **Parameters**

### **PasswordViewPolicy.name**

The name of the password view policy.

Required	Default Value	Valid Values
yes	N/A	String

### **PasswordViewPolicy.description**

A description of the password view policy.

Required	Default Value	Valid Values
no	N/A	String

### **PasswordViewPolicy.changePasswordOnView**

Set this parameter to true to instruct Credential Manager to change the password after a password view request.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.changePasswordOnSso**

Set this parameter to true to instruct Credential Manager to change the password after a password SSO request is retrieved but not viewed.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.passwordChangeInterval**

If the changePasswordOnView parameter is set to true, this parameter determines the length of time (in minutes) before Credential Manager changes the password.

Required	Default Value	Valid Values
Must be specified if PasswordViewPolicy.changePasswordOnView is true.	60	Numeric value greater than 0

#### **PasswordViewPolicy.checkinCheckoutRequired**

Set this parameter to true to indicate that an account must be checked out before anyone can view the password. When checked out, the account password cannot be changed.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.checkinCheckoutInterval**

Determines the length of time (in minutes) an account can remain checked out before it is automatically checked back in by the system.

Required	Default Value	Valid Values
Specify if PasswordViewPolicy.checkinCheckoutRequired is true	60	Numeric value greater than 0

#### **PasswordViewPolicy.dualAuthorization**

Set PasswordViewPolicy.dualAuthorization=true to indicate that a request to view a password must be approved by another user before proceeding. Note that the XML content returned by PAM shows this parameter with the name **dualAuthorizationRequired**.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.dualAuthorizationInterval**

This parameter determines the default length of time (in minutes) a password view request remains active in the system.

Required	Default Value	Valid Values
Must be specified if PasswordViewPolicy.dualAuthorization is true.	60	Numeric value greater than 0

#### **PasswordViewPolicy.retrospectiveApprovalRequired**

Set PasswordViewPolicy.retrospectiveApprovalRequired=true to indicate that a request to view a password requires retrospective approval. (Access is granted immediately and specified approvers notified.)

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.approvers**

Lists the users who are authorized to approve or deny password requests for accounts that use this password policy.

Required	Default Value	Valid Values
If PasswordViewPolicy.dualAuthorization is set to true, set this parameter or the PasswordViewPolicy.approverIDs parameter	N/A	List of comma-separated usernames. Example: jbauer,mdessler,dpalmer

#### **PasswordViewPolicy.approverIDs**

The list of user IDs who are authorized to approve or deny password requests for accounts that use this password policy.

Required	Default Value	Valid Values
If PasswordViewPolicy.dualAuthorization is true, set this parameter or the PasswordViewPolicy.approvers parameter	Use searchUser to retrieve a list of user IDs	List of comma-separated user IDs. Example: 11,19,15

#### **PasswordViewPolicy.authenticationRequiredSso**

Set this parameter to true to indicate that the requesting user must provide their own password before using the account for auto-connect.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.authenticationRequired**

Set this parameter to true to indicate that the requesting user must provide their own password before viewing the account password.

Required	Default Value	Valid Values
no	true	true, false

#### **PasswordViewPolicy.enableOneClickApproval**

Set this parameter to true to enable one click dual authorization approval. When enabled, dual authorization emails include links that allow the approval of requests without requiring the approver to log into the system.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.PasswordViewRequestMaxInterval**

The maximum Interval between the start and end date of a dual authorization password view request.

Required	Default Value	Valid Values
no	60	Numeric value greater than 0.

#### **PasswordViewPolicy.PasswordViewRequestMaxDays**

The maximum number of days in the future that a password view request can be requested.

Required	Default Value	Valid Values
no	14	Numeric value greater than 0.

#### **PasswordViewPolicy.emailNotificationRequired**

This parameter sends an email notification when someone views a password. If you set this value to true, specify at least one entry for the PasswordViewPolicy.emailNotificationUsers or PasswordViewPolicy.emailNotificationUserIDs parameters. If both parameters have at least one entry, Credential Manager uses the PasswordViewPolicy.emailNotificationUsers list.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.emailNotificationToDualAuthApprovers**

This parameter sends an email notification only to dual authorization approvers. If you set this parameter to true, specify at least one entry in the PasswordViewPolicy.approvers list.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.emailNotificationUsers**

Lists users that receive email notifications when someone views a password. User names in the list must be separated by a comma.

Required	Default Value	Valid Values
no	N/A	user name

#### **PasswordViewPolicy.emailNotificationUserIDs**

Lists user IDs for users that receive email notifications when someone views a password. User names in the list must be separated by a comma.

Required	Default Value	Valid Values
no	N/A	user IDs

#### **PasswordViewPolicy.emailNotificationToActiveUsers**

This parameter sends an email notification to any active user when someone views a password.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.passwordViewRequestBanner**

The banner description for the Password View Policy.

Required	Default Value	Valid Values
no	None	Alphanumeric, -, . and space character

#### **NOTE**

For more information on the following parameters, see their UI equivalents in the [Create a Basic Password View Policy](#) topic.

#### **PasswordViewPolicy.reasonRequiredView**

If set to true, a dialog appears when a user tries to view an Account password. The user selects a Reason and enters a Description and Reference Code to view the password. Select the View Credential (eye icon) for an Account on the Account List page or on the Account Details page.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.reasonRequiredSso**

If set to true, a dialog appears when a user tries to auto-connect. The user selects a Reason and enters an optional Description and optional Reference Code to auto-connect.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.exclusiveCheckoutRequired**

If set to true, this option specifies that credentials are checked in if all connections are closed.

#### **NOTE**

If you select this option, all view properties and the Check-out/Check-in property are unavailable.

If PasswordViewPolicy.exclusiveCheckoutRequired is selected with service desk integration, the Reason Required for View option is selected but disabled. Even though it is selected, the functionality of view password

does not work, as exclusive checkout takes precedence. Viewing of a password is disabled when the account is associated with exclusive checkout on auto connect.

Required	Default Value	Valid Values
no	false	true, false

### **PasswordViewPolicy.changePasswordOnSessionEnd**

If set to true, all passwords that are used to log in to target servers are changed when the user session in Privileged Access Manager ends. The connection can end because the user logs out, a session times out, or connectivity is lost. This option does not apply to "View Password."

Required	Default Value	Valid Values
no	false	true, false

### **PasswordViewPolicy.changePasswordOnConnectionEnd**

If set to true, the password is automatically changed when the user's SSH or RDP connection to a target server ends. The connection can end because the connection times-out, the user terminates the connection, or the connection is lost. This option does not apply to "View Password."

Required	Default Value	Valid Values
no	false	true, false

## **addRequestScript**

Use the addRequestScript command to add a request application to Credential Manager.

### **Example**

```
capam_command capame=capamServer adminUserID=admin cmdName=addRequestScript
RequestServer.hostName=myhostname.mydomain.com
```

```
RequestScript.name=example.pl RequestScript.executionPath=/usr/tmp/examples
RequestScript.filePath=/usr/tmp/examples RequestScript.type=Perl
```

### **Parameters**

#### ***RequestServer.hostName***

The request server host name on which the requesting application resides.

Required	Default Value	Valid Values
One of RequestServer.hostName or RequestServer.ID is required.	N/A	This value must match the request server name that is registered in Credential Manager.

#### **RequestServer.ID**

The request server ID on which the requesting application resides.

Required	Default Value	Valid Values
One of RequestServer.hostName or RequestServer.ID is required.	N/A	Use searchRequestServer to retrieve the RequestServer.ID.

### **RequestScript.name**

The requesting application name.

Required	Default Value	Valid Values
yes	N/A	String.

### **RequestScript.executionPath**

The location from which the requesting application is executed.

Required	Default Value	Valid Values
yes	N/A	String.

### **RequestScript.filePath**

The location in which the requesting application resides.

Required	Default Value	Valid Values
no	N/A	String.

### **RequestScript.type**

The programming language in which the requesting application is written.

Required	Default Value	Valid Values
yes	N/A	C, C++, C#, csh, Java, ksh, Perl, ksh, VB, VB.NET, VC++, Other

### **Attribute.descriptor1**

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String.

### **Attribute.descriptor2**

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String.

## addRequestServer

Use the addRequestServer command to add a request server (Privileged Access Manager Credential Manager client) to Privileged Access Manager Credential Manager. CA Technologies recommends that you use the auto-discovery feature for adding request servers.

### Example

```
cspmserver_admin adminUserID=admin cmdName=addRequestServer
RequestServer.hostName=myhostname.mydomain.com RequestServer.active=true
RequestServer.autoPatch=true
```

### Parameters

#### RequestServer.hostName

The host name of the request server.

Required	Default Value	Valid Values
yes	N/A	String

#### RequestServer.deviceName

The device name of the request server.

Required	Default Value	Valid Values
no	Same as host name.	String

#### RequestServer.active

Set RequestServer.active=true to activate the request server. Set RequestServer.active=false to deactivate the request server.

Required	Default Value	Valid Values
no	false	true, false

#### RequestServer.autoPatch

Set RequestServer.autoPatch=true to indicate that patches should be applied automatically.

Required	Default Value	Valid Values
no	false	true, false

#### RequestServer.preserveHostName

Set RequestServer.preserveHostName=true to indicate that the request server host name should not be overwritten each time the client registers.

Required	Default Value	Valid Values
no	Determined by the value of system property setting "AppDefaultPreserveClientHostName".	true, false

### Attribute.descriptor1

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String

### **Attribute.descriptor2**

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String

## **addRequestServerDefaults**

Use the addRequestServerDefaults command to add a request server defaults to Credential Manager.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=addRequestServerDefaults RequestServerDefaults.subnet=122.111.0.0/16

RequestServerDefaults.active=true RequestServerDefaults.type=CLIENT
RequestServerDefaults.descriptor1=awsApiProxy
```

### **Parameters**

#### **RequestServerDefaults.subnet**

The subnet filter to apply defaults to request servers.

Required	Default Value	Valid Values
yes	N/A	String

#### **RequestServerDefaults.type**

The type filter to apply defaults to request servers.

Required	Default Value	Valid Values
yes	N/A	CLIENT, AGENT, ALL

#### **RequestServerDefaults.active**

The default setting for RequestServer.active during auto-register.

Required	Default Value	Valid Values
yes	N/A	true, false

#### **RequestServerDefaults.descriptor1**

The default setting for Attribute.descriptor1 during auto-register.

Required	Default Value	Valid Values
no	N/A	String

### **RequestServerDefaults.descriptor2**

The default setting for Attribute.descriptor2 during auto-register.

Required	Default Value	Valid Values
no	N/A	String

## **addRole**

Use the addRole command to add a user role to Credential Manager.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=addRole
  Role.name=myRole Role.description="Manages patches"

Role.permissions="activatePatch,
  addPatch,deletePatch,getPatchDetail,listPatch,updatePatch"
```

### **Parameters**

#### **Role.name**

The name of the role.

Required	Default Value	Valid Values
yes	N/A	String. A unique name in Credential Manager

#### **Role.description**

The description of the role.

Required	Default Value	Valid Values
no	N/A	String

#### **Role.permissions**

A comma-delimited list of permissions.

Required	Default Value	Valid Values
yes	N/A	String. See <a href="#">Add or Modify Credential Manager Roles</a> for a list of valid permissions.

## addSSHKeyPairPolicy

Use the addSSHKeyPairPolicy command to add an SSH Key Pair Policy to Privileged Access Manager.

### Example

```
capam_command capam=capamServer adminUserID=super adminPassword=password
cmdName=addSSHKeyPairPolicy
```

```
SSHKeyPairPolicy.name=Testing SSHKeyPairPolicy.keyType=RSA
SSHKeyPairPolicy.keyLength=2048
```

### Parameters

#### SSHKeyPairPolicy.name

The policy name.

Required	Default Value	Valid Values
Yes	N/A	A String

#### SSHKeyPairPolicy.description

The policy description.

Required	Default Value	Valid Values
No	N/A	A String

#### SSHKeyPairPolicy.keyType

The key type.

Required	Default Value	Valid Values
Yes	N/A	ECDSA or RSA or DSA

#### SSHKeyPairPolicy.keyLength

The key length.

Required	Default Value	Valid Values
Yes	N/A	Varies depending on key type. The supported DSA key lengths are 512 bits and 1024 bits. The supported ECDSA key lengths are 256 bits, 384 bits, and 521 bits. The supported RSA key lengths are 1024 bits, 2048 bits, and 4096 bits.

## addTargetAccount

Use the **addTargetAccount** command to add a target account for credential management. In addition to the parameters in this topic, other parameters might be required, based on the Application Type and Target Connector that you configure.

For a description of these additional parameters, see the appropriate target connector topic. For example, see [Windows Remote Target Connector CLI Configuration](#) for target account parameters unique to Windows Remote.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=addTargetAccount
  TargetServer.hostName=myhostname.mydomain.com

TargetApplication.name=myApplication TargetAccount.userName=sysop1
  TargetAccount.password=sys0p2 TargetAccount.cacheBehavior=useCacheFirst

TargetAccount.cacheDuration=17 Attribute.descriptor1="Lab"
  Attribute.descriptor2="Ottawa"
```

## Parameters

### TargetServer.hostName

The host name for the target server on which the target account resides.

Required	Default Value	Valid Values
Either <code>TargetServer.hostName</code> and <code>TargetApplication.name</code> ; or <code>TargetApplication.ID</code> is required.	N/A	This value must match a target server name that is registered in Credential Manager.

### TargetApplication.name

The target application name on which the target account is hosted.

Required	Default Value	Valid Values
One of <code>TargetApplication.name</code> or <code>TargetApplication.ID</code> is required.	N/A	This value must match a target application name that is registered in Credential Manager.

### TargetApplication.ID

The target application ID on which the target account is hosted.

Required	Default Value	Valid Values
One of <code>TargetApplication.name</code> or <code>TargetApplication.ID</code> is required.	N/A	Use <code>searchTargetApplication</code> to retrieve the <code>TargetApplication.ID</code> .

### TargetAccount.userName

The user name for the target account.

Required	Default Value	Valid Values
yes	N/A	String. <code>TargetAccount.userName</code> must match exactly the user name in the target application.

**TargetAccount.password**

The password for the target account.

Required	Default Value	Valid Values
yes	N/A	The initial password must be the same as the password on the target account, unless a user with more privileges synchronizes this password. If a password policy is associated with the target application, the password value must adhere to the password policy. In addition to compliance with password policy constraints, a password must be a minimum of 1 character and a maximum of 255 characters.

**TargetAccount.cacheAllow**

This parameter is deprecated. Use `TargetAccount.cacheBehavior`. Set `TargetAccount.cacheAllow=true` to have credentials for this account that is cached in the Credential Manager client.

Required	Default Value	Valid Values
no	true	true, false

**TargetAccount.cacheBehavior**

To cache the credentials for this account in the Credential Manager client and used first, set this parameter to `useCacheFirst`. If the command is set to `useServerFirst`, the credentials for this account are cached in the Credential Manager client but the server is contacted first. To ensure that the credentials for this account are not cached in the Credential Manager client, set this parameter to `noCache`.

Required	Default Value	Valid Values
no	<code>useCacheFirst</code>	<code>useCacheFirst</code> , <code>useServerFirst</code> , <code>noCache</code>

**TargetAccount.cacheDuration**

Use `TargetAccount.cacheDuration` to specify the number of days the account credentials are permitted to reside in a Credential Manager client cache.

Required	Default Value	Valid Values
no	30	1 - 356

**TargetAccount.privileged**

Set `TargetAccount.privileged=true` to indicate that this account is a privileged account. Set `TargetAccount.privileged=false` to indicate that this account is an application-to-application account.

Required	Default Value	Valid Values
no	false	true, false

**TargetAccount.accessType**

Use this text field for reference purposes.

Required	Default Value	Valid Values
no	N/A	String.

**TargetAccount.synchronize**

Set `TargetAccount.synchronize=true` to indicate that the password that is stored in Credential Manager should be synchronized with the password on the target system. This functionality is not supported with Target Application Type Generic. This functionality is not supported when `TargetAccount.compoundAccount=true`.

Required	Default Value	Valid Values
no	false	true, false

**Attribute.descriptor1**

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String.

**Attribute.descriptor2**

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String.

**PasswordViewPolicy.name**

The name of a Password View Policy that is attached to this account.

Required	Default Value	Valid Values
no	The system default Password View Policy	String

**TargetAlias.name**

A comma separated list of `TargetAlias.name` values. This parameter depends on the value of `useTargetAliasNameParameter` being true.

Required	Default Value	Valid Values
no	N/A	comma-separated String values

**useTargetAliasNameParameter**

A flag of true adds or deletes Target Aliases for this account using the values that are specified in the `TargetAlias.name` parameter.

Required	Default Value	Valid Values
no.	false	true, false

**TargetAccount.compoundAccount**

A flag of true adds or deletes Compound Target Servers for this account using the values that are specified in the `TargetAccount.compoundServerIDs` parameter.

Required	Default Value	Valid Values
no.	false	true, false

**TargetAccount.compoundServerIDs**

List of target server IDs to use as compound servers.

Required	Default Value	Valid Values
no.	n/a	comma-separated target server ID values

**passwordIsBase64Encoded**

A flag of true indicates that the specified password has been Base 64-encoded and should be decoded before being stored.

Required	Default Value	Valid Values
no.	false	true, false

**addTargetAlias**

Use the `addTargetAlias` command to add a target alias to Privileged Access Manager Credential Manager.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=addTargetAlias
  TargetServer.hostName=myhostname.mydomain.com

TargetApplication.name=myApplication TargetAccount.userName=sysop1
TargetAlias.name=myaliasname
```

**Parameters****TargetServer.hostName**

The host name for the target server on which the target account resides.

Required	Default Value	Valid Values
Either <code>TargetServer.hostName</code> , <code>TargetApplication.name</code> , and <code>TargetApplication.name</code> ; or <code>TargetApplication.ID</code> is required.	N/A	This value must match a target server name that is registered in Credential Manager.

**TargetApplication.name**

The target application name on which the target account is hosted.

Required	Default Value	Valid Values
Either TargetServer.hostName, TargetApplication.name, and TargetApplication.name; or TargetApplication.ID is required.	N/A	This value must match a target application name that is registered in Credential Manager.

### **TargetAccount.userName**

The account user name that is associated with the target alias.

Required	Default Value	Valid Values
Either TargetServer.hostName, TargetApplication.name, and TargetApplication.name; or TargetApplication.ID is required.	N/A	This value must match a target account name that is registered in Credential Manager.

### **TargetAccount.ID**

The account ID associated with the target alias.

Required	Default Value	Valid Values
Either TargetServer.hostName, TargetApplication.name, and TargetApplication.name; or TargetApplication.ID is required.	N/A	Use searchTargetAccount to retrieve the TargetAccount.ID.

### **TargetAlias.name**

The name of this target alias.

Required	Default Value	Valid Values
yes	N/A	String. The target alias name must be unique within the Credential Manager server.

## **addTargetApplication**

Use the `addTargetApplication` command to add a target application to Credential Manager. More parameters may be required, depending upon the Target Application Type.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=addTargetApplication
```

```
TargetServer.hostName=myhostname.mydomain.com
```

```
TargetApplication.name=myApplication
```

```
TargetApplication.type=unixII Attribute.descriptor1="Vienna"
```

```
Attribute.descriptor2="Lab"
```

**Parameters****TargetServer.ID**

The ID of the target server on which the target application is hosted.

Required	Default Value	Valid Values
TargetServer.ID or TargetServer.hostName is required.	N/A	Use searchTargetServer to retrieve the TargetServer.ID.

**TargetServer.hostName**

The host name for the target server on which the target application resides.

Required	Default Value	Valid Values
TargetServer.ID or TargetServer.hostName is required.	N/A	This value must match a target server name that is registered in Credential Manager.

**TargetApplication.name**

The name of the target application.

Required	Default Value	Valid Values
yes	N/A	The target application name must be unique for a given target server.

**TargetApplication.type**

The target application connector name. Valid values depend upon which target connectors are installed on your system.

Required	Default Value	Valid Values
yes	N/A	Turnkey target connectors include: cisco, CiscoSSH, ldap, mssql, oracle, sybase, unixII (capitalize "i " twice after "unix "), unixAccountViaTelnet, windows, windowsDomainService . In addition, your system may contain custom target connectors.

**PasswordPolicy.name**

The name of the password policy that is associated with accounts belonging to this application.

Required	Default Value	Valid Values
no	null	If a password policy is not specified, manually entered passwords are not validated against a policy. In addition, Credential Manager generated passwords use the Credential Manager default password policy.

### **PasswordPolicy.ID**

The ID of the password policy that is associated with accounts belonging to this application.

Required	Default Value	Valid Values
no	null	Use <code>searchPasswordPolicy</code> to retrieve the <code>PasswordPolicy.ID</code> . If a password policy is not specified, manually entered passwords are not validated against a policy. In addition, Credential Manager generated passwords use the Credential Manager default password policy.

### **Attribute.descriptor1**

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String.

### **Attribute.descriptor2**

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String.

### **Attribute.enableAutoConnectTargetAccount**

A Boolean value to enable / disable `autoConnectTargetAccount` for an application instance.

Required	Default Value	Valid Values
no	false	true or false

## **addTargetServer**

Use the `addTargetServer` command to add a target server to Credential Manager.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=addTargetServer
TargetServer.hostName=myhostname.mydomain.com
```

```
Attribute.descriptor1="Lab" Attribute.descriptor2="Vienna"
```

## Parameters

### TargetServer.hostName

The host name for the target server.

Required	Default Value	Valid Values
yes	N/A	This must be the fully qualified host name as entered in the DNS server.

### TargetServer.deviceName

The device name for the target server.

Required	Default Value	Valid Values
no	Same as host name if not specified.	String

### Attribute.descriptor1

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String

### Attribute.descriptor2

A text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no	N/A	String

## addUser

Use the addUser command to add a Credential Manager user account. The Windows CLI allows up to nine parameters, including the mandatory adminUserID and cspmHostName. To enter the addUser command with more than nine parameters, use the batchSequence command with an XML formatted input file.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=addUser
User.userID=demo User.password="demo123$" User.authenticationType=CSPM

User.status=ACTIVE User.userGroupIDS=2 User.firstName=Demo User.lastName=User
User.email=jdoe@xceedium.com User.viewType=admin
```

**NOTE**

If you add a suspended user, then the user's deactivation reason is automatically set to **Other** in the UI.

**Parameters****User.userID**

The user name of the Credential Manager user.

Required	Default Value	Valid Values
yes	N/A	String.

**User.password**

The user's password.

Required	Default Value	Valid Values
This parameter is required if the authentication type is Privileged Access Manager Credential Manager.	N/A	String. Credential Manager passwords must contain 6-16 characters containing at least one alphabetic, one numeric, and one special character.

**User.authenticationType**

Authentication type of the user.

Required	Default Value	Valid Values
no	CSPM	CSPM, LDAP, SecurID, Kerberos, X509, or any installed authentication connector. See \$CSPM_SERVER_HOME/cspmserver/config/authentication.xml for a complete list of installed authentication connectors.

**User.status**

Set User.status=ACTIVE for active user accounts and User.Status=SUSPENDED to suspend a user account.

Required	Default Value	Valid Values
no	ACTIVE	ACTIVE or SUSPENDED

**User.userGroupIDS**

IDs of the User Groups to assign to this user.

Required	Default Value	Valid Values
no	null	Numeric IDs delimited by comma. Use searchUserGroups to retrieve user group IDs. Alternatively, you can specify the User.userGroupNames parameter. Values must match user groups that are registered in Credential Manager.

**User.userGroupNames**

Names of the User Groups to assign to this user.

Required	Default Value	Valid Values
no	null	String. A comma-delimited list of user group names.

**User.firstName**

First name of the user.

Required	Default Value	Valid Values
no	N/A	String.

**User.lastName**

Last name of the user.

Required	Default Value	Valid Values
no	N/A	String.

**User.email**

Email address of the user.

Required	Default Value	Valid Values
mandatory no	N/A	String.

**User.viewType**

Determines what GUI view this user has access to - administrative or general.

Required	Default Value	Valid Values
no	N/A	admin, general

**addUserGroup**

Use the addUserGroup command to add a credential group to Credential Manager.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=addUserGroup
  UserGroup.name=OttUserGroup UserGroup.description="Ottawa user group"
  UserGroup.roleID=11 UserGroup.groups=3,4
```

**Parameters****UserGroup.name**

The user group name.

Required	Default Value	Valid Values
yes	N/A	String. A unique Name in Credential Manager

### **UserGroup.description**

Description of the group.

Required	Default Value	Valid Values
no	N/A	String.

### **UserGroup.roleID**

The role identifier of this group.

Required	Default Value	Valid Values
yes	N/A	This value must match a role ID registered in Credential Manager.

### **UserGroup.groups**

An ArrayList of String values or a string ArrayList, each element containing a string value of a group ID.

Required	Default Value	Valid Values
no	true	N/A

#### **NOTE**

Each dynamic target group referenced in the listed group IDs *must have at least one* filter defined. If not, the group is not created.

### **UserGroup.readOnly**

The read-only flag for this user group. Warning, read-only cannot be deleted if you make a mistake.

Required	Default Value	Valid Values
no	false	true or false

## **archiveAuditData**

Use the `archiveAuditData` command to remove audit data up to the specified end date from the Credential Manager database and write it to a file.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=archiveAuditData
endDate=2018-11-01 storage=failover
```

**Parameters*****endDate***

All metric data up to and including the end date is removed from the Credential Manager database and stored in the archive file.

Required	Default Value	Valid Values
yes	N/A	YYYY-MM-DD

***storage***

Designate the mounted external storage for the archived data. This storage is either a primary or the failover storage that is established with the supported mount types. The external storage must be mounted and available for this command to succeed.

Required	Default Value	Valid Values
yes	N/A	Primary, Failover

***folder***

The name of the additional folder, or folders created at the root of the mounted external storage for the archived data.

Required	Default Value	Valid Values
no	blank	directory path

***fileName***

The file name (including the path) where the archive data is stored. If the file does not exist, it is created. Otherwise, data is appended. If not specified, this command creates a file in the external space that is indicated by the storage/folder parameters. The date stamp on the default file indicates the date/time when the archive command was issued, not the end archive date. `Hardware-id` is the Hardware ID found on the **Configuration, Licensing** page and the **System Info, Hardware Identifiers** page.

Required	Default Value	Valid Values
no	cspmserver_ <i>hardware-id</i> _auditlog_YYYY-MM-DD-HHMMSS	File path

***resultLimit***

The limit for the number of database records to be processed at a time. Set to -1 to specify no limit. **Caution:** A large value results in a larger rollback segment being allocated for each database transaction.

Required	Default Value	Valid Values
no	100	Integer

***compress***

Determine whether the archive results file should be compressed (gz file).

Required	Default Value	Valid Values
no	true	true, false

## archiveMetricData

Use the `archiveMetricData` command to remove metric data up to the specified end date from the Credential Manager database and write it to a file.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=archiveMetricData
  endDate=2018-01-01 storage=primary compress=false
```

### Parameters

#### *endDate*

All metric data up to and including the end date is removed from the Credential Manager database and stored in the archive file.

Required	Default Value	Valid Values
yes	N/A	YYYY-MM-DD

#### *storage*

Designate the mounted external storage for the archived data. This storage is either a primary or the failover storage that is established with the supported mount types. The external storage must be mounted and available for this command to succeed.

Required	Default Value	Valid Values
yes	N/A	Primary, Failover

#### *folder*

The name of the additional folder, or folders created at the root of the mounted external storage for the archived data.

Required	Default Value	Valid Values
no	blank	directory path

#### *fileName*

The file name (including the path) where the archive data is stored. If the file does not exist, it is created. Otherwise, data is appended. If not specified, this command creates a file in the external space that is indicated by the storage/folder parameters. The date stamp on the default file indicates the date/time when the archive command was issued, not the end archive date. `Hardware-id` is the Hardware ID found on the **Configuration, Licensing** page and the **System Info, Hardware Identifiers** page.

Required	Default Value	Valid Values
no	cspmserver_ <i>hardware-id</i> _metric_YYYY-M M-DD-HHMMSS	File path

#### *resultLimit*

The limit for the number of database records to be processed at a time. Set to -1 to specify no limit. **Caution:** A large value results in a larger rollback segment being allocated for each database transaction.

Required	Default Value	Valid Values
no	100	Integer

### ***compress***

Determine whether the archive results file should be compressed (gz file).

Required	Default Value	Valid Values
no	true	true, false

## **batchSequence**

Use the batchSequence command for bulk registration. The input to the batchSequence command is an XML formatted file.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=batchSequence
inputfile=myinput.xml outputfile=results.xml
```

## **Parameters**

### **inputfile**

The file containing the bulk registration input. The XML format for the input file is documented in [Credential Manager XML Schema for Batch Processing](#).

Required	Default Value	Valid Values
yes	N/A	String.

### **outputfile**

The file containing the XML formatted output result. If this parameter is not included, the output is sent to standard out.

Required	Default Value	Valid Values
no	standard output	String.

### **stopOnError**

Set stopOnError=true to indicate that the batch sequence is stopped when an error is encountered. Set stopOnError=false to indicate that the batch sequence continues with the next command when an error is encountered. If the data in the input file has dependencies, set stopOnError=true.

Required	Default Value	Valid Values
no	false	true, false

**multipleTransactions**

Set multipleTransactions=true to indicate that the batch sequence is treated as its own transaction. Set multipleTransactions=false to indicate that the batch sequence is treated as a single transaction. When the batch sequence is treated as a single transaction (multipleTransactions=false) the stopOnError is overridden to be true.

Required	Default Value	Valid Values
no	true	true, false

**canGetCredentials**

Use the canGetCredentials command to validate the ability of a specific script to retrieve credentials without making a credential request. This command does not verify the fingerprint of the request server or the requesting script hash. This command returns "Success 1" when the query result is true and "Success 0" when the query result is false.

Authorization mappings settings determine which values are validated. For example, if check execution ID is not set, then the execution ID parameter value does not affect the output result. The Windows CLI allows up to nine parameters, including mandatory adminUserID and cspmHostName. To invoke this command with more than nine parameters, use the batchSequence command with an XML formatted input file.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=canGetCredentials
  TargetAlias.name=myalias1 RequestScript.name=example.pl
```

```
RequestScript.filePath=/usr/tmp/examples RequestScript.executionPath=/usr/tmp/
examples Authorization.executionUser=admin
```

```
RequestServer.hostName=myhostname.mydomain.com RequestServer.osName=win
```

**Parameters****TargetAlias.name**

Alias name for which you want to validate the ability to get credentials.

Required	Default Value	Valid Values
yes	N/A	String

**RequestScript.name**

Name of the requesting script.

Required	Default Value	Valid Values
yes	N/A	String

**RequestScript.filePath**

File path where the requesting script resides.

Required	Default Value	Valid Values
no	N/A	String

### **RequestScript.executionPath**

Path from which the requesting script is run.

Required	Default Value	Valid Values
yes	N/A	String

### **Authorization.executionUser**

Username with which the requesting script will be run.

Required	Default Value	Valid Values
yes	N/A	String

### **RequestServer.hostName**

Request server hostname on which the requesting script is located.

Required	Default Value	Valid Values
yes	N/A	String

### **RequestServer.osName**

Operating System name for the request server host. Set this value if the Operating System is Windows. Any other value sets the Operating System as UNIX-based.

Required	Default Value	Valid Values
no	unix	win, unix

## **checkConnectionStatus**

Use the checkConnectionStatus command to check the status of a client.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=checkConnectionStatus
RequestServer.ID=1000
```

### **Parameter**

#### ***RequestServer.ID***

The ID of the target server being checked

Required	Default Value	Valid Values
Yes	N/A	integer

## checkDelete

Use the checkDelete command to determine if a target server or request server can be deleted or was previously deleted.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=checkDelete TargetServer.ID=1002
RequestServer.ID=1001
```

### Parameters

#### TargetServer.ID

The ID of the target server being checked

Required	Default Value	Valid Values
One or both of TargetServer.ID or RequestServer.ID is required	N/A	int.

#### RequestServer.ID

The ID of the request server being checked

Required	Default Value	Valid Values
One or both of TargetServer.ID or RequestServer.ID is required	N/A	int.

## checkInAccountPassword

Use the checkInAccountPassword command to check in a target account. This command can be run on a secondary site.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=checkInAccountPassword TargetAccount.ID=1
```

### Parameter

#### TargetAccount.ID

The user name for the target account.

Required	Default Value	Valid Values
yes	N/A	Integer. Identity of the target account.

## deleteAuthorization

Use the deleteAuthorization command to delete an existing authorization mapping.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteAuthorization
RequestServer.hostName=myhostname.mydomain.com RequestScript.name=example.pl
RequestScript.executionPath=/usr/tmp/examples TargetAlias.name=mytargetalias
```

**Parameters****Authorization.ID**

The unique identifier of the Authorization mapping.

Required	Default Value	Valid Values
TargetAlias.name, RequestServer.hostName, RequestScript.name, and RequestScript.executionPath or Authorization.ID is required.	N/A	Use searchAuthorization to retrieve the Authorization.ID.

**TargetAlias.name**

The target alias name.

Required	Default Value	Valid Values
Either TargetAlias.name or Authorization.targetGroupName is required	N/A	This value must match the target alias name that is registered in Credential Manager.

**RequestServer.hostName**

The request server host name on which the requesting application resides.

Required	Default Value	Valid Values
One of Authorization.requestGroupName, RequestServer.hostName, or RequestServer.hostName/ RequestScript.name/ RequestScript.executionPath	N/A	This value must match the request server name that is registered in Credential Manager.

**RequestScript.name**

The requesting application name.

Required	Default Value	Valid Values
One of Authorization.requestGroupName, RequestServer.hostName, or RequestServer.hostName/ RequestScript.name/ RequestScript.executionPath	N/A	This value must match the script name that is registered in Credential Manager.

**RequestScript.executionPath**

The requesting application execution path, as registered in Credential Manager.

Required	Default Value	Valid Values
One of Authorization.requestGroupName, RequestServer.hostName, or RequestServer.hostName/RequestScript.name/RequestScript.executionPath	N/A	This value must match the script execution path registered in Credential Manager.

### **Authorization.targetGroupName**

The target group name.

Required	Default Value	Valid Values
TargetAlias.name or Authorization.targetGroupName is required	N/A	This value must match the target group name that is registered in Credential Manager.

### **Authorization.requestGroupName**

The request group name.

Required	Default Value	Valid Values
One of Authorization.requestGroupName, RequestServer.hostName, or RequestServer.hostName/RequestScript.name/RequestScript.executionPath	N/A	This value must match the request group name that is registered in Credential Manager.

## **deleteFilter**

Use the deleteFilter command to delete a filter from a target group or request group. The group must first be added using the addGroup command.

### **Example**

```
capapm_command capam=capamServer adminUserID=admin cmdName=deleteFilter
Filter.ID=6
```

## **Parameters**

### **Filter.ID**

The Id of the request or target group

Required	Default Value	Valid Values
yes	N/A	N/A

## deleteGroup

Use the deleteGroup command to delete a target or request group. This command automatically deletes filters associated with this group.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteGroup Group.ID=3
```

### Parameters

#### Group.ID

ID of the group you wish to delete.

Required	Default Value	Valid Values
One of Group.name or Group.ID is required.	N/A	Numeric. This value must match the group ID registered in Credential Manager.

#### Group.name

The group name.

Required	Default Value	Valid Values
One of Group.name or Group.ID is required.	N/A	String. This value must match the group name registered in Credential Manager.

#### Group.type

The group type.

Required	Default Value	Valid Values
Optional unless Group.name is specified, and that value is not unique.	N/A	String. This value must match the group type registered in Credential Manager.

## deletePasswordPolicy

Use the deletePasswordPolicy command to delete a password policy.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=deletePasswordPolicy
PasswordPolicy.name=passwordPolicyName
```

### Parameters

#### PasswordPolicy.ID

The ID of the password policy.

Required	Default Value	Valid Values
yes or PasswordPolicy.name	null	Numeric

#### PasswordPolicy.name

The name of the password policy.

Required	Default Value	Valid Values
yes or PasswordPolicy.ID	null	String

## deletePasswordViewPolicy

Use the deletePasswordViewPolicy command to delete a password view policy from Privileged Access Manager Credential Manager.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=deletePasswordViewPolicy
PasswordViewPolicy.name=restrictedAccounts
```

### Parameters

#### PasswordViewPolicy.ID

The ID of the password view policy.

Required	Default Value	Valid Values
One of PasswordViewPolicy.ID or PasswordViewPolicy.name is required	N/A	The ID of a password view policy in Credential Manager. Use searchPasswordViewPolicy to retrieve the PasswordViewPolicy.ID.

#### PasswordViewPolicy.name

The name of the password view policy.

Required	Default Value	Valid Values
One of PasswordViewPolicy.ID or PasswordViewPolicy.name is required	N/A	A text string matching the name of a password view policy in Credential Manager.

## deletePasswordViewRequest

Use the deletePasswordViewRequest command to delete either a specific password view request or all expired password view requests

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=deletePasswordViewRequest
PasswordViewRequest.ID=1,2,3
```

### Parameters

#### PasswordViewRequest.ID

The ID of a password view request. Allow to input in comma separated format, such as, id2,id3,id5 etc

Required	Default Value	Valid Values
no	N/A	passwordviewrequestid from PasswordViewRequest table

## **deleteRequestScript**

Use the deleteRequestScript command to delete an existing requesting application. Requesting applications cannot be deleted if there is an authorization mappings associated with the application.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteRequestScript RequestScript.ID=7,8
```

## **Parameters**

### **RequestScript.ID**

The requesting application ID you wish to delete. This parameter may contain a comma separate list.

Required	Default Value	Valid Values
Either RequestScript.ID; or RequestServer.hostName, RequestScript.name, and RequestScript.executionPath is required.	N/A	Use searchRequestScript to retrieve the RequestScript.ID.

### **RequestServer.hostName**

The request server host name on which the requesting application resides.

Required	Default Value	Valid Values
Either RequestScript.ID; or RequestServer.hostName, RequestScript.name, and RequestScript.executionPath is required.	N/A	This value must match the request server name registered in Credential Manager.

### **RequestScript.name**

The requesting application name.

Required	Default Value	Valid Values
Either RequestScript.ID; or RequestServer.hostName, RequestScript.name, and RequestScript.executionPath is required.	N/A	String.

### **RequestScript.executionPath**

The location from which the requesting application will be executed.

Required	Default Value	Valid Values
Either RequestScript.ID; or RequestServer.hostName, RequestScript.name, and RequestScript.executionPath is required.	N/A	String.

## deleteRequestServer

Use the deleteRequestServer command to delete an existing request server from Credential Manager. You cannot delete a request server if there are any authorization mappings or request scripts associated with the request server.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteRequestServer
RequestServer.hostName=myhostname.mydomain.com
```

### Parameters

#### RequestServer.hostName

The host name of the request server.

Required	Default Value	Valid Values
RequestServer.hostName, RequestServer.hostName, or RequestServer.ID is required.	N/A	This value must match a request server name registered in Credential Manager.

#### RequestServer.deviceName

The device name of the request server.

Required	Default Value	Valid Values
RequestServer.hostName, RequestServer.hostName, or RequestServer.ID is required.	N/A	This value must match a request server name registered in Credential Manager.

#### RequestServer.ID: The unique ID for the request server.

Required	Default Value	Valid Values
RequestServer.hostName, RequestServer.hostName, or RequestServer.ID is required.	N/A	Use searchRequestServer to retrieve the RequestServer.ID.

## deleteRequestServerDefaults

Use the deleteRequestServerDefaults command to delete a request server defaults in Credential Manager.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteRequestServerDefaults
RequestServerDefaults.ID=1001
```

**Parameters****RequestServerDefaults.ID**

The id of the record to delete.

Required	Default Value	Valid Values
yes	N/A	Integer

**deleteRole**

Use the deleteRole command to delete roles from Credential Manager.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteRole Role.ID=11
```

**Parameters****Role.ID**

The unique ID of the role or a comma delimited list of roles you wish to delete.

Required	Default Value	Valid Values
yes	N/A	Numeric.

**deleteSSHKeyPairPolicy**

Use the deleteSSHKeyPairPolicy command to delete an SSH Key Pair policy.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteSSHKeyPairPolicy
SSHKeyPairPolicy.name=MySSHKeyPairPolicy
```

**Parameters****SSHKeyPairPolicy.ID**

The ID of the SSH Key Pair policy.

Required	Default Value	Valid Values
Yes if SSHKeyPairPolicy.name is not specified	N/A	Numeric or a String of comma-separated numeric values

**SSHKeyPairPolicy.name**

The name of the SSH Key Pair policy.

Required	Default Value	Valid Values
Yes if SSHKeyPairPolicy.ID is not specified	N/A	String

## deleteSystemProperty

Use the deleteSystemProperty command to delete a system property (that is, set isDeleted = 1).

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteSystemProperty propertyName=test
```

### Parameters

#### propertyName

The property key name.

Required	Default Value	Valid Values
yes	N/A	A valid value is one that exists in the system properties table.

## deleteTargetAccount

Use the deleteTargetAccount command to delete an existing target account from Credential Manager. Target accounts cannot be deleted if there is an authorization mapping associated with the account. Deleting a target account automatically deletes any target aliases associated with the account.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteTargetAccount
  TargetServer.hostName=myhostname.mydomain.com

  TargetApplication.name=myApplication TargetAccount.userName=sysopl
```

### Parameters

#### TargetServer.hostName

The host name of the target server on which the target application is hosted.

Required	Default Value	Valid Values
Either TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID is required.	N/A	This value must match a target server name registered in Credential Manager.

#### TargetApplication.name

The target application name on which the target account is hosted.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID is required.	N/A	This value must match a target application name registered in Credential Manager.

**TargetAccount.userName**

The user name for the target account.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID is required.	N/A	This value must match a target account name registered in Credential Manager.

**TargetAccount.ID**

The ID for the target account.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID is required.	N/A	Use searchTargetAccount to retrieve the TargetAccount.ID.

**deleteTargetAlias**

Use the deleteTargetAlias command to delete an existing target alias from the Credential Manager server. Target aliases cannot be deleted if there is an authorization mapping associated with the alias.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteTargetAlias TargetAlias.ID=12
```

**Parameters****TargetAlias.name**

The target alias name. This parameter is required if TargetAlias.ID is not specified.

Required	Default Value	Valid Values
TargetAlias.name or TargetAlias.ID is required.	N/A	The target alias name must match a target alias registered in Credential Manager.

**TargetAlias.ID**

The target alias unique identifier.

Required	Default Value	Valid Values
TargetAlias.name or TargetAlias.ID is required.	N/A	Use searchTargetAlias to retrieve the TargetAlias.ID.

**deleteTargetApplication**

Use the deleteTargetApplication command to delete an existing target application from Credential Manager. Target applications cannot be deleted if there is an authorization mapping associated with the application. Deleting a target application automatically deletes any target accounts and target aliases associated with the application.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteTargetApplication
TargetServer.hostName=myhostname.mydomain.com TargetApplication.name=myApplication
```

**Parameters****TargetServer.hostName**

The host name of the target server on which the target application is hosted.

Required	Default Value	Valid Values
TargetServer.hostName and TargetApplication.name; or TargetApplication.ID is required.	N/A	This value must match a target server name registered in Credential Manager.

**TargetApplication.name**

The target application name.

Required	Default Value	Valid Values
TargetServer.hostName and TargetApplication.name; or TargetApplication.ID is required.	N/A	This value must match a target application name registered in Credential Manager.

**TargetApplication.ID**

The target application ID.

Required	Default Value	Valid Values
TargetServer.hostName and TargetApplication.name; or TargetApplication.ID is required.	N/A	Use searchTargetApplication to retrieve the TargetApplication.ID.

**deleteTargetServer**

Use the deleteTargetServer command to delete an existing target server from Credential Manager. A target server cannot be deleted if there is a target alias associated with the server. Deleting a target server automatically deletes any target applications and target accounts associated with the server, never any aliases.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteTargetServer
TargetServer.hostName=myhostname.mydomain.com
```

**Parameters****TargetServer.ID**

The ID for the target server, or a comma-separated list of IDs.

Required	Default Value	Valid Values
TargetServer.ID, TargetServer.hostName, or TargetServer.deviceName is required.	N/A	Use searchTargetServer to retrieve the TargetServer.ID.

**TargetServer.hostName**

The host name of the target server.

Required	Default Value	Valid Values
TargetServer.ID, TargetServer.hostName, or TargetServer.deviceName is required.	N/A	String. This value must match a target server name registered in Credential Manager.

**TargetServer.deviceName**

The device name of the target server.

Required	Default Value	Valid Values
TargetServer.ID, TargetServer.hostName, or TargetServer.deviceName is required.	N/A	String. This value must match a target server name registered in Credential Manager.

**deleteUser**

Use the deleteUser command to delete a user account or list of user accounts.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteUser User.userID=demo
```

**Parameters****User.userID**

The user name of the Credential Manager user to be deleted or a comma delimited list of user names to be deleted.

Required	Default Value	Valid Values
yes	N/A	String

**deleteUserGroup**

Use the deleteUserGroup command to delete a user group.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=deleteUserGroup UserGroup.ID=18
```

**Parameters****UserGroup.ID**

The user group ID or a comma delimited list of user group IDs you wish to delete.

Required	Default Value	Valid Values
UserGroup.ID or UserGroup.name is required.	N/A	Numeric. A unique user group ID in Credential Manager.

**UserGroup.name**

The name of the user group.

Required	Default Value	Valid Values
UserGroup.ID or UserGroup.name is required.	N/A	String. A unique user group name in Credential Manager.

## disableCLIHostNameCheck

Use the disableCLIHostNameCheck command to disable host name checking when connecting via the CLI.

### Example

```
capam_command capam=capamServer adminUserID=admin
cmdName=disableCLIHostNameCheck
```

## disableFingerprinting

Use the disableFingerprinting command to disable hardware fingerprinting for request servers (Credential Manager clients). This command has no parameters. By default, this feature is disabled.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=disableFingerprinting
```

## enableCLIHostNameCheck

Use the enableCLIHostNameCheck command to force host name checking when connecting via the CLI.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=enableCLIHostNameCheck
```

## enableFingerprinting

Use the enableFingerprinting command to enable hardware fingerprinting for request servers (Credential Manager clients). This command has no parameters. By default, this feature is disabled.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=enableFingerprinting
```

## enableLicense

Use the enableLicense command to activate your Credential Manager server license.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=enableLicense license=dae1993ace1473a...
```

## Parameter

### license

A Credential Manager server license string. See your CA Technologies sales representative.

Required	Default Value	Valid Values
yes	N/A	String

## expirePasswordViewRequest

Use the expirePasswordViewRequest command to expires a password view request.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=expirePasswordViewRequest
PasswordViewRequest.ID=1000
```

### Parameter

#### PasswordViewRequest.ID

The ID of the password view request.

Required	Default Value	Valid Values
yes	N/A	Numeric vaue

## forceCheckInAccountPassword

Use the forceCheckInAccountPassword command to check in a target account checked out by another user. This command can be run on a secondary site.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=forceCheckInAccountPassword
TargetAccount.ID=1
```

### Parameters

#### TargetAccount.ID

The ID of the target account you are checking in.

Required	Default Value	Valid Values
TargetAccount.ID or PasswordViewRequest.ID must be specified.	N/A	Use searchTargetAccount to retrieve the TargetAccount.ID.

#### PasswordViewRequest.ID

The ID of the target account you are checking in.

Required	Default Value	Valid Values
TargetAccount.ID or PasswordViewRequest.ID must be specified.	N/A	Use searchPasswordViewRequest or searchPasswordViewRequestByRequestor to retrieve the PasswordViewRequest.ID.

## generateEncryptedPassword

Use the `generateEncryptedPassword` command to encrypt the password found in Tomcat `server.xml`.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=generateEncryptedPassword
password=cspmpublic
```

### Parameters

#### password

The password that you want to encrypt.

Required	Default Value	Valid Values
yes	N/A	Any string

## getAllScriptHash

Use the `getAllScriptHash` command to refresh each of the script hashes for a given request server. A script hash value is a SHA-1 message digest value of the script (file).

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=getAllScriptHash
RequestServer.hostName=myhostname.mydomain.com
```

### Parameters

#### RequestServer.hostName

The host name of the request server.

Required	Default Value	Valid Values
RequestServer.hostName or RequestServer.ID is required.	N/A	String

#### RequestServer.ID

The ID of the request server.

Required	Default Value	Valid Values
RequestServer.hostName or RequestServer.ID is required.	N/A	Use <code>searchRequestServer</code> to retrieve the RequestServer.ID

## getAwsManagementConsoleSessionUrl

Use the `getAwsManagementConsoleSessionUrl` command to retrieve a URL to an authenticated Amazon Web Services Management Console federation session.

### Example

```
capam_command capam=capamServer adminUserID=admin
cmdName=getAwsManagementConsoleSessionUrl AWS.accessKeyID=AKIAIUHQMBKFCROZL5NQ
```

```
AWS.secretAccessKey=l2YaoK/or4Jffi+XTlCds0x5mLUdRoCTcvXb/e9y
AWS.consoleUrl=https://console.aws.amazon.com/sns
```

```
AWS.issuerUrl=https://www.xceedium.com/ AWS.signinUrl=https://
signin.aws.amazon.com/federation
```

```
AWS.sessionDuration=3600 AWS.policy={\"Statement\": [{\"Action\": \"sns:*\",
\\\"Effect\": \"Allow\", \"Resource\": \"*\"]}}
```

## Parameters

### **AWS.accessKeyID**

The AWS access key.

Required	Default Value	Valid Values
yes	N/A	^[A-Z0-9]{20}\$

### **AWS.secretAccessKey**

The AWS secret access key.

Required	Default Value	Valid Values
yes	N/A	^[a-zA-Z0-9]{40}\$

### **AWS.issuerUrl**

The URL to which the user should be redirected when their federation session expires.

Required	Default Value	Valid Values
yes	N/A	https://[a-zA-Z0-9]{1,256}([a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256})?([a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256})?([a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256})?

### **AWS.consoleUrl**

The URL of the Management Console.

Required	Default Value	Valid Values
yes	N/A	https://[a-zA-Z0-9]{1,256}([a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256})?([a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256})?([a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256} \.[a-zA-Z0-9]{1,256})?

### **AWS.signinUrl**

The URL of the AWS federated signin service.

Required	Default Value	Valid Values
yes	N/A	https:\V[0-9a-zA-Z]([-\.\w]*[0-9a-zA-Z])*(:(0-9)*)*(V?)([a-zA-Z0-9\-\.\?\\'\ /]+\&#38;\\$#\_)*?

### **AWS.policy**

A policy that applies to the federated user.

Required	Default Value	Valid Values
no	N/A	String

### **AWS.stsEndpoint**

The STS endpoint to use if specified; otherwise, use the default endpoint.

Required	Default Value	Valid Values
no	N/A	String

### **AWS.sessionDuration**

The duration, in seconds, that the federation session should last. Acceptable durations are in the interval [3600 .. 129600].

Required	Default Value	Valid Values
yes	N/A	Integer

### **AWS.urlEncodeOption**

Optionally encode the session URL.

Required	Default Value	Valid Values
no	false	Boolean

### **AWS.federatedUserName**

The name of the federated user to display in the AWS Management Console.

Required	Default Value	Valid Values
yes	N/A	String

## **getErrorCodes**

Use the getErrorCodes command to retrieve an XML list of Credential Manager error codes. This command takes no parameters.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=getErrorCodes
```

## getEventProcessingMetrics

Use the getEventProcessingMetrics command to get metrics for processing of notification events (events sent to clients or proxies). This information can determine the throughput of the overall Credential Manager system in processing events sent to clients and proxies. If you determine that the throughput is not high enough, you can deploy additional Credential Manager servers.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=getEventProcessingMetrics
samplePeriodMinutes=720
```

### Parameters

#### samplePeriodMinutes

Sample period in minutes.

Required	Default Value	Valid Values
no	1440	1 through 1440

## getLocalProperty

Use the getLocalProperty command to retrieve the property value which matches the property name.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=getLocalProperty propertyName=sitename
```

### Parameters

#### propertyName

The property key name.

Required	Default Value	Valid Values
yes	N/A	A valid value is one that exist in the local properties table.

## getMostRecentPasswordHistory

Use the getMostRecentPasswordHistory command to retrieve the most recent password history for a target account.

### Example

```
capam_command capam=capamServer adminUserID=admin
cmdName=getMostRecentPasswordHistory TargetAccount.ID=100
```

### Parameter

#### TargetAccount.ID

The ID of the Target Account.

Required	Default Value	Valid Values
yes	N/A	Use searchTargetAccount to retrieve the TargetAccount.ID

## getMSOLFederatedSessionCmd

Use the getMSOLFederatedSessionCmd command to retrieve a federated session request sent to the Microsoft Online (MSOL) portal. The request is returned as a web form that is automatically submitted by the browser. Submitting the form launches a federated session with MSOL.

### Example

```
capam_command capam=capamServer adminUserID=super adminPassword=<PASSWORD>
cmdName=getMsolFederatedSession
```

```
MSOL.portalUrl=https%3A//login.microsoftonline.com/login.srf
MSOL.stsEndpointUrl=https%3A//fs.xcdpoc.com/adfs/services/trust/2005/
usernamemixed
```

```
MSOL.stsEndpointReferenceUri=urn%3Afederation%3AMicrosoftOnline MSOL.wctx=MEST
%3D0%26LoginOptions%3D2%26wa%3Dwsignin1.0%26rpsnv%3D2%26ct%3D1361461138%26rver
%3D6.1.6206.0%26wp%3DMCMBI%26wreply
```

```
%3Dhttps:%252F%252Fportal.microsoftonline.com%252Flanding.aspx%253Ftarget%253D
%25252fdefault.aspx%26lc%3D1033%26id%3D271346%26
TargetAccount.ID=100
```

## Parameters

### MSOL.stsEndpointUrl

The URL of the Security Token Service (STS) endpoint from which the security token shall be requested. In general, specify the appropriate URL that is exposed by your Active Directory Federation Service (ADFS). The endpoint must support the WS-Trust 2005 (username mixed mode) protocol. For example, https://<ADFS-HOST>/adfs/services/trust/2005/usernamemixed.

Required	Default Value	Valid Values
yes	N/A	URL

### MSOL.stsEndpointReferenceUri

The reference URI to which the security token request applies. When ADFS is federated with MSOL, this value is typically "urn:federation:MicrosoftOnline" (without quotes).

Required	Default Value	Valid Values
yes	N/A	URI

**MSOL.portalUrl**

The URL of the MSOL portal. For example, <https://login.microsoftonline.com/login.srf>.

Required	Default Value	Valid Values
yes	N/A	URL

**MSOL.wctx**

This parameter contains context information that is relevant to MSOL. The value is derived by following the procedure for creating a smart link, which is described in Microsoft documentation. For additional instructions, please refer to <http://community.office365.com/en-us/wikis/sso/using-smart-links-or-idp-initiated-authentication-with-office-365.aspx>.

Required	Default Value	Valid Values
yes	N/A	String

**TargetAccount.ID**

The ID of the Target Account that represents the federated user's credentials. The username and password will be retrieved and sent to ADFS in a security token request. If ADFS successfully authenticates the credentials then it will issue a security token response that contains SAML assertions that are good for authenticating the federated user to MSOL.

Required	Default Value	Valid Values
yes	N/A	Use searchTargetAccount to retrieve the TargetAccount.ID

**reason**

The reason you are requesting a password view.

Required	Default Value	Valid Values
yes	N/A	String.

**reasonDetails**

Detailed description of why you wish to view the password.

Required	Default Value	Valid Values
no	N/A	String

**PasswordViewRequest.requestPeriodStart**

If the account password view policy has dual authorization enabled, this parameter specifies the start time of the password view request.

Required	Default Value	Valid Values
no	N/A	Date string, of the format yyyy-MM-dd HH:mm

**PasswordViewRequest.requestPeriodEnd**

If the account password view policy has dual authorization enabled, this parameter specifies the end time of the password view request.

Required	Default Value	Valid Values
no	N/A	Date string, of the format yyyy-MM-dd HH:mm

### **referenceCode**

Displays the reference code.

Required	Default Value	Valid Values
no	N/A	String

## **getNumberOfAccounts**

Use the getNumberOfAccounts command to retrieve the number of target accounts registered in Credential Manager. This command takes no parameters.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=getNumberOfAccounts
```

## **getRequestServerDefaults**

Use the getRequestServerDefaults command to add a request server defaults to Credential Manager.

### **Example**

```
capam_command capam=capamServer adminUserID=admin  
cmdName=getRequestServerDefaults RequestServerDefaults.ID=1001
```

### **Parameters**

#### **RequestServerDefaults.ID**

The id of the record to get.

Required	Default Value	Valid Values
yes	N/A	Integer

## **getScriptHashAsynchronous**

Use the getScriptHashAsynchronous command to refresh a script hash for a specified request script on a request server (Credential Manager client). A script hash value is a SHA-1 message digest value of the script.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=getScriptHashAsynchronous RequestScript.ID=2
```

### **Parameters**

#### **RequestScript.ID**

The unique ID for the request script.

Required	Default Value	Valid Values
yes	N/A	Numeric. Use searchRequestScript to retrieve the RequestScript.ID

### **getServiceStatus**

Use the getServiceStatus command to inquire the state of services associated with a Windows domain target account. This command assumes the service information is stored in an extend attribute named 'serviceInfo'.

#### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=getServiceStatus
TargetAccount.ID=24
```

### **Parameters**

#### **TargetAccount.ID**

The ID of the TargetAccount

Required	Default Value	Valid Values
Either TargetAccount.ID or TargetServer.hostName, TargetApplication.name and TargetAccount.userName is required.	N/A	integer

#### **TargetServer.hostName**

The host name of the TargetServer

Required	Default Value	Valid Values
Either TargetAccount.ID or TargetServer.hostName, TargetApplication.name and TargetAccount.userName is required.	N/A	String

#### **TargetApplication.name**

The name of the TargetApplication

Required	Default Value	Valid Values
Either TargetAccount.ID or TargetServer.hostName, TargetApplication.name and TargetAccount.userName is required.	N/A	String

### **TargetAccount.userName**

The user name of the TargetAccount

Required	Default Value	Valid Values
Either TargetAccount.ID or TargetServer.hostName, TargetApplication.name, TargetAccount.userName is required.	N/A	String

## **getSystemProperty**

Use the getSystemProperty to retrieve the property value which matches the property name.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=getSystemProperty
propertyName=DBVersion
```

### **Parameters**

#### **propertyName**

The property key name.

Required	Default Value	Valid Values
yes	N/A	A valid value is one that exists in the system properties table.

## **listCurrentPasswordViewRequestSummary**

Use the listCurrentPasswordViewRequestSummary command to list password view requests that are presently in force for the user executing the command.

Use the listCurrentPasswordViewRequestSummary command to list password view requests that are presently in force for the user executing the command (as an approver or a requester).

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=listCurrentPasswordViewRequestSummary
PasswordViewRequest.status="approved"
```

**Parameters**

You can use the following parameters with the `listCurrentPasswordViewRequestSummary` command.

**TIP**

Any parameter that contains a space must be enclosed between quotation marks.

***PasswordViewRequest.targetAccountID***

Filter results for the specified `targetAccountID`.

Required	Default Value	Valid Values
no	N/A	Integer

***PasswordViewRequest.targetAccountUserName***

Filter results for the specified `targetAccountUserName`.

Required	Default Value	Valid Values
no	N/A	String

***PasswordViewRequest.status***

Filter results that contain the value that is specified.

Required	Default Value	Valid Values
no	N/A	<b>Dual authorization:</b> "approved" (or 1), "denied" (or 2), "pending" (or 3), "expiredapproved" (or 6), expiredpending (or 8) <b>Retrospective approval:</b> "acknowledged" (or 9), "declined" (or 10), "retrospectivePending" (or 11) <b>Checkin/checkout:</b> "checkout" (or 4), "checkedin" (or 5)

***PasswordViewRequest.ssoType***

If specified with the value "Any", list only current password view requests made to use the password for access. Otherwise, list all current password view requests.

Required	Default Value	Valid Values
no	Null (no value specified)	"Any"

***Page.Number***

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

***Page.Size***

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

### ***Sort.Property***

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	PasswordViewRequest.status	PasswordViewRequest.status, PasswordViewRequest.requestorID, PasswordViewRequest.approverID, PasswordViewRequest.targetAccountID

### ***Sort.Direction***

Sort.Direction specifies the order of the results. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	desc	asc, desc

## **listDBClusterMembers**

Use the listDBClusterMembers command to retrieve a list of all database cluster members in the system.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=listDBClusterMembers
```

## **listPasswordViewRequestByAccount**

Use the listPasswordViewRequestByAccount command to return a list of password view requests for a particular account.

### **Examples**

```
capam_command capam=capamServer adminUserID=admin
adminPassword=Myp@ss cmdName=listPasswordViewRequestByAccount
PasswordViewRequest.targetAccountID=1005
```

### **Parameters**

You can use the following parameters with the searchPasswordViewRequest command.

#### **TIP**

Any parameter that contains a space must be enclosed between quotation marks.

### ***PasswordViewRequest.ID***

Filter results for specified ID

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.requestorID***

Filter results for specified requestorID

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.requestorNameID***

Filter results for specified requestorNameID

Required	Default Value	Valid Values
no	N/A	String

### ***PasswordViewRequest.approverID***

Filter results for specified approverID

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.status***

Filter results that contain the value that is specified.

Required	Default Value	Valid Values
no	N/A	<b>Dual authorization:</b> "approved" (or 1), "denied" (or 2), "pending" (or 3), "expiredapproved" (or 6), expiredpending (or 8) <b>Retrospective approval:</b> "acknowledged" (or 9), "declined" (or 10), "retrospectivePending" (or 11) <b>Checked in or checked out:</b> "checkout" (or 4), "checkedin" (or 5)

### ***PasswordViewRequest.targetAccountID***

Filter results for specified target account ID.

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.isCheckedOut***

Filter results for accounts that are checked out.

Required	Default Value	Valid Values
no	N/A	"true" or "false"

### ***PasswordViewRequest.ssoType***

Filter results by the specified SSO type.

Required	Default Value	Valid Values
no	N/A	"Browser", "RDP", "SSH", "VNC", "AWSAPI", "Telnet", "Other"

### ***Page.Number***

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

### ***Page.Size***

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

### ***Sort.Property***

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	PasswordViewRequest.status	PasswordViewRequest.status, PasswordViewRequest.requestorID, PasswordViewRequest.approverID, PasswordViewRequest.targetAccountID

### ***Sort.Direction***

Sort.Direction specifies the order of the results. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	desc	asc, desc

## **listPasswordViewRequestByApproverSummary**

Use the listPasswordViewRequestByApproverSummary command to return a list of password view requests for which you are an approver.

## Example

```
capam_command capam=capamServer adminUserID=admin
cmdName=listPasswordViewRequestByApproverSummary
```

## Parameters

You can use the following parameters with the searchPasswordViewRequest command.

### TIP

Any parameter that contains a space must be enclosed between quotation marks.

### ***PasswordViewRequest.ID***

Filter results for specified ID

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.requestorID***

Filter results for specified requestorID

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.requestorNameID***

Filter results for specified requestorNameID

Required	Default Value	Valid Values
no	N/A	String

### ***PasswordViewRequest.approverID***

Filter results for specified approverID

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.status***

Filter results that contain the value that is specified.

Required	Default Value	Valid Values
no	N/A	<b>Dual authorization:</b> "approved" (or 1), "denied" (or 2), "pending" (or 3), "expiredapproved" (or 6), expiredpending (or 8) <b>Retrospective approval:</b> "acknowledged" (or 9), "declined" (or 10), "retrospectivePending" (or 11) <b>Checked in/checkout:</b> "checkout" (or 4), "checkedin" (or 5)

#### ***PasswordViewRequest.targetAccountID***

Filter results for specified target account ID.

Required	Default Value	Valid Values
no	N/A	Integer

#### ***PasswordViewRequest.targetAccountUserName***

Filter results for specified target account user name.

Required	Default Value	Valid Values
no	N/A	String

#### ***PasswordViewRequest.ssoType***

Filter results the specified SSO type.

Required	Default Value	Valid Values
no	N/A	"Browser", "RDP", "SSH", "VNC", "AWSAPI", "Telnet", "Other"

#### ***Page.Number***

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

#### ***Page.Size***

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

#### ***Sort.Property***

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	PasswordViewRequest.status	PasswordViewRequest.status, PasswordViewRequest.requestorID, PasswordViewRequest.approverID, PasswordViewRequest.targetAccountID

### **Sort.Direction**

Sort.Direction specifies the order of the results. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	desc	asc, desc

## **listPasswordViewRequestByRequestorSummary**

Use the listPasswordViewRequestByRequestorSummary command to return a list of password view requests for which you are an approver.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=listPasswordViewRequestByRequestorSummary
```

### **Parameters**

You can use the following parameters with the searchPasswordViewRequest command.

#### **TIP**

Any parameter that contains a space must be enclosed between quotation marks.

### **PasswordViewRequest.ID**

Filter results for specified ID.

Required	Default Value	Valid Values
no	N/A	Integer

### **PasswordViewRequest.approverID**

Filter results for specified approverID.

Required	Default Value	Valid Values
no	N/A	Integer

### **PasswordViewRequest.approverNameID**

Filter results for specified approverNameID (for approved password view requests).

Required	Default Value	Valid Values
no	N/A	String

**PasswordViewRequest.status**

Filter results that contain the value that is specified.

Required	Default Value	Valid Values
no	N/A	<b>Dual authorization:</b> "approved" (or 1), "denied" (or 2), "pending" (or 3), "expiredapproved" (or 6), expiredpending (or 8) <b>Retrospective approval:</b> "acknowledged" (or 9), "declined" (or 10), "retrospectivePending" (or 11) <b>Checked in or checked out:</b> "checkout" (or 4), "checkedin" (or 5)

**PasswordViewRequest.targetAccountID**

Filter results for specified target account ID (for approved password view requests).

Required	Default Value	Valid Values
no	N/A	Integer

**PasswordViewRequest.targetAccountUserName**

Filter results for the specified target account user name.

Required	Default Value	Valid Values
no	N/A	String

**PasswordViewRequest.policyApproverID**

Filter results for the specified policy approver ID (for unapproved password view requests).

Required	Default Value	Valid Values
no	N/A	Integer

**PasswordViewRequest.ssoType**

Filter results for specified SSO type.

Required	Default Value	Valid Values
no	N/A	"Browser", "RDP", "SSH", "VNC", "AWSAPI", "Telnet", "Other"

**Page.Number**

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

**Page.Size**

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

### ***Sort.Property***

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	PasswordViewRequest.status	PasswordViewRequest.status, PasswordViewRequest.requestorID, PasswordViewRequest.approverID, PasswordViewRequest.targetAccountID

### ***Sort.Direction***

Sort.Direction specifies the order of the results. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	desc	asc, desc

## **listPasswordViewRequestSummary**

Use the listPasswordViewRequestSummary command to return a list of password view requests.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=listPasswordViewRequestSummary
```

### **Parameters**

You can use the following parameters with the searchPasswordViewRequest command.

#### **TIP**

Any parameter that contains a space must be enclosed between quotation marks.

### ***PasswordViewRequest.requestorID***

Filter results for specified requestorID

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.requestorNameID***

Filter results for specified requestorNameID

Required	Default Value	Valid Values
no	N/A	String

**PasswordViewRequest.approverID**

Filter results for specified approverID

Required	Default Value	Valid Values
no	N/A	Integer

**PasswordViewRequest.approverNameID**

Filter results for specified approverNameID (for approved password view requests).

Required	Default Value	Valid Values
no	N/A	String

**PasswordViewRequest.status**

Filter results that contain the value that is specified.

Required	Default Value	Valid Values
no	N/A	<b>Dual authorization:</b> "approved" (or 1), "denied" (or 2), "pending" (or 3), "expiredapproved" (or 6), expiredpending (or 8) <b>Retrospective approval:</b> "acknowledged" (or 9), "declined" (or 10), "retrospectivePending" (or 11) <b>Checkin/checkout:</b> "checkout" (or 4), "checkedin" (or 5)

**PasswordViewRequest.targetAccountID**

Filter results for specified target account ID.

Required	Default Value	Valid Values
no	N/A	Integer

**PasswordViewRequest.targetAccountUserName**

Filter results for specified target account user name.

Required	Default Value	Valid Values
no	N/A	String

**PasswordViewRequest.policyApproverID**

Filter results for specified specified policy approver ID (for unapproved password view requests).

Required	Default Value	Valid Values
no	N/A	Integer

**PasswordViewRequest.policyApproverNameID**

Filter results for specified policy approver name ID (for unapproved password view requests).

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.ssoType***

Filter results the specified SSO type.

Required	Default Value	Valid Values
no	N/A	"Browser", "RDP", "SSH", "VNC", "AWSAPI", "Telnet", "Other"

### ***Page.Number***

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

### ***Page.Size***

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

### ***Sort.Property***

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	PasswordViewRequest.status	PasswordViewRequest.status, PasswordViewRequest.requestorID, PasswordViewRequest.approverID, PasswordViewRequest.targetAccountID

### ***Sort.Direction***

Sort.Direction specifies the order of the results. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	desc	asc, desc

## **listRequestServer**

Use the listRequestServer command to retrieve a detailed listing of all registered request servers (Credential Manager clients) or those that match the specified search criteria.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=listRequestServer
```

```
RequestServer.hostName=myhostname.mydomain.com RequestServer.active=true
```

## Parameters

### **RequestServer.ID**

Filter results for the specified request server ID.

Required	Default Value	Valid Values
no	N/A	Numeric

### **RequestServer.hostName**

Filter results for request server host names that contain the specified value.

Required	Default Value	Valid Values
no	N/A	String

### **RequestServer.exactHostName**

Filter results for request server host names that exactly match the specified value.

Required	Default Value	Valid Values
yes	N/A	String

### **RequestServer.deviceName**

Filter results for request server device names that contain the specified value.

Required	Default Value	Valid Values
no	Same as host name.	String

### **RequestServer.exactDeviceName**

Filter results for a request server device name that exactly match the specified value

Required	Default Value	Valid Values
no	N/A	String

### **RequestServer.ipAddress**

Filter results for request servers with an IP address that contains the specified value.

Required	Default Value	Valid Values
no	N/A	String

### **RequestServer.exactIpAddress**

Filter results for a request server with an IP address that exactly matches the specified value.

Required	Default Value	Valid Values
no	N/A	String

**RequestServer.clientVersion**

Filter results for request servers with a client version that contains the specified value.

Required	Default Value	Valid Values
no	N/A	String

**RequestServer.active**

Set RequestServer.active=true to filter results for request servers that have the active flag set to true. Set RequestServer.active=false to filter results for request servers that have the active flag set to false..

Required	Default Value	Valid Values
no	false	true, false

**RequestServer.actionRequired**

Set RequestServer.actionRequired=true to filter results for request servers that have the action required flag set to true. Set RequestServer.actionRequired=false to filter results for request servers that have the actionRequired flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

**Page.Number**

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

**Page.Size**

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

**Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	RequestServer.hostName	RequestServer.ID, RequestServer.hostName

**Sort.Direction**

Sort.Direction specifies the order in which results are displayed. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

## listRequestServerDefaults

Use the listRequestServerDefaults command to retrieve a list of Request Server defaults from the Privileged Access Manager Credential Manager datastore.

### Example

```
cspmserver_admin cspmHostName=paServer adminUserID=admin
cmdName=listRequestServerDefaults
```

### Parameters

#### RequestServerDefaults.ipAddress

The ip filter to apply to search.

Required	Default Value	Valid Values
no	N/A	String

#### RequestServerDefaults.type

The type filter to apply to search.

Required	Default Value	Valid Values
no		CLIENT, AGENT

## listUserAuthorization

Use the listUserAuthorization command to list user authorization mappings.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=listUserAuthorization
SecretAlias.name=test
```

### Parameters

#### UserAuthorization.ID

ID of the userAuthorization.

Required	Default Value	Valid Values
no	N/A	Numeric

#### TargetAlias.name

The name of the target alias.

Required	Default Value	Valid Values
no	N/A	String

#### TargetGroup.name

The name of the target group.

Required	Default Value	Valid Values
no	N/A	String

### **SecretAlias.name**

The name of the secret alias.

Required	Default Value	Valid Values
no	N/A	String

### **SecretGroup.name**

The name of the secret group.

Required	Default Value	Valid Values
no	N/A	String

### **User.userID**

The user name of the Credential Manager user.

Required	Default Value	Valid Values
no	N/A	String

### **UserGroup.name**

The user group name.

Required	Default Value	Valid Values
no	N/A	String

## **renameUser**

Use the renameUser command to rename a Credential Manager user. This command creates a copy of an existing user with a new name, and deletes the old user.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=renameUser
  User.userID=demo User.password=demo123$

User.newUserID=demo2
```

## **Parameters**

### **User.userID**

The user name of the Credential Manager user to be renamed.

Required	Default Value	Valid Values
yes	N/A	String

### **User.newUserID**

The user name of the Credential Manager user to be created.

Required	Default Value	Valid Values
yes	N/A	String

### **User.gkUserId**

The user ID to be associated with this user. If not specified, the existing value will be preserved.

Required	Default Value	Valid Values
optional (Credential Manager mode), rejected (PA mode)	N/A	Integer

## **resetClientCache**

The resetClientCache command informs all active clients that their caches of saved passwords should be reset. Use resetClientCache to reset all client caches.

### **WARNING**

We strongly recommend that you contact Broadcom Support before using this command.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=resetClientCache
```

## **resetDBHash**

Use the resetDBHash command to reset the database hash for an object. You can specify the types of objects as a comma separated list using the objectClass parameter.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=resetDBHash
objectClass=c.cw.m.ts
```

### **Parameter**

#### ***objectClass***

Required	Default	Value
No	c.cw.m.ts	

## resetGroupCache

Use the resetGroupCache command to refresh the group cache for all groups, or a single group. This command is asynchronous.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=resetGroupCache
Group.name=test_target_group
```

### Parameters

#### Group.name

Name of the group you wish to update in the group cache.

Required	Default Value	Valid Values
No. If not specified, all groups will be reset.	N/A	Numeric. This value must match the group ID registered in Credential Manager.

## searchAgent

Use the searchAgent command to retrieve a detailed listing of all the Windows Proxies registered in Credential Manager.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=searchAgent
```

### Parameters

#### Agent.ID

Filter results for the specified Agent.ID.

Required	Default Value	Valid Values
no	N/A	Numeric

#### Agent.hostName

Filter results based on the Agent.hostName specified.

Required	Default Value	Valid Values
no	N/A	String

#### Agent.ipAddress

Filter results based on the Agent.ipAddress specified.

Required	Default Value	Valid Values
no	N/A	String

**Agent.deviceName**

Filter results based on the Agent.deviceName specified.

Required	Default Value	Valid Values
no	N/A	String

**Agent.clientVersion**

Filter results based on the Agent.clientVersion specified.

Required	Default Value	Valid Values
no	N/A	String

**Agent.active**

Set Agent.active=true to filter results for active agents. Set Agent.active=false to filter results for inactive agents.

Required	Default Value	Valid Values
no	N/A	true, false

**Agent.actionRequired**

Set Agent.actionRequired=true to filter results for agents with the actionRequired flag set to true. Set Agent.actionRequired=false to filter results for agents with the actionRequired flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

**Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

**Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

**Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	RequestServer.hostName	RequestServer.ID, RequestServer.hostName

**Sort.Direction**

Set Sort.Direction=asc to have the results presented in ascending order. Set Sort.Direction=desc to have the results presented in descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

**searchAuthorization**

Use the searchAuthorization command to retrieve a detailed listing of authorization mappings registered in Credential Manager, which match the provided search criteria. When no search criteria are listed all authorization mappings are returned.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=searchAuthorization
Authorization.checkExecutionID=true
```

**Parameters****Authorization.executionUser**

Filter results for specified authorization execution user.

Required	Default Value	Valid Values
no	N/A	N/A

**Authorization.checkExecutionID**

Set Authorization.checkExecutionID=true to filter results for authorization mappings that have the check execution ID flag set to true. Set Authorization.checkExecutionID=false to filter results for script authorizations. that have the check execution ID flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

**Authorization.checkPath**

Set Authorization.checkPath=true to filter results for authorization mappings that have the check execution path flag set to true. Set Authorization.checkPath=false to filter results for authorization mappings that have the check execution path flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

**Authorization.checkFilePath**

Set Authorization.checkFilePath=true to filter results for authorization mappings that have the check file path flag set to true. Set Authorization.checkFilePath=false to filter results for authorization mappings that have the check file path flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

#### **Authorization.checkScriptHash**

Set Authorization.checkScriptHash=true to filter results for authorization mappings that have the check script hash flag set to true. Set Authorization.checkScriptHash=false to filter results for authorization mappings that have the check script hash flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

#### **Authorization.ID**

Filter results based on Authorization.ID specified.

Required	Default Value	Valid Values
no	N/A	Numeric.

#### **RequestServer.ID**

Filter results based on the RequestServer.ID specified.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchRequestServer to retrieve RequestServer.ID.

#### **RequestScript.ID**

Filter results based on the RequestScript.ID specified.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchRequestScript to retrieve RequestScript.ID.

#### **TargetAlias.ID**

Filter results based on the TargetAlias.ID specified.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchTargetAlias to retrieve the TargetAlias.ID.

#### **Authorization.targetGroupID**

Filter results based on the targetGroupId specified.

Required	Default Value	Valid Values
no	N/A	Numeric

### **Authorization.requestGroupId**

Filter results based on the requestGroupId specified.

Required	Default Value	Valid Values
no	N/A	Numeric

### **Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	TargetAlias.ID	Authorization.executionUser, Authorization.checkExecutionID, Authorization.checkPath, Authorization.checkFilePath, Authorization.checkScriptHash, Authorization.ID, RequestServer.ID, RequestScript.ID, TargetAlias.ID, Authorization.targetGroupId, Authorization.requestGroupId

### **Sort.Direction**

Set Sort.Direction=asc to have the results presented in ascending order. Set Sort.Direction=desc to have the results presented in descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

## searchFilter

Use the searchFilter command to retrieve a detailed listing of filters which match the provided search criteria. When no search criteria is listed, all registered filters are returned.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=searchFilter
```

## Parameters

### Filter.ID

Filter results for the specified filter.

Required	Default Value	Valid Values
no	N/A	Numeric

### Group.ID

Filter results for the unique identifier of a request or target group.

Required	Default Value	Valid Values
no	N/A	Numeric

### Filter.attribute

The filter attribute. For a list of attributes, see [Set up Command Filters](#).

Required	Default Value	Valid Values
no	N/A	String

### Filter.type

Filter results for the specified filter type.

Required	Default Value	Valid Values
no	N/A	equals, beginswith, contains, endswith

### Filter.expression

Filter results for the specified filter expression.

Required	Default Value	Valid Values
no	N/A	String

### Filter.objectClassId

Filter results for the specified object class ID.

Required	Default Value	Valid Values
no	N/A	String

### **Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	TargetAlias.ID	Group.ID, Filter.ID, Filter.attribute, Filter.type, Filter.expression, Filter.objectClassId

### **Sort.Direction**

Set Sort.Direction=asc to have the results presented in ascending order. Set Sort.Direction=desc to have the results presented in descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

## **searchGroup**

Use the searchGroup command to retrieve a list of target groups or request groups within Credential Manager.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=searchGroup
```

### **Parameters**

#### **Group.ID**

Filter results for the specified Group.ID.

Required	Default Value	Valid Values
no	N/A	String

### **Group.name**

Filter results for groups matching the specified name.

Required	Default Value	Valid Values
no	N/A	String

### **Group.description**

Filter results for groups matching the specified description.

Required	Default Value	Valid Values
no	N/A	String

### **Group.type**

Filter results for groups with the specified group type.

Required	Default Value	Valid Values
no	N/A	target, requestor

### **Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	Group.name	Group.ID, Group.name, Group.description, Group.type, Group.dynamic

### **Sort.Direction**

Set Sort.Direction=asc to have the results presented in ascending order. Set Sort.Direction=desc to have the results presented in descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

### **Group.isSecretType**

Use Group.isSecretType to search for secret groups.

Required	Default Value	Valid Values
no	false	string

## **searchPasswordPolicy**

Use the searchPasswordPolicy command to retrieve a detailed list of all the Password Composition policies that match the provided search criteria. If no search criteria are specified then all SSH Key Pair policies are returned.

### **Example**

```
capam_command capam=capamServer UserInputException cmdName=searchPasswordPolicy
```

### **Parameters**

#### **PasswordPolicy.name**

Filter results for specified policy name.

Required	Default Value	Valid Values
No	N/A	String

#### **PasswordPolicy.description**

Filter results for policy descriptions that contain the specified value.

Required	Default Value	Valid Values
No	N/A	String

#### **Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works with Page.Size.

Required	Default Value	Valid Values
No	1	Numeric

#### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
No	10000	Numeric

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
No	PasswordPolicy.name	PasswordPolicy.name, PasswordPolicy.description

### **Sort.Direction**

Sort.Direction determines the order in which results are displayed. Select **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
No	asc	asc, desc

## **searchPasswordViewPolicy**

Use the searchPasswordViewPolicy command to retrieve a list of all password view policies that match the search criteria. When no search criteria are listed, all password view policies are returned.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=searchPasswordViewPolicy PasswordViewPolicy.name=restrictedAccounts
```

### **Parameters**

#### **PasswordViewPolicy.name**

The name of the password view policy.

Required	Default Value	Valid Values
no	N/A	Any text string

#### **PasswordViewPolicy.description**

The description of the password view policy.

Required	Default Value	Valid Values
no	N/A	Any text string

#### **PasswordViewRequest.connectionTimeout**

Filter results for requests with connection idle timeouts greater than or equal to the specified value. (Useful for identifying extended timeout requests.)

Required	Default Value	Valid Values
no	N/A	Numeric

### **Page.Number**

Specifies which page to return when the results are divided among multiple pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	PasswordViewPolicy.name	PasswordViewPolicy.name, PasswordViewPolicy.description

### **Sort.Direction**

Sort.Direction specifies the order in which results are displayed. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

## **searchPasswordViewRequest**

Use the searchPasswordViewRequest command to list all password view requests. This information is useful for reporting purposes. The approver is the user executing the command.

### **NOTE**

Use the [searchPasswordViewRequestByApprover](#) command to see all password view requests that can be or have been approved by the user issuing the command. Use the [searchPasswordViewRequestByRequestor](#) command to see all password view requests made by the user issuing the command.

### **Example**

The following example shows how to use the searchPasswordViewRequest command. This example is for UNIX/Linux.

```
capam_command cmdName=searchPasswordViewRequest capam=uspam12.ca.com
adminUserID=admin adminPassword=test
```

```
"PasswordViewRequest.requestPeriodStart=2018-02-22 14:10"
```

```
"PasswordViewRequest.requestPeriodEnd=2018-02-22 15:00"
```

## Parameters

### ***PasswordViewRequest.status***

Filter results that contain the value that is specified.

Required	Default Value	Valid Values
no	N/A	<b>Dual authorization:</b> "approved" (or 1), "denied" (or 2), "pending" (or 3), "expiredapproved" (or 6), expiredpending (or 8) <b>Retrospective approval:</b> "acknowledged" (or 9), "declined" (or 10), "retrospectivePending" (or 11) <b>Checkin/checkout:</b> "checkout" (or 4), "checkedin" (or 5)

### ***PasswordViewRequest.connectionTimeout***

Filter results for requests with connection idle timeouts greater than or equal to the specified value (in minutes). (Useful for identifying extended timeout requests.)

Required	Default Value	Valid Values
no	N/A	Positive integer

### ***PasswordViewRequest.targetAccountID***

Filter results for the specified target account ID.

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.RequestorID***

Filter results for the specified requestor ID.

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.ApproverID***

Filter results for the specified requestor ID.

Required	Default Value	Valid Values
no	N/A	Integer

### ***PasswordViewRequest.requestPeriodStart***

Filter results are based on a specified start time.

Required	Default Value	Valid Values
no	N/A	N/A

The CLI includes any view request that is active within a specified start and end time. The results can include view requests that start before the specified start time, as long as the request is active. To understand which view requests are returned, see [Example: View Requests Returned in a Specified Time Period](#).

This parameter is intended to work with the PasswordViewRequest.requestPeriodEnd parameter. If you do not specify a start time, the start time defaults to the time of the first entry in the Credential Manager database.

Parameter syntax:

```
"PasswordViewRequest.requestPeriodStart=YYYY-MM-DD HH:MM"
```

The date format must be: YYYY-MM-DD HH:MM

### ***PasswordViewRequest.requestPeriodEnd***

Filter results are based on a specified end time.

Required	Default Value	Valid Values
no	N/A	N/A

The CLI includes any password view request that is active within a specified start and end time. The results can include view requests that end after the specified end time, as long as the request is active. To understand which view requests are returned, see the [Example: View Requests Returned in a Specified Time Period](#).

This parameter is intended to work with the PasswordViewRequest.requestPeriodStart parameter. However, if you do not specify an end time, the time defaults to when the CLI command is submitted to the appliance.

Parameter syntax:

```
"PasswordViewRequest.requestPeriodEnd=YYYY-MM-DD HH:MM"
```

The date format must be: YYYY-MM-DD HH:MM

### ***Example: View Requests Returned in a Specified Time Period***

This PasswordViewRequest.requestPeriodStart and PasswordViewRequest.requestPeriodEnd parameters work together to define a time period for returned view requests.

The following parameter example shows a start time of 14:10 and an end time of 15:00:

```
"PasswordViewRequest.requestPeriodStart=2018-02-22 14:10"
```

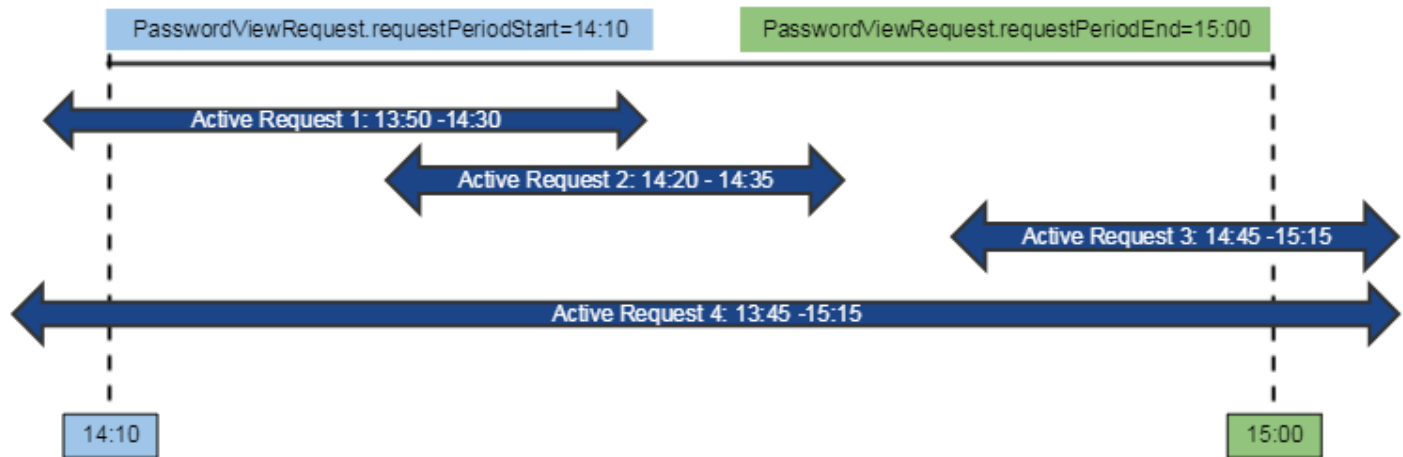

```
"PasswordViewRequest.requestPeriodEnd=2018-02-22 15:00"
```

Within the 14:10 to 15:00 time frame, the results include the following active requests:

Active Request Start	Active Request End
Starts at 13:50	Ends at 14:30
Starts at 14:20	Ends at 14:35
Starts at 14:45	Ends at 15:15
Starts at 13:45	Ends at 15:15

These results are illustrated in the following diagram:

**Figure 66: searchPasswordViewRequest Example**

### **Page.Number**

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

### **Page.Size**

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	PasswordViewRequest.status	PasswordViewRequest.status, PasswordViewRequest.approverID, PasswordViewRequest.targetAccountID

### **Sort.Direction**

Set Sort.Direction=asc to present the results in ascending order. Set Sort.Direction=desc to present the results in descending order.

Required	Default Value	Valid Values
no	desc	asc, desc

## searchPasswordViewRequestByApprover

Use the searchPasswordViewRequestByApprover command to list the password view requests for a particular approver. This information is useful for reporting purposes. The approver is the user executing the command.

### Example

The following example shows how to use the searchPasswordViewRequestByApprover command. This example is for UNIX/Linux.

```
capam_command cmdName=searchPasswordViewRequestByApprover capam=uspm12.ca.com
adminUserID=admin adminPassword=test
"PasswordViewRequest.requestPeriodStart=2018-02-22 14:10"
"PasswordViewRequest.requestPeriodEnd=2018-02-22 15:00"
```

### Parameters

#### ***PasswordViewRequest.requestorID***

Filter results for specified requestorID

Required	Default Value	Valid Values
no	N/A	Integer

#### ***PasswordViewRequest.status***

Filter results that contain the value that is specified.

Required	Default Value	Valid Values
no	N/A	<b>Dual authorization:</b> "approved" (or 1), "denied" (or 2), "pending" (or 3), "expiredapproved" (or 6), expiredpending (or 8) <b>Retrospective approval:</b> "acknowledged" (or 9), "declined" (or 10), "retrospectivePending" (or 11) <b>Checkin/checkout:</b> "checkout" (or 4), "checkedin" (or 5)

#### ***PasswordViewRequest.connectionTimeout***

Filter results for requests with connection idle timeouts greater than or equal to the specified value (in minutes). (Useful for identifying extended timeout requests.)

Required	Default Value	Valid Values
no	N/A	Positive integer

#### ***PasswordViewRequest.targetAccountID***

Filter results for specified target account ID.

Required	Default Value	Valid Values
no	N/A	Integer

#### ***PasswordViewRequest.requestPeriodStart***

Filter results are based on a specified start time.

Required	Default Value	Valid Values
no	N/A	N/A

The CLI includes any view request that is active within a specified start and end time. The results can include view requests that start before the specified start time, as long as the request is active. To understand which view requests are returned, see [Example: View Requests Returned in a Specified Time Period](#).

This parameter is intended to work with the PasswordViewRequest.requestPeriodEnd parameter. If you do not specify a start time, the start time defaults to the time of the first entry in the Credential Manager database.

Parameter syntax:

```
"PasswordViewRequest.requestPeriodStart=YYYY-MM-DD HH:MM"
```

The date format must be: YYYY-MM-DD HH:MM

### ***PasswordViewRequest.requestPeriodEnd***

Filter results are based on a specified end time.

Required	Default Value	Valid Values
no	N/A	N/A

The CLI includes any password view request that is active within a specified start and end time. The results can include view requests that end after the specified end time, as long as the request is active. To understand which view requests are returned, see the [Example: View Requests Returned in a Specified Time Period](#).

This parameter is intended to work with the PasswordViewRequest.requestPeriodStart parameter. However, if you do not specify an end time, the time defaults to when the CLI command is submitted to the appliance.

Parameter syntax:

```
"PasswordViewRequest.requestPeriodEnd=YYYY-MM-DD HH:MM"
```

The date format must be: YYYY-MM-DD HH:MM

### ***Example: View Requests Returned in a Specified Time Period***

This PasswordViewRequest.requestPeriodStart and PasswordViewRequest.requestPeriodEnd parameters work together to define a time period for returned view requests.

The following parameter example shows a start time of 14:10 and an end time of 15:00:

```
"PasswordViewRequest.requestPeriodStart=2018-02-22 14:10"
```

```
"PasswordViewRequest.requestPeriodEnd=2018-02-22 15:00"
```

Within the 14:10 to 15:00 time frame, the results include the following active requests:

Active Request Start	Active Request End
Starts at 13:50	Ends at 14:30
Starts at 14:20	Ends at 14:35
Starts at 14:45	Ends at 15:15
Starts at 13:45	Ends at 15:15

These results are illustrated in the following picture:

**Figure 67: searchPasswordViewRequestByApprover Example**

### Page.Number

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

### Page.Size

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

### Sort.Property

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	PasswordViewRequest.status	PasswordViewRequest.status, PasswordViewRequest.approverID, PasswordViewRequest.targetAccountID

### Sort.Direction

Set Sort.Direction=asc to present the results in ascending order. Set Sort.Direction=desc to present the results in descending order.

Required	Default Value	Valid Values
no	desc	asc, desc

## searchPasswordViewRequestByRequestor

Use the searchPasswordViewRequestByRequestor command to list the password view requests for a particular requestor. This information is useful for reporting purposes. The requestor is the user making the view request.

### Example

The following example shows how to use the searchPasswordViewRequestByRequestor command. This example is for UNIX/Linux.

```
capam_command cmdName=searchPasswordViewRequestByRequestor capam=uspsam12.ca.com
adminUserID=admin adminPassword=test
"PasswordViewRequest.requestPeriodStart=2018-02-22 14:10"
"PasswordViewRequest.requestPeriodEnd=2018-02-22 15:00"
```

### Parameters

#### ***PasswordViewRequest.approverID***

Filter results for specified approverID.

Required	Default Value	Valid Values
no	N/A	Integer.

#### ***PasswordViewRequest.status***

Filter results that contain the value that is specified.

Required	Default Value	Valid Values
no	N/A	<b>Dual authorization:</b> "approved" (or 1), "denied" (or 2), "pending" (or 3), "expiredapproved" (or 6), expiredpending (or 8) <b>Retrospective approval:</b> "acknowledged" (or 9), "declined" (or 10), "retrospectivePending" (or 11) <b>Checkin/checkout:</b> "checkout" (or 4), "checkedin" (or 5)

#### ***PasswordViewRequest.connectionTimeout***

Filter results for requests with connection idle timeouts greater than or equal to the specified value (in minutes). (Useful for identifying extended timeout requests.)

Required	Default Value	Valid Values
no	N/A	Positive integer

#### ***PasswordViewRequest.targetAccountID***

Filter results for specified target account ID.

Required	Default Value	Valid Values
no	N/A	Integer

#### ***PasswordViewRequest.isCheckedOut***

Filter results for accounts that are checked out.

Required	Default Value	Valid Values
no	N/A	"true" or "false"

### ***PasswordViewRequest.requestPeriodStart***

Filter results are based on a specified start time.

Required	Default Value	Valid Values
no	N/A	N/A

The CLI includes any view request that is active within a specified start and end time. The results can include view requests that start before the specified start time, as long as the request is active. To understand which view requests are returned, see [Example: View Requests Returned in a Specified Time Period](#).

This parameter is intended to work with the PasswordViewRequest.requestPeriodEnd parameter. If you do not specify a start time, the start time defaults to the time of the first entry in the Credential Manager database.

Parameter syntax:

```
"PasswordViewRequest.requestPeriodStart=YYYY-MM-DD HH:MM"
```

The date format must be: YYYY-MM-DD HH:MM

### ***PasswordViewRequest.requestPeriodEnd***

Filter results are based on a specified end time.

Required	Default Value	Valid Values
no	N/A	N/A

The CLI includes any password view request that is active within a specified start and end time. The results can include view requests that end after the specified end time, as long as the request is active. To understand which view requests are returned, see the [Example: View Requests Returned in a Specified Time Period](#).

This parameter is intended to work with the PasswordViewRequest.requestPeriodStart parameter. However, if you do not specify an end time, the time defaults to when the CLI command is submitted to the appliance.

Parameter syntax:

```
"PasswordViewRequest.requestPeriodEnd=YYYY-MM-DD HH:MM"
```

The date format must be: YYYY-MM-DD HH:MM

### ***Example: View Requests Returned in a Specified Time Period***

This PasswordViewRequest.requestPeriodStart and PasswordViewRequest.requestPeriodEnd parameters work together to define a time period for returned view requests.

The following parameter example shows a start time of 14:10 and an end time of 15:00:

```
"PasswordViewRequest.requestPeriodStart=2018-02-22 14:10"
```

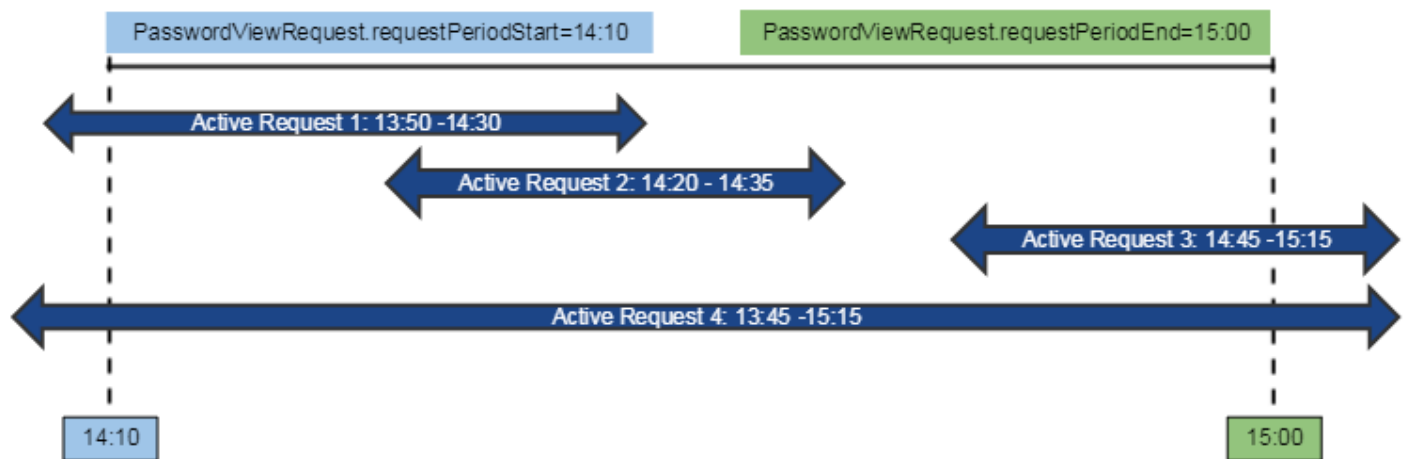

```
"PasswordViewRequest.requestPeriodEnd=2018-02-22 15:00"
```

Within the 14:10 to 15:00 time frame, the results include the following active requests:

Active Request Start	Active Request End
Starts at 13:50	Ends at 14:30
Starts at 14:20	Ends at 14:35
Starts at 14:45	Ends at 15:15
Starts at 13:45	Ends at 15:15

These results are illustrated in the following picture:

**Figure 68: searchPasswordViewRequestByRequestor Example**

### **Page.Number**

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

### **Page.Size**

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	PasswordViewRequest.status	PasswordViewRequest.status PasswordViewRequest.approverID PasswordViewRequest.targetAccountID

### **Sort.Direction**

Sort.Direction determines the sort order. Select **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	desc	asc, desc

## searchRequestScript

Use the searchRequestScript command to retrieve a detailed list of requesting applications that are registered with Credential Manager. The resulting list matches the search criteria. If no search criteria are specified, all registered requesting applications are returned.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=searchRequestScript
RequestScript.name=example.pl
```

### Parameters

#### RequestServer.ID

Filter results for specified RequestServer.ID.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchRequestServer to retrieve the RequestServer.ID

#### RequestScript.name

Filter results for specified request script name.

Required	Default Value	Valid Values
no	N/A	String

#### RequestScript.ID

Filter results for specified RequestScript.ID.

Required	Default Value	Valid Values
no	N/A	Numeric

#### RequestScript.filePath

Filter results for file paths that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

#### RequestScript.executionPath

Filter results for execution paths that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

### **Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	RequestScript.name	RequestServer.ID, RequestScript.name, RequestScript.ID, RequestScript.filePath, RequestScript.executionPath

### **Sort.Direction**

Sort.Direction specifies the order in which results are displayed. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

## **searchRequestServer**

Use the searchRequestServer command to retrieve a detailed list of request servers (Credential Manager clients) that are registered with Credential Manager. The resulting list matches the search criteria. If no search criteria is provided, all registered request servers are returned.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=searchRequestServer
RequestServer.hostName=mydomain
```

**Parameters****RequestServer.ID**

Filter results for specified RequestServer.ID.

Required	Default Value	Valid Values
no	N/A	Numeric

**RequestServer.hostName**

Filter results for request server host names that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

**RequestServer.deviceName**

Filter results for request server device names that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

**RequestServer.ipAddress**

Filter results for IP address that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

**RequestServer.clientVersion**

Filter results for request server client version that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

**RequestServer.active**

Set RequestServer.active=true to filter results for request servers that have the active flag set to true. Set RequestServer.active=false to filter results for request servers that have the active flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

**RequestServer.actionRequired**

Set RequestServer.actionRequired=true to filter results for request servers that have the action required flag set to true. Set RequestServer.actionRequired=false to filter results for request servers that have the actionRequired flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

**Page.Number**

List all request servers within the specified page.

Required	Default Value	Valid Values
no	1	N/A

**Page.Size**

Specify the size of each page.

Required	Default Value	Valid Values
no	10000	N/A

**Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	RequestServer.hostName	RequestServer.ID, RequestServer.hostName

**Sort.Direction**

Sort.Direction specifies the order in which results are displayed. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

**searchRole**

Use the searchRole command to retrieve roles from Credential Manager.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=searchRole
```

**Parameters****Role.ID**

Filter results for specified Role.ID.

Required	Default Value	Valid Values
yes	N/A	Numeric

**Role.name**

Filter results based on the Role.name specified.

Required	Default Value	Valid Values
yes	N/A	String

### **Role.description**

Filter results based on the Role.description specified.

Required	Default Value	Valid Values
no	N/A	String

### **Page.Number**

List all roles within the specified page.

Required	Default Value	Valid Values
no	1	Numeric

### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	Role.name	Role.ID, Role.name, Role.description

### **Sort.Direction**

Sort.Direction specifies the order in which results are displayed. Specify asc for ascending order or desc for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

## **searchSite**

Use the searchSite command to retrieve an XML list of all sites registered with Credential Manager. This command takes no parameters.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=searchSite
```

## searchSSHKeyPairPolicy

Use this command to retrieve a detailed list of all the SSH key pair policies that match the search criteria. If no search criteria are specified, all SSH Key Pair policies are returned.

### Example

```
capam_command capam=capamServer adminUserID=admin
cmdName=searchSSHKeyPairPolicy
```

### Parameters

#### ***SSHKeyPairPolicy.name***

Filter results for specified policy name.

Required	Default Value	Valid Values
No	N/A	String

#### ***SSHKeyPairPolicy.description***

Filter results for policy descriptions that contain the specified value.

Required	Default Value	Valid Values
No	N/A	String

#### ***Page.Number***

Specifies which page to return when the results are divided among multiple a pages. This parameter works with Page.Size.

Required	Default Value	Valid Values
No	1	Numeric

#### ***Page.Size***

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
No	10000	Numeric

#### ***Sort.Property***

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
No	SSHKeyPairPolicy.name	SSHKeyPairPolicy.name, SSHKeyPairPolicy.description

#### ***Sort.Direction***

Sort.Direction specifies the order in which results are displayed. Specify asc for ascending order or desc for descending order.

Required	Default Value	Valid Values
No	asc	asc, desc

## searchTargetAccount

Use the searchTargetAccount command to retrieve an XML listing of all target accounts that match the search criteria. If no search criteria are listed, all target accounts are returned.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=searchTargetAccount
TargetAccount.userName=root
```

### Parameters

#### TargetAccount.ID

Filter results for specified TargetAccount.ID.

Required	Default Value	Valid Values
no	N/A	Numeric

#### TargetApplication.ID

Filter results for specified TargetApplication.ID.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchTargetApplication to retrieve the TargetApplication.ID

#### TargetServer.ID

Filter results for specified TargetServer.ID.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchTargetServer to retrieve the TargetServer.ID

#### TargetApplication.name

Filter results for specified target application name.

Required	Default Value	Valid Values
no	N/A	String

#### TargetApplication.type

Filter results for specified target application type.

Required	Default Value	Valid Values
no	N/A	String

### **TargetAccount.userName**

Filter results for target account user names that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

### **TargetAccount.accessType**

Filter results for target account access types that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

### **TargetAccount.cacheAllow (Deprecated)**

Set TargetAccount.cacheAllow=true to filter results for target accounts that have the cache allow flag set to true. Set TargetAccount.cacheAllow=false to filter results for target accounts that have the cache allow flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

### **TargetAccount.cacheBehavior**

Set this parameter to **useCacheFirst** to cache the account credentials in the Credential Manager client and used first. Set the parameter to **useServerFirst** to cache the account credentials in the Credential Manager client but the server is contacted first. To not cache the account credentials, set this parameter to **noCache**.

Required	Default Value	Valid Values
no	useCacheFirst	useCacheFirst, useServerFirst, noCache

### **TargetAccount.cacheDuration**

Filter results for specified cache duration value.

Required	Default Value	Valid Values
no	N/A	Numeric

### **TargetAccount.privileged**

Set this parameter to **true** to filter results for target accounts with the privileged flag set to true. Select **false** to filter results for target accounts with the privileged flag set to false (A2A accounts).

Required	Default Value	Valid Values
no	N/A	true, false

### **TargetAccount.synchronize**

Set this parameter to **true** to filter results for target accounts with the synchronize flag set to true. Select **false** to filter results for target accounts with the synchronize flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

### **TargetAccount.passwordVerified**

Set this parameter to **true** to filter results for target accounts with the password verified flag set to true. Select **false** to filter results for target accounts with the password verified flag set to false.

Required	Default Value	Valid Values
no	N/A	true, false

### **Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

### **Sort.Property**

Use Sort.Property to specified which field to use for sorting the result.

Required	Default Value	Valid Values
no	TargetAccount.ID	TargetAccount.ID, TargetApplication.ID, TargetApplication.name, TargetApplication.type, TargetAccount.userName, TargetAccount.accessType, TargetAccount.cacheAllow, TargetAccount.cacheDuration, TargetAccount.privileged, TargetAccount.synchronize, TargetAccount.passwordVerified

### **Sort.Direction**

Sort.Direction specifies the order in which results are displayed. Specify asc for ascending order or desc for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

## searchTargetAlias

Use the searchTargetAlias command to retrieve an XML list of all target aliases that match the search criteria. If no search criteria are specified, all target aliases are returned.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=searchTargetAlias
TargetAlias.name=test
```

### Parameters

#### TargetAlias.name

Filter results for target alias names that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

#### TargetAccount.ID

Filter results for specified TargetAccount.ID.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchTargetAccount to retrieve the TargetAccount.ID

#### TargetAlias.ID

Filter results for specified TargetAlias.ID.

Required	Default Value	Valid Values
no	N/A	Numeric

#### TargetServer.hostName

Filter results for target server host names that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

#### TargetApplication.name

Filter results for target application names that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

#### TargetAccount.userName

Filter results for target account user names that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

### **Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	TargetAlias.name	TargetAlias.name, TargetAccount.ID, TargetAlias.ID

### **Sort.Direction**

Sort.Direction specifies the order in which results are displayed. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

## **searchTargetApplication**

Use the searchTargetApplication command to retrieve an XML listing of all target applications that match the search criteria. If no search criteria are specified, all target applications are returned.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=searchTargetApplication TargetApplication.type=oracle
```

### **Parameters**

#### **TargetApplication.ID**

Filter results for specified TargetApplication.ID.

Required	Default Value	Valid Values
no	N/A	Numeric

### **TargetServer.ID**

Filter results for specified TargetServer.ID.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchTargetServer to retrieve the TargetServer.ID

### **TargetApplication.name**

Filter results for target application names that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

### **TargetApplication.type**

Filter results for target application types that contain the value specified.

Required	Default Value	Valid Values
no	N/A	String

### **Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

### **Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

### **Sort.Property**

Use Sort.Property to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	TargetApplication.name	TargetApplication.ID, TargetServer.ID, TargetApplication.name, TargetApplication.type

### **Sort.Direction**

Sort.Direction specifies the order in which results are displayed. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

## searchTargetServer

Use the `searchTargetServer` command to retrieve an XML list of all target servers that match the search criteria. If no search criteria are specified, all target servers are returned.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=searchTargetServer
TargetServer.hostName=mydomain
```

## Parameters

### ts.TargetServer.ID

Filter results for a target server ID that contain the specified value. Add the table alias `ts` as a prefix.

```
capam_command capam=capamServer adminUserID=admin adminPassword=password
cmdName=searchTargetServer ts.TargetServer.ID=1000
```

Required	Default Value	Valid Values
no	N/A	String

### TargetServer.hostName

Filter results for target server host names that contain the specified value.

Required	Default Value	Valid Values
no	N/A	String

### TargetServer.ipAddress

Filter results for IP addresses that contain the specified value.

Required	Default Value	Valid Values
no	N/A	String

### TargetServer.deviceName

Filter results for target server device names that contain the specified value.

Required	Default Value	Valid Values
no	N/A	String

**Page.Number**

Specify which page to return when the results are divided among multiple pages. This parameter works with `Page.Size`.

Required	Default Value	Valid Values
no	1	Numeric

**Page.Size**

Specify the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

**Sort.Property**

Use `Sort.Property` to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	<code>TargetServer.hostName</code>	<code>TargetServer.hostName</code> , <code>TargetServer.ipAddress</code>

**Sort.Direction**

`Sort.Direction` specifies the order in which results are displayed. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

**searchUser**

Use the `searchUser` command to retrieve a list of Credential Manager users from the Credential Manager database.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=searchUser
  UserGroup.ID=4 User.authenticationType=CSPM
```

```
User.status=ACTIVE User.firstName=Demo User.lastName=User
```

**Parameters****UserGroup.ID**

Filter results for users belonging to the specified user group.

Required	Default Value	Valid Values
no	N/A	Numeric. Use <code>searchUserGroup</code> to retrieve the <code>UserGroup.ID</code>

**User.authenticationType**

Filter results on user authenticationType.

Required	Default Value	Valid Values
no	N/A	String

**User.status**

Filter results on user status.

Required	Default Value	Valid Values
no	N/A	ACTIVE

**User.firstName**

Filter results on user first name.

Required	Default Value	Valid Values
no	N/A	String

**User.lastName**

Filter results on user last name.

Required	Default Value	Valid Values
no	N/A	String

**UserGroup.includeInheritedUsers**

Use this parameter with the UserGroup.ID parameter alone. It causes the command to return all users who are direct members of the specified CM user group as well as those users who inherit the specified CM user group from some AM user group. All other filters such as User.firstName, User.lastName, are ignored if this filter is used.

Required	Default Value	Valid Values
no	false	Boolean (true/false)

**Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

**searchUserGroup**

Use the searchUserGroup command to retrieve a list of user groups from the Credential Manager database. If an individual user is specified, then only the groups in which that user belongs are displayed.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=searchUserGroup UserGroup.ID=1
```

**Parameters****UserGroup.ID**

Filter results for user groups matching the specified ID.

Required	Default Value	Valid Values
no	N/A	String

**UserGroup.name**

Filter results for user groups matching the specified name.

Required	Default Value	Valid Values
no	N/A	String

**UserGroup.description**

Filter results for user groups matching the specified description.

Required	Default Value	Valid Values
no	N/A	String

**UserGroup.userID**

Filter results for user groups in which the specified user belongs.

Required	Default Value	Valid Values
no	N/A	String

**Page.Number**

Specifies which page to return when the results are divided among multiple a pages. This parameter works in conjunction with Page.Size.

Required	Default Value	Valid Values
no	1	Numeric

**Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	10000	Numeric

**Sort.Property**

Use `Sort.Property` to specify which field to use for sorting the result.

Required	Default Value	Valid Values
no	UserGroup.name	UserGroup.ID, UserGroup.name, UserGroup.description, UserGroup.userID, UserGroup.amUserGroupID

### **Sort.Direction**

`Sort.Direction` specifies the order in which results are displayed. Specify **asc** for ascending order or **desc** for descending order.

Required	Default Value	Valid Values
no	asc	asc, desc

### **UserGroup.amUserGroupID**

`UserGroup.amUserGroupID` filters results for user groups in which the specified AM user group belongs.

Required	Default Value	Valid Values
no	N/A	Integer

### **UserGroup.includeInheritedCmGroups**

Use `UserGroup.includeInheritedCmGroups` with the `UserGroupID` parameter alone. It returns both direct and inherited CM user groups not a given user.

Required	Default Value	Valid Values
false	false	Boolean (true/false)

## **setDisasterRecoverySettings**

Use the `setDisasterRecoverySettings` command to enable or disable disaster recovery mode.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=setDisasterRecoverySettings enable=true
```

### **Parameters**

#### ***enable***

Set `enable=true` to enable the disaster recovery mode. Otherwise, set `enable=false` to disable it.

Required	Default Value	Valid Values
yes	false	true, false

## setInitProperty

Use the setInitProperty command to change the Credential Manager initialization property (database username and password) for DB2 databases. For all other databases, use the updateDBPassword command. This command can be executed at a secondary site.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=setInitProperty
propertyName=dbpassword propertyValue='12345'
```

### Parameters

#### propertyName

The property to set.

Required	Default Value	Valid Values
yes	N/A	dbpassword, dbusername, ddlpassword, ddlusername

#### propertyValue

String containing the property value.

Required	Default Value	Valid Values
yes	N/A	String. In UNIX, if special characters are included, the password must be enclosed in single quotes.

## setLocalProperty

Use the setLocalProperty command to set the site name of a primary or secondary site in a multi-site cluster. This command sets the site name in the site-local Credential Manager database.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=setLocalProperty
propertyName=sitename propertyValues=mySiteName
```

### Parameters

#### propertyName

The property to set.

Required	Default Value	Valid Values
yes	N/A	sitename

#### propertyValues

String containing the property value.

Required	Default Value	Valid Values
yes	N/A	String

## setPasswordViewReasons

Use the setPasswordViewReasons command to customize the reasons that a user can select for viewing a target account password.

### Example

```
capam_command capam=capamServer adminUserID=admin
cmdName=setPasswordViewReasons

reasons="System failure|System recovery|System update|Scheduled maintenance|
Other"
```

### Parameters

#### reasons

The list of reasons is delimited by the pipe character, (|). For UNIX, the list must be enclosed in quotes.

Required	Default Value	Valid Values
yes	N/A	String

## setPasswordViewRequestDeleteInterval

Use the setPasswordViewRequestDeleteInterval command to set the number of days to keep a password view request before they are deleted.

### Example

```
capam_command capam=capamServer adminUserID=admin
cmdName=SetPasswordViewRequestDeleteInterval deleteIntervalDays=30
```

### Parameters

#### deleteIntervalDays

The number of days to keep password view requests

Required	Default Value	Valid Values
yes	N/A	Numeric

## setReportRowLimit

Use the setReportRowLimit command to set the maximum number of entries that are displayed in a report.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=setReportRowLimit
rowLimit=10000
```

### Parameters

#### *rowLimit*

Specifies the maximum number of entries displayed by each report.

Required	Default Value	Valid Values
yes	N/A	Numeric

## setSystemProperty

Use the setSystemProperty command to set a Credential Manager system property.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=setSystemProperty
propertyName=lunaPassword

propertyValues='p@ssw0rd!' encryptValue=true
```

### Parameters

#### *propertyName*

The property to update or if it does not exist, to insert the property.

Required	Default Value	Valid Values
yes	N/A	String

#### *propertyValues*

String containing the property value.

Required	Default Value	Valid Values
yes	N/A	String

#### *encryptValue*

Set encryptValue to true to encrypt the propertyValues string. To leave the value unencrypted (in plain text), set encryptValue to false.

Required	Default Value	Valid Values
no	false	true, false

### ***propertyValueBlankAllowed***

Indicates that an empty propertyValue parameter is allowed.

Required	Default Value	Valid Values
no	false	true, false

### ***clientInactivityCheckHours***

This property is for use by CA Technologies Support to help debug customer issues. Do not change the default value.

Required	Default Value	Valid Values
no	30	

### ***eventsCountThresholdValue***

Used to set the threshold count of the unprocessed child events.

Required	Default Value	Valid Values
no	N/A	Integer

### ***eventProcessorPoolSize***

Sets the pool size of the event processor. If this property is not set, its default value is 10.

Required	Default Value	Valid Values
no	10	Integer

### ***targetAccountPasswordExpirationEnabled***

Set the property value to True to enable automatic updating of expired passwords.

Required	Default Value	Valid Values
no	false	true, false

### ***oneclickServerHost***

Credential Manager Primary Host name

Required	Default Value	Valid Values
no	N/A	Server name

### ***emailServerHost***

Host name of the mail server.

Required	Default Value	Valid Values
no	mail.yourdomain.com	true, false

### ***emailServerPort***

Port number the SMTP service listens

Required	Default Value	Valid Values
no	25	Port number

### ***emailTransportType***

Email transport type

Required	Default Value	Valid Values
no	smtp	smtp

### ***emailTargetAccountID***

ID of the target email account

Required	Default Value	Valid Values
no	N/A	account ID

### ***emailFromAddress***

The "From" address for emails.

Required	Default Value	Valid Values
no	N/A	view_requests@yourdomain.com

### ***emailRequestSubject***

Property for configuring the request email. This is an optional property.

Required	Default Value	Valid Values
no	Password View Request for target account @TargetAccount.getUserName@	N/A

### ***emailRequestBody***

Property for configuring the request email. This is an optional property.

Required	Default Value	Valid Values
no	Do not reply to this email. A password view request has been submitted by user @User.getUserID@ to view the password for account @TargetAccount.getUserName@ of application @TargetApplication.getName@ on server @TargetServer.getHostName@. The password view request reason is @PasswordViewRequest.getReason@ (@PasswordViewRequest.getReasonDescription@). Please login to the CPA system and manage this request.	N/A

#### ***emailRequestStatusSubject***

Property for configuring the request status email. This is an optional property.

Required	Default Value	Valid Values
no	Password View Request Status for account @TargetAccount.getUserName@	N/A

#### ***emailRequestStatusBody***

Property for configuring the request status email. This is an optional property.

Required	Default Value	Valid Values
no	Do not reply to this email. The status of your request to view password for the account @TargetAccount.getUserName@ of application @TargetApplication.getName@ in server @TargetServer.getHostName@, is: @PasswordViewRequest.getStatusString@.	N/A

#### ***emailPasswordViewSubject***

Property for configuring the password view email. This is an optional property.

Required	Default Value	Valid Values
no	Password of account @TargetAccount.getUserName@ has been accessed by @User.getUserID@	N/A

#### ***emailPasswordViewBody***

Property for configuring the password view email. This is an optional property.

Required	Default Value	Valid Values
no	Do not reply to this email. The Password for the account @TargetAccount.getUserName@ of application @TargetApplication.getName@ on server @TargetServer.getHostName@ has been accessed by user @User.getUserId@.	N/A

#### ***emailPasswordViewRequestExpiredSubject***

Property for configuring the expired password view request email. This is an optional property.

Required	Default Value	Valid Values
no	Password View Request for account @TargetAccount.getUserName@ requested by @User.getUserId@ has expired	N/A

#### ***emailPasswordViewRequestExpiredBody***

Property for configuring the expired password view request email. This is an optional property.

Required	Default Value	Valid Values
no	Do not reply to this email. The Password View Request for the account @TargetAccount.getUserName@ of application @TargetApplication.getName@ on server @TargetServer.getHostName@ requested by user @User.getUserId@ has expired.	N/A

#### ***emailOneClickPasswordApprovalSubject***

Property for configuring one click approval email. This is an optional property.

Required	Default Value	Valid Values
no	Do not reply to this email.   A password view request has been submitted with the following details:  Requestor : @User.getUserID@ Requested Account: @TargetAccount.getUserName@ Requested Account Target Application Name: @TargetApplication.getName@ Requested Account Target Server: @TargetServer.getHostName@ Request Reason: @PasswordViewRequest.getReason@ (@PasswordViewRequest.getReasonDescription@) Start Date: @PasswordViewRequest.getStartDate@ End Date: @PasswordViewRequest.getEndDate@  <a href='@ApprovalURL@'>Click here to Approve this Request</a>  <a href='@DenialURL@'>Click here to Deny this Request</a>	N/A

#### ***emailOneClickPasswordApprovalBody***

Property for configuring one click approval email. This is an optional property.

Required	Default Value	Valid Values
no	Password View Request for target account @TargetAccount.getUserName@	N/A

#### ***emailReportResultSubject***

Property for configuring the report results email. This is an optional property.

Required	Default Value	Valid Values
no	Report results for @reportName@	N/A

#### ***emailReportResultBody***

Property for configuring the report results email. This is an optional property.

Required	Default Value	Valid Values
no	Do not reply to this email. The @reportName@ report has been run. The attached results encompass the period from @reportStartDate@ to @reportEndDate@.	N/A

#### ***reportAttachmentLimit***

Specifies the maximum size of a report email attachment, for example, 1 MB.

Required	Default Value	Notes	encryptValue
no	5 MB	Set an integer value in MB	False

### ***ViewPasswordReasons***

When a user wants to view a password, the reasons are shown in a drop-down list. Multiple reasons are delimited by the pipe (|) character, such as reason1|reason2.

Required	Default Value	Valid Values
no	N/A	Severity 1: Manual recovery from server outage Severity 1: Manual change due to potential password breach Severity 2: Password composition audit Severity 3: Application migration Severity 3: Pre-production application testing Other

### ***viewPasswordApprovalReasons***

Use to view password approval reason, the options are shown in a drop-down list.

Required	Default Value	Valid Values
no	N/A	Approve

### ***viewPasswordDenialReasons***

When a user wants to view a password denial reason, the options are shown in a drop-down list. Multiple reasons are delimited by the pipe (|) character, such as reason1|reason2.

Required	Default Value	Valid Values
no	N/A	<ul style="list-style-type: none"> <li>Deny</li> <li>Password request outside permitted window</li> <li>Other</li> </ul>

### ***ViewPasswordAcknowledgeReasons***

When a user wants to view a password acknowledge reason (for retrospective approval), the options are shown in a drop-down list.

Required	Default Value	Valid Values
no	N/A	Acknowledge

### ***viewPasswordDeclineReasons***

When a user wants to view a password decline reason (for retrospective approval), the options are shown in a drop-down list. Multiple reasons are delimited by the pipe ( | ) character, such as reason1|reason2.

Required	Default Value	Valid Values
no	N/A	<ul style="list-style-type: none"> <li>Decline</li> <li>Other</li> </ul>

### ***lunaPassword***

Luna SA set partition password.

Required	Default Value	Valid Values
no	N/A	password

### ***getLogsMaxSize***

Specifies the file size for server logs, Windows proxy logs, or client logs.

Required	Default Value	Valid Values
no	20 MB	Integer

### ***defaultPasswordViewRequestBanner***

The banner description for the Password View Policy.

Required	Default Value	Valid Values
no	none	Alphanumeric, -, . and space character

## **updateAgent**

Use the updateAgent command to activate and manage the Windows Proxy configuration on the appliance. The Windows Proxy is considered an agent by PAM.

### **Example**

```
capam_command capam=capam_server adminUserId=super cmdName=updateAgent
Agent.ID=1000 Agent.active=true
```

```
Attribute.descriptor1=windows_proxy
```

## **Parameters**

### **Agent.ID**

The unique ID for the agent to be changed.

Required	Default Value	Valid Values
Yes	N/A	Numeric. Retrieve the Agent ID using the searchAgent command.

**Agent.hostName**

The updated value for the agent host name.

Required	Default Value	Valid Values
No. If this parameter is not included, the value is preserved.	N/A	String

**Agent.deviceName**

The updated value for the agent device name.

Required	Default Value	Valid Values
No. If this parameter is not included, the value is preserved.	N/A	String

**Agent.active**

Activates the Windows Proxy agent. Set this parameter to true to activate the agent or false to deactivate to agent.

Required	Default Value	Valid Values
No. If this parameter is not included, the existing value is preserved.	false	true, false

**Agent.port**

The port number the agent listens on for incoming requests.

Required	Default Value	Valid Values
No. If this parameter is not included, the existing port value is preserved.	N/A	Integer

**Agent.updatePortFlag**

This command indicates whether the port value is updated. If this value is set to true, the port parameter is set, the port value gets updated.

Required	Default Value	Valid Values
If you are passing the Agent.port parameter, this parameter is required. If this parameter is not included, the existing port value is preserved.	false	true, false

**Agent.acceptPendingFingerprint**

Accepts or denies the pending fingerprint. The fingerprint identifies the Windows Proxy installed on a Windows device.

Required	Default Value	Valid Values
No. If this parameter is not included, the existing value is preserved.	false	true, false

**Agent.preserveHostName**

Preserves the agent host name or lets it get overwritten each time the Windows Proxy Agent registers. To prevent the agent host name from being overwritten, set this parameter to true.

Required	Default Value	Valid Values
No. If this parameter is not included, the existing value is preserved.	false	true, false

### **Agent.patchStatus**

Disable or enable agent patch upgrade. If this parameter is set to Disabled, the agent does not apply the patch, even if the appliance finds a newer version.

Required	Default Value	Valid Values
No. If this parameter is not included, the existing value is preserved.	Disabled	Disabled, Enabled

### **Attribute.descriptor1**

The updated value for the text description field for the Windows Proxy Agent.

Required	Default Value	Valid Values
No. If this parameter is not included, the existing value is preserved.	N/A	String

### **Attribute.descriptor2**

The updated value for the text description field for the Windows Proxy Agent.

Required	Default Value	Valid Values
No. If this parameter is not included, the existing value is preserved.	N/A	String

## **updateAuthorization**

Use the updateAuthorization command to change authorization mapping information.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateAuthorization
  Authorization.ID=10
```

```
RequestServer.ID=17 RequestScript.ID=2 Authorization.checkExecutionID=true
  Authorization.executionUser=auser
```

```
Authorization.checkPath=true TargetAlias.ID=6
```

## **Parameters**

### **Authorization.ID**

The unique ID for the authorization mapping to be changed.

Required	Default Value	Valid Values
yes	N/A	Numeric. Use searchAuthorization to retrieve the Authorization.ID

### **TargetAlias.ID**

The updated value for the target alias ID.

Required	Default Value	Valid Values
TargetAlias.ID or Authorization.targetGroupId	N/A	Numeric. Use searchTargetAlias to retrieve the TargetAlias.ID

### **Authorization.targetGroupId**

The updated value for the target group ID.

Required	Default Value	Valid Values
TargetAlias.ID or Authorization.targetGroupId	N/A	Numeric

### **RequestServer.ID**

The updated value for the request server ID on which the requesting application resides.

Required	Default Value	Valid Values
RequestServer.ID and RequestScript.ID or Authorization.requestGroupId	N/A	Numeric. Use searchRequestServer to retrieve the RequestServer.ID

### **RequestScript.ID**

The updated value for request script ID.

Required	Default Value	Valid Values
RequestServer.ID and RequestScript.ID or Authorization.requestGroupId	N/A	Numeric. Use searchRequestScript to retrieve the RequestScript.ID

### **Authorization.requestGroupId**

The updated value for request group ID.

Required	Default Value	Valid Values
RequestServer.ID and RequestScript.ID or Authorization.requestGroupId	N/A	Numeric

### **Authorization.checkExecutionID**

Set Authorization.checkExecutionID=true to indicate that the execution user ID be validated.

Required	Default Value	Valid Values
yes	false	true, false

**Authorization.executionUser**

A comma delimited list of execution user IDs. The IDs are only validated if Authorization.checkExecutionID=true.

Required	Default Value	Valid Values
yes	N/A	N/A

**Authorization.checkPath**

Set Authorization.checkPath=true to indicate that the script execution path be validated.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is reset to null.	false	true, false

**Authorization.checkFilePath**

Set Authorization.checkFilePath=true to indicate that the script file path be validated.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is reset to null.	false	true, false

**Authorization.checkScriptHash**

Set Authorization.checkScriptHash=true to indicate script hash integrity verification be performed.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is reset to null.	false	true, false

**updateDBClusterMembers**

Use the updateDBClusterMembers command to update database information about a cluster member.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateDbClusterMember
database.ID=db1 active=false
```

**Parameters****database.ID**

Database ID of the cluster member to update

Required	Default Value	Valid Values
yes	N/A	String

**active**

Set this parameter to true to activate the specified cluster member. Specify false to deactivate the member.

Required	Default Value	Valid Values
yes	N/A	true, false

### **method**

Optional synchronization strategy values: "full" or "dump-restore"

Required	Default Value	Valid Values
no	Use <b>dump-restore</b> for MySQL 5.6 or higher and PostgreSQL 9.4 and higher. Use <b>full</b> for Oracle, DB2, SQL Server, and MySQL versions 5.5 or earlier.	full, dump-restore

## **updateDBPassword**

Use this command to change the administrator password for Data Manipulation Language (DML) or Data Definition Language (DDL) user accounts in all Credential Manager databases except DB2. This command can be executed at a secondary site. A DML user can manipulate data within database tables. A DDL user can define the database schema.

When DML and DDL user accounts share the database username, their passwords are changed in the init properties table of Credential Manager. To change database password in DB2 database, use the setInitProperty command.

### **WARNING**

Changing the password directly in the database prevents Credential Manager from operating. Use this command to change the password because Credential Manager uses proprietary key-hiding technology to store the database password securely.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateDBPassword
dbuserType=dml dbusername=admin dbpassword=test

updateLoginCredentials=true
```

### **Parameters**

#### **dbuserType**

The Credential Manager database user type. Data Manipulation Language (DML) or Data Definition Language (DDL).

Required	Default Value	Valid Values
yes	N/A	dml, ddl

#### **dbusername**

The Credential Manager database administrator username.

Required	Default Value	Valid Values
yes	N/A	String

***dbpassword***

Specifies the new Credential Manager database administrator password.

Required	Default Value	Valid Values
yes	N/A	String. In UNIX, passwords with special characters must be enclosed in single quotes.

***updateLoginCredentials***

Indicates whether to update the database user account. Set this parameter to true to update the database. Otherwise, set it to false.

Required	Default Value	Valid Values
no	true	true, false

**updateFilter**

Use the updateFilter command to update a target group or request group filter.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateFilter
  Filter.ID=6 Filter.objectClassId=c.cw.m.ts

  Filter.attribute=hostName Filter.type=contains Filter.expression=Ottawa
```

**Parameters****Filter.ID**

The ID of the filter. It must be an integer greater than or equal to 1.

Required	Default Value	Valid Values
yes	N/A	Integer

**Filter.objectClassId**

The type of object to filter. Class IDs are specific to group type.

Required	Default Value	Valid Values
yes	N/A	c.cw.m.ts, c.cw.m.tp, c.cw.m.ac, c.cw.m.rs, c.cw.m.sc

**Filter.attribute**

The filter attribute. If static, attribute must be ID. If dynamic, attributes are specific to objectClassId.

Required	Default Value	Valid Values
yes	N/A	String

### **Filter.type**

The filter type. If group is static, only equals is valid.

Required	Default Value	Valid Values
yes	N/A	equals, beginswith, contains, endswith, notcontains

### **Filter.expression**

The filter expression. If the group is static, the expression can only be an integer greater than or equal to 1.

Required	Default Value	Valid Values
yes	N/A	String, Integer

## **updateGroup**

Use the updateGroup command to change a target or request group.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateGroup
  Group.ID=5 Group.name="TokyoTargets"
```

```
Group.description="Targets in Tokyo" Group.type=target
```

## **Parameters**

### **Group.ID**

The ID of the group.

Required	Default Value	Valid Values
Group.name or Group.ID	N/A	Integer

### **Group.name**

The name of the target or request group.

Required	Default Value	Valid Values
Group.name or Group.ID	N/A	String

### **Group.description**

The description of the group.

Required	Default Value	Valid Values
no	N/A	String

### **Group.type**

Set this parameter to **requestor** for request groups. Set it to **target** for target groups.

Required	Default Value	Valid Values
yes	N/A	requestor, target

### **Group.dynamic**

Set this parameter to true for dynamic Request or Target groups. Set it to false for static Request or Target groups.

Required	Default Value	Valid Values
no	true	true, false

### **Group.permissions**

Array list object of filters, or XML encoded ArrayList of filters. If not set, the filters are cleared.

Required	Default Value	Valid Values
no	N/A	XML

## **updatePasswordPolicy**

Use the updatePasswordPolicy command to update a password policy.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updatePasswordPolicy
PasswordPolicy.ID=1
PasswordPolicy.name=passwordPolicyName
Attribute.composedOfUpperCaseCharacters=true
Attribute.firstCharacterUpperCase=true
```

### **Parameters**

#### **PasswordPolicy.ID**

The ID of the password policy.

Required	Default Value	Valid Values
yes	null	Numeric

#### **PasswordPolicy.name**

The name of the password policy.

Required	Default Value	Valid Values
yes	null	String

#### **PasswordPolicy.description**

The description of the password policy.

Required	Default Value	Valid Values
no	Blank	String

#### **Attribute.passwordPrefix**

The prefix for all passwords mandated by your password policy.

Required	Default Value	Valid Values
no	None	Constrained by your other settings.

#### **Attribute.composedOfUpperCaseCharacters**

Set to true if you wish to mandate that your password policy contain upper case characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.composedOfLowerCaseCharacters**

Set to true if you wish to mandate that your password policy contain lower case characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.composedOfNumericCharacters**

Set to true if you wish to mandate that your password policy contain numeric characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.composedOfSpecialCharacters**

Set to true if you wish to mandate that your password policy contain an special characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.specialCharacters**

The list of all special characters mandated by your password policy.

Required	Default Value	Valid Values
no	None	!#\$%()*+,-./:;=?@[\\]^_`{ }~

#### **Attribute.firstCharacterUpperCase**

Set to true if you wish to mandate that your password policy contain upper case characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.firstCharacterLowerCase**

Set to true if you wish to mandate that your password policy contain lower case characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.firstCharacterNumeric**

Set to true if you wish to mandate that your password policy contain numeric characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.firstCharacterSpecial**

Set to true if you wish to mandate that your password policy contain an special characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.firstCharacterSpecials**

The list of all special characters mandated by your password policy.

Required	Default Value	Valid Values
no	None	!#\$%()*+,-./:;=?@[\\]^_`{ }~

#### **Attribute.mustNotContainConsecutiveDuplicateCharacters**

Set to true if you wish to mandate that your password policy not allow any repeating characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.mustNotContainAnyDuplicateCharacters**

Set to true if you wish to mandate that your password policy not allow any duplicate characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.mustNotContainCharacters**

Set to true if you wish to mandate that your password policy not contain certain upper case, lower case, or numeric characters.

Required	Default Value	Valid Values
no	false	true, false

#### **Attribute.composedOfMustNotContainCharacters**

The list of all characters not allowed by your password policy. No overlap allowed with special characters.

Required	Default Value	Valid Values
no	Blank	ABCDEFGHIJKLMNOPQRSTUVWXYZabc defghijklmnopqrstuvwxyz0123456789

#### **Attribute.minLength**

Set the minimum length of characters you wish to mandate by your password policy.

Required	Default Value	Valid Values
no	4	Numeric

#### **Attribute.maxLength**

Set the maximum length of characters you wish to mandate by your password policy.

Required	Default Value	Valid Values
no	16	Numeric

#### **Attribute.minIterationsBeforeReuse**

Set the minimum number of iterations before a password can be reused.

Required	Default Value	Valid Values
no	0	Numeric

#### **Attribute.minDaysBeforeReuse**

Set the minimum number of days before a password can be reused.

Required	Default Value	Valid Values
no	0	Numeric

#### **Attribute.enableMaxPasswordAge**

Set to true if you wish to enable Maximum password age in your password policy.

Required	Default Value	Valid Values
no	false	true, false

### **Attribute.maxPasswordAge**

Set the Maximum password age.

Required	Default Value	Valid Values
yes, if Attribute.enableMaxPasswordAge is set to true	None	Numeric

## **updatePasswordViewPolicy**

Use the updatePasswordViewPolicy command to update a password view policy in Credential Manager.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=updatePasswordViewPolicy PasswordViewPolicy.ID=7

PasswordViewPolicy.checkinCheckoutRequired=true
PasswordViewPolicy.checkinCheckoutInterval=240
```

### **Parameters**

#### **PasswordViewPolicy.ID**

The ID of the password view policy.

Required	Default Value	Valid Values
yes	N/A	Use searchPasswordViewPolicy to retrieve the ID

#### **PasswordViewPolicy.name**

The updated name of the password view policy.

Required	Default Value	Valid Values
No. If not specified, the existing name is preserved.	N/A	String

#### **PasswordViewPolicy.description**

An updated description of the password view policy.

Required	Default Value	Valid Values
No. If not specified, the existing description is preserved.	N/A	String

**PasswordViewPolicy.changePasswordOnView**

Set PasswordViewPolicy.changePasswordOnView=true to indicate that Credential Manager should change the password after a password view request.

Required	Default Value	Valid Values
No. If not specified, the existing value is preserved.	false	true, false

**PasswordViewPolicy.changePasswordOnSso**

Set PasswordViewPolicy.changePasswordOnSso=true to indicate that Credential Manager should change the password after a password SSO request (retrieved but not viewed).

Required	Default Value	Valid Values
No. If not specified, the existing value is preserved.	false	true, false

**PasswordViewPolicy.passwordChangeInterval**

If the changePasswordOnView parameter is set to true, this parameter determines the amount of time (in minutes) before the password is changed.

Required	Default Value	Valid Values
yes, if PasswordViewPolicy.changePasswordOnView is true	If not specified, the existing value is preserved.	Numeric value greater than 0

**PasswordViewPolicy.checkinCheckoutRequired**

Set this parameter to true to indicate that an account must be checked out to view the password. When checked out, the account password cannot be changed.

Required	Default Value	Valid Values
If not specified, the existing value is preserved.	false	true, false

**PasswordViewPolicy.checkinCheckoutInterval**

This parameter determines the amount of time (in minutes) an account can be checked out before it is automatically checked back in by the system.

Required	Default Value	Valid Values
yes, if PasswordViewPolicy.checkinCheckoutRequired is true	If not specified, the existing value is preserved.	Numeric value greater than 0.

**PasswordViewPolicy.dualAuthorization**

Set the PasswordViewPolicy.dualAuthorization to true to indicate that another user must approve a request to view a password before proceeding. Note that the XML content returned by PAM shows this parameter with name **dualAuthorizationRequired**.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.dualAuthorizationInterval**

This parameter determines the default amount of time (in minutes) a password view request remains active in the system. This setting is valid provided the requesting user does not specify a start and end time for the password view request.

Required	Default Value	Valid Values
yes, if PasswordViewPolicy.dualAuthorization is true.	If not specified, the existing value is preserved	Numeric value greater than 0

#### **PasswordViewPolicy.retrospectiveApprovalRequired**

Set PasswordViewPolicy.retrospectiveApprovalRequired=true to indicate that a request to view a password must be retrospectively approved by an approver.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.approvers**

The list of users who are authorized to approve or deny password requests for accounts that use this password policy.

Required	Default Value	Valid Values
If PasswordViewPolicy.dualAuthorization is true, specify PasswordViewPolicy.approvers or PasswordViewPolicy.approverIDs	If not specified, the existing values are preserved	List of comma-separated usernames. Example: jbauer,mdessler,dpalmer

#### **PasswordViewPolicy.approverIDs**

The list of user IDs who are authorized to approve or deny password requests for accounts that use this password policy.

Required	Default Value	Valid Values
If PasswordViewPolicy.dualAuthorization is true, specify PasswordViewPolicy.approvers or PasswordViewPolicy.approverIDs	Use searchUser to retrieve a list of user IDs. If not specified, the existing values are preserved.	List of comma-separated user IDs. Example: 11,19,15

#### **PasswordViewPolicy.authenticationRequiredSso**

Set this parameter to true to indicate that the requesting user must provide their own password before using the account for auto-connect.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.authenticationRequired**

Set this parameter to true to indicate that the requesting user must provide their own password before viewing the account password.

Required	Default Value	Valid Values
no	true	true, false

#### **PasswordViewPolicy.enableOneClickApproval**

Set this parameter to true to enable dual authorization one click approval. When enabled, dual authorization emails include links that let the approver permit requests without logging into the system.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.PasswordViewRequestMaxInterval**

The maximum Interval between the start and end date of a dual authorization password view request.

Required	Default Value	Valid Values
no	60	Numeric value greater than 0.

#### **PasswordViewPolicy.PasswordViewRequestMaxDays**

The maximum number of days in the future that a password view request can be requested.

Required	Default Value	Valid Values
no	14	Numeric value greater than 0.

#### **PasswordViewPolicy.passwordViewRequestBanner**

The updated banner description for the Password View Policy.

Required	Default Value	Valid Values
no	none	Alphanumeric, -, . and space character

#### **NOTE**

For more information on the following parameters, see their UI equivalents in the [Create a Basic Password View Policy](#) topic.

#### **PasswordViewPolicy.reasonRequiredView**

If set to true, a dialog appears when a user tries to view an Account password. The user selects a Reason and enters a Description and Reference Code to view the password. Select the View Credential (eye icon) for an Account on the Account List page or on the Account Details page.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.reasonRequiredSso**

If set to true, a dialog appears when a user tries to auto-connect. The user selects a Reason and enters an optional Description and optional Reference Code to auto-connect.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.exclusiveCheckoutRequired**

If set to true, this option specifies that credentials are checked in if all connections are closed.

##### **NOTE**

If you select this option, all view properties and the Check-out/Check-in property are unavailable.

If PasswordViewPolicy.exclusiveCheckoutRequired is selected with service desk integration, the Reason Required for View option is selected but disabled. Even though it is selected, the functionality of view password does not work, as exclusive checkout takes precedence. Viewing of a password is disabled when the account is associated with exclusive checkout on auto connect.

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.changePasswordOnSessionEnd**

If set to true, all passwords that are used to log in to target servers are changed when the user session in Privileged Access Manager ends. The connection can end because the user logs out, a session times out, or connectivity is lost. This option does not apply to "View Password."

Required	Default Value	Valid Values
no	false	true, false

#### **PasswordViewPolicy.changePasswordOnConnectionEnd**

If set to true, the password is automatically changed when the user's SSH or RDP connection to a target server ends. The connection can end because the connection times-out, the user terminates the connection, or the connection is lost. This option does not apply to "View Password."

Required	Default Value	Valid Values
no	false	true, false

#### **updatePasswordViewRequestStatus**

Use the updatePasswordViewRequestStatus command to approve or deny a password view request. This command can be run on a secondary site.

## Example

```
capam_command capam=capamServer adminUserID=admin
cmdName=updatePasswordViewRequestStatusPasswordViewRequest.ID=1
PasswordViewRequest.status=approved
```

## Parameters

### **PasswordViewRequest.ID**

The ID of the password view request. Use listPasswordViewRequestByApprover to obtain the PasswordViewRequest.ID

Required	Default Value	Valid Values
yes	N/A	Integer

### ***PasswordViewRequest.status***

Filter results that contain the value that is specified.

Required	Default Value	Valid Values
no	N/A	<b>Dual authorization:</b> "approved" (or 1), "denied" (or 2) <b>Retrospective approval:</b> "acknowledged" (or 9), "declined" (or 10)

### **PasswordViewRequest.statusCode**

The status of the password view request.

Required	Default Value	Valid Values
PasswordViewRequest.statusCode	N/A	1 (approved), 2 (denied) 9 (acknowledged), 10 (declined)

### **PasswordViewRequest.approvalReason**

The approval reason for the password view request.

Required	Default Value	Valid Values
no	N/A	String

### **PasswordViewRequest.approvalReasonDescription**

The approval reason description for the password view request.

Required	Default Value	Valid Values
no	N/A	String

## updateRequestScript

Use the updateRequestScript command to change request application information.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateRequestScript
RequestServer.ID=17 RequestScript.ID=5
```

```
RequestScript.name=myExample.clas RequestScript.executionPath=/opt/cloakware/
cspmclient/examples
```

```
RequestScript.filePath=/opt/cloakware/cspmclient/bin RequestScript.type=java
```

**Parameters****RequestScript.ID**

The unique ID for the request script to be changed.

Required	Default Value	Valid Values
yes	N/A	Numeric. Use searchRequestScript to retrieve the RequestScript.ID.

**RequestServer.ID**

The updated value for the RequestServer.ID.

Required	Default Value	Valid Values
yes	N/A	Numeric. Use searchRequestServer to retrieve the RequestServer.ID

**RequestScript.name**

The updated value for the request script name.

Required	Default Value	Valid Values
yes	N/A	String

**RequestScript.executionPath**

The updated value for the location from which the requesting application will be run.

Required	Default Value	Valid Values
yes	N/A	String

**RequestScript.filePath**

The updated value for the location in which the requesting application resides.

Required	Default Value	Valid Values
yes	N/A	N/A

**RequestScript.type**

The updated value for the programming language in which the requesting application is written.

Required	Default Value	Valid Values
yes	N/A	C, C++, C#, csh, Java, ksh, Perl, ksh, VB, VB.NET, VC++, Other

#### **Attribute.descriptor1**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

#### **Attribute.descriptor2**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

## **updateRequestServer**

Use the updateRequestServer command to change request server information.

### **NOTE**

If you want to update the Windows Proxy configuration, use the updateAgent command.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateRequestServer
RequestServer.ID=17
```

```
RequestServer.hostName=myhostname2.mydomain.com Attribute.descriptor1="Lab"
Attribute.descriptor2="Vienna"
```

## **Parameters**

### **RequestServer.ID**

The unique ID for the request server to be changed.

Required	Default Value	Valid Values
yes	N/A	Numeric. Use searchRequestServer to retrieve RequestServer.ID.

### **RequestServer.hostName**

The updated value for the request server host name.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

### **RequestServer.deviceName**

The updated value for the request server device name.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

### **RequestServer.active**

Set RequestServer.active=true to activate the request server. Set RequestServer.active=false to deactivate to request server.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	false	true, false

### **RequestServer.port**

The port number the request server listens on for incoming requests. This value is optional.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	Integer

### **RequestServer.updatePortFlag**

If this value is set to true, and the RequestServer.port value is set, the port flag updates.

Required	Default Value	Valid Values
no. If this parameter is not included, the port is preserved.	false	true, false

### **RequestServer.acceptPendingFingerprint**

This command determines whether to accept or deny the pending fingerprint.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	false	true, false

### **RequestServer.preserveHostName**

Set `RequestServer.preserveHostName=true` to indicate that the request server host name should not be overwritten each time the client registers.

Required	Default Value	Valid Values
no	false	true, false

### **RequestServer.patchStatus**

Disables or enables request server patch upgrade. If this parameter is set to Disabled, the request server does not apply patch, even if newer version found and activated.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	Disabled	Disabled, Enabled

### **Attribute.descriptor1**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

### **Attribute.descriptor2**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

## **updateRequestServerDefaults**

Use the `updateRequestServerDefaults` command to update a request server defaults in Credential Manager.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=updateRequestServerDefaults
RequestServerDefaults.subnet=192.168.0.0/16
```

```
RequestServerDefaults.active=true RequestServerDefaults.type=CLIENT
RequestServerDefaults.descriptor1=awsApiProxy
```

### **Parameters**

#### **RequestServerDefaults.ID**

The id of the record to delete.

Required	Default Value	Valid Values
yes	N/A	Integer

### **RequestServerDefaults.subnet**

The subnet filter to apply defaults to request servers.

Required	Default Value	Valid Values
yes	N/A	String

### **RequestServerDefaults.type**

The type filter to apply defaults to request servers.

Required	Default Value	Valid Values
yes	N/A	CLIENT, AGENT, ALL

### **RequestServerDefaults.active**

The default setting for RequestServer.active during auto-register.

Required	Default Value	Valid Values
yes	N/A	true, false

### **RequestServerDefaults.descriptor1**

The default setting for Attribute.descriptor1 during auto-register.

Required	Default Value	Valid Values
no	N/A	String

### **RequestServerDefaults.descriptor2**

The default setting for Attribute.descriptor2 during auto-register.

Required	Default Value	Valid Values
no	N/A	String

## **updateRequestServerKey**

Use the updateRequestServerKey command to change the Request Server (Credential Manager client) encryption key.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=updateRequestServerKey RequestServer.hostName=myhostname.mydomain.com
```

**Parameters****RequestServer.hostName**

The host name of the request server.

Required	Default Value	Valid Values
One of RequestServer.hostName or RequestServer.ID is required.	N/A	String

**RequestServer.ID**

The ID of the request server.

Required	Default Value	Valid Values
One of RequestServer.hostName or RequestServer.ID is required.	N/A	Numeric. Use searchRequestServer to retrieve the RequestServer.ID

**updateRole**

Use the command to change role information in Credential Manager.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateRole Role.ID=11
  Role.name="Patch Management"
```

```
Role.description="Manages Patches" Role.permissions="activatePatch,
  addPatch, deletePatch, getPatchDetail, listPatch, listPatchDetailSummary, updatePatch"
```

**Parameters****Role.ID**

The ID of the role.

Required	Default Value	Valid Values
yes	N/A	Numeric

**Role.name**

The name of the role.

Required	Default Value	Valid Values
yes	N/A	String. A Unique Name in Credential Manager

**Role.description**

The description of the role.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is reset to null.	N/A	String

### **Role.permissions**

A comma delimited list of permissions.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is reset to null.	N/A	String. To see the available list of user permissions, see <a href="#">Add or Modify Credential Manager Roles</a> .

## **updateServerKey**

The updateServerKey command changes the Credential Manager server encryption key. The updateServerKey command reads every encrypted record in the database. The command decrypts the record with the old key, re-encrypts it with the new key, and writes the record back to the database. This command does not take parameters.

### **WARNING**

Before using this command, contact Broadcom Support.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateServerKey
```

## **updateSSHKeyPairPolicy**

Use the updateSSHKeyPairPolicy command to update an existing SSH Key Pair Policy.

### **Example**

```
capam_command capam=capamServer adminUserID=super adminPassword=test
cmdName=updateSSHKeyPairPolicy
SSHKeyPairPolicy.name=Testing SSHKeyPairPolicy.keyType=DSA
SSHKeyPairPolicy.keyLength=512
```

### **Parameters**

#### **SSHKeyPairPolicy.ID**

The policy ID.

Required	Default Value	Valid Values
Yes, if SSHKeyPairPolicy.name is not specified; otherwise no	N/A	An integer greater than or equal to 0

#### **SSHKeyPairPolicy.name**

The policy name.

Required	Default Value	Valid Values
Yes, if SSHKeyPairPolicy.ID is not specified; otherwise no	N/A	String

### **SSHKeyPairPolicy.description**

The policy description.

Required	Default Value	Valid Values
No	N/A	A String

### **SSHKeyPairPolicy.keyType**

The key type.

Required	Default Value	Valid Values
No	N/A	ECDSA or RSA or DSA

### **SSHKeyPairPolicy.keyLength**

The key length.

Required	Default Value	Valid Values
No	N/A	Varies depending on key type. The supported DSA key lengths are 512 bits and 1024 bits. The supported ECDSA key lengths are 256 bits, 384 bits, and 521 bits. The supported RSA key lengths are 1024 bits, 2048 bits, and 4096 bits..

## **updateTargetAccount**

Use the updateTargetAccount command to change target account information, including the target account password. Alternatively, use updateTargetAccountPassword to change the password. More parameters may be required, depending on the Target Application Type. For a description of these additional parameters, look up the appropriate turnkey target connector.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=updateTargetAccountvTargetAccount.ID=12
```

```
TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myApplication TargetAccount.userName=sysop1
```

```
TargetAccount.password='sys0p!@2' TargetAccount.cacheBehavior=useServerFirst
TargetAccount.cacheDuration=17
```

**Parameters****TargetAccount.ID**

The unique ID for the target account to be changed.

Required	Default Value	Valid Values
yes	N/A	Numeric. Use searchTargetAccount to retrieve the TargetAccount.ID

**TargetApplication.ID**

The updated value for TargetApplication.ID.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchTargetApplication to retrieve the TargetApplication.ID

**TargetAccount.userName**

The updated value for the target account user name.

Required	Default Value	Valid Values
yes.	N/A	String

**TargetAccount.password**

The updated value for the target account password.

Required	Default Value	Valid Values
no. If this parameter is not included, the password is unchanged	N/A	If a password policy is assigned to the target application, this value must adhere to the password policy. In addition to password policy requirements, a password must be minimum of 1 character and a maximum of 255 characters in length.

**TargetAccount.cacheAllow (Deprecated)**

Deprecated Parameter, use TargetAccount.cacheBehavior: Set TargetAccount.cacheAllow=true to have credentials for this account that is cached in the Credential Manager client.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	true, false

**TargetAccount.cacheBehavior**

To use the credentials that are cached at the target account first, set TargetAccount.cacheBehavior=useCacheFirst.  
To use the credentials that are cached at this target account but contact the Server first, set

TargetAccount.cacheBehavior=useServerFirst. To ensure that the credentials for this account are not cached at the target account, set TargetAccount.cacheBehavior=noCache.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	useCacheFirst	useCacheFirst, useServerFirst, noCache

### **TargetAccount.cacheDuration**

Use TargetAccount.cacheDuration to specify the number of days the account credentials are permitted to reside in a Credential Manager client cache.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	1-356

### **TargetAccount.privileged**

Set TargetAccount.privileged=true to indicate that this account is a privileged account. Set TargetAccount.privileged=false to indicate that this account is an application-to-application account.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	true, false

### **TargetAccount.accessType**

Use this text field for reference purposes.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is reset to null.	N/A	String

### **TargetAccount.synchronize**

Set TargetAccount.synchronize=true to indicate that the password that is stored in the Credential Manager database should be synchronized with the password on the target system. This functionality is not supported with Target Application Type Generic.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	true, false

### **Attribute.changePasswordAfterViewing (Deprecated)**

This parameter is no longer used.: Set Attribute.changePasswordAfterViewing=true to indicate that Credential Manager should change the password after a password view request (either from the GUI or CLI). This feature applies only to

accounts where TargetAccount.synchronize=true. This parameter is ignored if the Change Password After Viewing feature has been disabled on the Credential Manager server.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	true, false

#### **Attribute.descriptor1**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

#### **Attribute.descriptor2**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

#### **PasswordViewPolicy.ID**

The ID of a PasswordViewPolicy attached to this account.

Required	Default Value	Valid Values
No. If this parameter is not included, the value is preserved.	N/A	Numeric

#### **TargetAlias.name**

A comma-separated list of TargetAlias.name values. This parameter depends on the value of useTargetAliasNameParameter being true.

Required	Default Value	Valid Values
no. If not specified and useTargetAliasNameParameter is set to true, all associated target aliases are deleted	N/A	Comma-separated string

#### **useTargetAliasNameParameter**

If this parameter is set to true, Credential Manager adds target aliases for this account. If the value is false, the aliases are not used.

Required	Default Value	Valid Values
no.	false	true, false

#### **TargetAccount.compoundAccount**

If this parameter is set to true, Credential Manager adds compound target servers for this account, using the values of the `TargetAccount.compoundServerIDs` parameter. If the value is false, the compound target servers are not used.

Required	Default Value	Valid Values
no.	false	true, false

### **TargetAccount.compoundServerIDs**

This parameter adds (true) or deletes (false) compound servers to the list of compound server IDs for the target account.

Required	Default Value	Valid Values
no.	false	true, false

### **passwordIsBase64Encoded**

If this parameter is set to true, the specified password is Base64-encoded. The parameters instruct Credential Manager to decode the password before storing it.

Required	Default Value	Valid Values
no.	false	true, false

## **updateTargetAccountDescriptor**

Use the `updateTargetAccountDescriptor` command to change the descriptor value of a target account.

### **Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=updateTargetAccountDescriptor
```

```
TargetAccount.ID=5 Attribute.descriptor1=testvalue1
Attribute.descriptor2=testvalue2
```

## **Parameters**

### **TargetServer.hostName**

The host name for the target server on which the target account resides.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID	N/A	String. This value must match a target server name registered in Credential Manager.

### **TargetApplication.name**

The target application name on which the target account is hosted.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID	N/A	String. This value must match a target application name registered in Credential Manager.

### **TargetAccount.userName**

The user name for the target account.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID	N/A	String. This target account name must be unique for a given target application. This name must match the user name in the target application.

### **TargetAccount.ID**

The unique identifier of the target account. This value is required if TargetServer.hostName, TargetApplication.name and TargetAccount.userName are not specified.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID	N/A	Numeric. Use searchTargetAccount to retrieve the TargetAccount.ID

### **Attribute.descriptor1**

The updated value for the text description field. Use this field as a filter for dynamic target groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

### **Attribute.descriptor2**

The updated value for the text description field. Use this field as a filter for dynamic target groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

## **updateTargetAccountPassword**

Use the updateTargetAccountPassword command to change a target account password. The password can be specified or automatically generated based on the associated password policy. By default, this command works only for synchronized accounts. Set the **allowUnsynchronized** parameter to true to change the default nature.

**Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=updateTargetAccountPassword
TargetServer.hostName=myhostname.mydomain.com

TargetApplication.name=myApplication TargetAccount.userName=sysopl
```

**Parameters****TargetServer.hostName**

The host name for the target server on which the target account resides.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID	N/A	String. This value must match a target server name registered in Credential Manager.

**TargetApplication.name**

The target application name on which the target account is hosted.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID	N/A	String. This value must match a target application name registered in Credential Manager.

**TargetAccount.userName**

The user name for the target account.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID	N/A	String. This target account name must be unique for a given target application. This name must match the user name in the target application.

**TargetAccount.ID**

The unique identifier of the target account. This value is required if TargetServer.hostName, TargetApplication.name and TargetAccount.userName are not specified.

Required	Default Value	Valid Values
TargetServer.hostName, TargetApplication.name, and TargetAccount.userName; or TargetAccount.ID	N/A	Numeric. Use searchTargetAccount to retrieve the TargetAccount.ID.

**groupId**

The unique identifier of the target group for which the passwords will be updated.

Required	Default Value	Valid Values
no	N/A	Numeric. Use searchGroup to retrieve the groupId.

**password**

The password for the target account.

Required	Default Value	Valid Values
no	generated password	The password must conform to any applied password policies.

**confirmPassword**

The password for the target account.

Required	Default Value	Valid Values
no	generated password	The password must conform to any applied password policies. This must match the password value.

**allowUnsynchronized**

Allows the password to be updated for non-synchronized accounts.

Required	Default Value	Valid Values
no	false	String. Set the value to true to allow updates of unsynchronized accounts.

**TargetAccount.passwordVerified**

boolean

Required	Default Value	Valid Values
No	nothing (update all accounts)	true to update only verified accounts, false to verify accounts that failed verification

**updateTargetAlias**

Use the updateTargetAlias command to change target alias information.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateTargetAlias
  TargetAlias.ID=12 TargetAccount.ID=5

TargetAlias.name=myaliasname
```

**Parameters****TargetAlias.ID**

The unique ID for the target alias to be changed.

Required	Default Value	Valid Values
yes	N/A	Numeric. Use searchTargetAlias to retrieve the TargetAlias.ID

**TargetAccount.ID**

The updated value for the TargetAccount.ID.

Required	Default Value	Valid Values
yes	N/A	Numeric. Use searchTargetAccount to retrieve the TargetAccount.ID

**TargetAlias.name**

The updated value for the target alias name

Required	Default Value	Valid Values
no. If this parameter is not included, the value is set to null	N/A	String. The target alias name must be unique within the Credential Manager server.

**updateTargetApplication**

Use the updateTargetApplication command to change target application information. Additional parameters might be required, depending on the Target Application Type. For a description of these other parameters, look up the appropriate turnkey target connector. Prior to running updateTargetApplication, use searchTargetApplication to retrieve current parameter values.

**Example**

```
capam_command capam=capamServer adminUserID=admin
cmdName=updateTargetApplication TargetApplication.ID=5

TargetServer.ID=8 TargetApplication.name=myApplication
TargetApplication.type=Generic
```

**Parameters****TargetApplication.ID**

The unique ID for the target application to be changed.

Required	Default Value	Valid Values
yes	N/A	Use SearchTargetApplication to retrieve the TargetApplication.ID

### **TargetServer.ID**

The updated value for the ID of the target server on which the target application is hosted.

Required	Default Value	Valid Values
yes	N/A	Use searchTargetServer to retrieve the TargetServer.ID

### **TargetApplication.name**

The updated value for the name of the target application.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

### **TargetApplication.type**

The updated value for the target application connector name. Valid values depend upon which target connectors are installed on your system. If this parameter is not included, the target application type is preserved.

Required	Default Value	Valid Values
yes	N/A	See the addTargetApplication command for a list of valid application types.

### **PasswordPolicy.name**

The updated value for the name of the password policy that is applied to all accounts on associated with this application.

Required	Default Value	Valid Values
no. If PasswordPolicy.name or PasswordPolicy.ID is not included, the password policy is preserved.	N/A	If a password policy is not specified, manually entered passwords are not validated against a policy. In addition, Credential Manager generated passwords use the Credential Manager default password policy.

### **PasswordPolicy.ID**

The updated value for the ID of the password policy that is applied to all accounts on associated with this application.

Required	Default Value	Valid Values
no. If PasswordPolicy.name or PasswordPolicy.ID is not included, the password policy is preserved.	N/A	Use searchPasswordPolicy to retrieve this ID. If a password policy is not selected, manually entered passwords are not validated against a policy. In addition, Credential Manager-generated passwords use the default password policy.

#### **Attribute.descriptor1**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

#### **Attribute.descriptor2**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

#### **Attribute.enableAutoConnectTargetAccount**

A boolean value to enable / disable autoConnectTargetAccount for an application instance.

Required	Default Value	Valid Values
no	false	true, false

## **updateTargetServer**

Use the updateTargetServer command to change target server information.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateTargetServer
TargetServer.ID=17 TargetServer.hostName=myhostname2.mydomain.com
Attribute.descriptor1="Lab" Attribute.descriptor2="Vienna"
```

## **Parameters**

### **TargetServer.ID**

The unique ID for the target server to be changed.

Required	Default Value	Valid Values
yes. Required only if the TargetServer.hostName is changed.	N/A	Use searchTargetServer to retrieve the TargetServer.ID.

### **TargetServer.hostName**

The updated value for the host name of target server.

Required	Default Value	Valid Values
yes	N/A	This must be the fully qualified host name as entered in the DNS server.

### **TargetServer.deviceName**

The updated value for the device name of target server.

Required	Default Value	Valid Values
no	N/A	String

### **Attribute.descriptor1**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

### **Attribute.descriptor2**

The updated value for the text description field. Use this field as a filter for dynamic authorization groupings.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String

## **updateUser**

Use the updateUser command to change Credential Manager user information.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateUser
User.userID=demo User.password=demo123$
User.authenticationType=CSPM User.status=ACTIVE User.userGroupIDS=1,2
User.firstName=Demo User.lastName=User
```

### **NOTE**

Reactivating a suspended user clears the user's deactivation reason in the UI. Suspending an active user automatically sets the user's deactivation reason to **Other** in the UI.

**Parameters****User.userID**

The unique user name for the Credential Manager user to be changed.

Required	Default Value	Valid Values
yes	N/A	String

**User.password**

The updated value for the user's password.

Required	Default Value	Valid Values
This parameter is required if the authentication type is Credential Manager.	N/A	String. Credential Manager passwords must contain 6-16 characters containing at least one alphabetic, one numeric, and one special character.

**User.authenticationType**

The updated value for authentication type of the user.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	CSPM	CSPM, LDAP, SecurID, Kerberos, X509 or any installed authentication connector. For a complete list of installed authentication connectors, see \$CSPM_SERVER_HOME/cspmserver/config/authentication.xml f

**User.status**

The updated value for the user account status.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	ACTIVE	ACTIVE or SUSPENDED. Set to ACTIVE for active user accounts and to SUSPENDED to suspend a user account.

**User.userGroupIDS**

The updated value for IDs of the User Groups to assign to this user.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	Numeric IDs delimited by comma. Use listUserGroups to retrieve User Group IDs. Alternatively, you can specify the User.userGroupNames parameter. Values must match User Groups registered in Credential Manager.

**User.userGroupNames**

The updated value for names of the User Groups to assign to this user.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is preserved.	N/A	String containing the User Group names delimited by comma. Values must match User Groups registered in Credential Manager.

### **User.firstName**

The updated value for the first name of the user.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is reset to null.	N/A	String

### **User.lastName**

The updated value for the last name of the user.

Required	Default Value	Valid Values
no. If this parameter is not included, the value is reset to null.	N/A	String

### **User.email**

The updated value for the email address of the user.

Required	Default Value	Valid Values
no	N/A	String

### **User.viewType**

Determines what UI view this user has access to, administrative or general

Required	Default Value	Valid Values
no. If this parameter is not included, the existing value is preserved	N/A	admin, general

## **updateUserGroup**

Use the updateUserGroup command to change information for a user group.

### **Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=updateUserGroup
  UserGroup.ID=2 UserGroup.name=updatedUserGroupName
  UserGroup.description="Updated user group description" UserGroup.roleID=11
  UserGroup.groups=3,4
```

**Parameters****UserGroup.ID**

The user group ID.

Required	Default Value	Valid Values
yes	N/A	Numeric. A unique user group ID

**UserGroup.name**

The user group name.

Required	Default Value	Valid Values
yes	N/A	String. A unique user group name

**UserGroup.description**

The description of the group.

Required	Default Value	Valid Values
no. If this parameter is not included it will be reset to null.	N/A	String

**UserGroup.roleID**

The role identifier of this group.

Required	Default Value	Valid Values
yes	N/A	Numeric. This value must match a role ID registered in Credential Manager.

**UserGroup.groups**

A comma delimited list of group IDs.

Required	Default Value	Valid Values
no. If this parameter is not included it will be reset to null.	N/A	Numeric. Comma delimited list of group IDs

**NOTE**

Each dynamic target group referenced in the listed group IDs *must have at least one* filter defined. If not, the group is not updated.

**UserGroup.readOnly**

The read only flag for the user group.

Required	Default Value	Valid Value
no	N/A	true. False is not a valid value.

## updateUserPassword

Use the updateUserPassword command to change a user account password. If the account authentication type is CSPMA or Credential Manager, a user can only update their own password.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=updateUserPassword
User.password=tlger@
```

### Parameters

#### User.password

The new password.

Required	Default Value	Valid Values
yes	N/A	String. Credential Manager user passwords must be between 6 and 16 characters in length, and can contain alphabetical, numeric and special characters.

## updateUserStatus

Use the updateUserStatus command to change the status of a user account to ACTIVE or SUSPENDED. When the status is set to ACTIVE, the number of failed login attempts is reset to 0.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=updateUserStatus
userID=demo status=ACTIVE
```

### Parameters

#### *User.userID*

The user name.

Required	Default Value	Valid Values
yes	N/A	String

#### *User.status*

The new user status.

Required	Default Value	Valid Values
yes	N/A	ACTIVE, SUSPENDED

## verifyAccountPassword

Use the verifyAccountPassword command to validate the account password of a synchronized user or of all synchronized accounts in a target group. You can indicate whether to validate accounts that passed or failed verification.

### Example

```
capam_command capam=capamServer adminUserID=admin cmdName=verifyAccountPassword
groupID=1234
```

```
TargetAccount.passwordVerified=false
```

### Parameters

#### TargetAccount.ID

The target account ID.

Required	Default Value	Valid Values
Either this or groupID must be specified.	N/A	A whole number

#### groupID

The target group ID

Required	Default Value	Valid Values
Either this or TargetAccount.ID must be specified.	N/A	A whole number

#### TargetAccount.passwordVerified

This parameter determines which accounts get verified.

Required	Default Value	Valid Values
No	nothing (verify all accounts)	true - validates only verified accounts false - validates accounts that failed verification

## verifyDBHash

The verifyDBHash command confirms the hash value of most base model objects that are stored in the Credential Manager database. Use this command to verify the data integrity of the following objects:

All Agents	Authorizations
Request Servers	Scripts
Target Accounts	Target Aliases
Target Applications	Target Servers

This command has no parameters.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=verifyDBHash
```

**viewAccountPassword**

Use the `viewAccountPassword` command to retrieve a target account password.

**Example**

```
capam_command capam=capamServer adminUserID=admin cmdName=viewAccountPassword
  TargetAccount.ID=5

reason="Power outage reason" reasonDetails="Recover Tuesday am"
```

**Parameters****TargetAccount.ID**

The ID of the target account for which you are seeking the password.

Required	Default Value	Valid Values
yes	N/A	Use <code>searchTargetAccount</code> to retrieve the <code>TargetAccount.ID</code> .

**adminUserID**

Your Credential Manager user name.

Required	Default Value	Valid Values
yes	N/A	String. User must be a valid Credential Manager user with permission to view passwords.

**adminPassword**

Your Credential Manager user password.

Required	Default Value	Valid Values
yes	N/A	String

**reason**

The reason that you are requesting a password view.

Required	Default Value	Valid Values
Conditionally required when "Reason Required for View" or Reason Required for Auto-Connect" is enabled in the Password View Policy.	N/A	String

### reasonDetails

Detailed description of why you want to view the password.

Required	Default Value	Valid Values
Conditionally required when "Reason Required for View" or Reason Required for Auto-Connect" is enabled in the Password View Policy.	N/A	String

### selectedComponent

Compound server ID.

Required	Default Value	Valid Values
no	N/A	Integer

### ssoType

SSO type implies that a password was used but not viewed, so change is controlled by `CPoV && AllowCpovOnSso`.

Required	Default Value	Valid Values
no	N/A	"Browser", "RDP", "SSH", "VNC", "AWSAPI", "Telnet", "Other"

### PasswordViewRequest.requestPeriodStart

If the account password view policy has enabled dual authorization, this parameter specifies the start time of the password view request.

Required	Default Value	Valid Values
no	N/A	Date string, of the format <code>yyyy-MM-dd hh:mm:ss</code>

### PasswordViewRequest.requestPeriodEnd

If the account password view policy has enabled dual authorization, this parameter specifies the end time of the password view request.

Required	Default Value	Valid Values
no	N/A	Date string, of the format <code>yyyy-MM-dd hh:mm:ss</code>

### referenceCode

Reference Code.

Required	Default Value	Valid Values
Conditionally required when "Reason for View" or "Reason Required for Auto-Connect" is enabled in the Password View Policy.	N/A	S

### **PasswordViewRequest.comments**

Comments that the user wants to add to the view password request.

Required	Default Value	Valid Values
no	N/A	String

## **Secrets Management CLI Commands**

You can use the Remote CLI to control and configure Secrets Management. This command-line interface allows administrators to provide scripted functionality to complete management and integration tasks. The interface supports a subset of features that are available through the GUI.

Use the table of contents to access the command descriptions.

### **addVault**

Use this command to add a vault to PAM.

#### **Example**

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=addVault "Vault.name=test
vault" "Vault.description=my test vault" Vault.userIDs="1001,2001" Vault.userRoleIDs="5001,6001"
Vault.userGroupIDs="3001,4001" Vault.userGroupRoleIDs="7001,8001"
```

### **Parameters**

#### **Vault.name**

Specifies the name of the vault.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.description**

Specifies the description of the vault.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.userIDs**

A comma-delimited list of user IDs (users) that are associated with this vault.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.userRoleIDs**

A comma delimited list of role IDs. There must be a one-to-one mapping between the Vault.userIDs and Vault.userRoleIDs. For example, the first user ID in the Vault.userIDs list is assigned the first role ID from Vault.userRoleIDs. The second user ID in the Vault.userIDs list is assigned the second role ID from the Vault.userRoleIDs list, and so on.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.userGroupIDs**

A comma-delimited list of user group IDs that are associated with this vault.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.userGroupRoleIDs**

A comma delimited list of role IDs. There must be a one-to-one mapping between the Vault.userGroupIDs and Vault.userGroupRoleIDs. For example, the first user ID in the Vault.userGroupIDs list is assigned the first role ID from Vault.userGroupRoleIDs. The second user ID in the Vault.userGroupIDs list is assigned the second role ID from the Vault.userGroupRoleIDs list, and so on.

Required	Default Value	Valid Values
yes	N/A	String

## **updateVault**

Use this command to update a vault in PAM.

### **Example**

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=updateVault Vault.ID=1001
"Vault.name=test vault" Vault.userIDs="1001,2001" Vault.userRoleIDs="5001,6001"
Vault.userGroupIDs="3001,4001" Vault.userGroupRoleIDs="7001,8001"
```

## **Parameters**

### **Vault.ID**

Specifies the identifier of the vault.

Required	Default Value	Valid Values
yes	N/A	Numeric

### **Vault.name**

Specifies the name of the vault.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.description**

Specifies the description of the vault.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.userIDs**

A comma-delimited list of user IDs (users) that are associated with this vault.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.userRoleIDs**

A comma delimited list of role IDs. There must be a one-to-one mapping between the Vault.userIDs and Vault.userRoleIDs. For example, the first user ID in the Vault.userIDs list is assigned the first role ID from Vault.userRoleIDs. The second user ID in the Vault.userIDs list is assigned the second role ID from the Vault.userRoleIDs list, and so on.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.userGroupIDs**

A comma-delimited list of user group IDs that are associated with this vault.

Required	Default Value	Valid Values
yes	N/A	String

#### **Vault.userGroupRoleIDs**

A comma delimited list of role IDs. There must be a one-to-one mapping between the Vault.userGroupIDs and Vault.userGroupRoleIDs. For example, the first user ID in the Vault.userGroupIDs list is assigned the first role ID from Vault.userGroupRoleIDs. The second user ID in the Vault.userGroupIDs list is assigned the second role ID from the Vault.userGroupRoleIDs list, and so on.

Required	Default Value	Valid Values
yes	N/A	String

## getVault

Use this command to return information about a vault.

### Example

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=getVault Vault.name="test vault"
Vault.ID=1001
```

### Parameters

#### Vault.ID

Specifies the identifier of the vault. This value is required if Vault.name is not set.

Required	Default Value	Valid Values
yes (If Vault.name is not set)	N/A	Numeric

#### Vault.name

Specifies the name of the vault.

Required	Default Value	Valid Values
yes	N/A	String

## deleteVault

Use this command to delete an existing vault.

You can only delete an empty vault. You must delete all secrets from a vault before you can delete it. You cannot restore a deleted Vault. However, deleting the vault does not delete the users or user groups that are assigned to them.

### Example

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=deleteVault Vault.ID=18
```

### Parameters

#### Vault.name

Specifies the identifier of the vault.

Required	Default Value	Valid Values
yes	N/A	Numeric

## viewSecretPassword

Use the viewSecretPassword command to return a secret password value in clear text.

### Example

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=viewSecretPassword
Secret.vaultName="test vault" Secret.ID=10001
```

**Parameters****Secret.ID**

Specifies the identifier of the secret.

Required	Default Value	Valid Values
yes	N/A	String

**Secret.vaultName**

Specifies the name of the vault to which this secret belongs.

Required	Default Value	Valid Values
yes	N/A	String. The unique name of the device name in PAM.

**listVaults**

Use this command to retrieve a list of vaults in PAM.

**Example**

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=listVaults
```

**Parameters****Vault.columnNames**

Use `Vault.columnNames` to specify the filter criteria when searching for vaults.

Required	Default Value	Valid Values
no	name	String; name, description

**Vault.columnValues**

Use `Vault.columnValues` to specify the filter criteria when searching for vaults.

Required	Default Value	Valid Values
no	N/A	String

**Page.Number**

Specifies which page to return when the results are divided among multiple pages. This parameter works in conjunction with `Page.Size`.

Required	Default Value	Valid Values
no	1	Numeric

**Page.Size**

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	30	Numeric

### **Sort.Property**

Use `Sort.Property` to specified which field to use when sorting the result.

Required	Default Value	Valid Values
no	name	String; name description

### **Sort.Direction**

Specifies the alphabetical order of the results returned. Set `Sort.Direction=true` to have the results presented in descending order. Set `Sort.Direction=false` to have the results presented in ascending order.

Required	Default Value	Valid Values
no	false	String; true, false

## **addSecret**

Use this command to add a secret to a specified vault. The `addSecret` command allows up to 12 parameters. The `secret.name`, `secret.typeID`, and `secret.value`, `secret.formatID` parameters are required.

### **Example**

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=addSecret Secret.name="mySecret"
Secret.aliases="mySecret" Secret.typeID=1 Secret.vaultID=24001 "Secret.value=keep me secret"
```

## **Parameters**

### **Secret.name**

Specifies the name of the secret.

Required	Default Value	Valid Values
yes	N/A	String

### **Secret.aliases**

Specifies the alias of the secret.

Required	Default Value	Valid Values
yes	N/A	String. Separate multiple values by commas.

### **Secret.descriptor1**

Specifies the first descriptor of the secret.

Required	Default Value	Valid Values
no	N/A	String

### **Secret.descriptor2**

Specifies the second descriptor of the secret.

Required	Default Value	Valid Values
no	N/A	String

### **Secret.typeID**

Specifies the identifier of the secret type associated with the secret.

Required	Default Value	Valid Values
yes	N/A	Numeric

### **Secret.vaultID**

Specifies the identifier of the vault to which the secrets should be added.

Required	Default Value	Valid Values
no	N/A	Numeric

### **Secret.value**

Specifies the value of the secret.

Required	Default Value	Valid Values
yes	N/A	String

### **Secret.formatID**

Specifies the identifier of the secret format associated with the secret.

Required	Default Value	Valid Values
yes	N/A	String

### **Secret.autoExpire**

Specifies whether the secret expires at a specified date. Set this value to `true` to cause the secret to expire. Expired secrets are not removed from the system, but cannot be used. Use this parameter in conjunction with the `secret.autoExpireDate` parameter.

Required	Default Value	Valid Values
no	N/A	String; <code>true</code> , <code>false</code>

### **Secret.autoExpireDate**

Specifies the date and time that the secret should expire. Use this parameter in conjunction with the `secret.autoExpire` parameter.

Required	Default Value	Valid Values
no	N/A	Format: MM/dd/yyyy HH:mm:ss

### **Secret.autoDelete**

Specifies whether the secret is deleted at a specified date. Set this value to `true` to cause the secret to be deleted at the top of the hour. Deleted secrets are removed from the system. Use this parameter in conjunction with the `secret.autoDeleteDate` parameter.

Required	Default Value	Valid Values
no	N/A	String; <code>true</code> , <code>false</code>

### **Secret.autoDeleteDate**

Specifies the date and time that the secret should expire. Secrets are deleted at the top of the hour specified here. Use this parameter in conjunction with the `secret.autoDelete` parameter.

Required	Default Value	Valid Values
no	N/A	Format: MM/dd/yyyy HH:mm:ss

## **updateSecret**

Use this command to update a secret in a specified vault. The `updateSecret` command allows up to 13 parameters. The `secret.ID` parameter is required.

### **Example**

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=updateSecret Secret.ID=35001
Secret.name="mySecret" Secret.vaultID=24001 "Secret.value=updated secret"
```

## **Parameters**

### **Secret.ID**

Specifies the identifier of the secret.

Required	Default Value	Valid Values
yes	N/A	Numeric

### **Secret.name**

Specifies the name of the secret.

Required	Default Value	Valid Values
no	N/A	String

### **Secret.aliases**

Specifies the alias of the secret.

Required	Default Value	Valid Values
no	N/A	String. Separate multiple values by commas.

### **Secret.descriptor1**

Specifies the first descriptor of the secret.

Required	Default Value	Valid Values
no	N/A	String

### **Secret.descriptor2**

Specifies the second descriptor of the secret.

Required	Default Value	Valid Values
no	N/A	String

### **Secret.typeID**

Specifies the identifier of the secret type associated with the secret.

Required	Default Value	Valid Values
no	N/A	Numeric

### **Secret.vaultID**

Specifies the identifier of the vault to which the secrets should be added.

Required	Default Value	Valid Values
no	N/A	Numeric

### **Secret.value**

Specifies the value of the secret.

Required	Default Value	Valid Values
no	N/A	String

### **Secret.formatID**

Specifies the identifier of the secret format associated with the secret.

Required	Default Value	Valid Values
no	N/A	String

### **Secret.autoExpire**

Specifies whether the secret expires at a specified date. Set this value to `true` to cause the secret to expire. Expired secrets are not removed from the system, but cannot be used. Use this parameter in conjunction with the `secret.autoExpireDate` parameter.

Required	Default Value	Valid Values
no	N/A	String; <code>true</code> , <code>false</code>

### **Secret.autoExpireDate**

Specifies the date and time that the secret should expire. Use this parameter in conjunction with the `secret.autoExpire` parameter.

Required	Default Value	Valid Values
no	N/A	Format: MM/dd/yyyy HH:mm:ss

### **Secret.autoDelete**

Specifies whether the secret is deleted at a specified date. Set this value to `true` to cause the secret to be deleted at the top of the hour. Deleted secrets are removed from the system. Use this parameter in conjunction with the `secret.autoDeleteDate` parameter.

Required	Default Value	Valid Values
no	N/A	String; <code>true</code> , <code>false</code>

### **Secret.autoDeleteDate**

Specifies the date and time that the secret should expire. Secrets are deleted at the top of the hour specified here. Use this parameter in conjunction with the `secret.autoDelete` parameter.

Required	Default Value	Valid Values
no	N/A	Format: MM/dd/yyyy HH:mm:ss

## **getSecret**

Use this command to return information about a secret.

### **Example**

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=getSecret Secret.ID=1001
```

## **Parameters**

### **Secret.ID**

Specifies the identifier of the secret.

Required	Default Value	Valid Values
yes	N/A	String

## listSecrets

Use this command to retrieve a list of secrets in PAM.

### Example

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=listSecrets
```

### Parameters

#### Secret.columnNames

Use `Secret.columnNames` to specify the filter criteria when searching for secrets.

Required	Default Value	Valid Values
no	name	String; name, description

#### Secret.columnValues

Use `Secret.columnValues` to specify the filter criteria when searching for secrets.

Required	Default Value	Valid Values
no	N/A	String

#### Page.Number

Specifies which page to return when the results are divided among multiple pages. This parameter works in conjunction with `Page.Size`.

Required	Default Value	Valid Values
no	1	Numeric

#### Page.Size

Specifies the number of records to return on each page.

Required	Default Value	Valid Values
no	30	Numeric

#### Sort.Property

Use `Sort.Property` to specified which field to use when sorting the result.

Required	Default Value	Valid Values
no	name	String; name description

#### Sort.Direction

Specifies the alphabetical order of the results returned. Set `Sort.Direction=true` to have the results presented in descending order. Set `Sort.Direction=false` to have the results presented in ascending order.

Required	Default Value	Valid Values
no	false	String; true, false

## deleteSecret

Use this command to delete a secret or list of secrets. Deleting a secret removes it permanently from the vault and from PAM. You can neither restore nor recover a deleted secret. Secrets are deleted at the top of the hour.

### Example

```
cspmserver_admin cspmHostName=paServer adminUserID=admin cmdName=deleteSecret
Secret.IDs="1001,2001"
```

### Parameters

#### Secret.ID

Specifies the identifier of the secret.

Required	Default Value	Valid Values
yes	N/A	String; separate multiple values with commas.

## Integrate Applications with the Credential Manager A2A Client

This content describes the methods that Credential Manager provides for integration.

### A2A client on all platforms

Language	Integration Method	Example
Java	CSPMClient.jar See <a href="#">Integrate Applications Using Java</a> .	<a href="#">Integrate Java Applications with the Credential Manager A2A Client</a> .

### A2A client on UNIX

Language	Integration Method	Example
Perl	cspmclient See <a href="#">Integrate Applications Using the A2A Client</a> .	<a href="#">Integrate a Perl Script with A2A Client on UNIX or AIX</a> .
C++		<a href="#">Integrate a C or C++ Application with A2A Client on UNIX or AIX</a> .
C		<a href="#">Integrate a C or C++ Application with A2A Client on UNIX or AIX</a> .
Korn Shell		<a href="#">Integrate a Korn Shell Script with A2A Client on UNIX or AIX</a> .
C Shell		<a href="#">Integrate a C Shell Script with A2A Client on UNIX or AIX</a> .
PHP		<a href="#">Integrate a PHP Script with A2A Client on UNIX</a> .
Python		<a href="#">Integrate a Python Script with A2A Client on UNIX and AIX</a> .

**A2A client on Windows**

Language	Integration Method	Example
Perl	cspmclient.exe See <a href="#">Integrate Applications Using the A2A Client</a> .	<a href="#">Integrate a Perl Script with A2A Client on Windows.</a>
PowerShell	cspmclient.exe See <a href="#">Integrate Applications Using the A2A Client</a> .	<a href="#">Integrate a PowerShell Script with A2A Client on Windows.</a>
Visual Basic Visual C++ C#	cspmclientc.dll See <a href="#">Integrate Windows Applications and Scripts Using a Windows DLL</a> .	<a href="#">Integrate a Visual Basic Application.</a> <a href="#">Integrate a Visual C++ Application.</a> <a href="#">Integrate a C#.NET Application using IIS Application Server.</a>
Visual Basic Script	cspmclientatl.dll See <a href="#">Integrate Windows Applications and Scripts Using a Windows DLL</a> .	<a href="#">Integrate a Visual Basic, Java, or Windows Script.</a>
JavaScript	cspmclientatl.dll See <a href="#">Integrate Windows Applications and Scripts Using a Windows DLL</a> .	<a href="#">Integrate a Visual Basic, Java, or Windows Script.</a>

**A2A 64-bit Client on all platforms**

Language	Integration Method	Example
Java	CSPMClient.jar See <a href="#">#unique_1900</a> .	<a href="#">Integrate Java Applications with the Credential Manager A2A Client.</a>

**A2A 64-bit Client on UNIX and AIX**

Language	Integration Method	Example
Perl	cspmclient64 See <a href="#">#unique_1902</a> .	<a href="#">Integrate a Perl Script with A2A Client on UNIX or AIX</a>
C++		<a href="#">Integrate a C or C++ Application with A2A Client on UNIX or AIX</a>
C		<a href="#">Integrate a C or C++ Application with A2A Client on UNIX or AIX</a>
Korn Shell		<a href="#">Integrate a Korn Shell Script with A2A Client on UNIX or AIX</a>
C Shell		.
PHP <b>Note: PHP is not supported on AIX.</b>		<a href="#">Integrate a PHP Script with A2A Client on UNIX</a>
Python		<a href="#">Integrate a Python Script with A2A Client on UNIX and AIX</a>

**A2A 64-bit Client on Windows**

Language	Integration Method	Example
Perl	cspmclient64.exe See <a href="#">Integrate Applications Using the A2A Client</a> .	<a href="#">Integrate a Perl Script with A2A Client on Windows.</a>
PowerShell	cspmclient64.exe See <a href="#">Integrate Applications Using the A2A Client</a> .	<a href="#">Integrate a PowerShell Script with A2A Client on Windows.</a>

Visual Basic Visual C++ C#	cspmclientc64.dll See <a href="#">Integrate Windows Applications and Scripts Using a Windows DLL</a> .	<a href="#">Integrate a Visual Basic Application.</a> <a href="#">Integrate a Visual C++ Application.</a> <a href="#">Integrate a C#.NET Application using IIS Application Server.</a>
Visual Basic Script JavaScript	cspmclientatl64.dll See <a href="#">Integrate Windows Applications and Scripts Using a Windows DLL</a> .	<a href="#">Integrate a Visual Basic, Java, or Windows Script.</a>

## Integrate Applications Using Java

Use the `CSPMClient` Java class when integrating a Java application or an application that can launch external Java applications. Add the following reference to the classpath of the requesting application: `$CSPM_CLIENT_HOME/lib/CSPMClient.jar`. The requesting application creates an instance of the `CSPMClient` class when it is required.

### Java Integration Proces

The A2A Client requires OpenJDK Temurin Java 17.

#### Follow these steps:

1. Add the `CSPMClient.jar` file to your classpath. The file is located in `$CSPM_CLIENT_HOME/lib`.
2. Set the path of the folder containing the client configuration file. For UNIX and Windows, set the `CSPM_CLIENT_HOME` environment variable. This path is the location of the client installation directory.
  - UNIX example:  
`-Dcspm_client_config_file=$CSPM_CLIENT_HOME/config/cspm_client_config.xml`
  - Windows example:  
`-Dcspm_client_config_file=%CSPM_CLIENT_HOME%\config\cspm_client_config.xml`
3. If no `CSPM_CLIENT_HOME` value is set, use the current option in the Java command-line option to specify the file location. If no value is specified, use the default installation location values for `CSPM_CLIENT_HOME`.
  - For UNIX, use `/opt/cloakware`
  - For Windows, use `c:\cspm\cloakware`
4. Modify your source code to call the `CSPMClient` class as in [Integrate a Basic Java Application](#):
  - a. Add import classes: `import com.ca.pam.a2a.client.CSPMClient.`
  - b. Instantiate the `CSPMClient.class`.
  - c. Call `retrieveCredentials` to retrieve the credentials.
5. Add the requestor to Credential Manager. See [Add A2A Requestors](#).
6. Add authorization mapping to Credential Manager. See [Add A2A Authorization Mappings](#).

### CSPMClient and Related Java Classes

The `cwjcafips` and `cwjsssefips` classes do not have any methods that you can use but they are dependencies of the `CSPMClient` class. The following table lists the methods that are available from the `(com.ca.pam.a2a.client.CSPMClient)` Java class.

Method	Description
<code>CSPMClient()</code>	Constructor. Takes no parameters.
<code>void retrieveCredentials(String targetAlias)</code>	Retrieves the credentials (account name and password) for the given target alias. Takes one parameter: <ul style="list-style-type: none"> <li>• <code>target alias</code> of type <code>java.lang.String</code>.</li> </ul>

<code>void retrieveCredentials(String targetAlias, String bypassCacheFlag)</code>	Retrieves the credentials (account name and password) for the given target alias. Takes the following parameters: <ul style="list-style-type: none"> <li>target alias of type <code>java.lang.String</code></li> <li>bypass cache flag (either <code>true</code> or <code>false</code>)</li> </ul> If the bypass cache flag is set to <code>true</code> , the local cache is bypassed and the query goes directly to the Credential Manager Server.
<code>void retrieveCredentials(String targetAlias, String bypassCacheFlag, String xmlOutput)</code>	Retrieves the credentials (account name and password) for the given target alias. Takes the following parameters: <ul style="list-style-type: none"> <li>target alias of type <code>java.lang.String</code></li> <li>bypass cache flag (either <code>true</code> or <code>false</code>)</li> <li>(Optional) String <code>xmlOutput</code>. Specify <code>-x</code> to retrieve the output as an XML data string.</li> </ul> If the flag is set to <code>true</code> , the local cache is bypassed and the query goes directly to the Credential Manager Server.
<code>String getUserId()</code>	Returns the account name from the last <code>retrieveCredentials</code> call.
<code>String getPassword()</code>	Returns the password from the last <code>retrieveCredentials</code> call.
<code>String getStatusCode()</code>	Returns the <code>statusCode</code> of type <code>String</code> from the last <code>retrieveCredentials</code> call. For code definitions, see <a href="#">Return Data</a> .
<code>String getMessages()</code>	Returns any error messages.
<code>String getXMLData()</code>	Gets the data from the last <code>retrieveCredentials</code> invocation. Specify <code>-x</code> to retrieve the output as an XML data string.

### Integrate Applications Using the A2A Client

Use the A2A Client (`cspmclient`, `cspmclient64`, `cspmclient.exe`, or `cspmclient64.exe`) when integrating with a non-Java application. The requestor launches the A2A Client. Typically, you integrate an application using the A2A Client (`cspmclient`, `cspmclient64`, `cspmclient.exe`, or `cspmclient64.exe`) when the requestor is:

- Written in C
- Written in C++ or C# and you do not want to use a COM component
- Using a scripting language such as Perl or PowerShell

#### NOTE

Do not call the `cspmclient`, `cspmclient64`, `cspmclient.exe`, or `cspmclient64.exe` interfaces directly from the command line. A requestor calls the interfaces. The requestor cannot be a Bourne shell script, but the requestor can be a Korn shell script.

### A2A Client Integration Process

Use the following process to integrate an application using the A2A Client (`cspmclient`, `cspmclient64`, `cspmclient.exe`, or `cspmclient64.exe`):

- Set up environment variables.  
You can add the A2A Client to the `PATH` variable to avoid hardcoding the path of the A2A Client application.
- Modify your application:
  - For UNIX or Linux, call `cspmclient` or `cspmclient64` to retrieve credentials. For Windows, call `cspmclient.exe` or `cspmclient64.exe`.
  - Read standard output to get the return codes generated by the A2A Client. For code definitions, see [Return Data](#).
- Add the requestor to Credential Manager. See [Add A2A Requestors](#).
- Add authorization mapping to Credential Manager. See [Add A2A Authorization Mappings](#).

### ***cspmclient Constraints***

The default return value is space-delimited. As a result, account names and passwords cannot contain spaces. The string `null` is reserved. Account names and passwords cannot be the string `null`.

### ***cspmclient Usage***

For UNIX or Linux, use one of the following commands:

- For the 32-bit Client: `cspmclient targetAlias [bypassCacheFlag] [-b] [-x]`
- For the 64-bit Client: `cspmclient64 targetAlias [bypassCacheFlag] [-b] [-x]`

For Windows, use the following commands:

- For the 32-bit Client: `cspmclient.exe targetAlias [bypassCacheFlag] [-b] [-x]`
- For the 64-bit Client: `cspmclient64.exe targetAlias [bypassCacheFlag] [-b] [-x]`

Parameter	Description
String <code>targetAlias</code>	Predefined target account alias, which is used to retrieve the account credentials (user name and password).
String <code>bypassCacheFlag</code>	Specifying <code>true</code> directs the A2A Client to bypass the local cache and retrieve account credentials directly from the Credential Manager Server. The default is <code>false</code> .
<code>-b</code>	Short form option for setting <code>bypassCacheFlag</code> to <code>true</code> .
<code>-x</code>	Specifies to return output as an XML data string.

### ***cspmclient Return Values***

The `cspmclient`, `cspmclient64`, `cspmclient.exe` and `cspmclient64.exe` interfaces return the return code, `userID`, and password as a space-delimited string.

Return Value	Description
Return Code	Contains an integer value. See <a href="#">Return Data</a> .
UserID	Contains the account name. If the attempt was unsuccessful, the account name is set to the string <code>null</code> .
Password	Contains the account password. If the attempt was unsuccessful, the password is set to the string <code>null</code> .
message	Contains the error messages text string. If the attempt was unsuccessful, the message text of the associated errors is returned.

### **Integrate Windows Applications and Scripts Using a Windows DLL**

Use Windows Dynamic Link Library (DLL) to integrate a Windows application or a Windows client script that supports COM components. Credential Manager provides the following DLLs:

- Microsoft Foundation Class (MFC) DLL(`cspmclientc.dll` or `cspmclientc64.dll`). The Credential Manager MFC DLL works with applications that are written with Visual Basic or in C, C++, or C#. You cannot use the MFC DLL with scripts.
- Active Template Library (ATL) DLL(`cspmclientatl.dll` or `cspmclientatl64.dll`). The Credential Manager ATL DLL works with .NET applications and supports Visual Basic script and JavaScript.

Both Credential Manager DLLs are COM components. These DLLs allow linking to Windows applications and Windows client scripts that support COM DLLs. The application or script should create an instance of the COM component when it is required. The Windows DLLs are thread-safe if they are not used as a singleton.

### MFC DLL Integration Process

The integration process varies depending on the language that is used to write the application. The following process is a typical way to integrate a C++ application using the Credential Manager MFC DLL:

1. Import the Type Library file (TLB) by adding the following statements in your code: `#import "$CSPM_CLIENT_HOME/cspmclient/lib/cspmclientc.tlb" named_guids using namespace Cspmclientc; .The#import` directive incorporates the information from the type library. The content of the type library is converted into C++ classes to allow you to create the COM component. The `named_guids` argument creates the CLSID and IID to use in `CoCreateInstance`.
2. Create the COM component:  

```

Iccspmclientc *icspmClient = NULL; HRESULT hr = CoCreateInstance(CLSID_ccspmclientc, NULL,
    CLSCTX_INPROC_SERVER, DIID_Iccspmclientc, (void**) &icspmClient );

```
3. Call the `retrieveCredentials` method to retrieve the credentials for a given class. The following call is an example: `long retValue = icspmClient->retrieveCredentials("alias", "true", "");`
4. Add the requestor to Credential Manager. See [Add A2A Requestors](#).
5. Add authorization mapping to Credential Manager. See [Add A2A Authorization Mappings](#).

### ATL DLL Integration Process

The integration process varies depending on the scripting language. For examples, refer to [Integrate a Script](#).

### DLL Methods

The following methods are available from the Credential Manager MFC DLL and the Credential Manager ATL DLL.

Method	Description
<code>long retrieveCredentials(String targetAlias, String bypassCacheFlag, String xmlOutput)</code>	Retrieves the credentials (account name and password) for the given target alias. Returns the <code>statusCode</code> of the <code>getCredentials</code> call. Takes the following parameters: <ul style="list-style-type: none"> <li>• <code>String targetAlias</code> . The predefined target account alias, which is used to retrieve the account credentials (account name and password).</li> <li>• <code>String bypassCacheFlag</code> . Specify <code>true</code> to indicate that the credential should be retrieved from the Credential Manager Server. Specify <code>false</code> to retrieve the credential from the local cache.</li> <li>• (Optional) <code>String xmlOutput</code> . Specify <code>-x</code> to retrieve the output as an XML data string.</li> </ul>
<code>String getUserID()</code>	Returns the account name from the last <code>retrieveCredentials</code> call.
<code>String getPassword()</code>	Returns the password from the last <code>retrieveCredentials</code> call.
<code>String getXMLData()</code>	Gets the data from the last <code>retrieveCredentials</code> call.
<code>String getMessage()</code>	Gets the error message from the last <code>retrieveCredentials</code> call.

### DLL Constraints

Both Credential Manager Windows DLLs are only available for Windows platforms.

## A2A Integration Return Data

Each of the integration methods provides two ways to receive return data—string-based or XML-based. The default behavior returns the return code, account name, and password as strings. Optionally, you can request that the return data be formatted as an XML string.

### XML Return Schema

When you request an XML return string, the following schema is used:

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema" elementFormDefault="qualified">

  <xs:element name="credential">
    <xs:complexType>
      <xs:all>
        <xs:element name="TargetAlias" type="xs:string"/>
        <xs:element name="TargetAccount" type="xs:string"/>
        <xs:element name="TargetApplication" type="xs:string"/>
        <xs:element name="TargetServer" type="xs:string"/>
      </xs:all>
    </xs:complexType>
  </xs:element>

  <xs:element name="requestresult">
    <xs:complexType>
      <xs:all>
        <xs:element name="errorcode" type="xs:string"/>
        <xs:element name="errormessage" type="xs:string"/>
        <xs:element name="credential"/>
      </xs:all>
    </xs:complexType>
  </xs:element>

  <xs:element name="TargetAlias"/>
  <xs:element name="TargetAccount"/>
  <xs:element name="TargetApplication"/>
  <xs:element name="TargetServer"/>
</xs:schema>
```

### NOTE

When you use target connectors, there might be extra extended attributes that are defined within the target connector. The extended attributes are also returned in the XML return string. The schema that is used for these additional elements is defined in the configuration file for the specific target connector.

### XML Return Example

The following XML code is an example of an XML return string:

```
<?xml version="1.0" encoding="utf-8" ?>
<requestresult>
  <errorcode>400</errorcode>
  <errormessage>Success</errormessage>
  <credential>
```

```

## Integrate Java Applications with the Credential Manager A2A Client

This content in this section how to integrate Java applications with the A2A Client to use Credential Manager to retrieve target account credentials.

Use the table of contents to access the topics in this section.

### Integrate a Basic Java Application with the A2A Client

This content describes how to integrate a basic Java application with the A2A Client.

[Install the A2A client](#) on each system where a Java application is to be integrated.

The following example files are provided:

- **Example.java**  
Compile this java class source file to use it.
- **Run\_example**  
This file is a shell script executable. This script requires that you compile the source file. When compiling the source file, use this script for information about how to define the class path.

If you install an A2A Client on a UNIX system, copies of the example files are in the directory `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples`.

#### NOTE

A2A is referred to as **CSPM** in code samples, file, and environment variable names.

#### Example.java Code

```
/*
 * An example class to demonstrate calling the CSPMClient class.
 *
 * Note:
 *
 * You will need to ensure that the library path to the cspm library directory
 * is set by one of the following methods:
 *
 * a. Adding /opt/catech/cspmclient/lib to LD_LIBRARY_PATH, or
 *
 * b. Passing the following option on the java command line:
 *    -Djava.library.path=/opt/catech/cspmclient/lib
 */

public class Example {

    /**
     * Main entry point.
     *
     * @param args[0], String target alias
     */
}
```

```

* @param args[1], bypass cache flag. If set to:
*
*   "true", the cspm client will call the cspm server system
*
*   "false", the cspm client will 1st search the local cache
* @param args[2], xmlOption. (Optional) If set to:
*
*   "-x", Gives the XML data.
* @return int 0 if successful, 100 if an exception occurred, otherwise
* documented error codes for the CSPMClient class.
*
*/

public static void main(String[] args) {

    try {
        //check the arguments
        if(args.length != 2) {
            System.out.println("Missing CLI arguments");
            System.exit(256);
        }
        //initialize
        String targetAlias = args[0];
        String bypassCache = args[1];
String xmlOption= args[2];

        CSPMClient testInterface = new CSPMClient();

If(args.length>2){
xmlOption=args[2];
        testInterface.retrieveCredentials(targetAlias, bypassCache, xmlOption);
}else{

        //get the result
        String statusCode = testInterface.getStatusCode();
        String userId      = testInterface.getUserId();
        String password    = testInterface.getPassword();
String xmlData      = testInterface.getXMLData();

        System.out.println("Status Code: " + statusCode);
        System.out.println("UsedId:      " + userId);
        System.out.println("Password:   " + password);
        System.out.println("XML Data:    " + XmlData);

        //set the return value
        if ( statusCode.equals("400") ) {
            System.out.println("PASSED");
            System.exit(0);
        } else {
            System.out.println("FAILED");
            System.exit(Integer.parseInt(statusCode));
        }
    }
}

```

```

        } catch (Exception e) {
            e.printStackTrace();
            System.exit(100);
        }
    }
}

```

### **Run\_example Code**

The `Run_example` shell script calls `Example.class`. When executing the Java call, the `-D` option sets system property values that are used by the executing program as follows:

- `-Djava.library.path`. This option sets the Java library path; that is, the location of the `$CSPM_CLIENT_HOME/cspmclient/lib` directory. This option can also be set with the environment variable `LD_LIBRARY_PATH` (LIBPATH on AIX).
- `-Dcspm_client_config_file`. This option specifies the client configuration file directory. Use this file if the configuration file is in a non-standard location (that is, not in `/opt`).

```

#!/bin/sh
# This is an EXAMPLE script making use of Example.class in the same directory.
#
# All 2 Run_example CLI arguments are MANDATORY!
# Validate the command line parameters
if [ ! $# = 2 ]
then
    echo " "
    echo " syntax: $0 target_alias bypass_cache"
    echo
    exit 1
fi
# Setup Global Variables
CLASS_NAME=Example
CONFIG_FILE=/opt/cloakware/cspmclient/config/cspm_client_config.xml
JAVA_BINDIR=/opt/cloakware/cspmclient_thirdparty/java/bin
LIB=/opt/cloakware/cspmclient/lib
LOCAL_DIR=`pwd`;
CLASS_PATH=/opt/cloakware/cspmclient/lib/cspmclient.jar:$LOCAL_DIR
#Execute JAVA class
$JAVA_BINDIR/java -classpath $CLASS_PATH -Djava.library.path=$LIB \
-Dcspm_client_config_file=$CONFIG_FILE $CLASS_NAME $1 $2

```

### **Basic Java Integration with Database Connection**

Your installed A2A Client does not contain a soft copy of the following script.

```

/**
 * A sample java class to connect to a database.
 */
import java.sql.*;

import com.cloakware.cspm.client.CSPMClient;

public class DBConnect {

```

---

```

private int LOGIN_FAILED_CODE = 2003;
private String URL = "jdbc:mysql://host:port/database?autoReconnect=true";
private String DRIVER_CLASS = "com.mysql.jdbc.Driver";
// private String userID = "scott";
// private String password = "tiger";

private String TARGET_ALIAS = "TestAccount";
private CSPMClient cspmClient;
// ....
/**
 * Initialize credentials attribute and retrieve the credentials.
 */

private void initialize() {
    cspmClient = new CSPMClient ();
    cspmClient.retrieveCredentials( TARGET_ALIAS );
}

private Connection getConnection() {
    Driver driver = null;
    Connection connection = null;

    // check for initialization
    if ( cspmClient == null ) initialize();

    // check for system error
    if ( !cspmClient.getStatusCode().equals( "400" ) ) {

        // do some error handling.
    }

    try {
        Class.forName(DRIVER_CLASS);
        connection = DriverManager.getConnection( URL
  , cspmClient.getUserId()
  , cspmClient.getPassword() );
    } catch ( ClassNotFoundException ce ) {
        // ....
    } catch ( SQLException e ) {

        // DOUBLE PASS CHECK (OPTIONAL)
        // check for login failed
        if ( e.getErrorCode() == LOGIN_FAILED_CODE ) {
            // try again, bypass Password Authority cache, go directly to Password Authority server
            cspmClient.retrieveCredentials( TARGET_ALIAS, "true" );
            if ( !cspmClient.getStatusCode().equals( "400" ) ) {
                // do some error handling.
            }
            try {

```

```

        connection = DriverManager.getConnection( URL
  , cspmClient.getUserId()
  , cspmClient.getPassword());
    } catch ( SQLException e2 ) {
        // do stuff
    }
}
}
return connection;
}
// ....
}

```

### Register Requestor - Basic Java Application

See [Install and Activate an A2A Client on a Request Server](#) for the procedure to register your requestor with Credential Manager. You need the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension. Example: Run\_example
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type. Example: Java

When entering the file and execution paths, specify the absolute paths without links.

### Integrate a Standalone Java Application Using the A2A Client JDBC Wrapper

This content provides a description of how to use the A2A Client JDBC wrapper in a standalone Java application using the provided example application code as a model.

#### NOTE

For historical reasons, A2A is referred to as CSPM in code samples, file, and environment variable names.

The following line shows the pattern for the connection URL:

```
cspm:URL;CSPMDriver=target_driver;CSPMAlias=alias:
```

- *URL* specifies the usual vendor-specific JDBC URL
- *target\_driver* specifies the classname of the JDBC driver
- *alias* specifies the target alias representing the credentials to use when connecting

In the provided example, the connection URL, which shows a connection to a MySQL database cspm on host milocspm.cloakware.com using the MySQL driver and alias jdbcdemo , is:

```
Cspm:jdbc:mysql://milocspm.cloakware.com:3306/
cspm;CSPMDriver=com.mysql.jdbc.Driver;CSPMAlias=jdbcdemo
```

To obtain the required A2A Client files, [Install the A2A Client](#).

To compile the application, use the `cspmclient.jar` and `cloakwareJdbc.jar` files that are included with the A2A client.

To execute the application, use the previously mentioned JAR files and the vendor-specific JDBC driver JAR file, which in this case is `mysql-connector-java-5.1.8-bin.jar` because the connection is to a MySQL database.

When executing the application, identify the location of the client configuration file, `cspm_client_config.xml`, by specifying the following JVM option:

```
-Dcspm_client_config_file=<path>/cspm_client_config.xml
```

Identify the directory where the native code libraries reside by specifying the following JVM option:

```
-Djava.library.path=<path>/cloakware/cspmclient/lib
```

### **Application Code**

```
package com.cloakware.ps.jdbcdemo;

import java.sql.*;

public class JdbcDemoApp {
    private static final String
    JDBC_DRIVER_CLASS_NAME = "com.cloakware.jdbc.JdbcDriver";
    private static final String
    JDBC_URL = "cspm:jdbc:mysql://milocspm.cloakware.com:3306/
    cspm;CSPMDriver=com.mysql.jdbc.Driver;CSPMAlias=jdbcdemo";

    private Connection m_connection = null;

    public JdbcDemoApp() {

    try {

        System.out.println( "instantiating the JDBC driver" );

        Class.forName( JDBC_DRIVER_CLASS_NAME ).newInstance();

        System.out.println( "invoking the driver to obtain a connection to the database" );

        m_connection = DriverManager.getConnection( JDBC_URL );

        runDemo();

    } catch ( Exception ex ) {

        ex.printStackTrace();

    } finally {

        try {
```

```

if ( m_connection != null )
m_connection.close();
} catch ( SQLException ex ) {
}

}

}

private void runDemo() {

final String QUERY = "select count(*) from init_properties;";

try {
System.out.println( "executing query" );

Statement st = m_connection.createStatement();
ResultSet rs = st.executeQuery( QUERY );

while ( rs.next() ) {
System.out.println( "result= " + rs.getInt( 1 ) );
}

} catch ( SQLException ex ) {
ex.printStackTrace();
}

}

public static void main(String[] args) {

new JdbcDemoApp();

}

}

```

## Integrate a Java Application with the A2A Client on JBoss

This content describes an example that uses the A2A Client to manage the credentials that are used by a Java container JDBC connection pool within a JBoss application server version 4.2.2.

### NOTE

For historical reasons, A2A is referred to as CSPM in code samples, file, and environment variable names.

This example uses a credential viewer and an HSQLDB data store to show the following functionality:

- The credential viewer shows you how to view credentials that are stored in the Credential Manager server using the CSPMClient Java class. Use this example for simple integration and to test the ability to connect to Credential Manager and retrieve credentials. The example displays the credentials to the screen.
- The HSQLDB data store shows you how to configure a data store using the Credential Manager JdbcDriver Java class to retrieve credentials and connect to an HSQLDB data store. The example retrieves credentials and uses them to access a data store.

This example is available on all A2A Client installations in the following directories, for:

- **UNIX:** `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples/java/JBoss_Sample`
- **Windows:** `%CSPM_CLIENT_HOME%/cloakware/cspmclient/examples/java/JBoss_Sample`

File	Description
<code>ClassFactory.java</code>	Class factory that is used to create the objects that are used in the example web application. The class allows you to create the <code>CSPMClient</code> class and to perform a lookup in the Initial Context to retrieve the data source that is used to get a connection to the database.
<code>CredentialsViewer.java</code>	Servlet class that is used to connect to the Credential Manager server to retrieve credentials.
<code>ConnectionTester.java</code>	Servlet class that is used to create 10 connections to a database and execute a basic SQL statement. The class retrieves the <code>DataSource</code> class using the <code>ClassFactory</code> class.
<code>cspm_connect_hsql_org-ds.xml</code>	Configuration file showing how to configure a data source using the HSQLDB driver.
<code>cspm_connect_hsql-ds.xml</code>	Configuration file showing how to configure a data source using the Credential Manager <code>JdbcDriver</code> . The target driver is HSQLDB.

### **Integration Process for JBoss**

Use the following process to modify your application to use the Credential Manager server to manage credentials:

1. Configure the development environment. See [Configure your Development Environment for JBoss](#).
2. Optionally, integrate the A2A Client to retrieve credentials. See [JBoss Credential Viewer](#).
3. Create or modify the data source file. See [JBoss Connection Pool with HSQLDB Data Store](#).
4. Register requestor. See [Register JBoss Requestor](#).

### **Configure Your Development Environment for JBoss**

Configure your development environment for both JBoss development and Credential Manager integration.

The example contains an Apache ANT build file that is located in the build directory that you can use to create the WAR file and to deploy it. The build file is compatible with ANT 1.6.5 and above.

#### ***Configure Your Environment for JBoss Development***

Use the following procedure to configure your environment for JBoss development.

#### **Follow these steps:**

1. Install JBoss Application Server 4.2.2 GA. See <http://sourceforge.net/projects/jboss/files/JBoss/JBoss-4.2.2.GA>.
2. Set the `JBOSS_HOME` environment variable. See [https://docs.jboss.org/jbossas/docs/Installation\\_And\\_Getting\\_Started\\_Guide/5/html/setting\\_JBOSS\\_HOME.html](https://docs.jboss.org/jbossas/docs/Installation_And_Getting_Started_Guide/5/html/setting_JBOSS_HOME.html).
3. Install Apache ANT 1.6.5 or above. See <http://ant.apache.org/bindownload.cgi>.
4. Set the `ANT_HOME` environment variable. See <http://ant.apache.org/manual/install.html>.
5. Install the Java Database HSQLDB 1.8.0. See [http://sourceforge.net/project/showfiles.php?group\\_id=23316](http://sourceforge.net/project/showfiles.php?group_id=23316).
6. Set the `HSQL_HOME` environment variable to the path where you installed HSQL (for example, `opt/tools/hsqldb`).

#### ***Configure Your Environment for A2A Client Integration with JBoss***

Use the following procedure to configure your environment for A2A Client integration with JBoss.

**Follow these steps:**

1. **Install** the A2A Client
2. Create or add to the JAVA\_OPTS environment variable:
  - UNIX:
    - Djava.library.path=\$CSPM\_CLIENT\_HOME\lib
    - Dcspm\_client\_config\_file=\$CSPM\_CLIENT\_HOME\config\cspm\_client\_config.xml
  - Windows:
    - Djava.library.path=%CSPM\_CLIENT\_HOME%\lib
    - Dcspm\_client\_config\_file=%CSPM\_CLIENT\_HOME%\config\cspm\_client\_config.xml
3. Copy the `cloakwareJdbc.jar` file that is located in the A2A Client `tools` directory to the Jboss default deployment directory:
  - UNIX:
    - Source: \$CSPM\_CLIENT\_HOME/cspmclient/tools
    - Destination: \$JBASS\_HOME/server/default/lib
  - Windows:
    - Source: %CSPM\_CLIENT\_HOME%/cspmclient/tools
    - Destination: %JBASS\_HOME%/server/default/lib
4. Copy the `cspmclient.jar` file that is located in the A2A Client `lib` folder to the JBoss default deployment `lib` folder.

**NOTE**

Perform Step 2 and Step 3 using the ANT build file that is located in the following directories:

- UNIX: \$CSPM\_CLIENT\_HOME/examples/java/JBoss\_Sample/build
- Windows: %CSPM\_CLIENT\_HOME%/examples/java/JBoss\_Sample/build

Enter `ant deploy.driver.lib` from that directory.

**Deploy and Run the Sample JBoss Application**

Use the following procedure to compile and run the sample web application using an Apache Ant task.

Follow these steps:

1. Verify that the JBoss application server is running (default configuration).
2. Open a command line window.
3. Navigate to one of the following directories:
  - UNIX: \$CSPM\_CLIENT\_HOME/cloakware/cspmclient/examples/java/JBoss\_Sample/build
  - Windows: %CSPM\_CLIENT\_HOME%/cloakware/cspmclient/examples/java/JBoss\_Sample/build
4. Start the HSQLDB server by entering `ant start.hsqldb`.
5. Compile and deploy the example by entering `ant`.
6. Open a Web Browser.
7. Display the credential viewer web application by loading the following page: `http://localhost:8080/cspmJBossSample`.

**JBoss Credential Viewer**

This example servlet shows you how to use the A2A Client class to retrieve the credentials.

The `CSPMClient` class is created using a class factory.

***Class File***

```
package com.cloakware.cspm.sample.web;
```

```

import java.io.IOException;

import javax.servlet.RequestDispatcher;
import javax.servlet.ServletException;
import javax.servlet.http.HttpServlet;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import com.cloakware.jdbc.StatusCodeMapping;
import com.cloakware.cspm.client.CSPMClient;
import com.cloakware.cspm.sample.ClassFactory;

/**
 * This servlet class is used to retrieve credentials using the
 * CSPMClient class.<br>
 * <br>
 * The user enters a CSPMAlias Name and the servlet displays the information
 * returned by the CSPMClient class. <br>
 * <br>
 * Since the CSPMClient class only returns a status code, the base class
 * provides a class to convert the status code to a more meaningful sentence.
 */
public class CredentialsViewer extends HttpServlet {
    /* Attribute names */
    private final String ERROR_MSG = "errorMsg";

    /* Parameter names and attributes when refreshing the page */
    private final String ALIAS_NAME = "aliasName";
    private final String BYPASS_CACHE = "byPassCache";
    /* Attributes used when displaying credentials/response from
     * the CSPMClient class.
     */
    private final String RETURN_CODE = "returnCode";
    private final String RETURN_MSG = "returnMsg";
    private final String USERNAME = "username";
    private final String PASSWORD = "password";
    /* Error message */
    private final String MSG_ALIAS_EMPTY = "Alias cannot be empty";
    /* Response page */
    private final String TARGET_JSP = "/index.jsp";
    /**
     * Constructor of the object.
     */
    public CredentialsViewer() {
        super();
    }

    /**
     * The doGet method of the servlet. <br>
     *
     * This method is called when a form has its tag value method equals to get.
     * The method retrieves the alias name and the value of the checkbox

```

```

* indicating if the CSPMClient cache needs to be bypassed. It then calls
* the retrieveCredentials method of the CSPMClient class and displays the
* results. An error message is displayed if the alias name is missing.
*
* @param request the request send by the client to the server
* @param response the response send by the server to the client
* @throws ServletException if an error occurred
* @throws IOException if an error occurred
*/
public void doGet(HttpServletRequest request, HttpServletResponse response)
throws ServletException, IOException {

    // Retrieve the parameters
    String alias = (String)request.getParameter(ALIAS_NAME);
    Object byPassCache = request.getParameter(BYPASS_CACHE);
    // Make sure to redisplay the alias name.
    request.setAttribute(ALIAS_NAME, alias);
    request.setAttribute(BYPASS_CACHE,
        (byPassCache != null) ? "checked" : null);

    // if we have an alias
    if (alias != null && !"".equals(alias)) {
        // Class used to retrieve the credential.
        CSPMClient cspmClient = ClassFactory.getCSPMClient();

        // Retrieve the credentials.
        if (byPassCache == null) {
            cspmClient.retrieveCredentials(alias);
        } else {
            cspmClient.retrieveCredentials(alias, "true");
        }

        // Set the credentials in the request
        request.removeAttribute(ERROR_MSG);
        request.setAttribute(RETURN_CODE, cspmClient.getStatusCode());
        String statusMsg = StatusCodeMapping
            .getStatusText(cspmClient);
        request.setAttribute(RETURN_MSG, statusMsg);
        request.setAttribute(USERNAME, cspmClient.getUserId());
        request.setAttribute(PASSWORD, cspmClient.getPassword());
    } else {
        // return an error message.
        request.setAttribute(ERROR_MSG, MSG_ALIAS_EMPTY);
        request.removeAttribute(RETURN_CODE);
    }

    // Get the request dispatcher
    RequestDispatcher dispatcher = getServletContext()
        .getRequestDispatcher(TARGET_JSP);

    // Forward to the jsp file to display the credentials
    dispatcher.forward(request, response);
}

```

```
}
```

## **JBoss Connection Pool with HSQLDB Data Store**

This example shows you how to create or modify a data source to use the Credential Manager server for credential retrieval. The data source definitions are saved in files ending with the suffix `-ds.xml` and are located in the deployment folder.

To integrate the A2A Client to your application, change the JDBC driver that is used by the data source. The Credential Manager JDBC driver acts as a proxy JDBC driver serving any JDBC URL that is recognized as a Credential Manager JDBC URL. In the data source configuration, provide information regarding the targeted driver and the alias to use in the special Credential Manager style JDBC URL. The Credential Manager style JDBC URL format is:

```
cspm:[url];CSPMDriver=target.driver;CSPMAlias=alias
```

Form the Credential Manager URL as follows:

- Ensure that it begins with the `cspm:` prefix.
- Follow the prefix with the normal JDBC URL, omitting any user/password specification; for example, `jdbc:hsqldb:hsq://localhost:9001/cspml`.
- Set the URL to contain the `CSPMDriver` that indicates an explicit JDBC driver to use.
- Assign the `CSPMAlias`, which is the alias for the database user in the Credential Manager server, to the URL.

To use the Credential Manager JDBC driver, modify attributes in the configuration file.

### **Follow these steps:**

1. Set `connection-url` as specified previously.
2. Set `driver-class` to `com.cloakware.jdbc.JdbcDriver`.

This low-level driver management for connection acquisition means that all new connections that are obtained for a user whose database password has been changed (by the Credential Manager server) are made using the new password. This action occurs automatically without any knowledge or intervention by any owning data source.

While new connections are obtained using the new password, old connections that were obtained using an old password can linger in the data source pool. Also, if the Credential Manager alias is changed to a new user, then a connection pool has (at least temporarily) a mixture of connections for different actual database users.

Such connection management by the CA Technologies driver ensures that database password changes are transparent to the activities of the data source.

The XML file that is used in the example is located in one of the following locations:

- **UNIX:** `$CSPM_CLIENT_HOME/cspmclient/examples/java/JBoss_Sample/main/resources/datasources`
- **Windows:** `%CSPM_CLIENT_HOME%/cspmclient/examples/java/JBoss_Sample/main/resources/datasources`

### **Data Source**

```
<?xml version="1.0" encoding="UTF-8"?>

<!-- The Hypersonic embedded database JCA connection factory config -->
<datasources>
<local-tx-datasource>

<!-- The jndi name of the DataSource, it is prefixed with java:/ -->
<jndi-name>jdbc/CSPMSampleDS</jndi-name>

<connection-url>
```

```

cspm:jdbc:hsqldb:hsqldb://localhost:9001/cspm1;
CSPMAlias=hsqldb;CSPMDriver=org.hsqldb.jdbcDriver
</connection-url>

<!-- The driver class -->
<driver-class>com.cloakware.jdbc.JdbcDriver</driver-class>

<!-- The login and password -->
<user-name></user-name>
<password></password>

<!-- The minimum connections in a pool/sub-pool. -->
<min-pool-size>5</min-pool-size>

<!-- The maximum connections in a pool/sub-pool -->
<max-pool-size>10</max-pool-size>

<!-- The time before an unused connection is destroyed -->
<idle-timeout-minutes>1</idle-timeout-minutes>

<track-statements />

<prepared-statement-cache-size>32</prepared-statement-cache-size>

<!-- corresponding type-mapping in the standardjbosscomp-jdbc.xml -->
<metadata>
<type-mapping>Hypersonic SQL</type-mapping>
</metadata>

</local-tx-datasource>
</datasources>

```

### **Register JBoss Requestor**

See [Install and Activate an A2A Client on a Request Server](#) for the procedure to register your requestor with Credential Manager. Use the following data.

Parameter	Description
Script Name	com.cloakware.cspm.sample.web.CredentialsViewer
Execution Path	C:\jboss-4.2.2.GA\bin
Type	Java

Parameter	Description
Script Name	com.cloakware.client.jdbc.JdbcDriver
Execution Path	C:\jboss-4.2.2.GA\bin
Type	Java

### Register HSQLDB as a Target Application

See [Specify a Target Server](#) for the procedure to register HSQLDB as a target application with Credential Manager. Use the following data.

Parameter	Description
Application Name	HSQLDB Server
Application Type	HSQL
DB Port	9001

Parameter	Description
Application	HSQLDB Server
Account Name	sa
Password	admin
Database Name	cspm1

Parameter	Description
Application	HSQLDB Server
Account Name	TestUser
Password	Test
Database Name	cspm1
A2A Account	selected
Change Process	Select: - Use the following account to change password: SA

Parameter	Description
Targets Alias Name	hsq
Application	HSQLDB Server
Account	TestUser

### Register Mapping Between Request Server and Target Alias

See [Add A2A Authorization Mappings](#) for the procedure to register the mapping between the request server and the target alias. Use the following data.

Parameter	Description
Target Alias	Hsql
Request Server	Select your request server
Script	all

## HSQL Database Usage

HSQldb is an SQL relational database engine that is written in Java. It is used in the example as the database server.

Use the following procedure to start the database server.

### Follow these steps:

1. Open a command line window.
2. Navigate to one of the following directories:
  - UNIX: `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples/java/ApacheTomcat/build`
  - Windows: `%CSPM_CLIENT_HOME%/cloakware/cspmclient/examples/java/ApacheTomcat/build`
3. Start the HSQldb server by entering `ant start.hsldb`.

Use the following procedure to shut down the database server.

### Follow these steps:

1. Open a command line window.
2. Navigate to one of the following directories:
  - UNIX: `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples/java/ApacheTomcat/build`
  - Windows: `%CSPM_CLIENT_HOME%/cloakware/cspmclient/examples/java/ApacheTomcat/build`
3. Shut down the HSQldb server by entering `ant shutdown.hsldb`.

## Integrate a Java Application with the A2A Client on Tomcat

This content describes an example that uses the A2A Client to manage the credentials that are used by a Java container JDBC connection pool within a supported Apache Tomcat Application Server.

This example uses a credential viewer and an HSQldb data store to show the following functionality:

- The credential viewer shows you how to view credentials that are stored in the Credential Manager server using the CSPMClient Java class. Use this example for simple integration and to test the ability to connect to Credential Manager and retrieve credentials. The example displays the credentials to the screen.
- The HSQldb data store shows you how to configure a data store using the Credential Manager JdbcDriver Java class to retrieve credentials and connect to an HSQldb data store. The example retrieves credentials and uses them to access a data store.

### NOTE

For historical reasons, A2A is referred to as CSPM in code samples, file, and environment variable names.

This example is available on all A2A Client installations in one of the following directories:

- UNIX: `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples/java/Tomcat_Sample`
- Windows: `%CSPM_CLIENT_HOME%/cloakware/cspmclient/examples/java/Tomcat_Sample`

File	Description
<code>ClassFactory.java</code>	Class factory that is used to create the objects that are used in the example web application. The class allows you to create the CSPMClient class and to perform a lookup in the Initial Context to retrieve the data source that is used to get a connection to the database.
<code>CredentialsViewer.java</code>	Servlet class that is used to connect to the Credential Manager server to retrieve credentials.

ConnectionTester.java	Servlet class that is used to create 10 connections to a database and execute a basic SQL statement. The class retrieves the <code>DataSource</code> class using the <code>ClassFactory</code> class.
context.xml	Configuration file showing you how to configure a database resource using the HSQLDB driver and a second resource using the Credential Manager <code>JdbcDriver</code> Java class.

### **Integration Process for Tomcat**

Use the following process to modify your application to use the Credential Manager server to manage credentials:

1. Configure your development environment. See [Configure your Development Environment for Apache Tomcat](#).
2. Optionally, integrate the A2A Client to retrieve credentials. See [Apache Tomcat Credential Viewer](#).
3. Create or modify the context file. See [Apache Tomcat Connection Pool with HSQLDB Data Store](#).
4. Register the requestor. See [Register Apache Tomcat Requestor](#).

### **Configure Your Development Environment for Apache Tomcat**

Configure your development environment for both Apache Tomcat development and Credential Manager integration.

The example contains an Apache ANT build file that is located in the build directory that you can use to create the WAR file and to deploy it. The build file is compatible with ANT 1.6.5 and above.

#### ***Configure Your Environment for Apache Tomcat development***

Use the following procedure to configure your environment for Apache Tomcat development.

##### **Follow these steps:**

1. Install Apache Tomcat Application Server v5.5. See <http://archive.apache.org/dist/tomcat/tomcat-5>.
2. Install Apache ANT 1.6.5 or above. See <http://ant.apache.org/bindownload.cgi>.
3. Set the `ANT_HOME` environment variable. See <http://ant.apache.org/manual/install.html>.
4. Install the Java Database HSQLDB 1.8.0. See [http://sourceforge.net/project/showfiles.php?group\\_id=23316](http://sourceforge.net/project/showfiles.php?group_id=23316).
5. Set the `HSQL_HOME` environment variable to the path where you installed HSQL (for example, `opt/tools/hsqldb`).

#### ***Configure Your Environment for A2A Client Integration with Apache Tomcat***

Use the following procedure to configure your environment for A2A Client integration with Apache Tomcat.

##### **Follow these steps:**

1. [Install the A2A Client](#).
2. Copy the `cspmclient.jar` file that is located in the A2A Client `lib` directory to the Apache Tomcat Common Lib directory:
  - UNIX:  
Source: `$CSPM_CLIENT_HOME/cloakware/cspmclient/lib`  
Destination: `$APACHE_TOMCAT_HOME/common/lib`
  - Windows:  
Source: `%CSPM_CLIENT_HOME%/cloakware/cspmclient/lib`  
Destination: `%APACHE_TOMCAT_HOME%/common/lib`
3. Copy the `cloakwareJdbc.jar` file that is located in the A2A Client `tools` directory to the Apache Tomcat Common Lib directory:
  - UNIX:  
Source: `$CSPM_CLIENT_HOME/cspmclient/tools`  
Destination: `$APACHE_TOMCAT_HOME/common/lib`
  - Windows:

Source: %CSPM\_CLIENT\_HOME%/cspmclient/tools

Destination: %APACHE\_TOMCAT\_HOME%/common/lib

#### NOTE

Perform Steps 1 and using the ANT build file that is located in the following directories:

- UNIX: \$CSPM\_CLIENT\_HOME/examples/java/Tomcat\_Sample/build
- Windows: %CSPM\_CLIENT\_HOME%/examples/java/Tomcat\_Sample/build

Enter `ant deploy.driver.lib` from that directory.

4. Open the Apache Tomcat Properties dialog.
5. Click the Java tab.
6. Add the following text in the Java Options edit field:

– UNIX:

`-Djava.library.path=$CSPM_CLIENT_HOME\lib`

`-Dcspm_client_config_file=$CSPM_CLIENT_HOME\config\cspm_client_config.xml`

– Windows:

`-Djava.library.path=%CSPM_CLIENT_HOME%\lib`

`-Dcspm_client_config_file=$CSPM_CLIENT_HOME%\config\cspm_client_config.xml`

Substitute `CSPM_CLIENT_HOME` with the install directory of the client (for example, `c:\cloakware\cspmclient`).

7. Restart Apache Tomcat. (Stop and start the service.)

#### NOTE

Perform Step 2 and Step 3 using the ANT build file that is located in the following directories:

- UNIX: \$CSPM\_CLIENT\_HOME/examples/java/Tomcat\_Sample/build
- Windows: %CSPM\_CLIENT\_HOME%/examples/java/Tomcat\_Sample/build

Enter `ant deploy.driver.lib` from that directory.

### Deploy and Run the Sample Tomcat Application

Use the following procedure to compile and deploy the sample web application using an Apache Ant task.

Follow these steps:

1. Verify that Apache Tomcat is running.
2. With a text editor (such as Notepad or Vim), edit the `build.properties` file that is located in the following directories:
  - UNIX: \$CSPM\_CLIENT\_HOME/cloakware/cspmclient/examples/java/Tomcat\_Sample/build
  - Windows: %CSPM\_CLIENT\_HOME%/cloakware/cspmclient/examples/java/Tomcat\_Sample/build
3. Change the value of the `dir.server` property (for example, to `C:/Program Files/Apache Software Foundation/Tomcat 5.5`) and save the file.
4. Open a command line window.
5. Navigate to one of the following directories:
  - UNIX: \$CSPM\_CLIENT\_HOME/cloakware/cspmclient/examples/java/Tomcat\_Sample/build
  - Windows: %CSPM\_CLIENT\_HOME%/cloakware/cspmclient/examples/java/Tomcat\_Sample/build
6. Start the HSQLDB server by entering `ant start.hsqldb`.
7. Compile and deploy the example by entering `ant`.
8. Open a Web Browser.
9. Load the following page: <http://localhost:8088/cspmTomcatSample>.

## **Apache Tomcat Credential Viewer**

This example servlet shows you how to use the `CSPMClient` class to retrieve the credentials.

The `CSPMClient` class is created using a class factory.

### ***Class File***

```
package com.cloakware.cspm.sample.web;

import java.io.IOException;

import javax.servlet.RequestDispatcher;
import javax.servlet.ServletException;
import javax.servlet.http.HttpServlet;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import com.cloakware.jdbc.StatusCodeMapping;
import com.cloakware.cspm.client.CSPMClient;
import com.cloakware.cspm.sample.ClassFactory;

/**
 * This servlet class is used to retrieve credentials using the
 * CSPMClient class.<br>
 * <br>
 * The user enters a CSPMAlias Name and the servlet displays the information
 * returned by the CSPMClient class. <br>
 * <br>
 * Since the CSPMClient class only returns a status code, the base class
 * provides a class to convert the status code to a more meaningful sentence.
 */
public class CredentialsViewer extends HttpServlet {
    /* Attribute names */
    private final String ERROR_MSG = "errorMsg";

    /* Parameter names and attributes when refreshing the page */
    private final String ALIAS_NAME = "aliasName";
    private final String BYPASS_CACHE = "byPassCache";
    /* Attributes used when displaying credentials/response from
     * the CSPMClient class.
     */
    private final String RETURN_CODE = "returnCode";
    private final String RETURN_MSG = "returnMsg";
    private final String USERNAME = "username";
    private final String PASSWORD = "password";
    /* Error message */
    private final String MSG_ALIAS_EMPTY = "Alias cannot be empty";
    /* Response page */
    private final String TARGET_JSP = "/index.jsp";
    /**
     * Constructor of the object.
     */
    public CredentialsViewer() {
        super();
    }
}
```

```

}

/**
 * The doGet method of the servlet. <br>
 *
 * This method is called when a form has its tag value method equals to get.
 * The method retrieves the alias name and the value of the checkbox
 * indicating if the CSPMClient cache needs to be bypassed. It then calls
 * the retrieveCredentials method of the CSPMClient class and displays the
 * results. An error message is displayed if the alias name is missing.
 *
 * @param request the request send by the client to the server
 * @param response the response send by the server to the client
 * @throws ServletException if an error occurred
 * @throws IOException if an error occurred
 */
public void doGet(HttpServletRequest request, HttpServletResponse response)
throws ServletException, IOException {

    // Retrieve the parameters
    String alias = (String)request.getParameter(ALIAS_NAME);
    Object byPassCache = request.getParameter(BYPASS_CACHE);
    // Make sure to redisplay the alias name.
    request.setAttribute(ALIAS_NAME, alias);
    request.setAttribute(BYPASS_CACHE,
        (byPassCache != null) ? "checked" : null);

    // if we have an alias
    if (alias != null && !"".equals(alias)) {
        // Class used to retrieve the credential.
        CSPMClient cspmClient = ClassFactory.getCSPMClient();

        // Retrieve the credentials.
        if (byPassCache == null) {
            cspmClient.retrieveCredentials(alias);
        } else {
            cspmClient.retrieveCredentials(alias, "true");
        }

        // Set the credentials in the request
        request.removeAttribute(ERROR_MSG);
        request.setAttribute(RETURN_CODE, cspmClient.getStatusCode());
        String statusMsg = StatusCodeMapping
            .getStatusText(cspmClient);
        request.setAttribute(RETURN_MSG, statusMsg);
        request.setAttribute(USERNAME, cspmClient.getUserId());
        request.setAttribute(PASSWORD, cspmClient.getPassword());
    } else {
        // return an error message.
        request.setAttribute(ERROR_MSG, MSG_ALIAS_EMPTY);
        request.removeAttribute(RETURN_CODE);
    }
}

```

```
// Get the request dispatcher
RequestDispatcher dispatcher = getServletContext()
.getRequestDispatcher(TARGET_JSP);

// Forward to the jsp file to display the credentials
dispatcher.forward(request, response);
}
}
```

### **Apache Tomcat Connection Pool with HSQLDB Data Store**

This example shows you how to create or modify a resource to use the Credential Manager server for credential retrieval. You can add the data source definitions to the `context.xml` file located in the META-INF directory of the WAR file.

To integrate the A2A Client with your application, change the JDBC driver that is used by the data source. The Credential Manager JDBC driver acts as a proxy JDBC driver serving any JDBC URL that is recognized as a Credential Manager JDBC URL. In the data source configuration, provide information regarding the targeted driver and the alias to use in the special Credential Manager style JDBC URL. The Credential Manager style JDBC URL format is:

```
cspm:[url];CSPMDriver=target.driver;CSPMAlias=alias
```

Form the Credential Manager URL as follows:

- Ensure that it begins with the `cspm:` prefix.
- Follow the prefix by the normal JDBC URL, omitting any user/password specification; for example, `jdbc:hsqldb:hsqldb://localhost:9001/cspml`.
- Set the URL to contain the `CSPMDriver` that indicates an explicit JDBC driver to use.
- Assign the `CSPMAlias`, which is the alias for the database user in the Credential Manager server, to the URL.

Use the following procedure to modify to attributes in the configuration file to use the Credential Manager JDBC driver.

Follow these steps:

1. Set `url` as specified previously.
2. Set `driverClassName` to `com.cloakware.jdbc.JdbcDriver`.

This low-level driver management for connection acquisition means that all new connections that are obtained for a user whose database password has been changed (by the Credential Manager server) are made using the new password. This action occurs automatically without any knowledge or intervention by any owning data source.

While new connections are obtained using the new password, old connections that were obtained using an old password might linger in the data source pool. Also, if the CA Technologies alias is changed to a new user, then a connection pool has (at least temporarily) a mixture of connections for different actual database users.

Such connection management by the CA Technologies driver ensures that database password changes are transparent to the activities of the data source.

The XML file that is used in the example is located in the following locations:

- **UNIX:** `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples/java/Tomcat_Sample/main/resources/META-INF`
- **Windows:** `%CSPM_CLIENT_HOME%/cloakware/cspmclient/examples/java/Tomcat_Sample/main/resources/META-INF`

### **Data Source**

```
<Context docBase="SampleDataSources">

<Resource name="jdbc/CSPMSampleDS" auth="Container"
```

```

type="javax.sql.DataSource" maxActive="10" maxIdle="5" maxWait="10000"
username="hsqldb" password=""
driverClassName="com.cloakware.jdbc.JdbcDriver"
url="cspm:jdbc:hsqldb:hsqldb://localhost:9001/cspm1;
CSPMAlias=hsqldb;
CSPMDriver=org.hsqldb.jdbcDriver"
removeAbandoned="true"
removeAbandonedTimeout="30"
logAbandoned="true" />
</Context>

```

## Register Apache Tomcat Requestor

See [Add and Run Credential Manager A2A Requestors](#) for the procedure to register your requestor with Credential Manager. Use the following data:

Parameter	Description
Script Name	com.cloakware.cspm.sample.web.CredentialsViewer
Execution Path	C:\Program Files\Apache Software Foundation\Tomcat 5.5\bin
Type	Java

Parameter	Description
Script Name	com.cloakware.client.jdbc.JdbcDriver
Execution Path	C:\Program Files\Apache Software Foundation\Tomcat 5.5\bin
Type	Java

HSQldb is an SQL relational database engine that is written in Java. HSQldb is used in the example as the database server. See also:

- [Register HSQldb as a Target Application](#)
- [Register Mapping between Request Server and Target Alias](#)
- [HSQL Database Usage](#)

## Integrate a Java Application with the A2A Client on WebLogic

This example uses the A2A Client to manage the credentials that are used by a Java container JDBC connection pool within a supported Oracle WebLogic Server. You must [install](#) the A2A Client on each WebLogic server to be integrated..

This example uses a credential viewer and an HSQldb data store to show the following:

- The credential viewer shows you how to view credentials that are stored in the Credential Manager server using the CSPMClient Java class. Use this example for simple integration and to test the ability to connect to Credential Manager and retrieve credentials. The example displays the credentials to the screen.
- The HSQldb data store shows you how to configure a data store using the Credential Manager JdbcDriver Java class to retrieve credentials and connect to an HSQldb data store. The example retrieves credentials and uses them to access a data store.

### NOTE

For historical reasons, A2A is referred to as CSPM in code samples, file, and environment variable names.

This example is available on all A2A Client installations, in the following directories:

- **UNIX:** `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples/java/WebLogic_Sample`
- **Windows:** `%CSPM_CLIENT_HOME%/cloakware/cspmclient/examples/java/WebLogic_Sample`

File	Description
<code>ClassFactory.java</code>	Class factory that is used to create the objects that are used in the example Web application. The class allows you to create the <code>CSPMClient</code> class and to perform a lookup in the Initial Context to retrieve the data source used to get a connection to the database.
<code>CredentialsViewer.java</code>	Servlet class used to connect to the Credential Manager server to retrieve credentials.
<code>ConnectionTester.java</code>	Servlet class used to create 10 connections to a database and execute a basic SQL statement. The class retrieves the <code>DataSource</code> class using the <code>ClassFactory</code> class.

### Integration Process for WebLogic

Use the following process to modify your application to use the Credential Manager server to manage credentials:

1. Configure development environment. See [Configure your Development Environment for WebLogic](#)
2. Optionally, integrate the A2A Client to retrieve credentials. See [WebLogic Credential Viewer](#).
3. Create or modify the data source file. See [WebLogic Connection Pool with HSQLDB Data Store](#).
4. Register the requestor. See [Register WebLogic Requestor](#).

### Configure your Development Environment for WebLogic

You must configure your development environment for both WebLogic development and Credential Manager integration.

The example contains an Apache ANT build file located in the `build` directory that you can use to create the WAR file and to deploy it. The build file is compatible with ANT 1.6.5 and above.

Use the following procedure to configure your environment for WebLogic development.

#### Follow these steps:

1. Install WebLogic Server 10.0. See <http://www.oracle.com/technetwork/middleware/ias/downloads/101310-085449.html>.
2. With the WebLogic Configuration Wizard application, create a domain called `cspmSample` using the default settings. Consult the WebLogic documentation for further assistance.
3. Install Apache ANT 1.6.5 or above. See <http://ant.apache.org/bindownload.cgi>.
4. Set the `ANT_HOME` environment variable. See <http://ant.apache.org/manual/install.html>.
5. Install the Java Database HSQLDB 1.8.0. See [http://sourceforge.net/project/showfiles.php?group\\_id=23316](http://sourceforge.net/project/showfiles.php?group_id=23316).
6. Set the `HSQL_HOME` environment variable to the path where you installed HSQL (for example, `opt/tools/hsqldb`).

Use the following process to configure your environment for A2A Client integration with WebLogic.

#### Follow these steps:

1. Create or add to the `JAVA_OPTIONS` environment variable:
  - UNIX:
    - Djava.library.path=\$CSPM\_CLIENT\_HOME\lib
    - Dcspm\_client\_config\_file=\$CSPM\_CLIENT\_HOME\config\cspm\_client\_config.xml
  - Windows:
    - Djava.library.path=%CSPM\_CLIENT\_HOME%\lib
    - Dcspm\_client\_config\_file=%CSPM\_CLIENT\_HOME%\config\cspm\_client\_config.xml

2. Copy the `cspmclient.jar` file located in the A2A Client `lib` directory to the `lib` directory for your WebLogic domain:
  - UNIX:
    - Source: `$CSPM_CLIENT_HOME/cloakware/cspmclient/lib`
    - Destination: `$WEBLOGIC_HOME/user_projects/domains/$YOUR_DOMAIN/lib`
  - Windows:
    - Source: `%CSPM_CLIENT_HOME%/cloakware/cspmclient/lib`
    - Destination: `%WEBLOGIC_HOME%/user_projects/domains/%YOUR_DOMAIN%/lib`
3. Copy the `cloakwareJdbc.jar` file located in the A2A Client `tools` directory to the WebLogic home directory:
  - UNIX:
    - Source: `$CSPM_CLIENT_HOME/cspmclient/tools`
    - Destination: `$WEBLOGIC_HOME/user_projects/domains/$YOUR_DOMAIN/lib`
  - Windows:
    - Source: `%CSPM_CLIENT_HOME%/cspmclient/tools`
    - Destination: `%WEBLOGIC_HOME%/user_projects/domains/%YOUR_DOMAIN%/lib`

Step 1 and Step 2 are performed by the ANT build file located in the following directories:

- UNIX: `$CSPM_CLIENT_HOME/examples/java/WebLogic_Sample/build`
- Windows: `%CSPM_CLIENT_HOME%/examples/java/WebLogic_Sample/build`

Enter `ant deploy.driver.lib` from that directory.

### **Deploy and Run the Sample WebLogic Application**

Use the following procedure to compile and run the sample web application using an Apache Ant task.

#### **Follow these steps:**

1. Make sure WebLogic is running and using the domain that you created in [Configure your Development Environment for WebLogic](#).
2. With a text editor (such as NotePad or Vim), edit the `build.properties` file located in the following locations, for:
  - UNIX: `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples/java/WebLogic_Sample/build`
  - Windows: `%CSPM_CLIENT_HOME%/cloakware/cspmclient/examples/java/WebLogic_Sample/build`
3. Change the value of the following properties and save the file:
  - `dir.bea`. Points to the location where Bea WebLogic Server 10.0 is installed (for example, `C:/bea` )
  - `weblogic.adminurl`. Administration console URL (for example, `t3://localhost:7001` )
  - `weblogic.domain`. WebLogic domain to use for the deployment. This should match the `cspmSample` domain name that you created in [Configure your Development Environment for WebLogic](#).
  - `weblogic.server`. Name of the server instance to use for the deployment (for example, `AdminServer` )
  - `weblogic.username`. Administration console username (for example, `weblogic` )
  - `weblogic.password`. Administration console password (for example, `weblogic` )
4. Open a command line window.
5. Change directory to the following, for:
  - UNIX: `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples/java/WebLogic_Sample/build`
  - Windows: `%CSPM_CLIENT_HOME%/cloakware/cspmclient/examples/java/WebLogic_Sample/build`
6. Start the HSQLDB server by entering `ant start.hsqldb`.
7. Compile and deploy the example by entering `ant`.
8. Open a Web Browser.
9. Load the following page: `http://localhost:7001/cspmWeblogicSample`.

## WebLogic Credential Viewer

This example servlet shows you how to use the CSPMClient class to retrieve the credentials.

The CSPMClient class is created using a class factory.

### Class File

```
package com.cloakware.cspm.sample.web;

import java.io.IOException;

import javax.servlet.RequestDispatcher;

public void doGet(HttpServletRequest request, HttpServletResponse response)
    throws ServletException, IOException {

    // Retrieve the parameters
    String alias = (String)request.getParameter(ALIAS_NAME);
    Object byPassCache = request.getParameter(BYPASS_CACHE);
    // Make sure to redisplay the alias name.
    request.setAttribute(ALIAS_NAME, alias);
    request.setAttribute(BYPASS_CACHE,
        (byPassCache != null) ? "checked" : null);

    // if we have an alias
    if (alias != null && !"".equals(alias)) {
        // Class used to retrieve the credential.
        CSPMClient cspmClient = ClassFactory.getCSPMClient();

        // Retrieve the credentials.
        if (byPassCache == null) {
            cspmClient.retrieveCredentials(alias);
        } else {
            cspmClient.retrieveCredentials(alias, "true");
        }
    }
}

```

```

}

// Set the credentials in the request
request.removeAttribute(ERROR_MSG);
request.setAttribute(RETURN_CODE, cspmClient.getStatusCode());
String statusMsg = StatusCodeMapping
.getStatusText(cspmClient);
request.setAttribute(RETURN_MSG, statusMsg);
request.setAttribute(USERNAME, cspmClient.getUserId());
request.setAttribute(PASSWORD, cspmClient.getPassword());
} else {
// return an error message.
request.setAttribute(ERROR_MSG, MSG_ALIAS_EMPTY);
request.removeAttribute(RETURN_CODE);
}

// Get the request dispatcher
RequestDispatcher dispatcher = getServletContext()
.getRequestDispatcher(TARGET_JSP);

// Forward to the jsp file to display the credentials
dispatcher.forward(request, response);
}
}

```

### **WebLogic Connection Pool with HSQLDB Data Store**

This example shows you how to create or modify a data source to use the Credential Manager server for credential retrieval. You can create data source definitions using the WebLogic Server administration console or with Apache ANT scripts. The scripts use the `wlconfig` custom ANT task.

To integrate the A2A Client to your application, change the JDBC driver that is used by the data source. The Credential Manager JDBC driver acts as a proxy JDBC driver serving any JDBC URL that is recognized as a Credential Manager JDBC URL. In the data source configuration, provide information regarding the targeted driver and the alias to use in the special Credential Manager style JDBC URL. The Credential Manager style JDBC URL format is:

```
cspm:[url];CSPMDriver=target.driver;CSPMAlias=alias
```

Form the Credential Manager URL as follows:

- Ensure it begins with the `cspm:` prefix.
- Follow the prefix by the normal JDBC URL, omitting any user/password specification; for example, `jdbc:hsqldb:hsqldb://localhost:9001/cspm1`.
- Set the URL to contain the `CSPMDriver` that indicates an explicit JDBC driver to use.
- Assign, the `CSPMAlias`, which is the alias for the database user in the Credential Manager server, to the URL.

This low-level driver management for connection acquisition means that all new connections obtained for a user whose database password has been changed (by the Credential Manager server) are made using the new password. This action occurs automatically without any knowledge or intervention by any owning data source.

While new connections are obtained using the new password, old connections that were obtained using an old password may linger in the data source pool. Also, if the Credential Manager alias is changed to a new user, then a connection pool has (at least temporarily) a mixture of connections for different actual database users.

Such connection management by the CA Technologies driver ensures that database password changes are transparent to the activities of the data source.

You can configure your data source either with the WebLogic console interface or with the ANT scripts provided with this example.

The ANT scripts that are provided with this example automatically configure the required data sources, so this step is optional.

Execute the following steps in the WebLogic console to create the data source that uses a Credential Manager JDBC driver. Before starting make sure HSQLDB is running. See [HSQL Database Usage](#).

Use the following procedure to configure your data source using the WebLogic console.

**Follow these steps:**

1. From the main window of the console, navigate to **Services > JDBC > Data Sources**.
2. Select **Lock & Edit**.
3. Select **New**.
4. Enter a value for Name; for example, `ExamplesDS`.
5. Enter a value for JNDI Name. Example: `ExamplesDS`
6. For Database Type, select **Other**.
7. Select **Next**.
8. Select the appropriate **Transaction Options**.
9. Select **Next**.
10. For Database Name, enter `cspm1`.
11. For Host Name, enter `localhost`.
12. For Port, enter `9001`.
13. Leave **Database User Name** blank.
14. Leave **Password** and **Confirm Password** blank.
15. Select **Next**.
16. For **Driver Class Name**, enter `com.cloakware.jdbc.JdbcDriver`.
17. For **URL**, enter:  
`cspm:jdbc:hsqldb:hsqldb://localhost:9001/`  
`cspm1;CSPMAlias=hsqldb;CSPMDriver=org.hsqldb.jdbcDriver`
18. Leave **Database User Name** blank.
19. Leave **Password** and **Confirm Password** blank.
20. Leave **Properties** blank.
21. Leave **Test Table Name** blank.
22. Select **Test Connection**. WebLogic should display "Connection test succeeded" at the top of the panel.
23. Select **Next**.
24. Select the target server.
25. Select **Finish**.
26. Select **Activate Changes**.

The following Apache ANT target shows you how to create a connection pool using the Credential Manager JDBC Driver and the data source.

To configure data source using the WebLogic WLConfig Apache Ant task:

```
<!-- Define the wlconfig task -->
<taskdef name="wlconfig" classname="weblogic.ant.taskdefs.management.WLConfig">
<classpath path="${dir.bea.server.lib}/weblogic.jar"/>
</taskdef>
```

```

<!-- Define used to create a DataSource using Cloakware JdbcDriver -->
<target name="datasource.create" depends="">
<wlconfig url="${weblogic.adminurl}"
username="${weblogic.username}"
password="${weblogic.password}">

<query domain="${weblogic.domain}"
type="Server" name="${weblogic.server}"
property="adminserver"/>

<create type="JDBCConnectionPool" name="${datasource.pool.name}"
property="datasource.pool.cspm" >
<set attribute="CapacityIncrement" value="1"/>
<set attribute="DriverName" value="com.cloakware.jdbc.JdbcDriver"/>
<set attribute="InitialCapacity" value="5"/>
<set attribute="MaxCapacity" value="10"/>
<set attribute="RefreshMinutes" value="0"/>
<set attribute="ShrinkPeriodMinutes" value="1"/>
<set attribute="ShrinkFrequencySeconds" value="30"/>
<set attribute="ShrinkingEnabled" value="true"/>
<set attribute="TestConnectionsOnRelease" value="false"/>
<set attribute="TestConnectionsOnReserve" value="true"/>
<set attribute="URL" value="cspm:jdbc:hsqldb:hsqldb://localhost:9001/cspm1;
CSPMAlias=hsqldb;
CSPMDriver=org.hsqldb.jdbcDriver"/>
<set attribute="Targets" value="${adminserver}"/>
<set attribute="TestTableName" value="PUBLIC.TESTTBL"/>
</create>

<create type="JDBCDataSource"
name="${datasource.ds.name}"
property="datasource.cspm">
<set attribute="JNDIName" value="CSPM${datasource.jndi.name}"/>
<set attribute="PoolName" value="CSPM${datasource.pool.name}"/>
<set attribute="Targets" value="${adminserver}"/>
</create>
</wlconfig>
</target>

```

### **Register WebLogic Requestor**

See [Add and Run Credential Manager A2A Requestors](#) for the procedure to register your requestor with Credential Manager. Use the following data.

Parameter	Description
Script Name	com.cloakware.cspm.sample.web.CredentialsViewer
Execution Path	C:\bea\user_projects\domains\cloakware

Type	Java
------	------

Parameter	Description
Script Name	com.cloakware.client.jdbc.JdbcDriver
Execution Path	C:\bea\user_projects\domains\cloakware
Type	Java

HSQldb is an SQL relational database engine that is written in Java. It is used in the example as the database server. See also:

- [Register HSQldb as a Target Application](#)
- [Register Mapping between Request Server and Target Alias](#)
- [HSQL Database Usage](#)

## Integrate a Java Application with the A2A Client on WebSphere CE

This example uses the A2A Client to manage the credentials that are used by a Java container JDBC connection pool within WebSphere Application Server Community Edition (WebSphere CE).

This example uses a credential viewer and an HSQldb data store to show the following information:

- The credential viewer shows you how to view credentials that are stored in the Credential Manager server using the `CSPMClient` Java class. Use this example for simple integration and to test the ability to connect to Credential Manager and retrieve credentials. The example displays the credentials to the screen.
- The HSQldb data store shows you how to configure a data store using the `CredentialManagerJdbcDriver` Java class to retrieve credentials and connect to an HSQldb data store. The example retrieves credentials and uses them to access a data store.

### NOTE

For historical reasons, A2A is referred to as CSPM in code samples, file, and environment variable names.

This example is available on all A2A Client installations in the following directories:

- **UNIX:** `$CSPM_CLIENT_HOME/cloakware/cspmclient/examples/java/WebSphere_Sample`
- **Windows:** `%CSPM_CLIENT_HOME%/cloakware/cspmclient/examples/java/WebSphere_Sample`

File	Description
<code>ClassFactory.java</code>	Class factory that is used to create the objects that are used in the example web application. The class allows you to create the <code>CSPMClient</code> class and to perform a lookup in the Initial Context to retrieve the data source that is used to get a connection to the database.
<code>CredentialsViewer.java</code>	Servlet class that is used to connect to the Credential Manager server to retrieve credentials.
<code>ConnectionTester.java</code>	Servlet class that is used to create 10 connections to a database and execute a basic SQL statement. The class retrieves the <code>DataSource</code> class using the <code>ClassFactory</code> class.

## Integration Process for WebSphere CE

Use the following process to modify your application to use the Credential Manager server to manage credentials:

1. Configure development environment. See [Configure your Development Environment for WebSphere CE](#).

2. Optionally, integrate the A2A Client to retrieve credentials. See [WebSphere CE Credential Viewer](#).
3. Create or modify the data source file. See [WebSphere CE Connection Pool with HSQLDB Data Store](#).
4. Register requestor. See [Register WebSphere CE Requestor](#).

### **Configure your Development Environment for WebSphere CE**

You must configure your development environment for both WebSphere CE development and Credential Manager integration.

The example contains an Apache ANT build file that is located in the build directory that you can use to create the WAR file and to deploy it. The build file is compatible with ANT 1.6.5 and above.

#### **Configure Your Environment for WebSphere CE Development**

Use the following procedure to configure your environment for WebSphere CE development.

##### **Follow these steps:**

1. Install WebSphere Application Server Community Edition 2.0. See <http://www.ibm.com/developerworks/downloads/ws/wasce/>.
2. Install Apache ANT 1.6.5 or above. See <http://ant.apache.org/bindownload.cgi>.
3. Set the `ANT_HOME` environment variable. See <http://ant.apache.org/manual/install.html>.
4. Install the Java Database HSQLDB 1.8.0. See [http://sourceforge.net/project/showfiles.php?group\\_id=23316](http://sourceforge.net/project/showfiles.php?group_id=23316).
5. Set the `HSQL_HOME` environment variable to the path where you installed HSQL (for example, `opt/tools/hsqldb`).

#### **Configure Your Environment for A2A Client Integration with WebSphere CE**

Use the following procedure to configure your environment for A2A Client integration with WebSphere CE.

##### **Follow these steps:**

1. [Install the A2A Client](#).
2. Create or add to the `JAVA_OPTS` environment variable:
  - UNIX:
    - Djava.library.path=\$CSPM\_CLIENT\_HOME\lib
    - Dcspm\_client\_config\_file=\$CSPM\_CLIENT\_HOME\config\cspm\_client\_config.xml
  - Windows:
    - Djava.library.path=%CSPM\_CLIENT\_HOME%\lib
    - Dcspm\_client\_config\_file=%CSPM\_CLIENT\_HOME%\config\cspm\_client\_config.xml
3. Edit the `$WEBSPPHERE_HOME/var/config/config.xml` file. Locate the `<gbean name="TomcatAJPConnector">` XML element and modify the port attribute below it as follows:
 

From:

```
<gbean name="TomcatAJPConnector">
<attribute name="host">${ServerHostname}</attribute>
<attribute name="port">${AJPPrimary}</attribute>
```

To:

```
<gbean name="TomcatAJPConnector">
<attribute name="host">${ServerHostname}</attribute>
<attribute name="port">8010</attribute>
```
4. Register the `cspmclient.jar` file with WebSphere CE as an artifact. To do so, log in to the Administration Console and select Common Libs as follows:
  - a. Select Browse to locate the `cspmclient.jar` in the following locations:
    - UNIX: `$CSPM_CLIENT_HOME/cloakware/cspmclient/lib`
    - Windows: `%CSPM_CLIENT_HOME%/cloakware/cspmclient/lib`
  - b. Enter `cspmclient` for Group.
  - c. Enter `cspmclient` for Artifact.

- d. Enter 3.5 for Version.
  - e. Enter `jar` for Type.
  - f. Select **Install** to add the JAR file to the repository.
5. Register the `cloakwareJdbc.jar` file with WebSphere CE as an artifact. To do so, log in to the Administration Console and select Common Libs as follows:
- a. Select Browse to locate the `cloakwareJdbc.jar` in the following locations:
    - UNIX: `$CSPM_CLIENT_HOME/cloakware/cspmclient/tools`
    - Windows: `%CSPM_CLIENT_HOME%/cloakware/cspmclient/tools`
  - b. Enter `cloakwareJdbc` for Group.
  - c. Enter `cloakwareJdbc` for Artifact.
  - d. Enter 3.5 for Version.
  - e. Enter `jar` for Type.
  - f. Select **Install** to add the JAR file to the repository.

### **Configure Your Environment for HSQLDB**

Use the following process to configure your environment for HSQLDB.

#### **Follow these steps:**

1. Register the `hsqldb.jar` file with WebSphere CE as an artifact. To do so, log in to the Administration Console and select Common Libs as follows:
  - a. Select Browse to locate the `hsqldb.jar` in the following locations:
    - UNIX: `$HSQL_HOME/lib`
    - Windows: `%HSQL_HOME%/lib`
  - b. Enter `hsqldb` for Group.
  - c. Enter `hsqldb` for Artifact.
  - d. Enter 1.8.0.2 for Version.
  - e. Enter `jar` for Type.
  - f. Select **Install** to add the JAR file to the repository.

### **Configure Your Database Pool Using the WebSphere CE Administration Console**

Use the following procedure to configure your database pool using the WebSphere CE Administration Console.

#### **Follow these steps:**

1. Verify that HSQLDB is running. See [HSQL Database Usage](#).
2. From the main window of the console, navigate to the Database Pools display.
3. Select "Using the Geronimo database pool wizard" to create a database pool.
4. Enter a value for Name of Database Pool. For the example web application, you must enter `CSPMSampleDS`.
5. Select `Other` for Database Type.
6. Select **Next**.
7. For JDBC Driver Class, enter `com.cloakware.jdbc.JdbcDriver`.
8. For Driver JAR, press the **Ctrl** key and select all the following entries:
  - `cspmclient/cspmclient/3.5/jar`
  - `cloakwareJdbc/cloakwareJdbc/3.5/jar`
  - `hsqldb/hsqldb/1.8.0.2/jar`
9. Leave DB User Name blank.
10. Leave DB Password and Confirm Password blank.
11. Select **Next**.
12. For JDBC Connect URL, enter:
 

```
cspm:jdbc:hsqldb:hsqldb://localhost:9001/cspm1;CSPMAlias=hsqldb;CSPMDriver=org.hsqldb.jdbcDriver
```

13. Leave the Connection Pool Parameters blank.
14. Select **Test Connection**. WebSphere CE displays “Connected to HSQL Database Engine 1.8.0” at the top of the panel.
15. Select **Deploy**.

### **Create a Second Database Pool**

To run the sample WebSphere CE application, create a second database pool as follows:

#### **Follow these steps:**

1. From the main window of the console, navigate to the Database Pools display.
2. Select “Using the Geronimo database pool wizard” to create a database pool.
3. Enter `SampleDS` as the value for Name of Database Pool.
4. Select `Other` for Database Type.
5. Select **Next**.
6. Enter `org.hsqldb.jdbcDriver` for JDBC Driver Class.
7. Select `hsqldb/hsqldb/1.8.0.2/jar` for Driver JAR.
8. Enter `TestUser` for DB User Name.
9. Enter `Test` for DB Password and Confirm Password.
10. Select **Next**.
11. Enter `jdbc:hsqldb:hsq1://localhost:9001/cspm1` for JDBC Connect URL.
12. Leave the Connection Pool Parameters blank.
13. Select **Test Connection**. WebSphere CE displays “Connected to HSQL Database Engine 1.8.0” at the top of the panel.
14. Select **Deploy**.

### **Deploy and Run the Sample WebSphere CE Application**

Use the following procedure to compile and run the sample web application using an Apache ANT task.

#### **Follow these steps:**

1. Ensure WebSphere CE is running and you have completed the following steps:
  - The steps to configure your environment for A2A Client integration with WebSphere CE, described in [Configure your Development Environment for WebSphere CE](#)
  - The steps to configure your environment for HSQLDB, described in [Configure your Development Environment for WebSphere CE](#)
  - The steps to configure your database pool using the WebSphere CE Administration Console, described in [WebSphere CE Connection Pool with HSQLDB Data Store](#)
  - The steps to run the sample WebSphere CE application, described in [WebSphere CE Connection Pool with HSQLDB Data Store](#)
2. With a text editor (such as NotePad or Vim), edit the `build.properties` file located in the following directories:
  - UNIX: `$CSPM_CLIENT_HOME/cspmclient/examples/java/WebSphere_Sample/build`
  - Windows: `%CSPM_CLIENT_HOME%/cspmclient/examples/java/WebSphere_Sample/build`
3. Change the value of the `dir.server` property (for example, to `C:/Program Files/IBM/WebSphere/AppServerCommunityEdition`) and save the file.
4. Open a command line window.
5. Change directory to the following location:
  - UNIX: `$CSPM_CLIENT_HOME/cspmclient/examples/java/WebSphere_Sample/build`
  - Windows: `%CSPM_CLIENT_HOME%/cspmclient/examples/java/WebSphere_Sample/build`
6. Start the HSQLDB server by entering `ant start.hsqldb`.

7. Compile and deploy the example by entering `ant`.
8. Open a Web Browser.
9. Load the following page: <https://localhost:8443/cspmWebsphereSample>

### **WebSphere CE Credential Viewer**

This example servlet shows you how to use the `CSPMClient` class to retrieve the credentials.

The `CSPMClient` class is created using a class factory.

#### ***Class File***

```
package com.cloakware.cspm.sample.web;

import java.io.IOException;

import javax.servlet.RequestDispatcher;
import javax.servlet.ServletException;
import javax.servlet.http.HttpServlet;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import com.cloakware.jdbc.StatusCodeMapping;
import com.cloakware.cspm.client.CSPMClient;
import com.cloakware.cspm.sample.ClassFactory;

/**
 * This servlet class is used to retrieve credentials using the
 * CSPMClient class.<br>
 * <br>
 * The user enters a CSPMAlias Name and the servlet displays the information
 * returned by the CSPMClient class. <br>
 * <br>
 * Since the CSPMClient class only returns a status code, the base class
 * provides a class to convert the status code to a more meaningful sentence.
 */
public class CredentialsViewer extends HttpServlet {
    /* Attribute names */
    private final String ERROR_MSG = "errorMsg";

    /* Parameter names and attributes when refreshing the page */
    private final String ALIAS_NAME = "aliasName";
    private final String BYPASS_CACHE = "byPassCache";
    /* Attributes used when displaying credentials/response from
     * the CSPMClient class.
     */
    private final String RETURN_CODE = "returnCode";
    private final String RETURN_MSG = "returnMsg";
    private final String USERNAME = "username";
    private final String PASSWORD = "password";

    /* Error message */
    private final String MSG_ALIAS_EMPTY = "Alias cannot be empty";
```

---

```

/* Response page */
private final String TARGET_JSP = "/index.jsp";
/**
 * Constructor of the object.
 */
public CredentialsViewer() {
    super();
}

/**
 * Destruction of the servlet. <br>
 */
public void destroy() {
    // Just puts "destroy" string in log
    super.destroy();
}

/**
 * The doGet method of the servlet. <br>
 *
 * This method is called when a form has its tag value method equals to get.
 * The method retrieves the alias name and the value of the checkbox
 * indicating if the CSPMClient cache needs to be bypassed. It then calls
 * the retrieveCredentials method of the CSPMClient class and displays the
 * results. <br>
 * <br>
 * An error message is displayed if the alias name is missing.
 *
 * @param request
 *         the request send by the client to the server
 * @param response
 *         the response send by the server to the client
 * @throws ServletException
 *         if an error occurred
 * @throws IOException
 *         if an error occurred
 */
public void doGet(HttpServletRequest request, HttpServletResponse response)
    throws ServletException, IOException {

    // Retrieve the parameters
    String alias = (String)request.getParameter(ALIAS_NAME);
    Object byPassCache = request.getParameter(BYPASS_CACHE);
    // Make sure to redisplay the alias name.
    request.setAttribute(ALIAS_NAME, alias);
    request.setAttribute(BYPASS_CACHE,
        (byPassCache != null) ? "checked" : null);

    // if we have an alias
    if (alias != null && !"".equals(alias)) {
        // Class used to retrieve the credential.
        CSPMClient cspmClient = ClassFactory.getCSPMClient();

```

```

// Retrieve the credentials.
if (byPassCache == null) {
    cspmClient.retrieveCredentials(alias);
} else {
    cspmClient.retrieveCredentials(alias, "true");
}

// Set the credentials in the request
request.removeAttribute(ERROR_MSG);
request.setAttribute(RETURN_CODE, cspmClient.getStatusCode());
String statusMsg = StatusCodeMapping
    .getStatusText(cspmClient);
request.setAttribute(RETURN_MSG, statusMsg);
request.setAttribute(USERNAME, cspmClient.getUserId());
request.setAttribute(PASSWORD, cspmClient.getPassword());
} else {
    // return an error message.
    request.setAttribute(ERROR_MSG, MSG_ALIAS_EMPTY);
    request.removeAttribute(RETURN_CODE);
}

// Get the request dispatcher
RequestDispatcher dispatcher = getServletContext()
    .getRequestDispatcher(TARGET_JSP);

// Forward to the jsp file to display the credentials
dispatcher.forward(request, response);
}
}

```

### **WebSphere CE Connection Pool with HSQLDB Data Store**

This example shows you how to create or modify a data source to use the Credential Manager server for credential retrieval. The data source definitions are created with the WebSphere CE Administration Console.

To integrate the A2A Client to your application, change the JDBC driver that is used by the data source. The Credential Manager JDBC driver acts as a proxy JDBC driver serving any JDBC URL that is recognized as a Credential Manager JDBC URL. In the data source configuration, provide information regarding the targeted driver and the alias to use in the special Credential Manager style JDBC URL. The Credential Manager style JDBC URL format is:

```
cspm:[url];CSPMDriver=target.driver;CSPMAlias=alias
```

Form the Credential Manager URL as follows:

- Ensure it begins with the `cspm:` prefix.
- Follow the prefix by the normal JDBC URL, omitting any user/password specification; for example, `jdbc:hsqldb:hsqldb://localhost:9001/cspm1`.
- Set the URL to contain the `CSPMDriver` that indicates an explicit JDBC driver to use.
- Assign the `CSPMAlias`, which is the alias for the database user in the Credential Manager server, to the URL.

This low-level driver management for connection acquisition means that all new connections that are obtained for a user whose database password has been changed (by the Credential Manager server) are made using the new password. This action occurs automatically without any knowledge or intervention by any owning database pool.

While new connections are obtained using the new password, old connections that were obtained using an old password may linger in the database pool. Also, if the Credential Manager alias is changed to a new user, then a connection pool has (at least temporarily) a mixture of connections for different actual database users.

Such connection management by the CA Technologies driver ensures that database password changes are transparent to the database pool activities.

### Register WebSphere CE Requestor

See [Add and Run Credential Manager A2A Requestors](#) for the procedure to register your requestor with Credential Manager. Use the following data.

Parameter	Description
Script Name	com.cloakware.cspm.sample.web.CredentialsViewer
Execution Path	C:\Program Files (x86)\IBM\WebSphere\AppServerCommunityEdition\bin
Type	Java

Parameter	Description
Script Name	com.cloakware.client.jdbc.JdbcDriver
Execution Path	C:\Program Files (x86)\IBM\WebSphere\AppServerCommunityEdition\bin
Type	Java

HSQldb is an SQL relational database engine that is written in Java. HSQldb is used in the example as the database server. See also:

- [Register HSQldb as a Target Application](#)
- [Register Mapping between Request Server and Target Alias](#)
- [HSQldb Database Usage](#)

## Integrate Apps to Use the Credential Manager A2A Client on UNIX and AIX

This section includes examples of UNIX and AIX applications that have been integrated to use Credential Manager to retrieve target account credentials using the A2A Client.

Use the table of contents to access the topics in this section.

### Integrate a Perl Script with A2A Client on UNIX or AIX

This example uses the `example.pl` script in the `$CSPM_CLIENT_HOME/cspmclient/examples` directory. It uses a UNIX executable to integrate the A2A Client (`cspmclient`) with UNIX or AIX.

#### Code: Perl Script with A2A Client on UNIX or AIX

```
#!/usr/bin/perl -w

use strict;
use lib "/opt/catech/cspmclient/lib";
use CSPM_CLIENT;
```

```

my ($alias, $answer, $bypass_cache, $command, $password, $src, $userid, $msg, @a
ray,$isXMLOutput, $argv);

$msg="";
$bypass_cache = "";
$alias = "";
$isXMLOutput = 0;

foreach $argv (@ARGV){
    if($argv eq "-x"){
        $isXMLOutput = 1;
    }
}
# $GETCR = "GET CRedentials" ; defined in the CSPM_CLIENT.pm
# it is the main and only call when using Perl to retrieve
# the userid and password from the Password Authority Server

$command = qq{$GETCR @ARGV};
$answer = ` $command `;

if($isXMLOutput){
    print qq($answer\n);
}else{
    @array = split(/\s+/, $answer);
    print qq(Return Code: $array[0]\n);
    print qq(UserID:      $array[1]\n);
    print qq>Password:    $array[2]\n);

    if ($array[0] ne "400" ) {
        for my $i (3..$#array){
            $msg = $msg." ".$array[$i];
        }
        print qq(Message: $msg\n);
    } else {
        print qq(PASSED\n);
    }
}

# End of Main

__END__

```

### **Register Requestor - Perl Script with A2A Client on UNIX or AIX**

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, `example.pl`.
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, `Perl`.

When entering the file and execution paths, you must specify the absolute paths without links.

## Integrate a C or C++ Application with A2A Client on UNIX or AIX

This example uses the `example.c` script in the `$CSPM_CLIENT_HOME/cspmclient/examples` directory. It uses a UNIX executable to integrate the A2A Client (`cspmclient`) with UNIX or AIX.

The path to the binary client depends on `CSPM_CLIENT_HOME` being set. For the A2A Client, the path is `$CSPM_CLIENT_HOME/cspmclient/bin/cspmclient`.

The A2A Client (`cspmclient`) accepts up to two command line arguments. This example accepts and passes those arguments from the command line:

- `argv[1]`. Provides the target alias name. This argument is mandatory.
- `argv[2]`. Provides the Bypass Cache Flag, which can be `true` or `false`. The default is `false`. This argument is optional.

The `example.c` script has been compiled to produce the `example_c_interface_java` executable also located in the `$CSPM_CLIENT_HOME/cspmclient/examples` directory.

### Code: C Application with A2A Client on UNIX

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

#define CSPM_CLIENT_BINARY "/cspmclient/bin/cspmclient"
#define BUF_SIZE 256

int main (int argc, char **argv)
{
    FILE *results_file;

    /* Declarations, Allocations & Initializations */

    int error = 0;

    char *cspm_client_home, *return_code, *userid, *password;

    char a_buffer[BUF_SIZE];
    char command[BUF_SIZE];
    char bypass_cache_flag[BUF_SIZE];

    memset(a_buffer, '\0', BUF_SIZE);
    memset(command, '\0', BUF_SIZE);
    memset(bypass_cache_flag, '\0', BUF_SIZE);

    /* Validate Command Line Arguments */

    if ( argv[1] == NULL ) {
        printf("\nERROR: arg[1] cannot be NULL\n\n");
        exit(1);
    }

    if ( argv[2] == NULL ) {
```

```
    printf("\nNo Bypass Cache Flag provided - will use the default\n");
    sprintf(bypass_cache_flag, "%s", "false");
} else {
    sprintf(bypass_cache_flag, "%s", argv[2]);
}

/* Get the CSPM_CLIENT_HOME */

cspm_client_home=getenv("CSPM_CLIENT_HOME");

if ( cspm_client_home == NULL ) {
    printf("\nGlobal Environment Variable CSPM_CLIENT_HOME is not set\n");
    exit(1);
}

/*
Command Line Creation
NOTE: No space in the format string for the first 2 list elements - %s%s
*/

sprintf (
    command,
    "%s%s %s %s",
    cspm_client_home,
    CSPM_CLIENT_BINARY,
    argv[1],
    bypass_cache_flag
);

/* We will be using a popen call to execute but also to retrieve
the standard output returned by the client execution */

results_file = popen(command, "r");

while ( fgets(a_buffer,BUF_SIZE,results_file) != NULL ) {

    /* Parse the output to retrieve the fields we are interested in */

    if( (return_code = (char *) strtok(a_buffer," ")) != NULL ) {
        if ( (userid = (char *) strtok(NULL," ")) != NULL ) {
            if ( (password = (char *) strtok(NULL," ")) == NULL )
                error = 1;
        }
        else
            error = 1;
    }
    else
        error = 1;
}

pclose(results_file);

/* Print results */
```

```

if ( error ) {
    printf("\nFailed to retrieve the credentials\n");
    exit(99);
} else {
    printf("\nreturn_code:\t%s\n",return_code);
    printf("userid:\t\t%s\n",userid);
    printf("password:\t%s\n",password);
}
}

```

### **Register Requestor - C or C++ Application with A2A Client on UNIX or AIX**

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension. For example, example.c.
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type. For example, C or C++.

When entering the file and execution paths, you must specify the absolute paths without links.

### **Integrate a Korn Shell Script with A2A Client on UNIX or AIX**

This example uses the `example.ksh` script in the `$CSPM_CLIENT_HOME/cspmclient/examples` directory. It uses a UNIX executable to integrate the A2A Client (`cspmclient`) with UNIX or AIX.

The example applies to the Korn shell (`#!/bin/ksh`).

The path to the binary client depends on `CSPM_CLIENT_HOME` being set.

The A2A Client (`cspmclient`) accepts up to two command line arguments. This example accepts and passes these arguments from the command line:

- \$1. Provides the target alias name. This argument is mandatory.
- \$2. Provides the Bypass Cache Flag, which can be `true` or `false`. The default is `false`. This argument is optional.

### **Code: Korn shell script with A2A Client on UNIX or AIX**

```

#!/bin/ksh
CSPM_CLIENT_BINARY="/cspmclient/bin/cspmclient"

# Validate Required Arguments

if [ ! CSPM_CLIENT_HOME ]
then
    echo "Global Environment Variable CSPM_CLIENT_HOME is not set"
    echo "Aborting..."
    exit 1
fi

if [ ! $1 ]
then
    echo "No Target Alias provided "

```

```

    echo "Aborting..."
    exit 2
else
    target_alias="$1"
fi

if [ ! $2 ]
then
    bypass_cache="false"
else
    bypass_cache="$2"
fi

# Action

command="$CSPM_CLIENT_HOME$CSPM_CLIENT_BINARY $target_alias $bypass_cache"

result=`$command`

return_code=`echo $result | awk '{print($1)}'`
userid=`echo $result | awk '{print($2)}'`
password=`echo $result | awk '{print($3)}'`

echo "Return Code: $return_code"
echo "User ID:      $userid"
echo "Password:     $password"

```

### **Register Requestor - Adding a Korn shell script with A2A Client on UNIX or AIX**

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, `example.ksh`.
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, `Korn shell` script.

When entering the file and execution paths, you must specify the absolute paths without links.

### **Integrate a C Shell Script with A2A Client on UNIX or AIX**

This example uses the `example.csh` script in the `$CSPM_CLIENT_HOME/cspmclient/examples` directory. It uses a UNIX executable to integrate the A2A Client (`cspmclient`) with UNIX or AIX.

The path to the binary client depends on `CSPM_CLIENT_HOME` being set.

The A2A Client (`cspmclient`) accepts up to two command line arguments. This example accepts and passes these two arguments from the command line:

- \$1. This argument provides the target alias name. This argument is mandatory.
- \$2. This argument provides the Bypass Cache Flag, which can be `true` or `false`. The default is `false`. This argument is optional.

**Code: C Shell Script with A2A Client on UNIX or AIX**

```
#!/bin/csh
set CSPM_CLIENT_BINARY="/cspmclient/bin/cspmclient"

# Validate Required Arguments

if ( $CSPM_CLIENT_HOME == "" ) then
    echo "Global Environment Variable CSPM_CLIENT_HOME is not set"
    echo "Aborting..."
    exit 1
endif

if ( $1 == "" ) then
    echo "No Target Alias provided "
    echo "Aborting..."
    exit 2
else
    set target_alias="$1"
endif

if ( $2 == "" ) then
    set bypass_cache="false"
else
    set bypass_cache="$2"
endif

# Action

set command="$CSPM_CLIENT_HOME$CSPM_CLIENT_BINARY $target_alias $bypass_cache"

set result=`$command`

set return_code=`echo $result | awk '{print($1)}'`
set    userid=`echo $result | awk '{print($2)}'`
set    password=`echo $result | awk '{print($3)}'`

echo "Return Code: $return_code"
echo "User ID:      $userid"
echo "Password:     $password"
```

**Register Requestor - C shell Script with A2A Client on UNIX or AIX**

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, `example.csh`.
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, `C shell script`.

When entering the file and execution paths, you must specify the absolute paths without links.

## Integrate a PHP Script with A2A Client on UNIX

The following PHP script uses a UNIX executable to integrate the A2A Client (`cspmcclient`). Your installed A2A Client does not contain a soft copy of this script.

### IMPORTANT

PHP is *not* supported for use with AIX.

### Code: PHP Script with A2A Client on UNIX

```
<?php

#####
#
# Php example. To execute, do:
# prompt> php test2.php
#
#####

$alias="test";
$bypassCacheFlag="false";

$data = getCredential($alias,$bypassCacheFlag);
echo "Return code: $data[retCode]\n";
echo "User name: $data[user]\n";
echo "Password: $data[password]\n";

function getCredential($inAlias,$inFlag){

    $exec    = "/opt/cloakware/cspmcclient/bin/cspmcclient";
    $command = "$exec $inAlias $inFlag";
    $hndl=popen($command,'r') or die ("Unable to open pipe for command $command\n");

    echo "About to execute command: $command\n";
    $retVal=fread($hndl,2096) or die ("Unable to execute command $command\n");
    $n = sscanf($retVal, "%s %s %s", $retCode, $user, $password);
    $arr=array("retCode" => $retCode,
        "user"          => $user,
        "password"      => $password);
    return $arr;
}
?>
```

### Register Requestor - PHP Script with A2A Client on UNIX

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, the name of the PHP script example given in [Code: PHP Script with A2A Client on UNIX](#).
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, `PHP`.

When entering the file and execution paths, you must specify the absolute paths without links.

## Integrate a Python Script with A2A Client on UNIX and AIX

The following Python script uses a UNIX executable to integrate the A2A Client (`cspmclient`) with UNIX or AIX. Your installed A2A Client does not contain a soft copy of this script.

### **Code: Python Script with A2A Client on UNIX or AIX**

```
#!/usr/bin/env python

import commands
import os,time
import sys

def getCredential(alias, cacheflag, optflag):
    cmd = "/opt/cloakware/cspmclient/bin/cspmclient" + " " + alias+ " "+cacheflag+" "+optflag
    # print cmd
    f=os.popen(cmd)
    retVal= f.read()
    print retVal

if __name__ == "__main__":
    alias=""
    cacheflag=""
    optflag=""

    argc = len(sys.argv)
    if argc > 1:
alias=sys.argv[1]
        if (argc == 3) and (argc != "-x"):
            cacheflag = sys.argv[2]
        elif (argc == 3) and (argc == "-x"):
            optflag = sys.argv[2]
        elif (argc == 4):
            optflag = sys.argv[3]
        else:
dummy=1
            getCredential(alias, cacheflag, optflag)
```

### **Register Requestor - Python Script with A2A Client on UNIX or AIX**

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension. For example, the name of the Python script example given in the previous example.
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, `Other`.

When entering the file and execution paths, you must specify the absolute paths without links.

## Integrate Apps to Use the Credential Manager A2A Client on Windows

The content in this section provides examples of Windows applications that have been integrated to use Credential Manager to retrieve target account credentials using the A2A Client.

If you are using A2A Clients and the data returned (accounts and passwords) is limited to ANSI characters, no character set conversion is required. The client returns ANSI characters as single-byte UTF-8 characters. However, if you are using A2A Clients and the data returned includes non-ANSI UTF-8 characters, a character conversion may be required. Contact CA Support for assistance, and reference UTF-16 conversion.

Use the table of contents to access the topics in this section.

### Integrate a Perl Script with A2A Client on Windows

The following Perl script uses a Windows Perl Module (CSPM\_CLIENT\_WIN.pm) to integrate the A2A Client (cspmclient.exe). Your installed A2A Client contains CSPM\_CLIENT\_WIN.pm but does not contain a soft copy of the following script.

#### Code: Perl Script with A2A Client on Windows

```
#!/c:/perl/bin/perl -w
#Example to show how to get account info by using perl in windows.
#Need to: 1) Include a module, CSPM_CLIENT_WIN.pm.
# 2) Use the $EXEC string from the module.
# 3) Add Target server alias.

use strict;
use warnings;
use lib "c:/cspm/catech/cspmclient/lib";
use CSPM_CLIENT_WIN;

my $exec=$EXEC . "targetAlias" ;
my $param=`$exec`;
my @param2 = split(/\s+/, $param);
my $errorCode=$param2[0];
if($errorCode eq '400')
{
    my $userID=$param2[1];
    my $passWd=$param2[2];
    print "userId = " . $userID . "\n";
    print "password = " . $passWd . "\n";
}
else
{
    print "Failed to retrieve credentials... errorcode=" . $errorCode;
}
```

#### Register Requestor - Perl Script with A2A Client on Windows

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, the name of the Perl script example given in [Code: Perl Script with A2A Client on Windows](#).
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, Perl .

When entering the file and execution paths, you must specify the absolute paths without links.

## Integrate a Visual Basic Application

This example uses a Visual Basic project (Project1.vbp ) and the VB\_Sample.exe executable in the \$CSPM\_CLIENT\_HOME\cloakware\cspmclient\examples\VB\_Sample directory. It uses the CA Technologies MFC DLL (cspmclientc.dll ) to integrate the A2A Client.

### Code: Visual Basic Application

```
' From within your VB project:
'   Select Project
'   Projects
' From the References window, select Browse.
' Navigate to c:\cspm\cloakware\cspmclient\lib\
' Select the cspmclientc.dll file.
'
' Your project will now have a reference to the cspmclientc.dll.
'
' Next you need to uncommment the line - 'Dim X As New ccspmclientc' from the Command1_Click() method
'
```

```
Private Sub Command1_Click()

    '*** Uncomment the following line
    'Dim X As New ccspmclientc

    Dim ret As Long
    Dim userId As String
    Dim password As String
    Dim targetAlias As String
    Dim options As String
    Dim xml As String
    Dim bypassCache As String
    Dim xmlOutput As Boolean
    xmlOutput = False

    bypassCache = "false"

    targetAlias = Me.targetAliasName

    If (Me.bypassCacheCheck.Value = vbChecked) Then
        bypassCache = "true"
        options = options + "-b"
    End If
```

```

If (Me.xmlOutputCheck.Value = vbChecked) Then
    options = options + " -x"
    xmlOutput = True
End If

'Uncomment the line - 'Dim X As New ccspmlclientc' - at the begining of this method if you get an error on
this line.
ret = X.retrieveCredentials(targetAlias, bypassCache, options)

If (xmlOutput) Then
    Me.results = X.getXMLData
Else
    If (ret = 400) Then

        userId = X.getUserId()
        password = X.getPassword()
        xml = X.getXMLData

        MsgBox "userId = " + userId + ", password=" + password + Chr$(13) + xml, vbOKOnly, Me.Caption

    Else
        MsgBox "Failed to process request with errorCode: " + CStr(ret), vbOKOnly, Me.Caption
    End If
End If
End Sub

```

### **Register Requestor - Visual Basic Application**

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, `VB_Sample.exe`.
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, `Visual Basic`.

When entering the file and execution paths, you must specify the absolute paths without links.

### **Integrate a Visual C++ Application**

This example uses the `VC_Sample.dsp` project file and the `VC_Sample.cpp` file in the `$CSPM_CLIENT_HOME\cloakware\ccspmlclient\examples\VC_Sample` directory. It uses the CA Technologies MFC DLL to integrate the A2A Client.

#### **Code: Visual C++ Application**

```

// VC_Sample.cpp : Defines the entry point for the console application.
//
#include "stdafx.h"
#include <afxwin.h>
#include <atlbase.h>
#include "stdafx.h"

```

```

#import "c:\cspm\cloakware\cspmclient\lib\cspmclientc.tlb"

#define ERROR_CODE_SUCCESS400
#define ERROR_CODE_BADPARAM407

int main(int argc, char* argv[])
{
    USES_CONVERSION;
    _bstr_t targetAlias = _bstr_t("sample");
    _bstr_t bypassFlg = _bstr_t("false");
    _bstr_t bstrUserId, bstrPassword, bstrXMLData, bstrMessage;
    _bstr_t cliOpt = _bstr_t("");
    char* userId;
    char* password;
    char* xmlData;
    char* message;
    char *szTmp;
    BOOL isXMLOutput = FALSE;
    HRESULT hr;
    CLSID cls;

    using namespace Cspmclientc;

    if(argc>1)
    {
        targetAlias = _bstr_t(argv[1]);
        for (int pos = 2; pos < argc; pos++){
            if(pos == 2 && argv[pos][0] != '-'){
                bypassFlg = _bstr_t(argv[pos]);
            }else{
                if(!strcmp(argv[pos], "-x"))
                    isXMLOutput = TRUE;
                cliOpt = cliOpt+ " "+_bstr_t(argv[pos]);
            }
        }
        // Intializing the com component
        CoInitialize(NULL);
        hr = CLSIDFromProgID(OLESTR("cspmclientc.ccspmclientc"), &cls);
        Iccspmclientc *t;
        hr = CoCreateInstance(cls, NULL, CLSCTX_INPROC_SERVER, __uuidof(Iccspmclientc), (LPVOID *) &t);

        //printf("Retrieving credentials for %s\n", (char* )targetAlias);
        int retVal = -1;
        retVal = t->retrieveCredentials(targetAlias, bypassFlg, cliOpt); //call method
        if(isXMLOutput){
            bstrXMLData = t->getXMLData();
            xmlData = OLE2T(bstrXMLData);
            SysFreeString(bstrXMLData);
            printf("Block data: %s\n", xmlData);
        }
    }
}

```

```

}else if(retval==ERROR_CODE_SUCCESS){

    bstrUserId = t->getUserId();
    bstrPassword = t->getPassword();

    userId= OLE2T(bstrUserId);
    password= OLE2T(bstrPassword);

    printf("ErrorCode: %i\n",retval);
    printf("UserID: %s\n", userId);
    printf("Password: %s\n", password);

    SysFreeString(bstrUserId);
    SysFreeString(bstrPassword);

}else{

    bstrMessage = t->getMessage();
    message = OLE2T(bstrMessage);
    printf("ErrorCode: %i\n",retval);
    printf("UserID: %s\n", "null");
    printf("Password: %s\n", "null");
    printf("Message: %s\n", message);
    SysFreeString(bstrMessage);
}

t->Release();

CoUninitialize();
}else{
printf("ErrorCode: %i\n",ERROR_CODE_BADPARAM);
    printf("UserID: %s\n", "null");
    printf("Password: %s\n", "null");
    }
return 0;
}

```

### **Register Requestor - Visual C++ Application**

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, VC\_Sample.cpp .
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, Visual C++ .

When entering the file and execution paths, you must specify the absolute paths without links.

## Integrate a C#.NET Application using IIS Application Server

This example uses the A2A Client to manage the credentials used by a C#.NET connection class within an Internet Information Service (IIS) application server. The example uses a Windows DLL (`cspmclientc.dll`) to integrate the A2A Client.

This example uses a credential viewer and an SQL Server 2005 Express Edition data store to show the following:

- The credential viewer shows you how to view credentials stored in the Credential Manager server using the `CSPMClient` COM component. Use this example for simple integration and to test the ability to connect to Credential Manager and retrieve credentials. The example displays the credentials to the screen.
- The SQL Server 2005 Express Edition data store shows you how to configure a connection string used by the `Connection` class to retrieve credentials and connect to an SQL Server 2005 Express Edition data store. The example retrieves credentials and uses them to access a data store.

This example is available on A2A Client Windows installations, in the `$CSPM_CLIENT_HOME\cloakware\cspmclient\examples\Csharp\IIS` directory:

File	Description
<code>ConnectionFactory.cs</code>	Class used to create an <code>SqlConnection</code> object. The object is used to connect to the data store and perform SQL queries.
<code>CspmClientComObject.cs</code>	Implementation of the <code>CSPMClient</code> interface. The class is used to retrieve the credentials from the Privileged Access Manager appliance.
<code>Connect.aspx</code>	ASP page used to open a connection to a data store. The page creates the <code>Connection</code> object using the <code>ConnectionFactory</code> class.
<code>Web.config</code>	Configuration file showing how to configure a connection string for SQL Server 2005 Express Edition. The connection string is passed to the <code>ConnectionFactory</code> class.

### Integration Process for IIS

Use the following procedure to modify your application to use Credential Manager to manage credentials.

#### Follow these steps:

1. Configure development environment. See [Configure your Development Environment for IIS](#).
2. Optionally, integrate the A2A Client to retrieve credentials. See [IIS Credential Viewer](#).
3. Create or modify the context file. See [IIS Connection with SQL Server 2005 Express Edition Data Store](#).
4. Register requestor. See [Register IIS Requestor](#).

### Deploy and Run the Sample IIS Application

Use the following procedure to compile and deploy the sample Web application using Visual Studio 2005.

#### Follow these steps:

1. Ensure IIS is running.
2. Open the IIS Manager and create a virtual directory called `iCSPM`.
3. Open Visual Studio 2005 with Visual C# 2005.
4. Build the solution.
5. Click `iCSPM` project.
6. Select `Publish iCSPM` to deploy the application to IIS.
7. Open a Web browser.

8. Load the following page: <http://localhost/iCSPM/>.

### **Configure your Development Environment for IIS**

You must configure your development environment for IIS development.

The example contains a Visual Studio 2005 project that you can use to build the Web application and to deploy it.

Use the following procedure to configure your environment for IIS development.

#### **Follow these steps:**

1. Install ASP.NET Framework 2.0. See <http://msdn2.microsoft.com/en-us/netframework/default.aspx>.
2. Ensure the Internet Information Service (IIS) is installed.  
Note: If the target server is running a 64-bit version of Windows, ensure the 32-bit version of the ASP.NET Framework is enabled.
3. Enable the 32-bit version of ASP.NET. Access <http://support.microsoft.com/kb/894435> and read section "ASP.NET 2.0, 32-bit version".
4. Install SQL Server 2005 Express Edition. See <http://msdn2.microsoft.com/en-us/express/bb410791.aspx>.
5. Ensure the Microsoft Visual Studio 2005 and Microsoft Visual C# are installed.

### **IIS Credential Viewer**

This example servlet shows you how to use the `CSPMClient` class to retrieve the credentials.

You create the `CSPMClient` class using a class factory.

#### ***Class File***

```
package com.cloakware.cspm.sample.web;

import java.io.IOException;

import javax.servlet.RequestDispatcher;
import javax.servlet.ServletException; namespace iCSPM
{
    public partial class Default : System.Web.UI.Page
    {
        private const string ERR_MISSING_ALIAS = "Alias cannot be empty";

        protected void ViewBtn_Click(Object sender, EventArgs e)
        {
            // if the alias is missing
            if (aliasName.Text.Length == 0)
            {
                // Report the error
                errorMsg.Visible = true;
                errorMsg.Text = ERR_MISSING_ALIAS;
            }
            else
            {
                // Hide the error message field
                errorMsg.Visible = false;

                // Show the result table.
                resultTable.Visible = true;
            }
        }
    }
}
```

```
// Create CSPMClient COM Object
CspmClientObject obj;
if (useComObject.Checked)
{
obj = new CspmClientComObject();
}
else
{
obj = new CspmClientObject();
}

// Retrieve the credentials
Int32 statusCode = obj.RetrieveCredentials(aliasName.Text,
byPassCache.Checked ? "true" : "false", "");

// Initialize the return values.
returnCode.Text = statusCode.ToString();
returnMsg.Text = obj.GetStatusMsg(statusCode);
username.Text = obj.GetUserId;
password.Text = obj.GetPassword;

// Done with the object.
obj.Dispose();
}
}
}
```

## **IIS Connection with SQL Server 2005 Express Edition Data Store**

This example shows you how to create or modify a connection string used by the Credential ManagerConnectionFactory class. Use the ConfigurationManager class to retrieve the connection string from the Web.config file.

To integrate the A2A Client with your application, change the mechanism to create the connection. The Credential ManagerConnectionFactory retrieves the credentials using the A2A Client interface and then creates an SqlConnection object. In the Web.config file, you need to add the information regarding the alias to use. You add the alias as a parameter at the end of the connection string. The User ID and password parameters need to remain in the connection string as placeholders for the credentials, but leave them blank. The following is an example:

```
server=(local)\SQLEXPRESS;database=CSPMTest;uid=;pwd=;CSPMAlias=sql_svr
```

This management for connection acquisition means that all new connections obtained for a user whose database password has been changed (by the Credential Manager server) are made using the new password. This action occurs automatically without any knowledge or intervention by the owning connection pool.

While new connections are obtained using the new password, old connections that were obtained using an old password may linger in the connection pool. Also, if the Credential Manager alias is changed to a totally new user, then a connection pool has (at least temporarily) a mixture of connections for different actual database users.

Such connection management ensures that database password changes are completely transparent to connection activities.

The configuration file used in the example is located in %CSPM\_CLIENT\_HOME%\cloakware\csmpmclient\examples\Csharp\IIS.

## Data Source

```
<configuration>
<connectionStrings>
  <add name="CSPMSampleDS"
    connectionString="server=(local)\SQLExpress;
    database=CSPMTest;uid=;pwd=;
    CSPMAlias=sql_svr"
    providerName="System.Data.SqlClient"/>
</connectionStrings>
</configuration>
```

## Register IIS Requestor

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

Parameter	Description
Script Name	w3wp.exe
Execution Path	C:\WINDOWS\SysWOW64\inetsrv
Type	C

## Register SQL Server 2005 Express Edition as a Target Application

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

Parameter	Description
Application Name	SQL Server 2005 Express Edition
Application Type	MSSQL
Instance	SQLEXPRESS

Parameter	Description
Application	SQL Server 2005 Express Edition
Application Name	admin
Password	admin

Parameter	Description
Target Alias Name	sql_svr
Application	SQL Server 2005 Express Edition
Account	admin

## Integrate a Visual Basic, Java, or Windows Script

Scripts can be run from any application, such as Microsoft Internet Explorer.

## Visual Basic Script

This example uses a Visual Basic script sample (VBScriptSample.html ) in the \$CSPM\_CLIENT\_HOME \cloakware\cspmclient\examples\VB\_Script\_Sample directory. It uses the CA Technologies ATL DLL (cspmclientatl.dll ) to integrate the A2A Client.

### Code: Visual Basic Script

```
<html>
<head>
</head>
<body>
<script type="text/vbscript">

dim myobj
dim ret

set myobj = CreateObject("cspmclientatl.cspmclientatl")
document.write(" cspmclientatl dll is loaded. ")

ret= myobj.retrieveCredentials( "test","false", "whatever")
document.write(" The return value is: " & ret & ".")

ret= myobj.getUserId()
document.write(" User: " & ret & ",")

ret= myobj.getPassword()
document.write(" Password: " & ret & ",")

ret= myobj.getXMLData()
document.write(" XML data is: " & ret)
</script>
</body>
</html>
```

### Register Requestor - Visual Basic Script

See [Add and Run Credential Manager A2A Requestors](#) for the procedure to register your requestor with Credential Manager. Use the following data:

You need the following data to register your requestor with Credential Manager:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, VBScriptSample.html .
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, Visual Basic .

When entering the file and execution paths, you must specify the absolute paths without links. When an executable or script is run from a mapped network drive, Windows report the execution path using the UNC path. Use the UNC path when defining script path and execution path.

## Java Script

This example uses a Java script sample (JavaScriptSample.htm ) in the \$CSPM\_CLIENT\_HOME\cloakware\cspmclient\examples\Java\_Script\_Sample directory. It uses the CA Technologies ATL DLL (cspmclientatl.dll ) to integrate the A2A Client.

### Code: Java Script

```
<html>
<body>

<script type="text/javascript">
document.write("Client interface with Java Script");

try {
var XLApp = new ActiveXObject("cspmclientatl.cspmclientatl");

var retCode = XLApp.retrieveCredentials("test", "true", "no");
alert("The return code: " + retCode);
alert("The user name: " + XLApp.getUserId());
alert("The password: " + XLApp.getPassword());

} catch (e) {
alert("error: "+e.message);
}
</script>
</body>
</html>
```

### Register Requestor - Java Script

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

You need the following data to register your requestor with Credential Manager:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, JavaScriptSample.htm .
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, Java .

When entering the file and execution paths, you must specify the absolute paths without links. When an executable or script is run from a mapped network drive, Windows report the execution path using the UNC path. Use the UNC path when defining script path and execution path.

## Windows Script

This example uses a Windows script sample. It uses the CA Technologies ATL DLL (cspmclientatl.dll ) to integrate the A2A Client. Your installed A2A Client does not contain a soft copy of the following script.

### Code: Windows Script

```
Option Explicit

dim ret
```

```

dim cspmclient
dim credentialsRetrieved
dim success
dim bypasscache

'Instantiate the cspmclient
set cspmclient= CreateObject("cspmclientatl.ccspmclientatl")

'Retrieve the credentials using the cache first
bypasscache="false"
ret= cspmclient.retrieveCredentials( "test",bypassCache , "true")

if(ret = "400") then
WScript.Echo "accountName=" & cspmclient.getUserId()
WScript.Echo "password=" & cspmclient.getPassword()

'try to use it
'success = connectToApp(accountName,password)
success = false

'Retrieve credentials bypassing cache in the event of failure
if(success=false) then
bypasscache="true"
ret= cspmclient.retrieveCredentials( "test",bypassCache , "true")
if(ret = "400") then
WScript.Echo "accountName=" & cspmclient.getUserId()
WScript.Echo "password=" & cspmclient.getPassword()
'success = connectToApp(accountName,password)
else
WScript.Echo "Failed to retrieve credentials"
end if
end if
else
WScript.Echo "Failed to retrieve credentials"
end if
WScript.Quit

```

### **Register Requestor - Windows Script**

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension; for example, the name of the Windows script example given in [Windows Script](#).
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, WScript.

When entering the file and execution paths, you must specify the absolute paths without links. When an executable or script is run from a mapped network drive, Windows reports the execution path using the UNC path. Use the UNC path when defining script path and execution path.

## Integrate a PowerShell Script with A2A Client on Windows

The following PowerShell script uses Windows PowerShell to integrate the A2A Client (`cspmcclient.exe`). Your installed A2A Client contains a soft copy of the following 32-bit script and a 64-bit example.

### Code: PowerShell Script with A2A Client on Windows

```
#
# PowerShell (x86 32-bit) script example.
# To execute, do:
#   For 64-bit Windows system:
#   C:\> C:\Windows\SysWOW64\WindowsPowerShell\v1.0\powershell %CSPM_CLIENT_HOME%\cspmcclient\examples\example.ps1 <A2A alias>
#   For 32-bit Windows system:
#   C:\> powershell %CSPM_CLIENT_HOME%\cspmcclient\examples\example.ps1 <A2A alias>
#
param([Parameter(Mandatory=$true)][string]$p1,
      [string]$p2="true")

if ($env:CSPM_CLIENT_HOME -eq $null) { Write-Host "Environment variable CSPM_CLIENT_HOME is not set"; exit }

$command = $env:CSPM_CLIENT_HOME + '\cspmcclient\bin\cspmcclient.exe' + ' ' + $p1 + ' ' + $p2
$output = Invoke-Expression $command
$tokens = $output.split(' ')
$rc = $tokens[0]
$userid = $tokens[1]
$password = $tokens[2]
Write-Host "Return Code:" $rc
Write-Host "User ID:" $userid
Write-Host "Password:" $password
```

### Register Requestor - PowerShell Script with A2A Client on Windows

See [Integrate Applications with the Credential Manager A2A Client](#) for the procedure to register your requestor with Credential Manager. Use the following data:

- Script name. The name of the requestor file that contains the Credential Manager executable call including the file extension. For example, the name of the PowerShell script example given in [Code: PowerShell Script with A2A Client on Windows](#).
- File path. The absolute path to the application file that contains the executable call.
- Execution path. The absolute path from which the application is launched.
- Script type. The requestor script type; for example, PowerShell.

When entering the file and execution paths, you must specify the absolute paths without links.

## Remote HTTP Interface to a Credential Manager A2A Client

The A2A Client supports HTTP requests for credentials. You can retrieve credentials of a target account alias by entering a URL in your Web browser.

Access the URL to see the credentials in the following cases:

- Only the local host (where the A2A Client is installed). See [Access URL from only the Local Host](#).
- Only the systems within the network of the local host. See [Access URL from Local Host Network](#).
- Both the local host and the systems within its network. See [Access URL from Local Host and Local Host Network](#).

To enable this functionality, add the `httpRequestScriptAddress` tag and the `httpRequestScriptPort` tag in the client configuration file. The configuration file is named `cspm_client_config.xml`. It is located in the `$CSPM_CLIENT_HOME/cspmclient/config` directory. After you add the tags, restart the A2A Client daemon (on UNIX) or the A2A Client service (on Windows).

To disable this feature, remove or comment out the `httpRequestScriptAddress` tag and the `httpRequestScriptPort` tag in the `cspm_client_config.xml` file.

The following XML code is an example of the `cspm_client_config.xml` file with the tags.

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
<applicationtype>cspm</applicationtype>
<cacheallow>true</cacheallow>
<loglevel>FINE</loglevel>
<cspmserver>rh5x32stout2.cpa.intra</cspmserver>
<cspmserver_port></cspmserver_port>
<httpRequestScriptAddress>0.0.0.0</httpRequestScriptAddress>
<httpRequestScriptPort>12345</httpRequestScriptPort>
<daemonserver1_port>28088</daemonserver1_port>
<daemonserver2_port>28888</daemonserver2_port>
<logfile>/opt/cloakware/cspmclient/log/cspm_client_log.txt</logfile>
<c_logfile>/tmp/cspm_c_client_log.txt</c_logfile>
<patch>
<frequency>daily</frequency>
<starthour>0</starthour>
<endhour>5</endhour>
</patch>
<operation>production</operation>
</configuration>
```

To authorize a requestor (script) to retrieve credentials through a URL, the authorization mappings between the target alias and the request server must contain at least one script that produces URLs with the formats described in the following sections. See [Configure A2A Authorization Mappings](#) for more details on authorization mapping.

### **Access URL from Only the Local Host**

This case enables access from only the local host system where the A2A client is installed.

For this case, add the following tags to the `cspm_client_config.xml` file:

- `<httpRequestScriptAddress>localhost</httpRequestScriptAddress>`  
You can also specify the loop back IP address of the local host instead of the literal term `localhost`. For example, the following tags are equivalent:
  - `<httpRequestScriptAddress>127.0.0.1</httpRequestScriptAddress>` (IPv4),  
or `<httpRequestScriptAddress>::1</httpRequestScriptAddress>` (IPv6)
  - `<httpRequestScriptAddress>localhost</httpRequestScriptAddress>`
- `<httpRequestScriptPort> <port_no> </httpRequestScriptPort>`, where **<port\_no>** is the port number of the local host. The following tag is an example:
  - `<httpRequestScriptPort>12345</httpRequestScriptPort>`

For this case, use the following URL format on the local host system to get credentials:

`http:// <system> : <portnumber> /requestScript/retrieveCredentials?aliasName= <targetalias> &bypassCache=false&contentType=html`, where:

- **<system>** is the literal term `localhost` or the loop back IP address of the local host. This must match what was specified in the `<httpRequestScriptAddress>` tag for the A2A client on the system.
- **<portnumber>** is any valid and unused port number of the local host. This must match what was specified in the `<httpRequestScriptPort>` tag for the A2A client on the system.
- **<targetalias>** is the target alias for which credentials must be fetched

The following URL is an example:

```
http://127.0.0.1:12345/requestScript/retrieveCredentials?
aliasName=testalias&bypassCache=false&contentType=html
```

### **Access URL from Local Host Network**

This case enables access from only the systems that share the local network of the local host, but not from the local host itself.

For this case, add the following tags to the `cspm_client_config.xml` file:

- `<httpRequestScriptAddress><myhostname>.<mydomain></httpRequestScriptAddress>`
  - **<myhostname>** is the host name or the loop back IP address of the system where the A2A Client is installed
  - **<mydomain>** is the domain of the system where the A2A Client is installed
- `<httpRequestScriptPort> <port_no> </httpRequestScriptPort>` , where **<port\_no >** is any valid and unused port number of the system where the A2A Client is installed

For this case, use the following URL format on any system on the local network of the local host to get credentials:

```
http:// <myhostname> . <mydomain> : <portnumber> /requestScript/retrieveCredentials?
aliasName= <targetalias> &bypassCache=false&contentType=html , where:
```

- **<myhostname>** is the host name or the loop back IP address of the system where the A2A Client is installed. This must match what was specified in the `<httpRequestScriptAddress>` tag for the A2A client on the system.
- **<mydomain>** is the domain of the system where the A2A Client is installed. This must match what was specified in the `<httpRequestScriptPort>` tag for the A2A client on the system.
- **<portnumber>** is port number to access the local host. This must match what was specified in the `<httpRequestScriptPort>` tag for the A2A client on the system.
- **<targetalias>** is the target alias for which credentials must be fetched

The following URL is an example:

```
http://rh5x32stout.cpa.intra:12345/requestScript/retrieveCredentials?
aliasName=testalias&bypassCache=false&contentType=html
```

In the previous example:

- `rh5x32stout` is the host name of a system that shares the local host network
- `cpa.intra` is the domain of the system where the A2A Client is installed
- `12345` is port number to access the local host. This must match what was specified in the `<httpRequestScriptPort>` tag for the A2A client on the system.
- `testalias` is the target alias for which credentials must be fetched

### **Access URL from Local Host and Local Host Network**

This case enables access from the systems that share the local network of the local host and from the local host itself.

For this case, add the following tags to the `cspm_client_config.xml` file:

- `<httpRequestScriptAddress> 0.0.0.0 </RequestScriptAddress>`
- `<httpRequestScriptPort> <port_no> </httpRequestScriptPort>` , where **<port\_no>** is any valid and unused port number of the system where the A2A Client is installed

For this case, use the following URL format on the local host system to get credentials:

`http:// <system> : <portnumber> /requestScript/retrieveCredentials?aliasName= <targetalias> &bypassCache=false&contentType=html` , where:

- **<system>** is the literal term `localhost` or the loop back IP address of the local host
- **<portnumber>** is any valid and unused port number of the local host
- **<targetalias>** is the target alias for which credentials must be fetched

For this case, use the following URL format on any system on the local network of the local host to get credentials:

`http:// <myhostname> . <mydomain> : <portnumber> /requestScript/retrieveCredentials? aliasName= <targetalias> &bypassCache=false&contentType=html` , where:

- **<myhostname>** is the host name or the loop back IP address of the system where the A2A Client is installed.
- **<mydomain>** is the domain of the system where the A2A Client is installed.
- **<portnumber>** is port number to access the local host. This must match what was specified in the `<httpRequestScriptPort>` tag for the A2A client on the system.
- **<targetalias>** is the target alias for which credentials must be fetched

The following is an example of the URL to use from the local host system to get credentials:

`http://127.0.0.1:12345/requestScript/retrieveCredentials?`  
`aliasName=testalias&bypassCache=false&contentType=html` (IPv4), or  
`http://[::1]:12345/requestScript/retrieveCredentials?`  
`aliasName=testalias&bypassCache=false&contentType=html` (IPv6)

The following is an example of the URL to use from a system on the local network of the local host to get credentials:

`http://rh5x32stout.cpa.intra:12345/requestScript/retrieveCredentials?`  
`aliasName=testalias&bypassCache=false&contentType=html`

In the previous example:

- `rh5x32stout` is the host name of a system that shares the network of the local host
- `cpa.intra` is the domain of the system where the A2A Client is installed
- `12345` is port number to access the local host. This must match what was specified in the `<httpRequestScriptPort>` tag for the A2A client on the system.
- `testalias` is the target alias for which credentials must be fetched

## Reference

---

This section contains reference information about the PAM Client, Target Connectors, Messages, Logs Formats, and more. Use the table of contents to access the content.

### Privileged Access Manager Client Reference

The PAM Client enables you to log in to Privileged Access Manager and perform administrator and end-user activities without a customer-installed Web browser and Java engine. The PAM Client removes the maintenance that is required to keep Java and browser configurations compatible with Privileged Access Manager.

#### Installer

Run the installer file to provide a CA PAM Client instance on your workstation.

#### **Download Buttons**

From your client workstation, download an installer from the Privileged Access Manager login page. Point to Privileged Access Manager from an approved browser, and from the GUI login page, select **Symantec PAM Client**. Click to open a drop-down list and select a specific version for your OS type.

#### **Installer Program**

Run the installer file to open its InstallAnywhere wizard.

Set the installation parameters according to its interface.

- **License Agreement** – The acceptance button is activated only after you scroll the license text to the bottom of the panel.
- **Choose Install Set** – Select one of the following options:
  - **Typical**: install the client on the local workstation or
  - **Run**: The contents are extracted only to a temporary location and executed.
- **Installing...** – You cannot select **Previous** after the software starts installation or has completed it.

#### **Silent Installation**

For instructions on using the silent install feature, see [PAM Client Silent Install](#).

#### Client

Run the CA PAM Client program to access the following interfaces. From the client window, you can:

- Continue to the login screen, to the console screen or browser window
- Open the Configuration Settings window, or the About window, or the browser window

#### **Configure Settings**

The **Show settings dialog** gear icon opens the **Configuration Settings** window, with settings on the following tabs:

- **Proxy**: When applicable, identify the client proxy.
- **General**: You can set client memory size, change the client language, or restore security prompts. Select **Restore** to reverse a previous "Ignore host mismatch for this address" selection that is made in a **Verify Certificate** pop-up window during connection.
- **Cache**: Set and manage the client cache size.
- **Certificate**: Select an applicable security certificate, or import one.

The **Show About dialog** question mark icon opens the **About CA Privileged Access Manager** window, which has information about the client release level.

The Settings and About dialogs cannot be open simultaneously.

### **Connect**

To connect to a Privileged Access Manager instance, follow these steps:

1. Select its **Address**.

#### **NOTE**

If you enter an IPv6 address, make sure to enclose the address in brackets. If you want to enter a port number with the IPv6 address, add a colon, followed by the port number. For example:

[2001:db8:3333:4444:5555:6666:7777:8888]:443

2. Select a **Connect Mode**:

- a. **WEB** mode checks for client updates, and processes an update if one is found. It then opens a connection to the Privileged Access Manager server, and opens the PAM Client browser window, and closes the console.
- b. **CONNECT** mode checks for client updates, and processes an update if one is found. It then opens a connection to the Privileged Access Manager server, and maintains a status connection window. The PAM Client browser window can be opened from the status window.

You may receive a Verify Certificate window before the login screen appears.

3. On the Login screen, enter the appropriate values in the following fields, and select **Login**:

- a. **User**
- b. **Password**
- c. **Authentication Type**

Upon login, you are first presented with a console window or browser window, depending on your earlier **Connect Mode** choice.

- a. If you used **CONNECT**, the console screen takes the place of the login screen. This screen displays connections statistics, and allows you to **Launch Web Browser** or **Log Off**.
  - b. If you used **WEB**, CA PAM Client browser window appears without the connection information.
4. The browser window displays the traditional GUI, and its features operate in the same way. When you log out from the GUI in the browser window, you return to the login screen.

## **Data Formats**

The content in this section describes data formats that are used by Privileged Access Manager.

### **Multi-Byte Character Support**

#### ***Managed Object Names***

- Username in a User record that inherits from Import LDAP Users
- Groupname in a User Group record
- Device Name in a Device record
- Group Name in a Device Group record
- Application Name in a Target Application record
- Account Name in a Target Account record

#### ***Message Templates***

- License acceptance (at Login) – configured in Show License Warning in Global Settings
- Session recording warning – configured in Show Recording Warning in Global Settings
- Blacklist violation – configured in Blacklist Violation Message in Policies > Manage Policies: Manage Filters > Command Filter Config
- Whitelist violation – configured in Whitelist Violation Message in Policies > Manage Policies: Manage Filters > Command Filter Config

## **Port Numbers**

### **General Syntax**

Use the following conventions to represent port values when populating Privileged Access Manager GUI fields:

**All ports** (or, where the port number is not relevant)

\* = ("is equivalent to") Ports 1 through 65535, inclusive

all = ("is equivalent to") Ports 1 through 65535, inclusive

ALL = ("is equivalent to") Ports 1 through 65535, inclusive

**Specific ports** (a sequence of one or more port numbers that are delimited by spaces or commas)

X Y = Ports X and Y [and Z [...]]

Example: 2 3 18 39230 = Ports 2, 3, 18, and 39230

**Port Forwarding** (Port Mapping)

X:Y = (Remote) port X is mapped (or forwarded) to (local) port Y

Example: 345:1223 = Port 345 is forwarded to port 1223

**Port Range**

X-Y = Ports X through Y, inclusive

Example: 6-10 = Ports 6, 7, 8, 9, and 10

### **NOT PERMITTED**

Combination syntax cases such as those in the following examples have undefined values and, thus, are not permitted in Privileged Access Manager GUI fields:

X-Y:U-V does not mean: Port X through Y -onto- port U through V

X:Y U:V does not mean: Port X onto Y -and- port U onto V

Thus, the X-Y-U-V combinations that are shown above **must not be used**.

### **Rules for Specific Interfaces**

#### **Access page connection-method links:**

Pop-up window: Application path specification field, ports as specified in Service Definition

**Global Settings** editing fields:

**Access Methods:** *Each field:* One port only • No Range, No Mapping

**Services > TCP/UDP Services** editing fields:

**Basic Info:** Specific ports -or- one Range, with 1-500 ports -or- one Mapping

**> SSLVPN** editing fields:

**Basic Info:** All ports -or- Specific ports -or- one Range, with 1-500 ports -or- one Mapping

**Devices > Manage Devices** editing fields:

**Special Type:** Specific ports -or- one Range, with 1-500 ports • No Mapping

**Access Methods:** One port only • No Range, No Mapping

**Policies > Manage Policies :** Manage Filters > Socket Filter Config editing fields:

One port only • No Range, No Mapping

**> Socket Filter Lists** editing fields:

All ports -or- Specific ports -or- One Range • No Mapping

### Session Recording File Names

The session recording files on a storage share are named according to the following format: `H-NT.ext`

Where...	Example
H = Privileged Access Manager Hostname:	capam123
N = (Pseudorandom) ID number:	8732209813
T = Start Time of Recording: YYYYMMDDHHMMSSXXX	20120125145538987
“XXX” represents the millisecond resolution of the start time. If there is a collision with an existing file, this number is incremented by 1 until an available filename is found.	
ext = File Type Extension:	for a CLI session recording: <code>txt</code> for an RDP session recording: <code>gsr</code> for a VNC session recording: <code>vsr</code>

For example, the file name `capam123-873220981320120125145538987.txt` identifies a CLI recording file for appliance host `capam123` that was assigned ID number `8732209813` and is timestamped January 25, 2012 at 2:55:38.987 PM.

## Import and Export Data for Provisioning

This section describes how to import and export data from Privileged Access Manager for provisioning.

### File Imports

PAM-managed objects may be imported only from comma-separated value (CSV) files.

#### **File Import Preparation**

CSV files can be created in many text editors or spreadsheet programs and saved as plain text. If you support special characters such as UTF-8 (for example, Cyrillic or Chinese), confirm that your application supports them. Your version of Microsoft Excel® or Google Drive, for example, may or may not have that support.

You may want to use the provided sample files as templates and refer to the information in the following pages to populate the fields.

#### **File Import Process**

To handle attribute dependencies when provisioning multiple PAM objects using CSV files, import the files in the following order. You can use any file name, as long as you save the file in plain text with the CSV file extension.

Import CSV files by selecting the **Import/Export** button on the corresponding import page (identified in the following table) to perform object-specific error checking.

Import order	Managed Objects in File	Import/Export Page Location
1	Web Proxies	<b>Configuration, Network, Web Proxies</b>
2	Transparent Login	<b>Services, Transparent Login Configurations</b>
3	TCP/UDP Services	<b>Services, TCP/UDP Services</b>
4	Roles	<b>Users, Manage Roles</b>
5	User Groups, then Users	<b>Users, Manage User Groups</b> <b>Users, Manage Users</b>
6	Device Groups, then Devices	<b>Devices, Manage Device Groups</b> <b>Devices, Manage Devices</b>
7	Vaults	<b>Secrets, Manage Vaults</b>
8	Socket Filter Lists	<b>Policies, Manage Policy Filters, Socket Filters tab</b>
9	Command Filter Lists	<b>Policies, Manage Policy Filters, Command Filters tab</b>
10	Policies	<b>Policies, Manage Policies</b>

### ***File Import Content Considerations***

When importing files, consider the following constraints:

- CSV file fields are comma-separated. To use a comma in field content, surround the field with quotation marks (").
- CSV files that contain user group and user data must list them in that order. That is, the file must list all user groups before listing users.
- CSV files containing device group and device information must list them in that order. That is, the file must list all device groups before listing devices.
- Not all record content must be imported to create a record – the tables identify with asterisks \* which fields are required for particular record types.
- The first line in each file is for column names, which are used to identify record fields during import.
- CSV file columns may be rearranged as long as the corresponding CSV File Column Labels are preserved.
- After you import, you can check the results by clicking the Download CSV Import Results link that appears after the import, below any error messages.

### **File Export**

#### ***Exported File Names and Types***

Each exported file is downloaded with a timestamp in the file name according to the following syntax:

objecttypeYYYYMMDDHHMMSS.csv

Example: **devices20110715131849.csv**

#### ***Exported File Content Considerations***

When exporting files, consider the following facts:

- Several informational fields are added to a Users Group/Users export file. The export does not preserve the import column arrangement (they are inserted between field columns). These informational fields are identified in the tables by oblique names.
- Privileged Access Manager does not display stored passwords in User record exports. Each cell in the Password column (which is used only for imports) is empty.

## Transfers

CSV files are frequently used to transfer (export and import) from one PAM server to another.

### LDAP Users

LDAP user records draw data from two locations: fields from the LDAP source directory and any data to CA PAM-specific fields the administrator may add after the LDAP import.

To perform an LDAP transfer, recreate a baseline LDAP import, and then “overlay” the PAM fields:

1. At the source PAM server, **Export Users** to a CSV file.
2. At the destination PAM server, **Import LDAP Group** from the source LDAP directory(ies).
3. At the destination PAM server, **Import Users** with the CSV file obtained from the source Privileged Access Manager.

### Specific CSV File Formats

For details about specific types of CSV import and export format, use the table of contents to access the other topics in the section.

## Roles

In **Users, Manage Roles, Import/Export**, you can download a sample file and can populate it according to the specification in the following table.

In Record Type, \* = required. This import allows you to *create* roles – you are not limited to the set of preconfigured roles (such as “Auditor” and “Troubleshooter”).

CSV File Column Label	Permitted Values	Description / Notes
Type	role	Import record (row) type
Role Name	text*	Name of the Role
Description	text	Role description or other information
Role Privileges	text	Role privileges (not case-sensitive). The list of valid role privilege names can be retrieved from the Manage Roles page in the GUI. Multiple privileges are separated by:   (pipe)

## User Groups and Users

Import Users and User Groups from a specially formatted *User Import CSV file* using the controls from the **Users, Import/Export Users** page in the GUI.

### Export Users and User Groups to a CSV File

You can export your existing Users and User Groups to a User Import CSV file.

#### Follow these steps:

1. Go to **Users, Manage Users**.
2. Select the **Import/Export** button.
3. Select the **Export Users (User Groups)** button.

A CSV file of existing Users and User Groups is prepared and saved to your local drive. The default filename is usersYYYYMMDDHHSS.csv

## Download a Sample Import CSV File

To download a sample User Import CSV file, go to **Users, Manage Users**. Select **Import/Export**, and then select **Download Sample File**.

## Add Users and User Groups to the Import CSV File

To define Users and User Groups to import, add appropriate entries to the User Import CSV file.

### NOTE

For Users provisioned in an external repository (such as AWS or VMware), do *not* modify any field that was sourced from the external repository. For example, for LDAP users, do not change the User Principle Name (or other LDAP-sourced) fields.

The following table describes the fields in the User Import CSV file.

### How to read the table:

- **Bold** text (aside from table column labels) indicates either literal values to be entered into fields or literal values or legends that are displayed by the GUI or present in export files.
- **Table Columns:**
  - **CSV File Column Label**
    - Rows are shown here in the same order as the columns in the sample file.
    - Column order is not recognized by import processing – only the items in CSV File Column Labels are.
    - *Italic* text indicates columns that are generated solely for export files – they are not required in files for import.
    - Ensure that all required columns (with a \* in the Record Type column) are included in the CSV file.
    - Ensure that column headers are spelled as noted in CSV File Column Label or their values will not be imported.
    - Ensure that no (embedded) blank columns exist.
  - **Record Type**= Type of import record:
    - **U** = for inclusion in imported User record
    - **UG** = for inclusion in imported User Group record
    - **E** = data that is provided by Privileged Access Manager in an exported file (and not required in the import file)
    - \* = Indicates that this field is required to create a record of this type. (This does not identify what is necessary to function, however.)
  - **Description**
    - This column lists User or User Group label that differ from the corresponding column name for the import file.

CSV File Column Label	Record Type	Permitted Values	Description / Notes
Type	U* UG*	user, user group	Import record (row) type
UserName	U* UG*	text	User ID for login User record label: One of <b>Username</b> or <b>User Group ID</b> User Group record label: One of <b>Groupname</b> or <b>LDAP: DN</b>
<i>ShortName</i>	E		CN
First Name	U*	text	User first name. User record label: <b>Firstname</b>

Last Name	U*	text	User last name. User record label: <b>Lastname</b>
Password	U*	text	Plain text User password. <b>Note:</b> Users are forced to change their passwords at first login.
<i>Password Set Time</i>	E	UNIX timestamp	
Phone	U	text	User telephone number
Cell Phone	U	text	User mobile telephone number
Email	U*	text	Valid email address User record label: <b>e-mail</b>
Description	U UG	text	User or User Group description or other information
Active Flag	U	<b>f</b> = Disabled <b>t</b> = Enabled (Do not use uppercase 'F' and 'T') GUI default value: <b>f</b>	<b>Note:</b> This field is not related to GUI field "Activate Account" User record label: Account Status
Activation Time	U	UNIX timestamp GUI default value: 0	Account activation date. If empty, account will be activated after import. User record fields: Activate Account=Later (default=Now) ...triggers display of: Account Activation (= CSV label "Activation Time")
<i>Last Activation Time</i>	E	UNIX timestamp	
<i>Account Disabled Time</i>	E	UNIX timestamp	
Expiration Time	U	UNIX timestamp GUI default value: 0	Account expiration date. If empty, account never expires. User record label: <b>Account Expiration</b>
Authentication	U UG	One of: • local • ldap • radius • tacacs+ GUI default value: <b>local</b>	User or User Group Authentication type
Email on Login Contact	U	text	Send notification to this email address upon login by this user. User record label: <b>Email on Login</b>

Email Self on Login Flag	U	<b>f</b> = Disabled <b>t</b> = Enabled (Do not use uppercase 'F' and 'T') GUI default value: <b>f</b>	Send notification to this user by email upon their login. User record label: <b>Email Self on Login</b>
Terminate Session on Deactivation Flag	U	<b>f</b> = Disabled <b>t</b> = Enabled (Do not use uppercase 'F' and 'T') GUI default value: <b>f</b>	User record label: <b>Terminate session upon deactivation</b>
Access Times	U UG	<p>Each entry takes the following form:</p> <p><i>day=SMTWTFS timeFrom=minutes timeTo=minutes</i></p> <p><b>SMTWTFS</b> Specifies the days of the week where access is permitted. Each day where access permitted is represented by a "1" and each day where access is not permitted is represented as a "0"</p> <p><i>timeFrom</i> Specifies the number of minutes from midnight the time when access should start.</p> <p><i>timeTo</i> Specifies the number of minutes from midnight to the time when access should end.</p> <p>Example: An entry of day=0111110 timeFrom=480 timeTo=1080 means "Monday through Friday, from 8:00 AM to 6:00 PM"</p> <p>User record label: <b>Access Time : Access Days + From (time) + To (time)</b></p>	
Group Membership	U	text	User Group or User Groups of which the user is a member. Separate multiple User Groups with a   (pipe) character.
Applet Message	UG	<b>f</b> = Disabled <b>t</b> = Enabled (Do not use uppercase 'F' and 'T') GUI default value: <b>f</b>	Enable/Disable the Global Settings: Warnings: Show Recording Warning to this group User Group record label: <b>Applet Recording Warning</b>
Provision Type	E	One of: <ul style="list-style-type: none"> <li>• local</li> <li>• ldap</li> <li>• virtual</li> <li>• radius</li> <li>• pki</li> <li>• saml</li> </ul>	Source of the User or User Group information. Do <i>not</i> change this value if it is populated from an export. For new Users, use <b>local</b> .

Roles	U UG	<p>Syntax (in CSV cell, the string shown without quotes, either with value substitutions as shown, or without one or more values):</p> <p><b>"roleName=roleName roleUserGroups=roleUserGroups roleDeviceGroups=roleDeviceGroups"</b>.</p> <p>Separate adjacent role specifications with a comma.  <i>roleName</i> = Choose from the built-in and administrator-defined Access roles. GUI default value: <b>"Standard User"</b>  <i>roleUserGroups</i> =  <i>roleDeviceGroups</i> =</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>• roleName=Auditor roleUserGroups=roleDeviceGroups=</li> <li>• roleName=Global Administrator roleUserGroups=ALL roleDeviceGroups=ALL</li> </ul> <p>User / User Group record label: Available Roles</p>	
Smart Button Group	N/A	N/A	Obsolete. Maintained for backward compatibility only.
User Principle Name	E		Extracted from LDAP record (where applicable)
PA Group Membership	U	text (matching existing name)	The names of Credential Manager User Groups of which the user is a member, where each pair of User Group names is separated by: " " (pipe) character.
Login IP Ranges	UG	Valid IP Ranges for User in this Group	Example: 10.1.10.0/24, 10.7.0.0/16 (IPv4) or fd6d:8d64:af0c:1:0:242:22:233/80, fd6d:8d64:af0c:1:0:242:22:233/64 (IPv6)

API Keys	U only	<p>Each API Key cell has values that are represented by the following fields:</p> <pre> name=apiKeyName isActive=[t f] description=descriptionOfApiKey roles=rolename=rolename1OfApiKey1 [, rolename=rolename2OfApiKey1 [, ...]] [#&amp; rolename=rolename1OfApiKey1 [, rolename=rolename2OfApiKey1 [, ...]] [ ... ]]</pre> <p>Delimited with:</p> <pre> "before cell string , (space+comma) between each pair of roles in a key /; between each pair of fields in cell API Keys  #&amp; between each pair keys in field roles "after cell string</pre> <p>EXAMPLE:</p> <pre> "name=test123/;isActive=t/;description=Test 123. description./;roles=roleName=Service Manager roleUserGroups= roleDeviceGroups=. , roleName=Password Manager roleUserGroups=. roleDeviceGroups=#&amp;name=test234/;isActive=t/; description=Test 234. description./;roles=roleName=Service Manager roleUserGroups= roleDeviceGroups=. , roleName=Password Manager roleUserGroups= roleDeviceGroups="</pre>
----------	--------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**NOTE**

In the **Roles** field, do *not* assign any User **solely** the role "Password Manager". That role does not contain sufficient privileges for Privileged Access Manager access. Instead, when you intend to allow only password management privileges, add the role "Standard User" using Credential Manager. (Standard User is the default role that is populated in a newly created Privileged Access Manager user template.)

**Import Users and User Groups**

You can import Users and User Groups from an appropriately formatted User Import CSV file,

**Follow these steps:**

1. Go to **Users, Manage Users**.
2. Select the **Import/Export** button.
3. Select **Choose File**, find the file to import, and select **Open** in the **File Upload** dialog that appears.
4. Select **Import Users (User Groups)**.

## Device Groups and Devices

You can download a sample CSV file that defines devices. You can customize that file for your devices and then import or export the file (Devices, Manage Devices, Import/Export) for configuration purposes.

The following table lists the contents of the CSV file and the values that you can specify for each entry.

### TIP

In the **Record Type** column of the table, an asterisk indicates whether the entry is required for a Device (D), or a Device Group (DG).

Column Label	Record Type	Permitted Values	Description/Notes
Type	D* DG*	device or device group	Import record (row) type
DeviceName	D* DG*	text	Name of the Device or Device Group record label: Group Name
Address	D*	IP address or FQDN	Network location
Special Type Flag			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
Special Type Type			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
Special Type Login			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
Special Type Password			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
Special Type Protocol			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
Special Type Ports			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
Operating System	D	Enumerated options: <ul style="list-style-type: none"> <li>AIX BeOS FreeBSD</li> <li>HP-UX Linux NetBSD OpenBSD Other Solaris</li> <li>Embedded OS</li> <li>IBM AS/400</li> <li>Mac OS 9</li> <li>Mac OS X</li> <li>IBM Mainframe</li> <li>SCO UNIX</li> <li>Windows 2008</li> <li>Windows Vista</li> <li>Windows 7</li> <li>Windows Desktop</li> </ul>	Operating system of Device (Does not currently allow custom options)
Location	D	text	Device location (description)
FTP Mode	D	1	

Description	D DG	text	Device or Device Group description or other information
Access Methods	D		<p>Use the following template for each Access Method:  <b>'name=name custom_name=custom_name port =port property=property'</b></p> <p>Place holder options are:</p> <ul style="list-style-type: none"> <li><b>name:</b> VNC, Telnet, SSH, RDP If mainframe licensing is enabled, name options: TN3270, TN3270SSL, TN5250, TN5250SSL</li> <li><b>custom_name:</b> (optional) any string</li> <li><b>port:</b> Range for one port (only) is 0-65535. For VNC: leave empty or enter 0 if disabled</li> <li><b>property:</b> (empty); NULL</li> </ul> <p>Separate multiple access methods with the   (pipe) character.</p>
	D DG	VNC, Telnet, SSH, RDP	Access Method category (no specific access information)
Services	D DG	<p>Custom Services, or Built-in Services:</p> <ul style="list-style-type: none"> <li>sftpftp</li> <li>sftpftpemb</li> <li>sftpstftp</li> <li>sftpstftpemb</li> <li>TSWEB</li> </ul>	Specify built-in or custom Services. Separate any multiple Services by:   (pipe)
OOB Serial Host Flag			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
OOB Serial Host			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
OOB Serial Port			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
OOB KVM Host Flag			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
OOB KVM Host			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
OOB KVM Port			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
Power			DEPRECATED - Do not remove the column, but do not use it. Applicable to the out-of-band (OOB) device types.
Term Type	D	<ul style="list-style-type: none"> <li>ansi</li> <li>ibm</li> <li>scoansi</li> <li>vt100</li> <li>vt220</li> <li>vt320</li> <li>xterm</li> </ul>	Specify one terminal type
Term Key Mapping	D	<ul style="list-style-type: none"> <li>puttyDefault</li> <li>AT386.conf</li> <li>vt320.conf</li> </ul>	Specify one from allowed values
Term Customization	D	<p><b>0</b> = do not use settings</p> <p><b>1</b> = use settings</p>	Flag to use terminal customization settings: Term Character Encoding through Term End Select

Term Character Encoding	D	<ul style="list-style-type: none"> <li>UTF-8</li> <li>ISO-8859-1</li> </ul> (many other options)	Terminal character encoding type. (See GUI for full list, or Administration Guide for list and information.)
Term Font Family	D	<ul style="list-style-type: none"> <li>Monospaced</li> <li>Courier</li> <li>Courier New</li> </ul>	Select one from allowed values
Term Font Size	D	8–32	Terminal font size
Term Cursor Foreground	D	RGB hex triplet Example: #000000 (Black)	Cursor foreground color
Term Cursor Background	D	RGB hex triplet Example: #FFFFFF (White)	Cursor background color
Term Foreground Color	D	RGB hex triplet Example: #FFFFFF (White)	Foreground color
Term Background Color	D	RGB hex triplet Example: #000000 (Black)	Background color
Term Terminal Size	D	[width, height] in pixels Example: [80,24]	Terminal window size NOTE: Include brackets in setting.
Term Buffer Size	D	integer	Buffer size in bytes
Term Scroll Position	D	left or right	Select one from allowed values
Term End Select	D	0 or 1	Flag to use “End” to select
Device Monitor			DEPRECATED - Do not remove column, but do not use it. Applicable to deprecated Device Monitoring feature.
Tags	D	text	Free-form text attributes (zero or more) can be assigned to any device. Embedded spaces are allowed. Separate each pair of tags by:   (pipe)
Type Access	D	<b>f</b> = False <b>t</b> = True	Marker for an Access type Device
Type Password	D	<b>f</b> = False <b>t</b> = True	Marker for a Password Management type Device
Type A2A	D	<b>f</b> = False <b>t</b> = True	Marker for an A2A type Device
Target Server Description 1	D	text	If Type Password = t, this option is available
Target Server Description 2	D	text	If Type Password = t, this option is available
Request Client Description 1	D	text	If Type A2A = t, this option is available
Request Client Description 2	D	text	If Type A2A = t, this option is available
Request Client Active	D	<b>f</b> = False <b>t</b> = True	If Type A2A = t, this option is available
Host Name Preserved	D	<b>f</b> = False <b>t</b> = True	If Type A2A = t, this option is available

ProvisionType	DG	0 - 4	The provision type of the Device Group: 0 = Local 1 = AWS 2 = VMware 3 = LDAP 4 = Azure
AlternateId	D	text	Only a virtual Device can have an AlternateID .
Group Membership	D	text	Groups that the Device is member of, separated by:   (pipe) Device record label: Available Groups
Credential Source Name	DG	text	Separate multiple credential source names with the   (pipe) character.
Password Push	DG	1 = Enabled 0 = Disabled	This setting is maintained by a checkbox on the Enabled tab of the Device Group window: Provide Credentials for "Always Prompt for Password"
Override Address	D	f = False t = True	Applicable only to provisioned virtual devices.
Transparent Login Parameters	D	text	This setting resides on the Transparent Login tab of the Device. It combines the <b>Full Path To</b> and the <b>Password Prompt</b> for the <code>sudo</code> and <code>pbrun</code> commands. The command values are separated by a pipe, and the path from the password prompt by a semicolon. For example: <code>/etc/sudo;su /ext/pbrun;pwd</code>
Transparent Login Type	D	None or sudo/pbrun	This setting resides on the Transparent Login tab of the Device.
Handle Legal Notice	DG	1 = Enabled 0 = Disabled	This setting is maintained by a checkbox on the Enabled tab of the Device Group window: Handle "Legal Notice" on Logon screen.
Kerberos KDC server	D DG	IP address of a configured KDC server	This setting resides on the KDC Server tab of the Device.

## CSV Files for Services

In Services, Import/Export Services, you can download a sample file and can populate it according to the specifications in the following table. In Record Type, \* = required for that type of record (TCP/UDP, TCP/UDP: Web Portal, SSL VPN, or Application).

CSV File Column Label	Record Type	Permitted Values	Description / Notes
Type	All*	TCP/UDP Application	Import record (row) type
Service Name	All*	text	Name of the service Application record label: <b>App Name</b>
Local IP	TCP*	IPv4 local address or ' : : 1 ' for IPv6 address	The local IP address of this service. Must be on the Class A 127 network.

<b>TCP Ports</b>	TCP SSL	Port value	<p>The service TCP ports. Either:</p> <ul style="list-style-type: none"> <li>One or more port numbers that are separated by space or comma</li> <li>One port range with 1-500 port</li> <li>One port mapping</li> </ul> <p>For TCP/UDP services, if a value is specified for both TCP Ports and UDP Ports, the values must match exactly. For both types of services, a port value is required for at least one of TCP Ports and UDP Ports.</p> <p>TCP/UDP Service record labels: <b>Port(s) + Protocol</b></p>
<b>UDP Ports</b>	TCP SSL	Port value	<p>The service UDP ports. Either:</p> <ul style="list-style-type: none"> <li>One or more port numbers that are separated by space or comma</li> <li>One port range with 1-500 port</li> <li>One port mapping</li> </ul> <p>For TCP/UDP services, if a value is specified for both TCP Ports and UDP Ports, the values must match exactly. For both types of services, a port value is required for at least one of TCP Ports and UDP Ports.</p> <p>TCP/UDP Service record labels: <b>Port(s) + Protocol</b></p>
<b>Description</b>	All	Text	<p>Service description.</p> <p>TCP/UDP Service record label: Comments</p>
<b>Enabled</b>	TCP* SSL*	<p><b>t</b> = enabled <b>f</b> = disabled Do not use uppercase 'T' or 'F'</p>	<p>Disable the Service globally; or enable, subject to policy</p>
<b>Show in Column</b>	TCP*	<p><b>t</b> = enabled <b>f</b> = disabled Do not use uppercase 'T' or 'F'</p>	<p>Access page display mode</p>
<b>Application Protocol</b>	TCP*	<p><b>ICA</b> <b>RDP</b> <b>VNC</b></p>	<p>Service application protocol. In contrast to the GUI: Disabled, Console, and Web Portal are not used here.</p> <p>A Web Portal is specified by the presence of an address in the Web Portal Launch URL field.</p>
<b>Web Portal Launch URL</b>	TCP: Web	<p>Mapped URL - Use the following form: <b>http[s]://&lt;Local IP&gt;:&lt;First Port&gt;/[path, if any]</b></p> <ul style="list-style-type: none"> <li>The target address is specified by the Device using the Portal</li> <li>A target DNS address for the portal can be identified by the Host Header (and Aliases, if applicable)</li> </ul>	

<b>Launch Path</b>	App*	Path	Location of the remote application that is used in application publishing. Applicable only to targets running Microsoft Terminal Services.
<b>Client Application</b>	TCP	Path	Location of the local application that is launched when the service is initiated.
<b>Host Header</b>	TCP: Web	FQDN	Specify the FQDN of the target website in this field. Per HTTP 1.1, if the Web Portal resides on a single IP address which hosts several websites (such as Apache NameVirtualHost or IIS Host Header Access), this setting is used to identify the correct website target. <b>Note:</b> If Web Portal Launch URL is empty, this field does not populate.
<b>Aliases</b>	TCP: Web	text	If the target web portal is referred to by several different names, enter those names here. Example: If Host Header contains " <a href="http://www.example.com">www.example.com</a> ", while some links on that portal page point to " <a href="http://example.com">example.com</a> " and " <a href="http://someserver.example.com">someserver.example.com</a> ", enter " <a href="http://example.com">example.com</a> " and " <a href="http://someserver.example.com">someserver.example.com</a> " here (without quotes, separated by space or comma) so that requests to that site is handled successfully. <b>Note:</b> If Web Portal Launch URL is empty, this field does not populate.
<b>Hide Web Portal</b>	TCP: Web	t = enabled f = disabled Do not use uppercase 'T' or 'F'	If this portal is not intended to be user-facing - for example, for a graphics file server - select this checkbox so as not to display an access link for the user on the Access page. TCP/UDP Service record: Hide From User

## Messages and Log Formats

This content in this section describes Privileged Access Manager messages that are used in log entries, real-time UI warnings, and other informational output.

**NOTE**

The preformatted messages that are identified here are included in most syslog output (MSG field). Not every message is used in a syslog emission, and not all syslog emissions include a message. For example, some messages are used solely for user interaction. See Syslog Message Formats for more information.

**Message Code List Available from Server**

Use the `getErrorCodes` CLI command to produce a complete list of Credential Manager error codes. The command takes no parameters, and returns an XML structure listing each error code and its description.

For improved readability of the output, we recommend that you direct the XML structure to a separate file, and open it with an XML editor.

**Example**

This example directs the output of the `getErrorCodes` CLI command to a file called `error_codes.xml`.

To retrieve a complete list of Credential Manager error codes:

1. Use the following command: `capam_command -u admin -p password capam=mycompany.com cmdName=getErrorCodes > error_codes.xml` Where *password* is the password of the admin account. Credential Manager returns an XML command string to the `error_codes.xml` file.
2. Open the `error_codes.xml` file with an XML editor, such as Notepad++.

**TIP**

Use the table of contents to access the topics in this section.

**Syslog Message Formats**

Privileged Access Manager has two major formats for Syslog messages, and a few minor ones. The Application field denotes the major component source of the log message.

From 4.0.2 onwards, Privileged Access Manager administrators can standardize Credential Manager Syslog output to Space Delimited instead of XML, and the option to standardize to the JSON format in 4.1.5 and onwards. As a PAM admin, you can standardize syslog audit and metric logs, irrespective of the log.

The default is XML, but you can also use Space Delimited or JSON. For more information, see [Configure a Remote Syslog Server](#), [Configure a Server Control User Activity Server](#), and [Syslog Message Formats](#).

**IMPORTANT**

**IMPORTANT UPDATES to LOGS:** Releases after 4.0.2 implement the following changes for XML attribute tags where duplication was found, as shown in the following table. These updates impact the audit log and the returned data for some CLI commands. To support both backwards compatibility and the new Space Delimited or JSON formats, PAM returns both old and new tags in the audit log and in the CLI returned data for the affected classes.

Class Name	Old Attribute Tag	New Attribute Tag
Agent <c.cw.m.ag>	<ac> = Ack	<ack> = Ack
Patch <c.cw.m.pa>	<ac> = Activated	<avd> = Activated
Authorization <c.cw.m.sa>	<ta.id> = Target.Alias.ID	<al.id> = Target.Alias.ID
Compound.Server <c.cw.m.cs>	<ta.id> = Target.Account.ID	<ac.id> = Target.Account.ID
Password.View.Request.Summary <c.cw.m.pvrs>	<rn> = Requestor.Name	<reqn> = Requestor.Name
Site <c.cw.m.st>	<pr> = Type	<ty> = Type

Event.Base <c.cw.m.evb>	<pi> = Parent.ID	<pri.id> = Parent.ID
-------------------------	------------------	----------------------

**NOTE**

The Message Format you select when you [Configure a Remote Syslog Server](#) **ONLY** applies to the audit and metric logs.

This section describes the formats of these different Syslog messages.

**Session Management Log Formats****Format**

`<PRIORITY>APPLICATION[PID]: MSG`

**PRIORITY** is produced by a standard IETF syslog grid of Facility by Severity. Syslog servers might extrapolate the Facility and Severity values. For example, 13 is "user-level" facility and "Notice" severity. See [Syslog Priority Facility Severity Grid](#) for more information.

**APPLICATION** denotes the major component source of the log message. For Session Management (formerly known as GateKeeper), this value is **gkpsyslog**.

**PID** is the process ID associated with the logged activity, which can help group log messages.

**MSG** includes 12 fields common to Session Logs in the product UI, separated by commas, except after Date/Time.

**MSG Fields**

- **Date/Time:** This field is not labeled, but sent as "created = yyyy-mm-dd hh:mm:ss" (The date and time are sent in UTC.) Example: *created = 2017-11-14 19:55:22*
- **Private IP:** "Private Address" in the UI; if none, a space is logged
- **Public IP:** "Public Address" in the UI; if none, a space is logged
- **Nat/Proxy IP:** "Nat/Proxy Address" in the UI; if none, a space is logged
- **User:** "User Name" in the UI; should not be empty
- **Transaction:** should not be empty
- **Address:** if none, *space, dash, space, dash* is logged; for example: *Address: - -*,
- **Device Name:** if none, *space, dash, space, dash* is logged; for example: *Device Name: - -*,
- **User Group:** if none, *space, dash, dash* is logged; for example: *User Group: --*,
- **Port:** if none, *space, dash, space, dash* is logged; for example: *Port: - -*,
- **Access/Protocol:** "Applet" in the UI; if none, *space, dash, space, dash* is logged; for example: *Access/Protocol: - -*,
- **Service/App:** "Service" in the UI; if none, *space, dash, space, dash* is logged; for example: *Service/App: - -*,
- **Details:** The log messages that are included in the Details field are listed in the [Messages and Log Formats](#) section. This field should not be empty.

Each Session Management Syslog message ends in hex code 0A.

**Examples****Log Records Viewed**

```
<13>gkpsyslog[14289]: created = 2017-11-14 19:55:22 Private IP: , Public IP: , Nat/Proxy
IP: , User: super, Transaction: admin,
Address: - -, Device Name: - -, User Group: --, Port: - -, Access/Protocol: - -,
Service/App: - -,
Details: PAM-CMN-1371: Log records viewed
```

**Session Recording Reconciliation**

```
<28>gkpsyslog[355]: created = 2017-11-14 18:17:03 Private IP: , Public IP: , Nat/Proxy
IP: , User: sessionReconciliation,
Transaction: system, Address: - -, Device Name: - -, User Group: --, Port: - -, Access/
Protocol: - -,
Service/App: - -, Details: PAM-CMN-1989: Ending session recording reconciliation.
0 session recording rows added to table. 0 sidecar(.inf) files added to share.
0 nearly empty files deleted from share.
```

### Super logged in

```
<85>gkpsyslog[9632]: created = 2017-11-14 20:17:06 Private IP: , Public IP: , Nat/Proxy
IP: 130.200.78.105, User: super,
Transaction: login, Address: - -, Device Name: - -, User Group: --, Port: - -, Access/
Protocol: - -,
Service/App: - -, Details: PAM-CMN-0917: User super logged in successfully via local
authentication.
```

## Credential Management Log Formats

### Format

```
<PRIORITY>VERSION
TIMESTAMP
HOSTNAME
APPLICATION
MSG
```

**Priority** is produced by a standard IETF syslog grid of Facility by Severity. Syslog servers might extrapolate the Facility and Severity values. For example, 134 is "local0" facility and "Info" severity. See [Syslog Priority Facility Severity Grid](#) for more information.

**Version** is the version number of the Syslog protocol standard. Currently, the only valid value is "1".

**Timestamp** uses the IETF RFC5424 format including date, time, and time zone. In practice, it is always UTC. For example: 2017-11-12T19:08:18+00:00

**Hostname** is the host name of the originating Privileged Access Manager instance.

**Application** denotes the major component source of the log message. For Credential Management, this value is **pam**.

**MSG** includes either Metric Data or Audit Data.

### Metric Data

Metric log entries result from functions that must be recorded as successes or failures, such as login attempts and password changes.

Each metric log entry contains an object that has several built-in fields. These fields are applied as tag names, and usually have object-specific extended attributes. For example, target accounts use extended attributes to store information that depends on the type of account. Fields are used to store information common to all target accounts. Extended attributes are stored within a tag with attribute ("k") and value ("v") pairs.

The following fields appear in Metric log entries:

- **type:** This field describes type of metric, such as login, or password change. The metric type determines the contents of the description field.
- **level:** This field is not used, and is always set to "1".
- **errorCode:** If the operation failed, the error code identifying the reason for the failure is identified here. A value of "0" denotes success.
- **adminUserId:** This field identifies the user (not necessarily an administrator) that performed the activity in question.
- **Success:** This field identifies whether the operation was successful. If not, the errorCode field identifies why.
- **description:** This field contains an embedded field (typically a hashmap) representing details specific to the type of metric.

Credential Management metric log entries appear as strings, but can be reformatted to display their structure.

The following code provides a sample in XML format. For a space-delimited example, see [Metric Detail Space-Delimited Example](#). For a JSON formatted example, see [Metric Detail JSON Example](#).

```
<Metric>
  <type>viewAccountPassword</type>
  <level>1</level>
  <description>
    <hashmap>
      <k>commandInitiator</k><v>USER</v>
      <k>adminUserID</k><v>super</v>
      <k>reason</k><v></v>
      <k>selectedComponent</k><v>0</v>
      <k>Attribute.descriptor2</k><v></v>
      <k>Attribute.descriptor1</k><v></v>
      <k>TargetAccount.ID</k><v>1005</v>

      <bm.ha>Wpkmh+aP0lrWk/A...s57Mjowo=</bm.ha>
      <at.na>descriptor2</at.na>
      <at.ob.id>1004</at.ob.id>
      <at.ob.cl>c.cw.m.ts</at.ob.cl>
    </c.cw.m.at>
  </bm.at.li>
```

```

    <hn>123.123.123.000</hn>
    <ip>123.123.124.000</ip>
    <dn>redhat</dn>
</c.cw.m.ts>

```

These log entries are wrapped by <c.cw.m...> tags.

- c.cw.m = com.cloakware.model.

#### NOTE

"Cloakware" is an internal name for the Credential Management function.

- bm = BaseModel is the parent of all object types. This tag is found in all objects for their common attributes.
- id = identification number for this object
  - For example, "id" may be a target account ID, a target server ID, or a Password View Request ID.
  - The name of a target account may change but its ID does not.
  - Metric log entries only specify the ID, but not the name. The session log entries are comprehensive, so you can find an ID when given the name.

Class IDs begin with c.cw.m. The fourth element identifies the object. The elements specific to that object follow each object code.

```

ac = Account
    ca = cache allowed
    cd = cache duration
    pv = password verified
    um = unmanaged
    un = User Name
    uoid = owner user

```

## GKMonitor

### Format

```
<PRIORITY>APPLICATION[PID]: MSG
```

**PRIORITY** is produced by a standard IETF syslog grid of Facility by Severity. Syslog servers might extrapolate the Facility and Severity values. For example, 85 is “security/auth” facility and “Notice” severity. See [Syslog Priority Facility Severity Grid](#) for more information.

**APPLICATION** denotes the major component source of the log message. For these messages, this value is `gkmonitor`.

**PID** is the process ID associated with the logged activity, which can help group log messages.

**MSG** includes only a simple log message. The date and time are not sent.

### Example

#### User account disabled

```
<85>gkmonitor[12371]: PAM-CMN-2135="Disabled user account: {0} removed from PAM
```

## Logwatch

### Format

```
<PRIORITY>APPLICATION[PID]: MSG
```

**PRIORITY** is produced by a standard IETF syslog grid of Facility by Severity. Syslog servers might extrapolate the Facility and Severity values. For example, 28 is “system” facility and “Warning” severity. See [Syslog Priority Facility Severity Grid](#) for more information.

**APPLICATION** denotes the major component source of the log message. For these messages, this value is `logwatch`.

**PID** is the process ID associated with the logged activity, which can help group log messages.

**MSG** includes only a simple log message. The date and time are not sent.

### Example

#### Starting up logwatch

```
<28>logwatch[1]: Starting up logwatch
```

## Other Messages

### Format

```
<PRIORITY>VERSION
TIMESTAMP
HOSTNAME
MSG
```

**PRIORITY** is produced by a standard IETF syslog grid of Facility by Severity. Syslog servers might extrapolate the Facility and Severity values. For example, 134 is "local0" facility and "Info" severity. See [Syslog Priority Facility Severity Grid](#) for more information.

**VERSION** is the version number of the Syslog protocol standard. Currently, the only valid value is "1".

**TIMESTAMP** does not conform to IETF specifications. The year and time zone are not included, and the month is an English abbreviation. In practice, it is always UTC. **For example:** Sep 18 22:09:54

**HOSTNAME** is the hostname of the originating Privileged Access Manager instance.

**MSG** entries are tagged as <Metric> or formatted like Audit entries, but not labeled as such. The audit-type entries are typically paired with a Metric entry.

### Examples

#### System Startup

```
<134>1 Sep 18 20:09:25 uslipam13-133 <Metric>systemStartup 1 0 system true 130.200.13.133 uslipam13-133</Metric>

## Syslog Priority Facility Severity Grid

The Priority value that Privileged Access Manager sends to Syslog servers is derived from a standard IETF syslog grid of Facility by Severity. Syslog servers might extrapolate the Facility and Severity values. Find the value, from 0 to 191, in the grid, and see the column and row values. For example, a Priority value of 13 is “user-level” Facility and “Notice” Severity.

	Severity	Emergency	Alert	Critical	Error	Warning	Notice	Info	Debug
Facility		0	1	2	3	4	5	6	7
kernel	0	0	1	2	3	4	5	6	7
user-level	1	8	9	10	11	12	13	14	15
mail	2	16	17	18	19	20	21	22	23
system	3	24	25	26	27	28	29	30	31

secur/auth	4	32	33	34	35	36	37	38	39
syslog	5	40	41	42	43	44	45	46	47
lpd/printer	6	48	49	50	51	52	53	54	55
news/nntp	7	56	57	58	59	60	61	62	63
uucp	8	64	65	66	67	68	69	70	71
time	9	72	73	74	75	76	77	78	79

## PAM-AGT: CA PAM Access Agent Messages

PAM-AGT-1000: This version of PAM is not supported by the Agent. Please connect to another PAM server.

PAM-AGT-1001: CA PAM Agent Service is not started. Please start this service before continuing.

PAM-AGT-1002: Cannot connect to the PAM server at this address. Please re-check your server name/IP, and ensure your PAM instance is running.

PAM-AGT-1003: This service has already been activated.

PAM-AGT-1004: A Password View Request for this Credential is already pending.

PAM-AGT-1005: Reason is required, please select one

PAM-AGT-1006: Error importing certificate. Please check your certificate and try again.

PAM-AGT-1007: Error exporting certificate.

PAM-AGT-1008: Error removing the certificate

PAM-AGT-1009: Host and Port values are required for this proxy mode.

PAM-AGT-1010: Proxy URL is required for this proxy mode.

PAM-AGT-1011: Cannot activate this service. Another service with the same device and local port(s) has already been activated.

PAM-AGT-1012: Error occurred during authentication.

PAM-AGT-1013: Error launching installer. If this problem persists, please contact support.

PAM-AGT-1013: Dual authorization for this credential is still pending. Try again after approval.

PAM-AGT-1014: Dual authorization for this credential has been denied.

PAM-AGT-1100: Service activation failed. Please restart the PAM Agent and the PAM Agent service and try again.

PAM-AGT-1101: Error setting up Agent services. Please restart the PAM Agent and the PAM Agent service and try again.

## PAM-CF: Connector Framework Messages

PAM-CF-0001 = The Custom Connector server is inaccessible or its configuration is invalid.

PAM-CF-0002 = There is an error on the Custom Connector server.

PAM-CF-0005 = Failed to validate target connector attributes. {0}

PAM-CF-0006 = Invalid connector framework configuration parameters : {0}

PAM-CF-0007 = Connector Framework Certificate is expiring in less than {0} day(s).

PAM-CF-0008 = Connector Framework Certificate has expired.

## PAM-CLNT: PAM Client Messages

PAM-CLNT-0000 = Application error occurred in RDP client: {0}

PAM-CLNT-0001 = Wrong Web SSO configuration.

PAM-CLNT-0002 = Incorrect login URL.

PAM-CLNT-0003 = Unknown Web SSO status: {0}

PAM-CLNT-0004 = Auto login inner error. Reason: {0}

PAM-CLNT-0005 = Auto login timeout expired, possibly due to wrong credentials.

PAM-CLNT-0006 = SSO credentials are invalid.

PAM-CLNT-0007 = Session disconnected due to a problem with session recording.

PAM-CLNT-0008 = Session can't be established due to a problem with session recording

PAM-CLNT-0009 = Local folder has been created by user {0}

PAM-CLNT-0010 = Local file has been created by user {0}

PAM-CLNT-0011 = Remote folder has been created by user {0}

PAM-CLNT-0012 = Remote file has been created by user {0}

PAM-CLNT-0013 = Local folder has been renamed to {0} by user {1}

PAM-CLNT-0014 = Local file has been renamed to {0} by user {1}

PAM-CLNT-0015 = Remote folder has been renamed to {0} by user {1}

PAM-CLNT-0016 = Remote file has been renamed to {0} by user {1}

PAM-CLNT-0017 = Local folder has been deleted by user {0}

PAM-CLNT-0018 = Local file has been deleted by user {0}

PAM-CLNT-0019 = Remote folder has been deleted by user {0}

PAM-CLNT-0020 = Remote file has been deleted by user {0}

PAM-CLNT-0021 = Uploaded {0} to {1} as user {2}

PAM-CLNT-0022 = Downloaded {0} from {1} as user {2}

PAM-CLNT-0023 = Executed '{0}' using transparent login as {1}

PAM-CLNT-0024 = A connection from {0} to service '{1}' was attempted by an unauthorized session '{2}' on '{3}'PAM-CLNT-0025="{0}"

## PAM-CM: Credential Manager Messages

The following messages are created by Credential Manager. Certain messages are grouped by subheading.

PAM-CM-0000 = Downloaded Certificate {0}

PAM-CM-0001 = Downloaded CSR {0}

PAM-CM-0002 = Downloaded private key file {0}

PAM-CM-0004 = Downloaded database file {0}

PAM-CM-0005 = User tried and failed to upload a database or configuration file with invalid characters in the file name and / or an improper file extension.

PAM-CM-0006 = Config file {0} uploaded successfully

PAM-CM-0007 = Database file {0} uploaded successfully

PAM-CM-0008 = Run ping on host {0}.

PAM-CM-0009 = Run traceroute on host {0}.

PAM-CM-0010 = Run Port Scan on IP address: {0}. Ports: {1}.

PAM-CM-0011 = Run nslookup on host {0}.

PAM-CM-0012 = {0} export completed.

PAM-CM-0013 = {0} import completed.

PAM-CM-0014 = Uploaded license file {0}

PAM-CM-0015 = Downloaded log file {0}.

PAM-CM-0016 = File {0} uploaded successfully. For this change to take effect, please restart Tomcat.

PAM-CM-0018 = File {0} uploaded successfully! Please delete the Node Secret file if it exists to clear old cache.

PAM-CM-0019 = Job {0} deleted.

PAM-CM-0020 = Job {0} cancelled.

PAM-CM-0021 = Unable to load PAM certificate for SSO user {0}. User will not be able to log-in

PAM-CM-0022 = Account Scan Profile {0} created.

PAM-CM-0023 = Account Scan Profile {0} deleted.

PAM-CM-0024 = Account Scan Profile {0} updated.

PAM-CM-0025 = Config exception: {0}

PAM-CM-0026 = Error creating object: {0}

PAM-CM-0027 = CA Single Sign-On Web Agent disabled. For this change to take effect, please restart Apache.

PAM-CM-0028 = Restarting Apache Web Server

PAM-CM-0029 = Configuration of CA Single Sign-On Web Agent complete. For this change to take effect, please restart Apache.

PAM-CM-0030 = Registration failed ('{0}');

PAM-CM-0032 = CA Single Sign-On Web Agent registration failed. Host config object not found.

PAM-CM-0033 = CA Single Sign-On Web Agent registration failed. Invalid credentials.

PAM-CM-0034 = CA Single Sign-On Web Agent registration failed. Unknown administrator.

PAM-CM-0035 = Object empty: {0}

PAM-CM-0036 = Updated system certificate to {0}

PAM-CM-0037 = Problem updating system certification {0}

PAM-CM-0038 = Problem updating system certification

PAM-CM-0039 = Unable to perform the operation. Please contact System Administrator.

PAM-CM-0040 = Created Self-Signed Certificate {0}

PAM-CM-0041 = Created CSR {0}

PAM-CM-0042 = There is invalid CRL URL format: {0}

PAM-CM-0043 = There is invalid CRL file: {0}

PAM-CM-0044 = CRL file: {0} was added.

PAM-CM-0045 = Disabling SAML IdP component

PAM-CM-0046 = SAML IdP is already disabled

PAM-CM-0047 = Restarting after SAML IdP change

PAM-CM-0048 = SAML IdP is already enabled

PAM-CM-0049 = Enabling SAML IdP component

PAM-CM-0050 = CA PAM SAML Identity Provider configuration updating: Entity ID = {0}, FQDN = {1}, Certificate = {2}

PAM-CM-0051 = The CA PAM database has been compacted successfully

PAM-CM-0052 = Reset CA PAM database failed: {0}

PAM-CM-0053 = Database backup schedule saved successfully

PAM-CM-0054 = Database backup schedule deleted successfully

PAM-CM-0055 = Mount unsuccessful. Please contact administrator.

PAM-CM-0056 = NFS mount operation unsuccessful. Mount point: {0} Hostname: {1}

PAM-CM-0057 = NFS mounting performed successfully. Mount point: {0} Hostname: {1}

PAM-CM-0058 = CIFS mount operation unsuccessful. Mount point: {0} Hostname: {1}  
PAM-CM-0059 = CIFS mounting performed successfully. Mount point: {0} Hostname: {1}  
PAM-CM-0060 = Mount unsuccessful. Please contact administrator. Not existent S3 bucket {0}  
PAM-CM-0061 = Mount unsuccessful. Please contact administrator {0}  
PAM-CM-0062 = S3 mounting performed successfully  
PAM-CM-0063 = The CA PAM database has been reset successfully  
PAM-CM-0064 = CA PAM configuration restored successfully from file {0}. CA PAM is being rebooted.  
PAM-CM-0065 = Could not restore CA PAM configuration: {0}  
PAM-CM-0066 = Could not restore the database because disk is over half full.  
PAM-CM-0067 = CA PAM database restored successfully from file {0}. CA PAM is being rebooted.  
PAM-CM-0068 = Could not restore the database: {0}. Contact your CA PAM administrator.  
PAM-CM-0069 = Unable to save the database to a file: {0}  
PAM-CM-0070 = Unable to save CA PAM configuration to a file: {0}  
PAM-CM-0071 = {0} CA PAM configuration saved successfully to {1}  
PAM-CM-0073 = Database file {0} deleted successfully.  
PAM-CM-0074 = Unable to delete database file {0}: File not found.  
PAM-CM-0075 = Unable to delete database file {0}: {1}.  
PAM-CM-0076 = Unmounting performed successfully  
PAM-CM-0077 = Unmount operation unsuccessful.  
PAM-CM-0078 = Account {0} managed.  
PAM-CM-0081 = Device {0} managed.  
PAM-CM-0082 = Session recording '{0}' was viewed  
PAM-CM-0083 = Monitor started successfully  
PAM-CM-0084 = Monitor stopped successfully  
PAM-CM-0085 = Updated monitoring configuration. Admin email: {0}., SMTP Server: {1}., From Address: {2}.  
PAM-CM-0086 = Problem updating the configuration: {0}  
PAM-CM-0087 = Changed Monitor startup flag to on.  
PAM-CM-0088 = Changed Monitor startup flag to off.  
PAM-CM-0089 = Added new route: Destination: {0} Netmask: {1} Gateway: {2} Device: {3} Metric: {4}  
PAM-CM-0090 = Added new route: Destination: {0} Gateway: {1} Device: {2}  
PAM-CM-0091 = Deleted route: Destination: {0} Netmask: {1} Gateway: {2} Device: {3} Metric: {4}  
PAM-CM-0092 = Deleted route: Destination: {0} Gateway: {1} Device: {2}  
PAM-CM-0093 = Successfully restarted networking  
PAM-CM-0094 = Network Interface: {0} disabled.  
PAM-CM-0095 = Network Interface: {0} Speed: {1}, Duplex: {2}, IP address: {3}, Netmask: {4}, Broadcast: {5}, IPv6 Address: {6}.  
PAM-CM-0096 = Network settings updated successfully . Hostname: {0}, Domain Name: {1}, Default Gateway: {2}, DNS Servers: {3}  
PAM-CM-0097 = Device Scan Profile {0} created.  
PAM-CM-0098 = Device Scan Profile {0} deleted.  
PAM-CM-0099 = Device Scan Profile {0} updated.  
PAM-CM-0100 = Updated Microsoft Office 365 configuration  
PAM-CM-0101 = Cleared Microsoft Office 365 configuration  
PAM-CM-0102 = Office 365 configuration test: Connected successfully to the supplied URLs  
PAM-CM-0103 = Office 365 configuration test: Error connecting to the supplied URLs  
PAM-CM-0104 = The user has acknowledged the warnings related to rebooting an appliance (for activating or deactivating FIPS) while the cluster is running.  
PAM-CM-0105 = Activated FIPS Mode  
PAM-CM-0106 = Deactivated FIPS Mode  
PAM-CM-0107 = The user has acknowledged the warnings related to rebooting an appliance (for activating or deactivating FIPS) while the cluster is running. Activated FIPS Mode  
PAM-CM-0108 = The user has acknowledged the warnings related to rebooting an appliance (for activating or deactivating FIPS) while the cluster is running. Deactivated FIPS Mode

PAM-CM-0109 = The user has acknowledged the warnings related to rebooting an appliance while the cluster is running. The appliance will now be powered off.

PAM-CM-0110 = Powered off the appliance

PAM-CM-0111 = Shutting down...

PAM-CM-0112 = The user has acknowledged the warnings related to rebooting an appliance while the cluster is running. The appliance will now be rebooted.

PAM-CM-0113 = Rebooted the appliance

PAM-CM-0114 = Rebooting...

PAM-CM-0115 = {0} Configuration Updated Successfully! Added server {1}:{2}

PAM-CM-0116 = {0} Configuration Updated Successfully! Deleted server {1}:{2}

PAM-CM-0117 = Object not found: {0}

PAM-CM-0118 = Radius server on {0}: port {1} not found.

PAM-CM-0119 = File {0} deleted successfully. For this change to take effect, please restart Tomcat.

PAM-CM-0120 = File {0} deleted successfully!

PAM-CM-0121 = {0}

PAM-CM-0122 = Connected successfully to the ActiveMQ Console on host {0}

PAM-CM-0123 = Could not connect to the ActiveMQ Console on host {0}

PAM-CM-0124 = Server Control integration module was activated

PAM-CM-0125 = Server Control integration module was deactivated

PAM-CM-0126 = Could not activate Server Control integration module

PAM-CM-0127 = Could not deactivate Server Control integration module

PAM-CM-0128 = Unable to delete {0}

PAM-CM-0129 = {0} deleted successfully

PAM-CM-0130 = Certificate Upload: Unknown Format ({0})

PAM-CM-0131 = Unknown Format

PAM-CM-0132 = An error occurred while setting the cluster tuning mode.

PAM-CM-0133 = Database error

PAM-CM-0134 = Data is being collected. Graphs will begin to be generated within the next twenty minutes.

PAM-CM-0135 = An error occurred setting debug SSHD Mode

PAM-CM-0136 = Created System Diagnostic file

PAM-CM-0137 = The license was not updated. Uploaded license file could not be verified or read.

PAM-CM-0138 = Log file {0} deleted successfully.

PAM-CM-0139 = Unable to delete log file {0}: File not found.

PAM-CM-0140 = Unable to delete log file {0}: {1}.

PAM-CM-0141 = Mount unsuccessful. Please contact administrator

PAM-CM-0142 = All logs have been purged.

PAM-CM-0143 = Unable to purge the logs. Please, contact your administrator.

PAM-CM-0144 = Purged logs up till {0}

PAM-CM-0145 = Changed automatic Log Purge Settings. Status: Enabled, Purge interval: {0}, Email flag: {1}, Email size: {2} MB.

PAM-CM-0146 = Changed automatic Log Purge Settings. Status: Disabled

PAM-CM-0147 = External Log Settings saved successfully.

PAM-CM-0148 = Created new log table on the external server.

PAM-CM-0149 = Created new log\_user\_group table on the external server.

PAM-CM-0150 = Created new log\_device\_group table on the external server.

PAM-CM-0151 = Connection to the database established successfully and tables created.

PAM-CM-0152 = Connection to the database established successfully.

PAM-CM-0153 = Saved logs up till {0}

PAM-CM-0154 = Unable to write the logs to a file! Please, contact your administrator!

PAM-CM-0155 = Updated Syslog Settings. Status: Enabled, Remote Server(s): {0}, with port: {1}

PAM-CM-0156 = Updated Syslog Settings. Status: Disabled

PAM-CM-0157 = Keystroke Logging configuration updated successfully. Syslog: {0}. NFS/CIFS/S3 CLI Recording: {1}. NFS/CIFS/S3 Graphical Recording: {2}.

PAM-CM-0158 = {0}. Settings saved successfully. Mount point: {1}. Hostname: {2}  
PAM-CM-0159 = Updated Session Recording to be Security Safe  
PAM-CM-0160 = Updated Session Recording to be Operationally Safe  
PAM-CM-0161 = You do not have sufficient permissions to perform this operation.  
  
PAM-CM-0162 = Payload id does not match url id: {0} != {1}  
PAM-CM-0163 = Must specify all filter parameters (column, op, value) or none  
PAM-CM-0164 = Invalid Operator filter. Valid values = EQ, NE  
PAM-CM-0165 = Error retrieving object by id: {0}  
PAM-CM-0166 = Error retrieving object by name: {0}  
PAM-CM-0167 = Error updating object: {0}  
PAM-CM-0168 = Call to PAM service controller failed: {0}  
PAM-CM-0169 = Error connecting to the database. Transaction canceled  
PAM-CM-0170 = Transaction error with the database. Transaction canceled  
PAM-CM-0171 = Target Server not found for host: {0}  
PAM-CM-0172 = Number of devices that were successfully managed: {0}  
PAM-CM-0173 = Number of devices that were NOT successfully managed: {0}  
PAM-CM-0174 = Target Application not found: {0}  
PAM-CM-0175 = Target Account {0} already exists. No modifications made.  
PAM-CM-0176 = {0} is not a valid {1} IP Address.  
PAM-CM-0177 = Profile name is not defined.  
PAM-CM-0178 = {0} name {1} already exists.  
PAM-CM-0179 = {0} is not a valid parameter.  
  
PAM-CM-0180 = Radius server on {0}: port {1} already exists.  
PAM-CM-0181 = Splunk server on {0}: port {1} already exists.  
PAM-CM-0182 = Account management failed for account {0} with the following error: {1}  
PAM-CM-0183 = Logo was reverted to original logo.  
PAM-CM-0184 = Logo file {0} was successfully uploaded.  
PAM-CM-0185 = Action was applied for {0} {1}.  
PAM-CM-0186 = Shared Key is not allowed to download  
PAM-CM-0187 = Private Key is not allowed to be downloaded  
PAM-CM-0188 = Required Remedy licensed files could not be found.  
PAM-CM-0189 = {0} is not defined.  
PAM-CM-0190 = Please enter the required password that will be used to encrypt the private key!  
PAM-CM-0191 = Please enter the confirmed password that will be used to encrypt the private key!  
PAM-CM-0192 = The confirmed password does not match the password!  
PAM-CM-0193 = The passphrase contains invalid space or - characters!  
PAM-CM-0194 = Unable to upload file  
PAM-CM-0195 = The key file for the certificate {0} is missing  
PAM-CM-0196 = Could not change {0}  
PAM-CM-0197 = Cannot update CRL configuration: {0}  
PAM-CM-0198 = The IdP settings cannot be updated while the cluster is on  
PAM-CM-0199 = Unknown certificate {0} selected  
PAM-CM-0200 = SAML Metadata file must be an XML file  
PAM-CM-0201 = Verification Error {0}  
PAM-CM-0202 = Invalid Tomcat log level submitted  
PAM-CM-0203 = Tomcat Log Level updated.  
PAM-CM-0204 = Tomcat Log Level could not be updated.  
PAM-CM-0205 = Database updated successfully  
PAM-CM-0206 = Applet Log Level updated.  
PAM-CM-0207 = Applet Log Level could not be updated.  
PAM-CM-0208 = Web service log level updated successfully  
PAM-CM-0209 = Web service log level could not be updated

PAM-CM-0212 = CA PAM As SAML SP Log Level updated  
PAM-CM-0213 = CA PAM As SAML IdP Log Level updated  
PAM-CM-0214 = CA PAM As SAML IdP Log Level could not be updated  
PAM-CM-0216 = An error occurred setting Maintenance Mode  
PAM-CM-0217 = Maintenance mode has been enabled for this appliance  
PAM-CM-0218 = Maintenance mode has been disabled for this appliance  
PAM-CM-0219 = AACTRL debug mode has been enabled for this appliance  
PAM-CM-0220 = AACTRL debug mode has been disabled for this appliance  
PAM-CM-0221 = Remote CA PAM Debugging Services active until {0} UTC  
PAM-CM-0222 = Remote CA PAM Debugging Services turned off  
PAM-CM-0223 = Cluster tuning mode turned on  
PAM-CM-0224 = Cluster tuning mode turned off  
PAM-CM-0228 = External REST API Access has been Enabled  
PAM-CM-0229 = External REST API Access has been Disabled  
PAM-CM-0230 = External Password Authority API Access has been Enabled  
PAM-CM-0231 = External Password Authority API Access has been Disabled  
PAM-CM-0232 = VMware console could not be Enabled  
PAM-CM-0233 = VMware console could not be Disabled  
PAM-CM-0234 = No common name specified  
PAM-CM-0235 = IPv6 is not supported  
PAM-CM-0236 = You entered an invalid value for Subject Alternative Name. Please enter only IP addresses and/or FQDNs  
PAM-CM-0237 = Unknown certificate {0} selected  
PAM-CM-0238 = Invalid Password Entry  
PAM-CM-0239 = Invalid Confirmed Password Entry  
PAM-CM-0240 = Invalid Provider Entry  
PAM-CM-0241 = Confirmed Password Does Not Match The Password  
PAM-CM-0242 = The SAML entity ID for the IdP is required  
PAM-CM-0243 = The fully qualified hostname for the SAML IdP is required  
PAM-CM-0244 = The fully qualified hostname for the SAML IdP is not a valid hostname  
PAM-CM-0245 = Invalid Signature Algorithm Specified! Valid values are: {0}  
PAM-CM-0246 = Applied patch {0} : {1}  
PAM-CM-0247 = Message 32026: Patch with name {0} has been uploaded successfully.  
PAM-CM-0248 = Invalid file type of {0}. Import supports only CSV files of types: csv.  
PAM-CM-0249 = Need to provide /approve or /deny as path parameter.  
PAM-CM-0250 = Deleted Certificate: {0}  
PAM-CM-0251 = Error updating configuration (split tunnel)  
PAM-CM-0252 = Error updating configuration (net)  
PAM-CM-0253 = Mask must be integer number between 16 and 29 bits  
PAM-CM-0254 = Error updating configuration (mask)  
PAM-CM-0255 = SSL VPN Configuration updated; Network: {0}/{1}; Split tunneling enabled  
PAM-CM-0256 = SSL VPN Configuration updated; Network: {0}/{1}  
PAM-CM-0257 = Configuration updated  
PAM-CM-0258 = RSA authentication manager configuration file names must be sdconf.rec or sdopts.rec  
PAM-CM-0259 = BMC Remedy SDK file names must be arapi8\*.jar, arapi9\*.jar, arutil81\*.jar, or arutil91\*.jar.  
PAM-CM-0260 = Error uploading BMC Remedy SDK file {0}. Please check version.  
PAM-CM-0261 = CA Privileged Access Manager is collecting and analyzing limited information about your client system and sessions  
PAM-CM-0262 = Successfully connected to BAP server  
PAM-CM-0263 = Unable to retrieve Risk Levels from BAP server. Invalid or missing API token  
PAM-CM-0264 = Unable to retrieve Risk Levels from BAP server  
PAM-CM-0265 = Command String has been Enabled  
PAM-CM-0266 = Command String has been Disabled

PAM-CM-0267 = Invalid characters or extension in your filename! No spaces or special characters allowed.(Extension should be ".gz.bin" or ".cfg")

PAM-CM-0268 = File {0} uploaded successfully. You can use it to restore the Config now.

PAM-CM-0269 = File {0} uploaded successfully. You can use it to restore the Database now.

PAM-CM-0274 = FIPS mode can not be activated when logging to an external server is enabled. Disable external logging first

PAM-CM-0275 = Could not activate FIPS mode because SNMP is configured for unsecured access. Please configure SNMP (poll server and traps) for v3 access only and try again.

PAM-CM-0276 = Could not activate FIPS mode because CA PAM as a SAML SP is configured to accept assertions signed using a SHA1 based algorithm. SHA1 based algorithms are not supported in FIPS mode.

PAM-CM-0277 = Can not start Monitor. Please verify the information in General Monitoring Parameters.

PAM-CM-0278 = Can not stop Monitor

PAM-CM-0279 = The Email logs option may only be enabled if you have a valid Admin Email, SMTP Server, and Appliance From Address configured under the Monitor tab.

PAM-CM-0280 = "Date and Time","Private IP","Public IP","NAT/Proxy IP","User","Transaction","Address","Device Name","Port","Access/Protocol","Service/App","Details","Target Account","Password View Request ID"

PAM-CM-0281 = Attaching of additional storage attached to this virtual appliance ({0}) initiated, this appliance will be rebooted.

PAM-CM-0282 = Attachment of additional storage completed successfully

PAM-CM-0283 = Detaching of additional storage from this virtual appliance initiated, this appliance will be rebooted

PAM-CM-0284 = Downloaded database backup public key file {0}

PAM-CM-0285 = Error downloading database backup public key file: {0}

PAM-CM-0286 = Session recording purging settings updated.

PAM-CM-0287 = Problem changing the SNMP Agent startup flag: {0}

PAM-CM-0288 = SNMP Agent startup flag changed successfully. Start at boot: {0}

PAM-CM-0289 = Can not save SNMP daemon configuration: {0}

PAM-CM-0290 = SNMP poll configuration saved successfully. Read-only Community: {0}

PAM-CM-0291 = SNMP Agent started successfully

PAM-CM-0292 = Problem starting SNMP Agent: {0}

PAM-CM-0293 = SNMP Agent stopped successfully

PAM-CM-0294 = Problem stopping SNMP Agent: {0}

PAM-CM-0295 = Invalid characters for Read-Only Community

PAM-CM-0296 = xceedium is not a valid SNMPv3 username

PAM-CM-0297 = Invalid characters for SNMPv3 Username

PAM-CM-0298 = Authentication Passphrase must be at least eight (8) characters in length

PAM-CM-0299 = Private Passphrase can be omitted or should be at least eight (8) characters in length

PAM-CM-0300 = SNMPv3 User "{0}" already exists

PAM-CM-0301 = SNMPv3 user "{0}" added successfully

PAM-CM-0302 = SNMPv3 user "{0}" updated successfully

PAM-CM-0303 = SNMPv3 Username "{0}" not found

PAM-CM-0304 = SNMPv3 user "{0}" deleted successfully

## **SSH Certificate Policy Messages**

- PAM-CM-1892=The SSH Certificate Policy ID is missing.
- PAM-CM-1893=The specified SSH Certificate Policy ID is invalid; it must be an integer greater than zero.
- PAM-CM-1894=The SSH Certificate Policy name is missing.
- PAM-CM-1895=The specified SSH Certificate Policy name is invalid; it must consist of characters [a-z, A-Z, 0-9].
- PAM-CM-1896=The specified SSH Certificate Policy name is too long; reduce the number of characters that it contains.
- PAM-CM-1897=The SSH Certificate Policy description is missing.
- PAM-CM-1898=The SSH Certificate Policy description is invalid; it must consist of characters [a-z, A-Z, 0-9].
- PAM-CM-1899=The SSH Certificate Policy description is too long; reduce the number of characters that it contains.
- PAM-CM-1900=The SSH Certificate Policy force command is too long; reduce the number of characters that it contains.
- PAM-CM-1901=The specified SSH Certificate Policy permit-x11-forwarding is invalid; it must be true or false.
- PAM-CM-1902=The specified SSH Certificate Policy permit-pty is invalid; it must be true or false.
- PAM-CM-1903=The specified SSH Certificate Policy permit-port-forwarding is invalid; it must be true or false.
- PAM-CM-1904=The specified SSH Certificate Policy permit-user-rc is invalid; it must be true or false.
- PAM-CM-1905= An SSH Certificate Policy ID or Name must be specified.
- PAM-CM-1906=Failed to load an SSH Certificate Policy having the specified ID or Name.
- PAM-CM-1907=Must specify either an SSH Certificate Policy ID or a Name but not both.
- PAM-CM-1908=Failed to add an SSH Certificate Policy having the specified ID or Name.
- PAM-CM-1909=The SSH Certificate Policy permit-x11-forwarding is missing.
- PAM-CM-1910=The SSH Certificate Policy permit-pty is missing.
- PAM-CM-1911=The SSH Certificate Policy permit-port-forwarding is missing.
- PAM-CM-1912=The SSH Certificate Policy permit-user-rc is missing.
- PAM-CM-1913=Cannot delete Default policy.
- PAM-CM-1914=Cannot update Default policy's name.

## **PAM-CMN: Common Messages**

Messages display a category in the second group of letters in the message. For example, PAM-CMN refers to Common errors. Common Messages is the largest category, so it is divided into smaller categories which are described individually in the topics in this section.

**Use the table of contents to access the common message category topics.**

### **Other Message Categories**

- CLNT = CA PAM Client
- CM = Credential Manager
- LDAP = LDAP Importer
- MGC = Management Console
- PRX = Proxy
- SPFD = Secure Port Forwarding Daemon
- SRM = Session Recording Manager
- UI = User Interface
- UPD = Session Clean-up and Storage Status Messages

## General Error Messages

PAM-CMN-0000 = Error occurred while trying to complete request. ({0})  
PAM-CMN-0001 = Expected an array {0}, got a scalar.  
PAM-CMN-0002 = Values {0} must be either 't' (true) or 'f' (false).  
PAM-CMN-0003 = Not authorized to perform this action.  
PAM-CMN-0004 = Unable to retrieve Privilege Manager.  
PAM-CMN-0005 = Privilege Manager unable to retrieve user.  
PAM-CMN-0006 = Cannot build Privilege Manager with data supplied.  
PAM-CMN-0007 = Invalid numeric data. {0}  
PAM-CMN-0008 = Invalid sort order  
PAM-CMN-0009 = Your login has timed out.  
PAM-CMN-0010 = Error occurred while trying to complete request.  
PAM-CMN-0011 = Invalid log database type {0}. Consult your system administrator  
PAM-CMN-0012 = Invalid search by field {0}  
PAM-CMN-0013 = No more rows.  
PAM-CMN-0014 = Same origin policy violation; possible cross-site request forgery.  
PAM-CMN-0015 = Too many rows to sort by. Use search criteria to narrow the result set and try again.  
PAM-CMN-0016 = All Devices  
PAM-CMN-0017 = All Users  
PAM-CMN-0018 = Duplicate entry  
PAM-CMN-0019 = Missing required field {0}  
PAM-CMN-0020 = Error occurred while trying to complete request. ({0})  
PAM-CMN-0021 = No data returned.  
PAM-CMN-0022 = SSH login to appliance from address {0}.

## Message Fragments Used by Other Messages

PAM-CMN-0023 = add  
PAM-CMN-0024 = update  
PAM-CMN-0025 = delete  
PAM-CMN-0026 = user groups  
PAM-CMN-0027 = device groups  
PAM-CMN-0028 = Connected  
PAM-CMN-0029 = Waiting  
PAM-CMN-0030 = Unknown  
PAM-CMN-0031 = Detection  
PAM-CMN-0032 = Intervention  
PAM-CMN-0033 = Tampering  
PAM-CMN-0034 = Password Authority Groups  
PAM-CMN-0035 = VMware provisioning request  
PAM-CMN-0036 = Activated  
PAM-CMN-0037 = Deactivated

## Network Service Messages

PAM-CMN-0038 = Service name is required.  
PAM-CMN-0039 = Local IP address is required.  
PAM-CMN-0040 = Invalid IP address specified.  
PAM-CMN-0041 = Protocol is required.  
PAM-CMN-0042 = Invalid protocol specified.  
PAM-CMN-0043 = Web Portal is required.  
PAM-CMN-0044 = Invalid Web Portal value specified.

PAM-CMN-0045 = Show in Column is required.  
PAM-CMN-0046 = Invalid Show in Column value specified.  
PAM-CMN-0047 = Enabled is required.  
PAM-CMN-0048 = Invalid Enabled value specified.  
PAM-CMN-0049 = Port settings are required.  
PAM-CMN-0050 = Invalid port setting(s) specified: {0}.  
PAM-CMN-0051 = Application protocol is required.  
PAM-CMN-0052 = Invalid application protocol value specified.  
PAM-CMN-0053 = Launch URL is required.  
PAM-CMN-0054 = Invalid launch URL specified.  
PAM-CMN-0055 = Invalid characters in comment.  
PAM-CMN-0056 = Invalid characters in service name. Semicolons, commas, percent signs, and backslashes are invalid.  
PAM-CMN-0057 = Existing service could not be found.  
PAM-CMN-0058 = Service {0} already exists.  
PAM-CMN-0059 = Service {0} created.  
PAM-CMN-0060 = Unable to delete service. Service does not exist.  
PAM-CMN-0061 = Service deleted.  
PAM-CMN-0062 = Service name cannot be changed.  
PAM-CMN-0063 = SSL VPN service must have at least 1 port defined.  
PAM-CMN-0064 = Invalid TCP ports value specified. Values must be valid TCP ports or TCP port ranges.  
PAM-CMN-0065 = Invalid UDP ports value specified. Values must be valid UDP ports or UDP port ranges.  
PAM-CMN-0066 = Service not found.  
PAM-CMN-0067 = Service {0} updated.  
PAM-CMN-0068 = Unrecognized service type.  
PAM-CMN-0069 = Invalid port range specified. {0} greater than {1}.  
PAM-CMN-0070 = Maximum number of ports in range, 500, exceeded for specified port range {0}. Consider using SSL VPN solution.  
PAM-CMN-0071 = Invalid port combination/redirection {0}. Combination/redirection format should be <Remote Port>:<Local Port>.  
PAM-CMN-0072 = Local IP must be on the 127 network.  
PAM-CMN-0073 = Web portal TCP/UDP services must have LeapFrog Prevention disabled.  
PAM-CMN-0074 = Web portal TCP/UDP services cannot have a client application.  
PAM-CMN-0075 = Launch path is required.  
PAM-CMN-0076 = Service not added.  
PAM-CMN-0077 = Database corruption - more than one service was inserted.  
PAM-CMN-0078 = Service {0} not found or another user deleted it.  
PAM-CMN-0079 = Database corruption - more than one service with the same id was deleted.  
PAM-CMN-0080 = {0} service(s) deleted  
PAM-CMN-0081 = {0} service(s) not deleted because not authorized.  
PAM-CMN-0082 = {0} service(s) not deleted because not found.  
PAM-CMN-0083 = {0} service(s) not deleted because of unknown error.  
PAM-CMN-0084 = {0} service(s) deleted {1} {2} {3}  
PAM-CMN-0085 = Only the Local IP, Port Settings, Enabled, Show in Column, Client Application, and Comments of the standard service sftpftp can be updated.  
PAM-CMN-0086 = Only the Local IP, Port Settings, Enabled, Show in Column, and Comments of the standard service sftpftpemb can be updated.  
PAM-CMN-0087 = Only the Local IP, Port Settings, Enabled, Show in Column, and Comments of the standard service TSWEB can be updated.  
PAM-CMN-0088 = Standard service sftpftp can not be deleted.  
PAM-CMN-0089 = Standard service sftpftpemb can not be deleted.  
PAM-CMN-0090 = Standard service TSWEB can not be deleted.  
PAM-CMN-0091 = Standard service sftpsftp can not be deleted.

PAM-CMN-0092 = Only the Local IP, Port Settings, Enabled, Show in Column, Client Application, and Comments of the standard service sftpsftp can be updated.

PAM-CMN-0093 = Local socket {0}:{1} of Web Portal {2} must be unique across all web portal services. Local socket already used by Web Portal {3}.

PAM-CMN-0094 = Standard service sftpsftpemb can not be deleted.

PAM-CMN-0095 = Only the Local IP, Port Settings, Enabled, Show in Column, and Comments of the standard service sftpsftpemb can be updated.

PAM-CMN-0096 = Invalid Hide Web Portal specified.

PAM-CMN-0097 = Hide Web Portal is required.

PAM-CMN-0098 = Both Show In Column and Hide Web Portal cannot be checked.

PAM-CMN-0099 = Maximum number of ports in range, 500, exceeded for the sum of all specified port ranges. Consider using SSL VPN solution.

PAM-CMN-0100 = A web application must have an application protocol of 'Web Portal'.

PAM-CMN-0101 = Invalid web portal browser type specified. Valid types are native and CA.

PAM-CMN-0102 = Invalid domain in web portal access list: {0}.

PAM-CMN-0103 = AWS Management Console SSO service can not be deleted.

PAM-CMN-0104 = AWS Management Console SSO is a reserved service name.

PAM-CMN-0105 = The only properties of the AWS Management Console SSO service that can be changed are enabled, show in column, and access list.

PAM-CMN-0106 = MS Office 365 is a reserved service name.

PAM-CMN-0107 = MS Office 365 service can not be deleted.

PAM-CMN-0108 = AWS Proxy Service is a reserved service name.

PAM-CMN-0109 = The properties of the AWS proxy service can not be changed.

PAM-CMN-0110 = The only properties of the MS Office 365 service that can be changed are enabled, show in column, and access list.

PAM-CMN-0111 = AWS Proxy service can not be deleted.

PAM-CMN-0112 = At least one SAML Subject Name Identifier Format must be selected for the SAML service.

PAM-CMN-0113 = SAML Entity ID is a required field.

PAM-CMN-0114 = SAML PEM Certificate is a required field.

PAM-CMN-0115 = The specified SAML {0} certificate is not a valid PEM encoded certificate.

PAM-CMN-0116 = The SAML encryption type is a required field.

PAM-CMN-0117 = The SAML initiating party field is invalid: Valid values are sp or idp.

PAM-CMN-0118 = Invalid SAML encryption type. Valid values are: None,Nameld,Assertion.

PAM-CMN-0119 = A SAML service with an entity ID of {0} already exists. SAML entity IDs must be unique.

PAM-CMN-0120 = An error occurred while parsing the SAML metadata file: {0}

PAM-CMN-0121 = {0} service cannot not be deleted.

PAM-CMN-0122 = Invalid SAML require signed authentication request value specified. Valid values are: t, f.

PAM-CMN-0123 = The SAML encryption certificate is required if Nameld or Assertion encryption is enabled.

PAM-CMN-0124 = The SAML signing certificate is required if Require Signed Authn Requests is enabled.

PAM-CMN-0125 = There are no SAML 2.0 SPs defined with binding urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST (SAML 1.1 SPs are not supported).

PAM-CMN-0126 = CA PAM requires an AssertionConsumerService element with binding urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST.

PAM-CMN-0127 = SAML service {0} with entity ID {1} {2}.

PAM-CMN-0128 = The following device(s) were {0} to host the SAML assertion consumer services: {1}.

PAM-CMN-0129 = Device group {0} was provisioned with the provisioned assertion consumer devices as members. This will facilitate managing policy for all SAML devices.

PAM-CMN-0130 = SAML attribute with index {0} is missing the required name field.

PAM-CMN-0131 = SAML attribute with index {0} is missing the required friendly name field.

PAM-CMN-0132 = There are multiple SAML attributes with the same name: {0}. Names must be unique.

PAM-CMN-0133 = There are multiple SAML attributes with the same friendly name: {0}. Friendly names must be unique.

PAM-CMN-0134 = SAML attribute {0} can not be deleted. It is used in the following policies: {1}.

PAM-CMN-0135 = The following SAML Name Identifier Formats can not be deleted: {0}. They are used in the following policies: {1}.

PAM-CMN-0136 = The auto-login method of SAML services can not be changed.

PAM-CMN-0137 = Invalid web portal auto-login method specified.

PAM-CMN-0138 = SAML services with the Route Through CA PAM setting enabled require the browser type setting to be set to the CA Browser.

PAM-CMN-0139 = SAML services using the CA browser must be IdP initiated.

PAM-CMN-0140 = VMware NSX API Proxy Service is a reserved service name.

PAM-CMN-0141 = An auto-login method was provided, but only web portals can have auto-login methods.

PAM-CMN-0142 = This service is configured to be recorded and must use the CA browser type. The service is configured to be recorded in the following policies: {0}.

PAM-CMN-0143 = SAML service data is not valid

## User Management Messages

PAM-CMN-0144 = User id must be a positive integer.

PAM-CMN-0145 = User {0} not found.

PAM-CMN-0146 = The super user may not be deleted.

PAM-CMN-0147 = User {0} deleted.

PAM-CMN-0148 = User {0} not found or another user deleted them.

PAM-CMN-0149 = Database corruption - more than one user with the same id was deleted.

PAM-CMN-0150 = User or user group {0} already exists. Names must be unique.

PAM-CMN-0151 = User {0} added.

PAM-CMN-0152 = User {0} not added.

PAM-CMN-0153 = Database corruption - more than one user was inserted.

PAM-CMN-0154 = User {0} updated.

PAM-CMN-0155 = User {0} was not updated.

PAM-CMN-0156 = Database corruption - more than one user was updated.

PAM-CMN-0157 = Access time day string is 7 digits long; 1 = access permitted 0 = access forbidden.

PAM-CMN-0158 = AD Indirect Flag must be 0 or 1.

PAM-CMN-0159 = {0} time invalid.

PAM-CMN-0160 = From time must be earlier than To time.

PAM-CMN-0161 = Invalid characters in user name {0}. Semicolons, commas, percent signs, single and double quotes, and backslashes are invalid.

PAM-CMN-0162 = First name is a required field.

PAM-CMN-0163 = Last name is a required field.

PAM-CMN-0164 = Email is a required field.

PAM-CMN-0165 = Invalid email address.

PAM-CMN-0166 = Password is a required field.

PAM-CMN-0167 = Special characters quote, double quote, backslash, and percent are not allowed in the password.

PAM-CMN-0168 = Password length must be between {0} and {1} characters long.

PAM-CMN-0169 = Password must include both an alphabetic and a numeric character.

PAM-CMN-0170 = Password must include both upper and lower case alphabetic characters.

PAM-CMN-0171 = Password must include a special character ~!?'@#\$%^&\*()\_+=+;,,<>{}|/-.[].

PAM-CMN-0172 = Password must include at least two lowercase letters, two uppercase letters, two numbers and two special characters.

PAM-CMN-0173 = Authorization must be Local, RSA, PKI, RADIUS, or LDAP.

PAM-CMN-0174 = Password reset flag must be set on when creating a user.

PAM-CMN-0175 = Active flag must be true or false.

PAM-CMN-0176 = Database corruption - active flag not >= -1.

PAM-CMN-0177 = Expiration date must be in the future or not set.

PAM-CMN-0178 = Role structure passed in is incorrect - missing {0}.

PAM-CMN-0179 = User must belong to one of the following groups {0}.

PAM-CMN-0180 = Your role does not allow you to {0} this user without any groups.

PAM-CMN-0181 = You may only add users to the following groups {0}.

PAM-CMN-0182 = You may not delete this user. You may only remove group assignments from it.

PAM-CMN-0183 = {0} user(s) deleted.

PAM-CMN-0184 = {0} user(s) deleted, {1} user(s) not deleted.

PAM-CMN-0185 = User or group name may not be changed from {0}.

PAM-CMN-0186 = Virtual user flag must be 1 (true), or 0 (false).

PAM-CMN-0187 = Invalid access time passed in. Missing a required key field.

PAM-CMN-0188 = Malformed user group structure. See log for details.

PAM-CMN-0189 = Invalid provisioning type {0}.

PAM-CMN-0190 = User super may not have its roles changed.

PAM-CMN-0191 = Non-local users may not have passwords defined in CA PAM.

PAM-CMN-0192 = {0} users attempted, {1} users successfully added, {2} users not added.

PAM-CMN-0193 = Short name may only be used for users with provision type of LDAP or PKI.

PAM-CMN-0194 = Short name required for an LDAP provisioned user.

PAM-CMN-0195 = Provision type may not be changed.

PAM-CMN-0196 = Invalid user type.

PAM-CMN-0197 = Active flag is required.

PAM-CMN-0198 = PAP/CHAP must be specified for RADIUS authentication and only for RADIUS authentication.

PAM-CMN-0199 = Warning: Global administrators may not have limited access times - any such settings will be ignored.

PAM-CMN-0200 = {0} user(s) were requested to be enabled, {1} user(s) were actually enabled.

PAM-CMN-0201 = An invisible (shadow) user named {0} already exists. Please choose another name.

PAM-CMN-0202 = A user or group named {0} already exists. Please contact your system administrator.

PAM-CMN-0203 = {0} user(s) not deleted because not authorized.

PAM-CMN-0204 = {0} user(s) not deleted because not found.

PAM-CMN-0205 = {0} user(s) not deleted because of unknown error.

PAM-CMN-0206 = {0} user(s) deleted {1} {2} {3} {4} {5}

PAM-CMN-0207 = Can't specify the user as their own login contact. Use the Email Self on Login checkbox.

PAM-CMN-0208 = Login contact {0} not found.

PAM-CMN-0209 = Users provisioned from LDAP may not be deleted directly, only by deleting their LDAP group.

PAM-CMN-0210 = {0} LDAP users not deleted

PAM-CMN-0211 = User names, group names, and short names may not be the same.

PAM-CMN-0212 = Inconsistent provision and authentication types.

PAM-CMN-0213 = Inconsistent data - a source user cannot be provided on an update.

PAM-CMN-0214 = Invalid User Id provided for copy

PAM-CMN-0215 = Unauthorized attempt to retrieve the list of users.

PAM-CMN-0216 = Unauthorized attempt to add a user.

PAM-CMN-0217 = Unauthorized attempt to assign a user to a group.

PAM-CMN-0218 = Unauthorized attempt to retrieve user details.

PAM-CMN-0219 = Unauthorized attempt to delete user from group(s).

PAM-CMN-0220 = Unauthorized attempt to delete user.

PAM-CMN-0221 = Unauthorized attempt to update global administrator account.

PAM-CMN-0222 = Unauthorized attempt to update a user.

PAM-CMN-0223 = Unauthorized attempt to update user's properties.

PAM-CMN-0224 = Unauthorized attempt to reactivate user(s).

PAM-CMN-0225 = Invalid RDP user name {0}.

PAM-CMN-0226 = Mainframe Display Name entry has invalid characters. Allowed characters are (alpha, numeric, underscore)

PAM-CMN-0227 = Unauthorized attempt to view the effective policy of user {0}.

PAM-CMN-0228 = An LDAP provisioned user may not be added directly, only imported via LDAP.

PAM-CMN-0229 = LDAP-provisioned user {0}'s LDAP groups may not be changed except via LDAP import or refresh.

PAM-CMN-0230 = Shadow user {0}'s membership in RADIUS group {1} may not be changed.

PAM-CMN-0231 = A shadow user may not be added directly, only created via logon.

PAM-CMN-0232 = User {0} may not be added to RADIUS group {1}.

PAM-CMN-0233 = Duplicate Password Authority username {0}. User not added. Please contact your system administrator.

PAM-CMN-0234 = User add failed. Please contact your system administrator.

PAM-CMN-0235 = User is not allowed to manage the Password Authority group {0}.

PAM-CMN-0236 = Roles with the Manage Credential privilege must have at least one Password Authority group to manage.

PAM-CMN-0237 = Password Authority user group name {0} not found.

PAM-CMN-0238 = Super user cannot change Password Authority user groups.

PAM-CMN-0239 = User {0} cannot be deleted because of a Password Authority error.

PAM-CMN-0240 = Duplicate user principal name {0}. User cannot be {1}.

PAM-CMN-0241 = Devices provisioned from LDAP may not be deleted directly, only by deleting their LDAP group.

PAM-CMN-0242 = The user has been configured to manage a Password Authority group but does not have a role with sufficient privileges.

PAM-CMN-0243 = Maximum of {0} AWS API Proxy users licensed. Please remove that privilege from one or more users before proceeding to add this one.

PAM-CMN-0244 = API keys must be an array of arrays of individual API keys containing id, name, target account id, active status and set of roles.

PAM-CMN-0245 = Required API key array element client name not found.

PAM-CMN-0246 = Required API key array element target account id not found.

PAM-CMN-0247 = Required API key array element isActive not found.

PAM-CMN-0248 = Required API key array element roles not found.

PAM-CMN-0249 = API key array element roles must be an array.

PAM-CMN-0250 = API keys must be deleted before the rest of the user.

PAM-CMN-0251 = Existing API key {0} either does not belong to user {1} or does not exist at all.

PAM-CMN-0252 = Users with provision type {0} can not be added to LDAP groups: {1}.

PAM-CMN-0253 = The following user ids are not valid: {0}.

PAM-CMN-0254 = You cannot specify an API key id when creating a user.

PAM-CMN-0255 = Pap/Chap must be null if authentication type is not radius or tacacs.

PAM-CMN-0256 = A user may not be locally added to an LDAP provisioned group.

PAM-CMN-0257 = The following user fields may not be changed locally for an ldap user: activationDate, authType, description, email, expiration, firstName, lastName, password, phone, resetPasswordFlag.

PAM-CMN-0258 = A valid password is required. Empty passwords not allowed.

PAM-CMN-0259 = User not found.

PAM-CMN-0260 = Maximum length of email field is 60 characters.

PAM-CMN-0261 = The super user account's authentication method cannot be set to SAML.

PAM-CMN-0262 = A user may not have two API keys with the same name. Change the API keys so that only one is named {0}.

PAM-CMN-0263 = User with local authentication must have a password set.

PAM-CMN-0264 = Password has been already used. You have to enter a new password.

PAM-CMN-0265 = Invalid old password.

PAM-CMN-0266 = Password must be new

PAM-CMN-0267 = Special characters " ' % and are not allowed in the password

PAM-CMN-0268 = Password length must be "{0}" - "{1}" characters.

PAM-CMN-0269 = Must include both an alphabetic and numeric character.

PAM-CMN-0270 = Must include both upper and lower case alphabetic characters.

PAM-CMN-0271 = Must include a special character ~!?'@#\$%^&\*()\_+=+;,<.>{}|/[-[]

PAM-CMN-0272 = Password must include at least two lowercase letters, two uppercase letters, two numbers and two special characters.

PAM-CMN-0273 = User {0} must be associated with Password Authority user group {1}.

PAM-CMN-0274 = The old password you entered is not correct.

PAM-CMN-0275 = Password change failed. Unknown error.

PAM-CMN-0276 = User groups for a SAML JIT user can only be changed by SAML.

PAM-CMN-0277 = A {0} provisioned user must belong to at least one group.

PAM-CMN-0278 = A SAML JIT user such as {0} can only have their user groups changed by SAML.

PAM-CMN-0279 = A SAML JIT user like {0} may not be added directly, only loaded from an identity provider on login.

PAM-CMN-0280 = User {0} cannot be deleted because it is configured as the login contact for the following list of users: {1}.

PAM-CMN-0281 = {0} user(s) configured as login contact(s) not deleted

PAM-CMN-0282 = The user has been assigned a role which requires a password authority user group to be associated with it, but no such group was specified.

PAM-CMN-5405 = Unable to delete user, because it is configured for Forced Deactivation Alert.

PAM-CMN-5470="User deactivation reason set to others."

PAM-CMN-5471="User deactivation reason is cleared."

PAM-CMN-5472="User deactivation reason must be 0 (Others) or 1 (Inactivity)."

PAM-CMN-5473="Failed to update login history for user {1}."

PAM-CMN-5600="Invalid value specified for Disable Inactive After. The value for Disable Inactive After must be greater than the value for Remind Before Deactivation."

PAM-CMN-5601="Invalid value specified for Remind Before Deactivation. The value must be greater than zero."

PAM-CM-6001: {0} inactive user(s) have been auto deactivated for exceeding maximum allowable inactivity period of {1} day(s).

PAM-CM-6002: Deactivation reminder notification email has been sent to {0} inactive user(s).

PAM-CM-6003: Inactive users are deactivated on-demand.

PAM-CM-6004: Deactivation reminder notification emails have been sent on-demand.

PAM-CM-6005: Failed to deactivate inactive users on-demand.

PAM-CM-6006: Failed to send deactivation reminder notification emails on-demand.

PAM-CM-6007: Deactivation notification email has been sent to {0} deactivated user(s).

PAM-CM-6008: Failed to send deactivation notification email. Please check the email server configuration.

PAM-CM-6009: Failed to send deactivation reminder notification email. Please check the email server configuration.

PAM-CM-6010: Started the user deactivation reminder task.

PAM-CM-6011: No users were found that require a deactivation reminder.

PAM-CM-6012: Started the user deactivation task.

PAM-CM-6013: No users were found that require deactivation.

PAM-CM-6014: Failed to run the user deactivation task.

## Smart Button Group Messages

PAM-CMN-0283 = Smart button group name is required.

PAM-CMN-0284 = Invalid smart button group configuration file id specified.

PAM-CMN-0285 = Smart button group id required.

PAM-CMN-0286 = Invalid smart button group users specified.

PAM-CMN-0287 = Invalid smart button group id specified.

PAM-CMN-0288 = Invalid smart button group description specified.

PAM-CMN-0289 = A smart button group with name {0} already exists.

PAM-CMN-0290 = Invalid smart button group configuration file id specified.

PAM-CMN-0291 = Smart button group {0} not found.

PAM-CMN-1358 = Unexpected result from deleting smart button group

PAM-CMN-1456 = Successfully deleted selected Smart Button group {0}.

PAM-CMN-1551 = Unauthorized attempt to update smart button group {0} by {1}

PAM-CMN-1552 = Unauthorized attempt to add smart button group {0} by user {1}

PAM-CMN-1553 = Smart Button group {0} added.

PAM-CMN-1554 = Smart Button group {0} not added

PAM-CMN-1555 = Database corruption - more than one Smart Button group was added  
PAM-CMN-1556 = Unauthorized attempt to delete smart button group {0} by {1}  
PAM-CMN-1557 = Successfully deleted smart button group {0}  
PAM-CMN-1558 = Smart Button group {0} was not found and not deleted  
PAM-CMN-1559 = Unexpected result from deleting smart button group  
  
PAM-CMN-1590 = User {0} tried to retrieve the list of smart button groups without authorization  
  
PAM-CMN-2400 = Smart Button group {0} updated  
PAM-CMN-2401 = Database corruption - more than one Smart Button group was updated  
PAM-CMN-2402 = Smart Button group {0} updated, but users: {1} already belong to a smart button group

## User Group Management Messages

PAM-CMN-0292 = User group id must be a positive integer.  
PAM-CMN-0293 = User group not found.  
PAM-CMN-0294 = User group {0} deleted.  
PAM-CMN-0295 = User group {0} not found or another user deleted it.  
PAM-CMN-0296 = Database corruption - more than one user group with the same id was deleted.  
PAM-CMN-0297 = User group or user {0} already exists. Names must be unique.  
PAM-CMN-0298 = User group {0} added.  
PAM-CMN-0299 = User group {0} not inserted.  
PAM-CMN-0300 = Database corruption - more than one user group with the same id was inserted.  
PAM-CMN-0301 = User group {0} updated.  
PAM-CMN-0302 = User group {0} was not updated.  
PAM-CMN-0303 = Database corruption - more than one user group with the same id was updated.  
PAM-CMN-0304 = Invalid user group type.  
PAM-CMN-0305 = User group name may not be blank.  
PAM-CMN-0306 = {0} user group(s) deleted.  
PAM-CMN-0307 = {0} user group(s) deleted, {1} user group(s) not deleted.  
PAM-CMN-0308 = User group not deleted.  
PAM-CMN-0309 = {0} user group(s) not deleted because not authorized.  
PAM-CMN-0310 = {0} user group(s) not deleted because not found.  
PAM-CMN-0311 = {0} user group(s) not deleted because of unknown error.  
PAM-CMN-0312 = {0} user group(s) deleted. {1} {2} {3}  
PAM-CMN-0313 = Unspecified user group name.  
PAM-CMN-0314 = Locally provisioned user groups can not have an authentication type of RSA.  
PAM-CMN-0315 = Locally provisioned user groups can not have an authentication type of LDAP+RSA.  
PAM-CMN-0316 = Invalid network range. {0}  
PAM-CMN-0317 = Locally provisioned user groups can not have an authentication type of LDAP+RADIUS.  
PAM-CMN-0318 = The following user group ids are not valid: {0}.  
PAM-CMN-0319 = Auth type {0} not supported.  
PAM-CMN-0320 = User {0} not successfully added to user group. No other users added.  
PAM-CMN-0321 = The following user fields may not be changed locally for an LDAP user group: description, shortName.  
PAM-CMN-0322 = Group id is required for an update and must be an integer > 0.

## Device Management Messages

PAM-CMN-0323 = Power must be On, Off, or Unknown.  
PAM-CMN-0324 = Device {0} not found.  
PAM-CMN-0325 = Device task enabled must be On or Off.  
PAM-CMN-0326 = Device property terminal customization must be 0 or 1.

PAM-CMN-0327 = Device property endselect must be 0 or 1.  
PAM-CMN-0328 = Device console type must be KDM, PPP, or Serial.  
PAM-CMN-0329 = Device service enabled must be On or Off.  
PAM-CMN-0330 = Device {0} deleted.  
PAM-CMN-0331 = Device {0} not found or another user deleted them.  
PAM-CMN-0332 = Database corruption - more than one device with the same id was deleted.  
PAM-CMN-0333 = Device or device group name {0} already exists. Names must be unique.  
PAM-CMN-0334 = Device {0} added.  
PAM-CMN-0335 = Device {0} not added.  
PAM-CMN-0336 = Database corruption - more than one device with the same id was inserted.  
PAM-CMN-0337 = Device {0} updated.  
PAM-CMN-0338 = Device {0} was not updated due to Password Authority authorization errors.  
PAM-CMN-0339 = Database corruption - more than one device with the same id was updated.  
PAM-CMN-0340 = Device {0} power status updated.  
PAM-CMN-0341 = Device {0} power status was not updated.  
PAM-CMN-0342 = Database corruption - more than one device's power status was updated.  
PAM-CMN-0343 = {0} {1} {2} Failed.  
PAM-CMN-0344 = {0} {1} {2} Successful.  
PAM-CMN-0345 = Unknown power status of {0}: multiple power ports do not match.  
PAM-CMN-0346 = Unsuccessful checking power status of {0}.  
PAM-CMN-0347 = Special type device {0} already exists.  
PAM-CMN-0348 = Special type device not found.  
PAM-CMN-0349 = Special type device {0} not inserted.  
PAM-CMN-0350 = Database corruption - more than one special type device was inserted.  
PAM-CMN-0351 = Special type device {0} was not updated.  
PAM-CMN-0352 = Database corruption - more than one special type device was updated.  
PAM-CMN-0353 = Device group name is required.  
PAM-CMN-0354 = Device domain name is required.  
PAM-CMN-0355 = A device must belong to one of the following groups {0}.  
PAM-CMN-0356 = Your role does not allow you to {0} this device without any groups.  
PAM-CMN-0357 = You may only add or delete device membership from the following groups {0}.  
PAM-CMN-0358 = You may not delete this device, only remove group assignments from it.  
PAM-CMN-0359 = Device name may not be blank.  
PAM-CMN-0360 = {0} device(s) deleted.  
PAM-CMN-0361 = {0} device(s) deleted, {1} device(s) not deleted.  
PAM-CMN-0362 = Device special type must be specified.  
PAM-CMN-0363 = Invalid device special type specified.  
PAM-CMN-0364 = Operating System is a required field.  
PAM-CMN-0365 = Invalid operating system specified.  
PAM-CMN-0366 = Invalid device id(s) {0}.  
PAM-CMN-0367 = Device terminal data is required.  
PAM-CMN-0368 = Device terminal type is required.  
PAM-CMN-0369 = Device terminal type is invalid: {0}.  
PAM-CMN-0370 = Device terminal type was not added.  
PAM-CMN-0371 = Configuring device {0} as a {1} device will exceed the number of licensed {2} devices.  
PAM-CMN-0372 = Expect string must be specified for all expect/response pairs.  
PAM-CMN-0373 = User requires Device/Group Manager or Delegated Administrator role to add discovered devices to CA PAM.  
PAM-CMN-0374 = Device cannot have both sftpftp and sftpftplib services.  
PAM-CMN-0375 = {0} device(s) not deleted because not authorized.  
PAM-CMN-0376 = {0} device(s) not deleted because not found.  
PAM-CMN-0377 = {0} device(s) not deleted because of unknown error.  
PAM-CMN-0378 = {0} device(s) deleted {1} {2} {3}

PAM-CMN-0379 = Invalid characters in device name {0}. Semicolons, commas, apostrophes and backslashes are invalid.

PAM-CMN-0380 = Task {0} port setting, {1}, already in use on device.

PAM-CMN-0381 = Mainframe access methods are not permitted without a Mainframe-capable license.

PAM-CMN-0382 = Access method {0} has duplicate name {1}.

PAM-CMN-0383 = Multiple access methods of type {0} must have different names.

PAM-CMN-0384 = Device cannot have both sftpsftp and sftpsftpemb services.

PAM-CMN-0385 = A custom name for a device task may not have colons, semicolons, commas, or backslashes.

PAM-CMN-0386 = Device cannot have both telnet and ssh2telnet access methods.

PAM-CMN-0387 = Invalid tag format

PAM-CMN-0388 = Tag {0} can not be deleted

PAM-CMN-0389 = {0} Tags deleted out of {1} requested

PAM-CMN-0390 = Tag {0} was NOT renamed to {1}

PAM-CMN-0391 = Maximum number of ports in range, 500, exceeded for specified port range {0}.

PAM-CMN-0392 = Port {0} out of range. Must be less than {1}.

PAM-CMN-0393 = Port {0} out of range. Must be greater than {1}.

PAM-CMN-0394 = No access is currently permitted because this CA PAM appliance is over-provisioned. Please contact your systems administrator.

PAM-CMN-0395 = This CA Privileged Access Manager appliance currently has more Devices defined than the configured license permits. Please either obtain a new license from Broadcom support or delete devices to bring this appliance back within its license constraints. Access is disabled until this is remediated.

PAM-CMN-0396 = Each power task must have a unique combination of power device and port.

PAM-CMN-0397 = Maximum number of ports in range, 500, exceeded for all specified port ranges.

PAM-CMN-0398 = Invalid value for device type Access.

PAM-CMN-0399 = Invalid value for device type Password Management.

PAM-CMN-0400 = Invalid value for device type A2A.

PAM-CMN-0401 = Request server type must be CLIENT or AGENT.

PAM-CMN-0402 = Invalid value for host name preserved.

PAM-CMN-0403 = Invalid value for autopatch.

PAM-CMN-0404 = Invalid value for request server active flag.

PAM-CMN-0405 = Invalid value for device type search.

PAM-CMN-0406 = Invalid value for request server id.

PAM-CMN-0407 = Request server id required for autoregistration.

PAM-CMN-0408 = Can't assign request server id to a device that is not a request server.

PAM-CMN-0409 = Operation aborted because Password Authority request server cannot be deleted. See log for details.

PAM-CMN-0410 = Operation aborted because Password Authority target server cannot be deleted. See log for details.

PAM-CMN-0411 = Device {0} not deleted because of Password Authority errors.

PAM-CMN-0412 = Device Import cannot add virtual devices only update them. Device Name = {0}.

PAM-CMN-0413 = Failed to connect to {0}.

PAM-CMN-0414 = Invalid definition of virtual device {0}.

PAM-CMN-0415 = Physical device {0} may not have an alternate id.

PAM-CMN-0416 = Virtual device not available.

PAM-CMN-0417 = Target Application {0} was not added or updated due to Password Authority authorization errors.

PAM-CMN-0418 = Device group must have a provision type.

PAM-CMN-0419 = A device group's provision type may not be changed. Delete and recreate the group.

PAM-CMN-0420 = {0} device refresh failed due to error. See log for details.

PAM-CMN-0421 = Target server {0} not found.

PAM-CMN-0422 = Request server not found.

PAM-CMN-0423 = Special device {0} may not be changed.

PAM-CMN-0424 = Connection error - is DNS working? See log for details.

PAM-CMN-0425 = A target server with the address {0} already exists. Target server {1} not added.

PAM-CMN-0426 = A request server with the address {0} already exists. Request server {1} not added.

PAM-CMN-0427 = Invalid device type (access, password, a2a) specified.

PAM-CMN-0428 = {0} provisioning already in progress. Please wait.

PAM-CMN-0429 = Terminal type VT100 is not compatible with TN5250 or TN5250SSL access methods.

PAM-CMN-0430 = Device import cannot add VMware device groups only update them. Group name = {0}.

PAM-CMN-0431 = Could not reassign user to PA user.

PAM-CMN-0432 = General error with password checkin. See log for details.

PAM-CMN-0433 = {0} is a reserved {1} name. Please use another name.

PAM-CMN-0434 = {0} is a reserved device address. Please use another address.

PAM-CMN-0435 = Device may not have applets if not of typeAccess.

PAM-CMN-0436 = Device may not have services if not of typeAccess.

PAM-CMN-0437 = Target server fields may not be defined if device is not of typePassword.

PAM-CMN-0438 = Request server fields may not be defined if device is not of typeA2A.

PAM-CMN-0439 = Device import cannot add VMware Device Groups, it may only update them (Group name = {0}).

PAM-CMN-0440 = Configuring device {0} as a {1} device will exceed the number of licensed {2} devices. Device added without the type.

PAM-CMN-0441 = Internal error occurred while updating the runtime status of a device.

PAM-CMN-0442 = Service AWS Management Console SSO can not be added to a device.

PAM-CMN-0443 = {0} VMware devices were not deleted. See logs for details. VMware credentials are kept but the configuration is now inactive.

PAM-CMN-0444 = {0} AWS devices were not deleted. See logs for details. AWS credentials are kept but the configuration is now inactive.

PAM-CMN-0445 = AWS region code may not be changed on update. Delete this row and enter a new one.

PAM-CMN-0446 = AWS region code required.

PAM-CMN-0447 = Invalid AWS region code {0}.

PAM-CMN-0448 = This AWS access key and region are already provisioned.

PAM-CMN-0449 = The access key id must reference an actual Access Key target account.

PAM-CMN-0450 = The active checkbox must have a value of t or f.

PAM-CMN-0451 = Target application {0} from device {1} was not deleted.

PAM-CMN-0452 = Target application {0} was deleted from device {1}.

PAM-CMN-0453 = Service AWS API Proxy can not be added to a device.

PAM-CMN-0454 = Target group {0} not added to Password Authority. Error Message: {1}.

PAM-CMN-0455 = Unable to delete target group {0} from Password Authority. Error Message: {1}.

PAM-CMN-0456 = Request group {0} not added to Password Authority. Error Message: {1}.

PAM-CMN-0457 = Unable to delete request group {0} from Password Authority. Error Message: {1}.

PAM-CMN-0458 = AWS Proxy client authorization mapping failed. Error Message: {0}.

PAM-CMN-0459 = Deleting the AWS Proxy client authorization mapping failed. Error Message: {0}.

PAM-CMN-0460 = AWS Access key not found.

PAM-CMN-0461 = No such credential source as {0}. Device group {1} was added without it.

PAM-CMN-0462 = No such credential source as {0}. Device group {1} was updated, but the old credential was left in place.

PAM-CMN-0463 = Invalid value for password push flag.

PAM-CMN-0464 = {0} device group membership may not be changed locally. The {1} device groups were restored.

PAM-CMN-0465 = A target server with the device name {0} already exists. Target server not added.

PAM-CMN-0466 = A request server with the device name {0} already exists. Request server not added.

PAM-CMN-0467 = A Password Authority problem prevented completing the request. Message: {0} Check log for details.

PAM-CMN-0468 = The tag "{0}" has a length greater than {1}

PAM-CMN-0469 = Command {0} not supported for transparent login. Only the commands {1} are supported.

PAM-CMN-0470 = Password prompt for {0} command may not contain equals sign or semi-colon.

PAM-CMN-0471 = Password prompt is required for transparent login.

PAM-CMN-0472 = Full path must begin with a forward slash (/).

PAM-CMN-0473 = Must specify both full path and prompt or neither.

PAM-CMN-0474 = The same user may not be assigned twice to the same vCenter for provisioning.

PAM-CMN-0475 = Target account id is required for update of target account {0}.

PAM-CMN-0476 = Either the hostname and the target application application name, or the target application id is required to add the target account {0}.

PAM-CMN-0477 = Target account id and user name are both required to update a target account.

PAM-CMN-0478 = VMware URL most commonly should be in the form https://<domain>[:port]/sdk. Please enter a URL.

PAM-CMN-0479 = Provision id required.

PAM-CMN-0480 = Only the url or the active status may be changed, and one of them must be changed on an update.

PAM-CMN-0481 = Device must be at least of type Access, Password, or A2A.

PAM-CMN-0482 = Invalid device group ids specified. The array must contain only numeric ids.

PAM-CMN-0483 = The following ids are not ids of existing device groups: {0}.

PAM-CMN-0484 = Invalid device service ids specified. The array must contain only numeric ids.

PAM-CMN-0485 = The following ids are not ids of valid TCP/UDP or RDP application services: {0}.

PAM-CMN-0486 = Invalid device VPN service ids specified. The array must contain only numeric ids.

PAM-CMN-0487 = The following ids are not ids of valid VPN services: {0}.

PAM-CMN-0488 = The following ids are not ids of valid TCP/UDP services: {0}.

PAM-CMN-0489 = The following ids are not ids of valid RDP application services: {0}.

PAM-CMN-0490 = Invalid device credential source ids specified. The array must contain only numeric ids.

PAM-CMN-0491 = The following ids are not ids of valid password devices: {0}.

PAM-CMN-0492 = Invalid device group service ids specified. The array must contain only numeric ids.

PAM-CMN-0493 = Invalid device group VPN service ids specified. The array must contain only numeric ids.

PAM-CMN-0494 = Invalid device ids specified. The array must contain only numeric ids.

PAM-CMN-0495 = The following ids are not ids of existing devices: {0}.

PAM-CMN-0496 = Target application {0} was not found.

PAM-CMN-0497 = X11 Forwarding can only be applied to the SSH applet.

PAM-CMN-0498 = Only X11 Forwarding (x11forwarding) is a valid task property.

PAM-CMN-0499 = A virtual device may not be added via local means.

PAM-CMN-0500 = Device name and domain name of a virtual device may not be changed via local means.

PAM-CMN-0501 = Virtual device {0} may not be deleted via local means.

PAM-CMN-0502 = Special device {0} may not be deleted.

PAM-CMN-0503 = Device was not found.

PAM-CMN-0504 = The specified device is not a password type device.

PAM-CMN-0505 = A target application with the specified id was not found or does not belong to the specified device.

PAM-CMN-0506 = Target account not found.

PAM-CMN-0507 = Device was not found or was not a target server.

PAM-CMN-0508 = Target application does not belong to device.

PAM-CMN-0509 = A target application with the same name already exists for the device.

PAM-CMN-0510 = Invalid target application type specified. Valid types are: Generic, UnixII.

PAM-CMN-0511 = Error occurred provisioning the target account.

PAM-CMN-0512 = A target account with the specified id was not found or does not belong to the specified device or target application.

PAM-CMN-0513 = Error occurred updating the target account.

PAM-CMN-0514 = Tags must be an array of tag names.

PAM-CMN-0515 = The device already has the following {0} services: {1}.

PAM-CMN-0516 = Tag id must be an integer.

PAM-CMN-0517 = Transparent login parameters must be in the form command;prompt|command;prompt. Semicolon, comma, and pipe may not be used as part of the command or the prompt.

PAM-CMN-0518 = Invalid transparent login type.

PAM-CMN-0519 = Transparent login type and parameters out of sync.

PAM-CMN-0520 = Secondary SSO must be defined as <Device Name>|<TargetApplication Name>|<TargetAccount user name>.

PAM-CMN-0521 = Failed to assign '{0}' tag to device. '{1}' tag prefix is reserved for vSphere NSX Security {2}.

PAM-CMN-0522 = Service VMware NSX API Proxy can not be added to a device.

PAM-CMN-0523 = NSX Proxy is a reserved {0} name. Please use another name.

PAM-CMN-0524 = [ca.nsx.vmware.com](https://ca.nsx.vmware.com) is a reserved device address. Please use another address.

PAM-CMN-0525 = Tags may not be defined on non-local groups.

PAM-CMN-0526 = Invalid value for Override Address.

PAM-CMN-0527 = Cannot delete Password Management device {0} because it is configured as a VMware vCenter device for CA PAM.

PAM-CMN-0528 = Command string {0} begins with a forward slash (/), which is not allowed in transparent login command strings.

PAM-CMN-0529 = Invalid value for Handle Legal Notice flag.

PAM-CMN-0530 = Cannot get name for a target or request group if no group ID is supplied.

PAM-CMN-0531 = Device {0} had missing terminal data; default terminal data has been assigned.

PAM-CMN-0532 = Device name {0} was successfully managed.

PAM-CMN-0533 = {0} device(s) not deleted because they are in use.

PAM-CMN-0534 = Device Manager user couldn't delete device {0} because it is a Password Management or A2A device and the user lacks privileges to delete those types of device.

PAM-CMN-0535 = Device Manager user couldn't change name of device {0} because it is a Password Management or A2A device and the user lacks privileges to rename those types of device.

PAM-CMN-0536 = Device Manager user couldn't change domain name of device {0} because it is a Password Management or A2A device and the user lacks privileges to change domain names for those types of device.

PAM-CMN-0537 = Role was not found.

## Role and Privilege Messages

PAM-CMN-0538 = Update of role {0} failed. No matching id.

PAM-CMN-0539 = Role requested to be assigned a non-existent privilege.

PAM-CMN-0540 = Role id must be an integer, not {0}.

PAM-CMN-0541 = Default roles may not be deleted or updated.

PAM-CMN-0542 = Role not found to {0}.

PAM-CMN-0543 = Role not deleted because there are still users assigned to it.

PAM-CMN-0544 = Role id required when updating a role.

PAM-CMN-0545 = Role id already assigned at start of add. Role was not added.

PAM-CMN-0546 = Duplicate role name {0}.

PAM-CMN-0547 = Create role failed for role {0}.

PAM-CMN-0548 = Role name may not be changed.

PAM-CMN-0549 = Role {0} missing required {1}.

PAM-CMN-0550 = Role {0} with these groups may not be added to a user by this user.

PAM-CMN-0551 = Role {0} may not have its {1} changed by this user.

PAM-CMN-0552 = The Autodiscovery role requires Device/Group Manager role or the Delegated Administrator Role as well.

PAM-CMN-0553 = A role must contain at least one privilege.

PAM-CMN-0554 = Due to role restrictions, group {0} may not be added to a user except by a Global Administrator.

PAM-CMN-0555 = Roles containing the AWS API Proxy privilege may not be added to groups.

PAM-CMN-0556 = Role with id {0} not found.

PAM-CMN-0557 = The following user groups for role {0} do not exist: {1}.

PAM-CMN-0558 = The following device groups for role {0} do not exist: {1}.

PAM-CMN-0559 = The API key {0} for user {1} has privileges the user does not. The API key will be disabled until this is fixed.

## Device Group Management Messages

PAM-CMN-0560 = Device group name is required.

PAM-CMN-0561 = Invalid device group name specified.

PAM-CMN-0562 = Invalid device group description specified.

PAM-CMN-0563 = Invalid device group id specified.

PAM-CMN-0564 = Device group name {0} already exists.

PAM-CMN-0565 = Device group with name {0} not found.  
PAM-CMN-0566 = Device group with id {0} not found.  
PAM-CMN-0567 = {0} field must be an array.  
PAM-CMN-0568 = Device group {0} not inserted.  
PAM-CMN-0569 = Database corruption - more than one device group with the same id was inserted.  
PAM-CMN-0570 = Device group {0} not updated.  
PAM-CMN-0571 = Database corruption - more than one device group with the same id was updated.  
PAM-CMN-0572 = Device group {0} not deleted.  
PAM-CMN-0573 = Database corruption - more than one device group with the same id was deleted.  
PAM-CMN-0574 = {0} device group(s) deleted.  
PAM-CMN-0575 = {0} device group(s) deleted, {1} user group(s) not deleted.  
PAM-CMN-0576 = Device group cannot have both sftpftp and sftpftpemb services.  
PAM-CMN-0577 = {0} device group(s) not deleted because not authorized.  
PAM-CMN-0578 = {0} device group(s) not deleted because not found.  
PAM-CMN-0579 = {0} device group(s) not deleted because of unknown error.  
PAM-CMN-0580 = {0} device group(s) deleted. {0} {1} {2}  
PAM-CMN-0581 = Device group cannot have both sftpsftp and sftpsftpemb services.  
PAM-CMN-0582 = A device group with a network address cannot have services or access methods defined.  
PAM-CMN-0583 = Invalid network address {0}.  
PAM-CMN-0584 = The following device groups do not exist: {0}.  
PAM-CMN-0585 = VMware device group {0} may not be deleted locally.  
PAM-CMN-0586 = Device group not found.  
PAM-CMN-0587 = The device group already has the following access methods: {0}.  
PAM-CMN-0588 = The device group already has the following {0} services: {1}.  
PAM-CMN-0589 = The specified access method id does not belong to the device group or is invalid.  
PAM-CMN-0590 = The specified service id does not belong to the device group or is invalid.  
PAM-CMN-0591 = The specified VPN service id does not belong to the device group or is invalid.

## Global Settings and Device Task Messages

PAM-CMN-0592 = Task name or id is required.  
PAM-CMN-0593 = Invalid task port specified.  
PAM-CMN-0594 = Task enabled is required.  
PAM-CMN-0595 = Invalid task enabled specified.  
PAM-CMN-0596 = Invalid task id specified.  
PAM-CMN-0597 = Task not found.  
PAM-CMN-0598 = Invalid task name specified.  
PAM-CMN-0599 = Device group contains invalid task name(s): {0}.  
PAM-CMN-0600 = Device group contains invalid service name(s): {0}.  
PAM-CMN-0601 = Device group contains invalid SSL VPN service name(s): {0}.  
PAM-CMN-0602 = Device group contains invalid device name(s): {0}.  
PAM-CMN-0603 = Device group cannot contain other device groups: {0}.  
PAM-CMN-0604 = Access method may not be defined twice on the same device.  
PAM-CMN-0605 = Invalid access method type(s) {0}.

## LDAP Messages

PAM-CMN-0606 = LDAP entry must be of type UserGroupType to retrieve group users.

PAM-CMN-0607 = LDAP user group does not contain any users.

PAM-CMN-0608 = LDAP connection failure: {0}.

PAM-CMN-0609 = LDAP bind failure: {0}.

PAM-CMN-0610 = LDAP query failure: {0}.

PAM-CMN-0611 = Starting point for browsing LDAP directory is not under configured browse points.

PAM-CMN-0612 = LDAP domain not found.

PAM-CMN-0613 = LDAP update in progress, please try again later.

PAM-CMN-0614 = LDAP Group {0} imported into CA PAM. {1} Users Processed: {2} New Users, {3} Updated Users, {4} Deleted Users, {5} Failed New Users, {6} Failed Updated Users, {7} Failed Deleted Users.

PAM-CMN-0615 = LDAP import failed: {0}

PAM-CMN-0616 = {0} LDAP group(s) completed with errors. Please check the audit log on the cluster master for more details.

PAM-CMN-0617 = There are no imported LDAP groups to refresh.

PAM-CMN-0618 = Warning: user {0} from LDAP group {1} has same short name, {2}, as user {3} from LDAP group {4}. RADIUS authentication process will not be able to differentiate between the two users. Both user accounts will be deactivated.

PAM-CMN-0619 = Unauthorized attempt to retrieve the configuration for LDAP domains.

PAM-CMN-0620 = Connection failed to LDAP domain {0} using server {1}. Failing over to the next configured LDAP server.

PAM-CMN-0621 = Import Warning For LDAP Group {0}: {1}

PAM-CMN-0622 = Import Error For LDAP Group {0}: {1}

PAM-CMN-0623 = Invalid LDAP group(s) specified: {0}.

PAM-CMN-0624 = LDAP Group {0} imported into CA PAM. {1} Devices Processed: {2} New Devices, {3} Updated Devices, {4} Deleted Devices, {5} Failed New Devices, {6} Failed Updated Devices, {7} Failed Deleted Devices.

PAM-CMN-0625 = Adding LDAP group {0} aborted. The LDAP group and all its registered members will be deleted.

PAM-CMN-0626 = STARTTLS LDAP connection made to {0}.

PAM-CMN-0627 = LDAP connection made to {0}.

PAM-CMN-0628 = An LDAP operation is in progress.

PAM-CMN-0629 = LDAPS connection made to {0}.

PAM-CMN-0630 = LDAP is configured but the appliance is unlicensed. License the appliance before launching the LDAP browser.

PAM-CMN-1932 = "Invalid LDAP Domain Id {0}"

PAM-CMN-5405 = "Unable to delete user, because it is configured for Forced Deactivation Alert."

## CSV Import/Export Related Messages

PAM-CMN-0631 = Invalid file type of {0}. Import supports only CSV files of types: {1}.

PAM-CMN-0632 = Import file cannot be found.

PAM-CMN-0633 = Invalid CSV row type {0} on line {1}.

PAM-CMN-0634 = Error importing user on line {0}:

PAM-CMN-0635 = User group {0} does not exist.

PAM-CMN-0636 = Role {0}, does not exist: {1}.

PAM-CMN-0637 = Role user group, {0}, does not exist: {1}.

PAM-CMN-0638 = Role device group, {0}, does not exist: {1}.

PAM-CMN-0639 = Invalid import file. CSV headers are missing.

PAM-CMN-0640 = Unrecognized CSV header: {0}.

PAM-CMN-0641 = Number of CSV data fields ({0}) does not match CSV header count ({1}) on line {2}.

PAM-CMN-0642 = First CSV header must be Type.

PAM-CMN-0643 = User created successfully.

PAM-CMN-0644 = User updated successfully.

PAM-CMN-0645 = User Group created successfully.

PAM-CMN-0646 = User Group updated successfully.

PAM-CMN-0647 = Error occurred during import.

PAM-CMN-0648 = Device Group {0} does not exist.

PAM-CMN-0649 = Device created successfully.

PAM-CMN-0650 = Device updated successfully.

PAM-CMN-0651 = Device Group created successfully.

PAM-CMN-0652 = Device Group updated successfully.

PAM-CMN-0653 = Invalid task name specified: {0}.

PAM-CMN-0654 = Console device {0} does not exist.

PAM-CMN-0655 = Power device {0} does not exist: {1}.

PAM-CMN-0656 = Device access method types do not exist: {0}.

PAM-CMN-0657 = Device services do not exist: {0}.

PAM-CMN-0658 = TCP/UDP services with both TCP and UDP ports defined must have the same port value(s).

PAM-CMN-0659 = Service created successfully.

PAM-CMN-0660 = Service updated successfully.

PAM-CMN-0661 = Invalid role privileges: {0}.

PAM-CMN-0662 = Role created successfully.

PAM-CMN-0663 = Role updated successfully.

PAM-CMN-0664 = Policy created successfully.

PAM-CMN-0665 = Policy updated successfully.

PAM-CMN-0666 = Device {0} does not have access method {1}.

PAM-CMN-0667 = Device {0} does not have access method {1}, with name {2}.

PAM-CMN-0668 = Device {0} does not have service {1}.

PAM-CMN-0669 = Device {0} does not have VPN service {1}.

PAM-CMN-0670 = Invalid {0} value. Valid values are: t, f.

PAM-CMN-0671 = Socket filter list entry created successfully.

PAM-CMN-0672 = Socket filter list entry updated successfully.

PAM-CMN-0673 = Command filter list entry created successfully.

PAM-CMN-0674 = Command filter list entry updated successfully.

PAM-CMN-0675 = Import failed: CSV file not specified.

PAM-CMN-0676 = Device {0} does not have target application {1}.

PAM-CMN-0677 = Device {0} does not have target account {1}.

PAM-CMN-0678 = Target account {0} does not have the correct id.

PAM-CMN-0679 = Socket filter list entry already exists and therefore will not be added.

PAM-CMN-0680 = Import failed: SAML metadata file not specified.

PAM-CMN-0681 = The policy for the specified SAML Service Policy doesn't exist. Provision the policy before importing the SAML Service.

PAM-CMN-0682 = The SAML service {0} doesn't exist.

PAM-CMN-0683 = The specified SAML service has not been assigned to the device.

PAM-CMN-0684 = CSV import of type {0} initiated.

PAM-CMN-0685 = Device Group {0} does not have credential source {1}.

## Office365 Integration Messages, SAML IdP and SP Messages

PAM-CMN-0686 = Default default contact user {0} does not exist.

PAM-CMN-0687 = Invalid default contact method {0} specified.

PAM-CMN-0688 = Device monitor protocol required.

PAM-CMN-0689 = Device monitor port required for protocol {0}.

PAM-CMN-0690 = Device monitor contact required for protocol {0}.

PAM-CMN-0691 = Device monitor contact method required for protocol {0}.

PAM-CMN-0692 = Invalid device monitor protocol specified.

PAM-CMN-0693 = Invalid device monitor port {0} specified for protocol {1}.

PAM-CMN-0694 = Invalid device contact method specified for protocol {0}.

PAM-CMN-0695 = Device monitor contact {0} does not exist.

PAM-CMN-0696 = Maximum buffer size is 8192.

PAM-CMN-0697 = Invalid web session recording quality specified. Valid values are high and low.

PAM-CMN-0698 = Unauthorized attempt to delete policies associated with the Office365 service.

PAM-CMN-0699 = Calculating the certificate fingerprint for IdP {0} failed. The IdP configuration will not be saved.

PAM-CMN-0700 = The SAML SP's {0} is a required field. Please enter a valid value.

PAM-CMN-0701 = The SAML SP's Fully Qualified Hostname is not a valid hostname.

PAM-CMN-0702 = The {0} of Identity Provider {1} is a required field. Please enter a valid value.

PAM-CMN-0703 = Invalid Identity Provider SSO binding specified for Identity Provider {0}. Valid values are: {1}.

PAM-CMN-0704 = The Single Sign On Service URL for Identity Provider {0} is not a valid HTTP URL.

PAM-CMN-0705 = The specified {0} of Identity Provider {1} is invalid. Valid values are: true or false.

PAM-CMN-0706 = The specified certificate for Identity Provider {0} is not a valid PEM certificate.

PAM-CMN-0707 = Invalid Signature Algorithm specified for Identity Provider {0}. Valid values are: {1}.

PAM-CMN-0708 = Invalid Name ID Formats specified for Identity Provider {0}. Valid values are: {1}.

PAM-CMN-0709 = Invalid Authentication Contexts specified for Identity Provider {0}. Valid values are: {1}.

PAM-CMN-0710 = Identity Provider entity IDs must be unique. There are multiple identity providers with the following entity ID(s): {0}.

PAM-CMN-0711 = Invalid SAML version specified for Identity Provider {0}. Valid values are: 1.1, 2.0

PAM-CMN-0712 = CA PAM as SAML SP configuration updated.

PAM-CMN-0713 = Identity Provider friendly names must be unique. There are multiple identity providers with the following friendly name(s): {0}.

PAM-CMN-0714 = Invalid vulnerability reporting level specified. Valid values are 'Log' or 'Log And Warn'.

PAM-CMN-0715 = Invalid vulnerability enabled specified.

PAM-CMN-0716 = The following required fields in the SAML SP configuration must be specified before the configuration can be saved or an IdP can be configured: Entity ID, Fully Qualified Hostname, Certificate Key Pair.

PAM-CMN-0717 = The required field, 'Fully Qualified Hostname', in the SAML configuration on cluster member {0} has not been defined. Please specify a value for the field before downloading metadata.

PAM-CMN-0718 = SAML SP metadata for remote IdP {0} downloaded.

PAM-CMN-0719 = An attempt was made to access the SAML IdP Proxy service when CA PAM is not deployed in a cluster.

PAM-CMN-0720 = An error occurred while completing this request. Please contact your administrator for further assistance.

PAM-CMN-0721 = An attempt was made to access the SAML IdP Proxy service on this node but this node is not the cluster master.

PAM-CMN-0722 = The following remote IdP(s) have been deleted: {0}.

PAM-CMN-0723 = The following remote IdP(s) have been added: {0}.

PAM-CMN-0724 = The id of identity provider {0} is not a valid id: {1}.

PAM-CMN-0725 = Invalid value specified ({0}). Integer expected.

PAM-CMN-0726 = Invalid value specified for SAML Accept RSA-SHA1 Signed Responses. Valid values are: t,f.

PAM-CMN-0727 = Invalid value specified for Client Distribution Intranet URL. Only domain names and IP addresses are allowed.

PAM-CMN-0728 = Invalid port specified for Client Distribution Intranet URL.

PAM-CMN-1818 = No user name supplied for Office 365.

PAM-CMN-1921 = Updated Microsoft Office 365 configuration

PAM-CMN-1922 = Cleared Microsoft Office 365 configuration

PAM-CMN-1923 = Office 365 configuration test: Connected successfully to the supplied URLs

PAM-CMN-1924 = Office 365 configuration test: Error connecting to the supplied URLs

PAM-CMN-2346 = Updated Microsoft Office 365 configuration

PAM-CMN-2347 = Cleared Microsoft Office 365 configuration

PAM-CMN-2348 = Office 365 configuration test: Connected successfully to the supplied URLs

PAM-CMN-2349 = Office 365 configuration test: Error connecting to the supplied URLs

## Policy Management Messages

PAM-CMN-0729 = Unexpected from location for policy request of {0}.

PAM-CMN-0730 = Invalid service specified in policy.

PAM-CMN-0731 = Invalid task specified in policy.

PAM-CMN-0732 = Invalid socket filter specified in policy.

PAM-CMN-0733 = Invalid command filter specified in policy.

PAM-CMN-0734 = Invalid CLI session recording flag in policy.

PAM-CMN-0735 = Invalid graphical session recording flag in policy.

PAM-CMN-0736 = Invalid bidirectional flag in policy.

PAM-CMN-0737 = Invalid VPN service specified in policy.

PAM-CMN-0738 = Invalid restrict login if agent is not running value. Valid values are: t, f.

PAM-CMN-0739 = AWS Policy can be specified only for AWS service.

PAM-CMN-0740 = Unable to display credentials. See log for details.

PAM-CMN-0741 = Web portal recording can only be enabled for policies that contain a web portal services utilizing the CA browser. Please set the browser type property of the service to CA.

PAM-CMN-0742 = Policies involving [ca.aws.amazon.com](https://ca.aws.amazon.com) may not be imported or exported via csv.

PAM-CMN-0743 = Attempt to add a target account {0} to a policy that does not have access to it.

PAM-CMN-0744 = There is credentials conflict in Transparent Login Window with title '{0}' ('{1}' and '{2}' RDP Applications).

PAM-CMN-0745 = The policy data structure specified is invalid. {0}.

PAM-CMN-0746 = The policy's device does not offer any access methods for policy. Please add access methods to the device first.

PAM-CMN-0747 = The policy's device does not offer device access methods with the following id(s): {0}.

PAM-CMN-0748 = The policy's device does not offer any TCP/UDP nor RDP application services for policy. Please add services to the device first.

PAM-CMN-0749 = The policy's device does not offer TCP/UDP nor RDP application services with the following id(s): {0}.

PAM-CMN-0750 = The policy's device does not offer any VPN services for policy. Please add VPN services to the device first.

PAM-CMN-0751 = The policy's device does not offer VPN services with the following id(s): {0}.

PAM-CMN-0752 = The specified target account id is invalid: {0}.

PAM-CMN-0753 = The restrict login flag requires a socket filter list to be set for this policy.

PAM-CMN-0754 = No applets or services which support CLI recording are selected.

PAM-CMN-0755 = No applets or services which support graphical recording are selected.

PAM-CMN-0756 = No applets or services which support bidirectional CLI recording are selected.

PAM-CMN-0757 = The specified device does not offer any target accounts for viewing. Please add target accounts to the device first.

PAM-CMN-0758 = A policy must specify either an access method, a service, a vpn service, or target accounts.

PAM-CMN-0759 = The bidirectional flag may only be set on if CLI recording is selected.

PAM-CMN-0760 = Transparent login not defined for any selected access method or service.

PAM-CMN-0761 = A policy association between user (group) {0} and device (group) {1} doesn't exist.

PAM-CMN-0762 = No such policy exists.

PAM-CMN-0763 = The specified user or user group id was not found.

PAM-CMN-0764 = The specified device or device group id was not found.

PAM-CMN-0765 = The specified account id is not selected in the policy for viewing.

PAM-CMN-0766 = The policy does not contain the access method with id {0}. Use POST for adding.

PAM-CMN-0767 = The policy already contains the access method with id {0}. Use PUT for updates.

PAM-CMN-0768 = The policy does not contain the service with id {0}. Use POST for adding.

PAM-CMN-0769 = The policy already contains the service with id {0}. Use PUT for updates.

PAM-CMN-0770 = The policy already contains the SSLVPN service with id {0}.

PAM-CMN-0771 = The policy is already configured to allow viewing the password for the account with id {0}.

PAM-CMN-0772 = The following account id(s) do not belong to the specified device: {0}.

PAM-CMN-0773 = A policy association between the specified user (group) and device (group) already exists.

PAM-CMN-0774 = A mapping for the required SAML attribute, {0}, for users with provision type {1} must be defined.

PAM-CMN-0775 = The following SAML attributes have not been mapped to a valid value: {0}.

PAM-CMN-0776 = The following provision types have multiple Subject Name Identifier mappings defined: {0}. There can only be one mapping defined per provision type.

PAM-CMN-0777 = The following SAML requested attribute ids for SAML resolved attributes are invalid: {0}.

PAM-CMN-0778 = The format for the following SAML attribute is invalid: {0}. Expected format is: {1}.

PAM-CMN-0779 = Requested SAML attribute with name {0} doesn't exist.

PAM-CMN-0780 = Target servers and all associated applications and accounts were deleted from policies.

PAM-CMN-0781 = Target applications and all associated accounts were deleted from policies.

PAM-CMN-0782 = Target accounts were deleted from policies.

PAM-CMN-0783 = Target account belonging to device {0} for target application {1} with user name {2} not found.

PAM-CMN-0784 = Policies involving [ca.nsx.vmware.com](https://ca.nsx.vmware.com) may not be imported or exported via csv.

PAM-CMN-0785 = AWS Policy value is not specified for AWS service.

PAM-CMN-0786 = ssoWindow winId {0} is not valid for RDP Application service id {1}. Either the winId doesn't exist or it is not assigned to the service.

PAM-CMN-0787 = Invalid account triplet specified: {0}.

## Management Console Messages

PAM-CMN-0788 = Invalid policy name specified. Policy name must be alpha-numeric.

PAM-CMN-0789 = Policy name required.

PAM-CMN-0790 = Invalid policy version specified.

PAM-CMN-0791 = Invalid policy description specified.

PAM-CMN-0792 = CA PAM appliance already imported into management console.

PAM-CMN-0793 = Working set with the specified name already exists.

PAM-CMN-0794 = Invalid policy module specified.

PAM-CMN-0795 = A policy must contain at least one module before associating it with an CA PAM appliance.

PAM-CMN-0796 = Unable to successfully authenticate to server {0}.

PAM-CMN-0797 = Invalid policy specified.

PAM-CMN-0798 = CA PAM credentials not specified. Please set the credentials for the server or set the default credentials for all servers.

PAM-CMN-0799 = Unable to establish connection to CA PAM appliance {0}.

### **Management Console API Messages**

PAM-CMN-4800 = External API License is required for Management Console licensing.

PAM-CMN-4801 = Once an appliance is a management console it may never revert to an ordinary PAM appliance.

PAM-CMN-4802 = Invalid value for PAM Management Console.

PAM-CMN-4803 = Internal user for collecting data for PAM Management Console.

PAM-CMN-4804 = API key for collecting data for PAM Management Console.

PAM-CMN-4805 = Successfully created internal user {0} for PAM Management Console.

PAM-CMN-4806 = Failed to properly initialize PAM Management Console.

PAM-CMN-4807 = Allows read only access to the PAM Management Console.

PAM-CMN-4808 = Allows create and update access to the PAM Management Console.

PAM-CMN-4809 = Allows access to PAM Management Console Administration UI.

PAM-CMN-4810 = Failed to define proper password for MCApiUser's API key.

PAM-CMN-4811 = Allows the user to view the PAM Management Console.

PAM-CMN-4812 = Allows the user to change the PAM Management Console.

PAM-CMN-4813 = Allows the user to access the PAM Management Console Administration UI.

PAM-CMN-4814 = The PAM Management Console API user may not have its roles changed.

PAM-CMN-4815 = The PAM Management Console API user may not be deleted.

PAM-CMN-4850 = User defined roles may not contain the Global Administrator privilege nor any PAM Management Console related privilege.

### **Managed Server Service Messages**

PAM-CMN-0800 = CA PAM appliance is already being managed by a management console.

PAM-CMN-0801 = Apply policy {0} failed.

### **Command and Socket Filter Messages**

PAM-CMN-0802 = Violations before action value must be a positive number.

PAM-CMN-0803 = Violations before action value must be greater than 0.

PAM-CMN-0804 = Invalid intervention action specified.

PAM-CMN-0805 = Invalid agent listening port. Port must be a valid TCP port.

PAM-CMN-0806 = Invalid CA PAM appliance ID. ID must be numeric and between 1 and 254.

PAM-CMN-0807 = SFA Monitoring is required.

PAM-CMN-0808 = Socket filter list name required.

PAM-CMN-0809 = Socket filter list type required.

PAM-CMN-0810 = Invalid characters in socket filter list name. Semicolons, commas, percent signs, and backslashes are invalid.

PAM-CMN-0811 = Invalid socket filter list type. Valid types are: black, white.

PAM-CMN-0812 = Socket filter host address required.

PAM-CMN-0813 = Invalid socket filter host address. Address must be a valid IP address.

PAM-CMN-0814 = Socket filter port required.

PAM-CMN-0815 = Invalid socket filter port {0}. Port must be a valid TCP port.

PAM-CMN-0816 = A socket filter list with name {0} already exists.

PAM-CMN-0817 = Socket filter list not found.

PAM-CMN-0818 = Command filter list name required.

PAM-CMN-0819 = Command filter list type required.

PAM-CMN-0820 = Invalid characters in command filter list name. Semicolons, commas, percent signs, and backslashes are invalid.

PAM-CMN-0821 = Invalid command filter list type. Valid types are: black, white.

PAM-CMN-0822 = Invalid command filter alert value. Valid values are: t, f.

PAM-CMN-0823 = Invalid command filter block value. Valid values are: t, f.

PAM-CMN-0824 = Invalid command filter regular expression value. Valid values are: t, f.

PAM-CMN-0825 = Command filter keyword required.

PAM-CMN-0826 = A command filter list with name {0} already exists.

PAM-CMN-0827 = Socket filter list id must be a positive integer.

PAM-CMN-0828 = Command filter list id must be a positive integer.

PAM-CMN-0829 = Command filter list not found.

PAM-CMN-0830 = Duplicate entry, {0}, defined for socket filter list.

PAM-CMN-0831 = Duplicate keyword, {0}, defined for command filter list.

PAM-CMN-0832 = Duplicate ports {0} for socket filter host {1}.

PAM-CMN-0833 = SFA Log All Access value required.

PAM-CMN-0834 = Either (comma delimited) individual ports or a single port range must be specified, not ({0}).

PAM-CMN-0835 = A comma delimited port string cannot be more than 512 characters long.

PAM-CMN-0836 = Invalid AWS policy name {0}. Name must only have alphanumeric characters and =, . @ or -.

PAM-CMN-0837 = AWS policy not found.

PAM-CMN-0838 = AWS policy name cannot be longer than 128 characters.

PAM-CMN-0839 = AWS policy name {0} must be unique.

PAM-CMN-0840 = AWS policy is in use and may not be deleted.

PAM-CMN-0841 = AWS session duration invalid.

PAM-CMN-0842 = JSON for AWS policy invalid.

PAM-CMN-0843 = AWS policy too large to compile. See log for details.

PAM-CMN-0844 = AWS policy invalid. See log for details.

PAM-CMN-0845 = AWS policy required.

PAM-CMN-0846 = In order to create an AWS policy at least one Access Key must be defined in Password Authority.

PAM-CMN-0847 = Invalid filter list type specified. Valid values are: white, black.

PAM-CMN-0848 = The enabled filter is not supported for SSLVPN service type.

PAM-CMN-0849 = The command filter {0} has been deleted.

PAM-CMN-0850 = The socket filter {0} has been deleted.

## Logging and Reporting Messages

PAM-CMN-0851 = Cannot add an existing report.

PAM-CMN-0852 = Report name required.

PAM-CMN-0853 = Choose either relative or absolute date range.

PAM-CMN-0854 = Badly formed relative date interval.

PAM-CMN-0855 = Invalid relative date reporting interval.

PAM-CMN-0856 = Invalid relative date reporting amount.

PAM-CMN-0857 = At least one column must be specified for a report.

PAM-CMN-0858 = Invalid email address specified. Multiple addresses must be separated by a comma.

PAM-CMN-0859 = Email address required.

PAM-CMN-0860 = The interval between emails is not defined properly.

PAM-CMN-0861 = The time to send the email is not defined properly.

PAM-CMN-0862 = Email send interval required.

PAM-CMN-0863 = Only the original author of a report or a Global Administrator may update or delete it.

PAM-CMN-0864 = Relative report dates must specify the number of days, weeks or months to include in the report.

PAM-CMN-0865 = Log report not found.

PAM-CMN-0866 = Invalid date range format.

PAM-CMN-0867 = Start date must be before end date.  
 PAM-CMN-0868 = Invalid list of columns for report.  
 PAM-CMN-0869 = Unable to locate recording data. The file may have been removed, or the mount may be down.  
 PAM-CMN-0870 = Session Recording Integrity Failure: This session recording appears to have been modified since it was recorded. Proceed at your own risk.  
 PAM-CMN-0871 = A report named {0} already exists for this user.  
 PAM-CMN-0872 = startDate must be specified if endDate is specified.  
 PAM-CMN-0873 = endDate must be specified if startDate is specified.  
 PAM-CMN-0874 = Session recording can not be started for '{0}' in {1} safe mode because mount is down.  
 PAM-CMN-0875 = Session recording can not be started for '{0}' because {1} session recording is disabled.  
 PAM-CMN-0876 = Network mount for session recording unavailable.  
 PAM-CMN-0877 = Invalid format of Start Date.  
 PAM-CMN-0878 = Invalid format of End Date.  
 PAM-CMN-0879 = Invalid selected range type format.  
 PAM-CMN-0880 = Email daily time required.  
 PAM-CMN-1080 = Unauthorized attempt to add a message to the audit log: {0}  
 PAM-CMN-1371 = Log records viewed

#### NOTE

The PAM-CMN-1371 message appears twice when someone logs into the CA PAM UI. This is expected behavior as the UI queries the log to obtain information to appear under **Recent Events** and to populate the **Dashboard Overview Tab**.

PAM-CMN-1372 = Downloaded log records  
 PAM-CMN-1373 = Failed to update status of log row {0}  
 PAM-CMN-1374 = Log report {0} successfully added  
 PAM-CMN-1375 = Log report {0} not added  
 PAM-CMN-1376 = Log report {0} updated  
 PAM-CMN-1377 = Update of log report {0} failed  
 PAM-CMN-1378 = Log report {0} was deleted  
 PAM-CMN-1379 = Log report {0} was not deleted  
 PAM-CMN-1490 = Unable to purge the logs! Please, contact your administrator!  
 PAM-CMN-1491 = All logs have been purged!  
 PAM-CMN-1492 = Log file {0} deleted successfully  
 PAM-CMN-1493 = Unable to delete log file {0}  
 PAM-CMN-1494 = Changed automatic Log Purge Settings. Status: Enabled, Purge interval: {0} Hour(s), Email flag: {1} Email size: {2}MB  
 PAM-CMN-1495 = Changed automatic Log Purge Settings. Status: Disabled  
 PAM-CMN-1496 = External Log Settings saved successfully.  
 PAM-CMN-1497 = Cannot create log table on the external server.  
 PAM-CMN-1498 = Created new log table on the external server.  
 PAM-CMN-1499 = Cannot create log\_user\_group table on the external server.  
 PAM-CMN-1500 = Created new log\_user\_group table on the external server.  
 PAM-CMN-1501 = Cannot create log\_device\_group table on the external server.  
 PAM-CMN-1502 = Created new log\_device\_group table on the external server.  
 PAM-CMN-1920 = Downloaded log file {0}.  
 PAM-CMN-2008 = logwatch[{0}]: "mail error: {1}"  
 PAM-CMN-2009 = logwatch[{0}]: "Log id {1} to {2} deleted, no mail sent."  
 PAM-CMN-2010 = logwatch[{0}]: "Log id {1} to {2} deleted, mail sent OK."  
 PAM-CMN-2011 = logwatch[{0}]: "Log id {1} to {2} deleted, mail error: {3}"  
 PAM-CMN-2012 = logwatch[{0}]: "Problem deleting log id {1} to {2}, no mail sent."

PAM-CMN-2013 = logwatch[{0}]: "Problem deleting log id {1} to {2}, mail sent OK."

PAM-CMN-2014 = logwatch[{0}]: "Problem deleting log id {1} to {2}, mail error: {3}"

PAM-CMN-2015 = logwatch[{0}]: "Starting up logwatch"

PAM-CMN-2345 = Downloaded log file {0}.

PAM-CMN-2590 = Not connected to the external log server.

PAM-CMN-2591 = No logs to send.

PAM-CMN-2603 = No log files exist!

PAM-CMN-3136 = Metrics auto archive failed. Please check Settings, Credential Manager Settings, Auto-Archive.

PAM-CMN-3137 = Audit Log auto archive failed. Please check Settings, Credential Manager Settings, Auto-Archive.

## Policy Conflict Messages

PAM-CMN-0881 = Updating the group membership for {0} will cause a {1} filter policy conflict for {2} from the following policies:

PAM-CMN-0882 = Socket filter {0} list policy {1} from association between user {2} and device {3}.

PAM-CMN-0883 = Command filter {0} list policy {1} from association between user {2} and device {3}.

PAM-CMN-0884 = Adding {0} to group {1} will cause a {2} filter policy conflict for {3} from the following policies:

PAM-CMN-0885 = Adding device {0} to {1} will cause a {2} filter policy conflict for {3} from the following policies:

PAM-CMN-0886 = Adding {0} to group {1} will cause a {2} filter policy conflict for {3} from the following policies:

PAM-CMN-0887 = Policy settings for association will cause a {0} filter policy conflict for {1} and {2} from the following policies:

PAM-CMN-0888 = Not authorized to retrieve policy conflicts.

PAM-CMN-0889 = Policy conflicts exist in CA PAM. Navigate to the policy conflict page to view the conflicts.

PAM-CMN-0890 = Credential {0} from association between user {1} and device {2}.

PAM-CMN-0891 = Updating the group membership for {0} will cause a credential policy conflict for access method {1} on {2} from the following policies:

PAM-CMN-0892 = Adding {0} to group {1} will cause a credential policy conflict for access method {2} on {3} from the following policies:

PAM-CMN-0893 = Adding device {0} to {1} will cause a credential policy conflict for {2} for access method {3} from the following policies:

PAM-CMN-0894 = Adding access method {0} to {1} will cause a credential policy conflict for {2} from the following policies:

PAM-CMN-0895 = Adding {0} to group {1} will cause a credential policy conflict for {2} for access method {3} from the following policies:

PAM-CMN-0896 = Adding access method {0} to group {1} will cause a credential policy conflict for {2} on {3} from the following policies:

PAM-CMN-0897 = Policy settings for association will cause a credential policy conflict for {0} and access method {1} on {2} from the following policies:

PAM-CMN-0898 = Policy settings cause a credential conflict for secondary login. See your CA PAM Administrator and check the log for details.

## Authentication-Related Messages

PAM-CMN-0899 = Invalid authentication method: {0}.

PAM-CMN-0900 = Bad User ID ({0}) or Password.

PAM-CMN-0901 = You are not allowed to login at this time.

PAM-CMN-0902 = To login you have to accept the terms of the license.

PAM-CMN-0903 = This account is deactivated. See your CA PAM Administrator.

PAM-CMN-0904 = No Email Contact to Alert: {0}

PAM-CMN-0905 = Email alert sent to user {0}: {1}

PAM-CMN-0906 = User {0} deactivated due to reaching the password failure limit.

PAM-CMN-0907 = Account {0} has expired. See your CA PAM Administrator.

PAM-CMN-0908 = Account {0} is not yet activated. See your CA PAM Administrator.

PAM-CMN-0909 = Account {0} has been deactivated due to extended inactivity. See your CA PAM Administrator.

PAM-CMN-0910 = Unable to create security context for user {0}.

PAM-CMN-0911 = Due to account modifications, please change your password.

PAM-CMN-0912 = Due to password timeout, please change your password.

PAM-CMN-0913 = Due to increased password security, please change your password.

PAM-CMN-0914 = User {0} has logged into the CA Privileged Access Manager appliance {1}.

PAM-CMN-0915 = User {0} logged in.

PAM-CMN-0916 = This CA PAM appliance is in maintenance mode. Only admin level users can login.

PAM-CMN-0917 = User {0} logged in successfully via {1} authentication.

PAM-CMN-0918 = User deactivated.

PAM-CMN-0919 = Deactivated account {0}. Exceeded inactivity limit.

PAM-CMN-0920 = Deactivated account {0}. Account expired.

PAM-CMN-0921 = Single Sign On authentication failed. Please retry login.

PAM-CMN-0922 = You are logged out of CA PAM.

PAM-CMN-0923 = Single sign-on session expired. Please re-login.

PAM-CMN-0924 = Multiple CA PAM user accounts map to the same SAML identity ({0}). Rejecting the SAML authentication request and deactivating all the user accounts. Please activate one account that will be used to map to the SAML identity.

PAM-CMN-0925 = User {0} from SAML enabled group {1} has the same SAML user name {2} from SAML attribute {3}. User account deactivated.

PAM-CMN-0926 = Single sign-on authentication failed. Please contact your system administrator.

PAM-CMN-0927 = SAML user {0} not found in CA PAM or does not belong to a SAML enabled group.

PAM-CMN-0928 = SAML assertion {0} timestamp exceeds validity window by approximately {1} minutes. Assertion Issued: {2}.

PAM-CMN-0929 = SAML assertion issuer, {0}, does not match configured issuer {1}.

PAM-CMN-0930 = Invalid SAML assertion recipient URL: {0}.

PAM-CMN-0931 = SAML assertion recipient, {0}, not recognized. Valid recipients are: {1}.

PAM-CMN-0932 = SAML assertion received by authentication service at time {0} is before SAML Not-Before Condition {1}.

PAM-CMN-0933 = SAML assertion received by authentication service at time {0} is after SAML Not-On-Or-After Condition {1}.

PAM-CMN-0934 = SAML assertion received with a non-successful status code {0}.

PAM-CMN-0935 = CA PAM appliance in FIPS mode. SAML SSO disabled.

PAM-CMN-0936 = User attempted to login via SAML SSO but SAML SSO is not enabled.

PAM-CMN-0937 = SAML assertion not found in request.

PAM-CMN-0938 = Unable to decode SAML assertion.

PAM-CMN-0939 = SAML assertion failed schema validation.

PAM-CMN-0940 = Verification of SAML assertion failed: Certificate of SAML assertion producer has not been uploaded to CA PAM.

PAM-CMN-0941 = Saving the SAML assertion to a temporary file failed.

PAM-CMN-0942 = SAML assertion failed signature verification.

PAM-CMN-0943 = There are no user or user groups with an authentication method of SAML.

PAM-CMN-0944 = Login failed for user {0} due to multiple active RADIUS users having the same login name. All RADIUS users with login name {1} will be deactivated.

PAM-CMN-0945 = Login Failed. Please contact your system administrator for further assistance.

PAM-CMN-0946 = Authentication Daemon communication failure: {0}

PAM-CMN-0947 = Authentication Daemon access rejected message: {0}

PAM-CMN-0948 = Authentication Daemon General Error occurred ({0}). Please check if the Authentication Daemon is properly set up.

PAM-CMN-0949 = RADIUS user is not registered. Contact your CA PAM Administrator.

PAM-CMN-0950 = Authentication failed for RADIUS user {0}. RADIUS authentication succeeded but unable to retrieve the user's RADIUS group.

PAM-CMN-0951 = Authentication failed for RADIUS user {0}. RADIUS authentication succeeded but the user's RADIUS group changed from {1} to {2}. The new RADIUS group is not registered with CA PAM. User account deleted.

PAM-CMN-0952 = RADIUS user {0} moved from RADIUS group {1} to RADIUS group {2}.

PAM-CMN-0953 = Authentication failed for RADIUS user {0}. RADIUS authentication succeeded but the user's RADIUS group, {1}, is not registered. User will be logged out.

PAM-CMN-0954 = Adding RADIUS user {0} to CA PAM failed with message(s): {1}.

PAM-CMN-0955 = Authentication user {0} returned an invalid {1} challenge response for {2} authentication. Authentication request denied.

PAM-CMN-0956 = Unrecognized RADIUS challenge type {0}. Authentication request for user {1} denied.

PAM-CMN-0957 = SAML RADIUS authentication succeeded but the RADIUS group was not passed to CA PAM. User will be deleted and logged out.

PAM-CMN-0958 = Cisco SSO RADIUS user {0} moved to registered RADIUS group {1}.

PAM-CMN-0959 = User is not logged in.

PAM-CMN-0960 = Verify user credentials does not support the authentication method configured for the user.

PAM-CMN-0961 = User not found.

PAM-CMN-0962 = Determining the least-loaded CA PAM appliance for user ({0})'s session failed. Granting the user a session on this appliance.

PAM-CMN-0963 = Invalid attempt to acquire a session on this CA PAM appliance as user {0} via CA PAM load balance redirect.

PAM-CMN-0964 = Login failed for user {0} due to multiple active RSA users having the same login name. All RSA users with login name {1} will be deactivated.

PAM-CMN-0965 = Login Failed. Please contact your system administrator for further assistance.

PAM-CMN-0966 = User {0} selected to authenticate via {1} but the configured authentication method for the user is {2}.

PAM-CMN-0967 = The Active Directory user with user principal name {0} or samAccountName {1} is not registered with CA PAM.

PAM-CMN-0968 = The LDAP user with attribute {0}={1} is not registered with CA PAM

PAM-CMN-0969 = User {0} session is set for post-authentication load balancing to member {1}. The user's session will be destroyed on this member and resumed on member {2}.

PAM-CMN-0970 = User {0} session has been post-authentication load balanced to this member. The user's session will be resumed on this member.

PAM-CMN-0971 = User {0} failed LDAP+RSA authentication. The LDAP authentication failed.

PAM-CMN-0972 = User {0} failed LDAP+RSA authentication. The RSA authentication failed with RSA user name {1}.

PAM-CMN-0973 = User {0} attempted to access from an unauthorized IP: {1}. The only authorized networks are [{2}].

PAM-CMN-0974 = You have attempted to gain access from an invalid network. Please contact your administrator.

PAM-CMN-0975 = You have not been authorized to connect.

PAM-CMN-0976 = User {0} attempted an invalid PKI authentication.

PAM-CMN-0977 = PKI authentication failed with error: {0}

PAM-CMN-0978 = PKI user {0} not approved for access. Registration deleted.

PAM-CMN-0979 = LDAP authentication failed for user {0} with error code ({1}) and error string ({2}).

PAM-CMN-0980 = User {0} selected to authenticate via {1} but the user is required to authenticate via SAML from the SAML authentication inherited from the following group(s): {2}.

PAM-CMN-0981 = User {0} with authentication type SAML is mapped to the same SAML user name, {1}, as other CA PAM accounts. User account deactivated.

PAM-CMN-0982 = SAML SSO Authentication Failure: Status Code: {0}. Status Message: {1}. SubStatus Code: {2}.

PAM-CMN-0983 = Just-In-Time provisioning of user {0} failed because the userGroup attribute of the SAML assertion does not contain a valid CA PAM user group name. The groups specified in the SAML assertion are: {1}.

PAM-CMN-0984 = Just-In-Time provisioning of user {0} failed due to the following errors: {1}.

PAM-CMN-0985 = Just-In-Time provisioning of user {0} failed due to missing required attribute {1}.

PAM-CMN-0986 = SAML user {0} was not found on CA PAM but the remote identity provider {1} is configured for Just In Time provisioning. CA PAM will attempt to provision an account for the user in the following CA PAM groups: {2}.

PAM-CMN-0987 = The user initiated a SAML SSO Test to remote identity provider {0}.

PAM-CMN-0988 = The validation of the SAML assertion of user identity {0} from remote IdP {1} succeeded but mapping the user to a SAML-enabled CA PAM account failed.

PAM-CMN-0989 = User {0} logged in successfully via {1} authentication from remote IdP {2}.

PAM-CMN-0990 = A SAML reauthentication request was received for a password view request but the remote IdP entity ID is missing from the user's session.

PAM-CMN-0991 = The SAML reauthentication to view the password for account {0} failed: Status Code: {1}. Status Message: {2}. SubStatus Code: {3}.

PAM-CMN-0992 = The SAML reauthentication to view the password for account {0} failed: {1}.

PAM-CMN-0993 = The user attempted to verify their password to view an account password using SAML authentication but the user did not authenticate to CA PAM via SAML authentication.

PAM-CMN-0994 = The SAML reauthentication to view the password for account {0} failed. The user identity in the SAML assertion, {1}, does not match the identity of the CA PAM user that initiated the password view request.

PAM-CMN-0995 = Your LDAP password has been reset. You are required to change your password.

PAM-CMN-0996 = Your LDAP password has expired. You are required to change your password.

PAM-CMN-0997 = The user's LDAP domain is not configured with CA PAM to use TLS and therefore CA PAM will not enable the user to change their password.

PAM-CMN-0998 = User {0} logged in successfully via {1} authentication but will be required to change their password.

PAM-CMN-0999 = A user authenticated with login name {0} but a user with the specified login name is not registered with CA PAM.

PAM-CMN-1000 = User {0} failed LDAP+RADIUS authentication. The LDAP authentication failed.

PAM-CMN-1001 = User {0} failed LDAP+RADIUS authentication. The RADIUS authentication failed with RADIUS user name {1}.

PAM-CMN-1002 = PKI user(s) {0} not approved for access.

PAM-CMN-1003 = Invalid pending PKI user ids specified: {0}.

PAM-CMN-1004 = PKI user(s) {0} approved for access.

PAM-CMN-1005 = Unable to approve the pending PKI user {0} for access: {1}.

PAM-CMN-1006 = CA PAM as a SAML SP received an authentication request for unknown SAML identity provider {0}.

PAM-CMN-1007 = An error occurred while processing SAML assertion: {0}.

PAM-CMN-1008 = SAML SSO Authentication Failure: The received assertion did not include a subject name identifier nor the userName SAML attribute.

PAM-CMN-1009 = SAML password view request out-of-sync ({0} != {1}): The user's internal id did not match the id contained in the user's session.

PAM-CMN-1010 = Please accept the license to proceed.

PAM-CMN-1011 = The user was required to accept the license but canceled. Access denied.

PAM-CMN-1012 = The following group names contained in the SAML assertion do not exist in CA PAM and will be ignored in the Just In Time provisioning of the user {0}: {1}.

PAM-CMN-1013 = User {0} re-logged in successfully via {1} authentication.

PAM-CMN-1014 = User {0} failed {1} re-authentication.

PAM-CMN-1015 = Authentication type mismatch on re-authentication.

PAM-CMN-1016 = User mismatch on re-authentication.

PAM-CMN-1017 = Proxy authentication failed. Cannot find corresponding CA PAM user.

PAM-CMN-1018 = Configuration Password is still the default value.

PAM-CMN-1019 = PKI user {0} approved. User was created.

PAM-CMN-1020 = Attempt to approve PKI user {0} failed. Message was {1}.

PAM-CMN-1021 = SAML SSO of Just-In-Time provisioned user {0} failed due to missing required attribute {1}.

PAM-CMN-1022 = SAML SSO of Just-In-Time provisioned user {0} failed because the userGroup attribute of the SAML assertion does not contain a valid CA PAM user group name. The groups specified in the SAML assertion were: {1}.

PAM-CMN-1023 = The user groups of the Just-In-Time provisioned user {0} has been updated: {1}.

PAM-CMN-1024 = The user groups of the Just-In-Time provisioned user {0} has been updated: {1}. The following user groups contained in the assertion are not valid CA PAM user groups and will be ignored: {2}.

PAM-CMN-1025 = SAML SSO Authentication Failed: Updating the user groups of SAML SSO Just-In-Time provisioned user {0} failed: {1}

PAM-CMN-1026 = SAML SSO of Just-In-Time provisioned user {0} succeeded. The user's group membership has not changed. The assertion also contained the following group names that do not exist in CA PAM: {1}.

PAM-CMN-1027 = LDAP user account {0} is disabled in Active Directory.

PAM-CMN-3252 = Authentication failed. Please contact administrator or try again later.

PAM-CMN-3253 = User {0} failed to access device {1}. The primary site is unreachable and the cluster is configured for security-safe mode. Credentials cannot not be serviced from the local database in security safe mode.

PAM-CMN-3254 = Unauthorized access to RADIUS configuration.

PAM-CMN-3255 = Failed to save the RADIUS configuration on member {0}. Unable to establish a connection to the CA PAM appliance.

PAM-CMN-3256 = Saving RADIUS configuration on all cluster members failed for {0}/{1} members: {2}.

PAM-CMN-3257 = RADIUS configuration saved on all cluster members.

PAM-CMN-3258 = GateKeeper RADIUS configuration saved.

PAM-CMN-3259 = Failed to retrieve the RADIUS configuration from primary member {0}. Unable to establish a connection to the CA PAM appliance.

PAM-CMN-3260 = Synchronizing RADIUS configuration from primary cluster member {0} failed.

PAM-CMN-3261 = RADIUS configuration retrieved from primary cluster member successfully.

PAM-CMN-3263 = Gatekeeper RDPProxy configuration saved.

PAM-CMN-3264 = Failed to save the RDP configuration on member {0}. Unable to establish a connection to the CA PAM appliance.

PAM-CMN-3265 = Saving RDPProxy configuration on all cluster members failed for {0}/{1} members: {2}.

PAM-CMN-3266 = RDPProxy configuration saved on all cluster members.

PAM-CMN-3267 = Failed to retrieve the RDPProxy configuration from primary member {0}. Unable to establish a connection to the CA PAM appliance.

PAM-CMN-3268 = Synchronizing RDPProxy configuration from primary cluster member {0} failed.

PAM-CMN-3269 = RDPProxy configuration retrieved from primary cluster member successfully.

PAM-CMN-3351 = The Kerberos Authentication for the device "{0}" will be disabled because device is defined by IP address.

PAM-CMN-3352 = The Kerberos Authentication requires device to be defined by it's FQDN. Kerberos for the device "{0}" will be disabled.

PAM-CMN-3353 = The device "{0}" has more than one Kerberos KDC server defined for on Group level. Kerberos Authentication will be disabled until conflict is resolved.

## Access Service Messages

PAM-CMN-1029 = Task not enabled.

PAM-CMN-1030 = Unexpected command filter policy conflict - launch aborted.

PAM-CMN-1031 = Unexpected socket filter policy conflict - launch aborted.

PAM-CMN-1032 = Missing required device data - launch aborted.

PAM-CMN-1033 = Unauthorized attempt by user {0} to view the access page for user {1}.

PAM-CMN-1034 = Unexpected filter policy conflict - launch aborted.

PAM-CMN-1035 = Unexpected credential conflict - launch aborted.

PAM-CMN-1036 = Unauthorized attempt to set LDAP browser port.

PAM-CMN-1037 = Unauthorized attempt to update LDAP browser domain destination.

PAM-CMN-1038 = Unexpected AWS policy conflict - launch aborted.

PAM-CMN-1039 = AWS Policy {0} missing.

PAM-CMN-1040 = Unable to launch AWS Management Console. If this problem persists then ask your Administrator to investigate.

PAM-CMN-1041 = User {0} attempted to launch recorded web portal {1} but the mount is down. Due to the configured security safe policy, the user's connection attempt will be denied

PAM-CMN-1042 = User {0} attempted to launch recorded web portal {1} but the mount is down. Due to the configured operational safe policy, the user's connection attempt will be granted but not recorded.

PAM-CMN-1043 = CA PAM denied web portal {0}'s connection to host {1} because it does not match an entry in the web portal's access list.

PAM-CMN-1044 = CA PAM denied a request to proxy an HTTP connection to host {0} because the request could not be verified to have originated from an CA browser instance.

PAM-CMN-1045 = CA PAM denied the user's access to web portal {0}. The CA browser is not supported on the {1} operating system.

PAM-CMN-1046 = CA PAM denied user's unauthorized access to web portal {0} on host {1}.

PAM-CMN-1047 = CA PAM unable to find connection data authorizing service {0}'s access to host {1}.

PAM-CMN-1048 = CA PAM denied the user's access to web portal {0}. The CA browser requires a 32-bit JRE.

PAM-CMN-1049 = CA PAM denied the user's SSO access to the AWS Management Console with: invalid SSO credentials specified.

PAM-CMN-1050 = No Office365 HTML was generated.

PAM-CMN-1051 = Unable to launch Office 365 portal: Error code {0}: {1}.

PAM-CMN-1052 = Unable to launch Office 365 portal: Office 365 parameters are not configured.

PAM-CMN-1053 = Unable to launch Office 365 portal: Login credential not found.

PAM-CMN-1054 = Access to credential denied because authorization is required. Authorization request sent. Try again later.

PAM-CMN-1055 = Access to credential denied because the credential is already checked out by someone else. Try again later.

PAM-CMN-1056 = Access to credential denied because authorization request is still pending. Try again later.

PAM-CMN-1057 = Unable to generate AWS proxy account. Please contact CA PAM administrator

PAM-CMN-1058 = Unable to generate NSX proxy account. Please contact CA PAM administrator

PAM-CMN-1059 = The session URL does not match with the URL triggered by the UI

PAM-CMN-1060 = Access denied because of internal failure. Please contact CA PAM administrator.

PAM-CMN-1061 = Access denied because a credential was not chosen or is not available. Please launch the service and choose an available credential.

PAM-CMN-1062 = Access denied because dual authorization is required. If a password view request is not pending please launch the service to create one.

PAM-CMN-1063 = Proxy was not launched because the user failed to correctly respond to the pop up in time.

## Credential Management Messages

PAM-CMN-1064 = Credential daemon is not available.

PAM-CMN-1065 = Credential id not found.

PAM-CMN-1066 = No credential sources available.

PAM-CMN-1067 = Could not update or save credential. Check that the title is not already in use.

PAM-CMN-1068 = Password Authority invalid authentication.

PAM-CMN-1069 = Password Authority unavailable.

PAM-CMN-1070 = Unexpected error in source response.

PAM-CMN-1071 = This password is a privileged password; it cannot be used for single sign-on for target device.

PAM-CMN-1072 = No Password Authority username and password provided.

PAM-CMN-1073 = The credential service did not find a cryptographic encryption key. Regenerating key; existing credentials will be lost.

PAM-CMN-1074 = The credential service was not able to contact database.

PAM-CMN-1075 = The internal credential source storage is currently disabled by administrator.

PAM-CMN-1076 = The credential daemon has been given an invalid input.

PAM-CMN-1077 = The requested credential is corrupted or cannot be decrypted.

PAM-CMN-1078 = Unexpected error sent by credential daemon; please contact your administrator.

PAM-CMN-1079 = Credential not available. Please contact your administrator.

## View and Search Messages

PAM-CMN-1081 = Badly formed data - operation not performed

PAM-CMN-1082 = This view should be updated, not added.

PAM-CMN-1083 = View {0} not added.

PAM-CMN-1084 = Invalid search specified for view.

PAM-CMN-1085 = Duplicate view name.

## Cluster Management Messages

PAM-CMN-1086 = Unauthorized access to cluster configuration.

PAM-CMN-1087 = Passphrase is required to generate the shared cluster key.

PAM-CMN-1088 = Cluster shared key is required.

PAM-CMN-1089 = Cluster shared key must be a 40-character-long hexadecimal string.

PAM-CMN-1090 = The interface to use for cluster communications must be specified.

PAM-CMN-1091 = Invalid cluster interface specified. Valid values are {0}.

PAM-CMN-1092 = Virtual Management IP Address is required.

PAM-CMN-1093 = Virtual Management IP Address must be a valid IP address.

PAM-CMN-1094 = Virtual Management IP Domain Name must be a valid hostname.

PAM-CMN-1095 = Invalid cluster member list specified.

PAM-CMN-1096 = Cluster must contain at least two members, including this CA PAM appliance.

PAM-CMN-1097 = The IP address specified for this CA PAM appliance in the cluster member list cannot be assigned to the cluster interface.

PAM-CMN-1098 = This CA PAM appliance must be a member of the cluster.

PAM-CMN-1099 = The subnet of the CA PAM appliance cluster interface is required.

PAM-CMN-1100 = Invalid cluster subnet format specified.

PAM-CMN-1101 = Invalid cluster subnet network address {0}.

PAM-CMN-1102 = Invalid cluster subnet network mask {0}.

PAM-CMN-1103 = The specified cluster subnet does not have enough host addresses ({0}) for all cluster members ({1}).

PAM-CMN-1104 = The specified NAT address {0} is not a valid IP address or hostname.

PAM-CMN-1105 = The specified PAT address {0} is not a valid IP address or hostname.

PAM-CMN-1106 = The specified PAT port {0} is not a valid port number.

PAM-CMN-1107 = Failed to authenticate to cluster member {0}. Please confirm that the shared key has been configured on the cluster member.

PAM-CMN-1108 = Failed to save the cluster configuration on member {0}. Error(s) received: {1}

PAM-CMN-1109 = Failed to save the cluster configuration on member {0}. Unable to establish a connection to the CA PAM appliance.

PAM-CMN-1110 = Failed to start the cluster due to configuration errors.

PAM-CMN-1111 = The cluster configuration values do not match for fields: {0}.

PAM-CMN-1112 = Failed to start the cluster. The cluster configuration on members {0} and {1} are not the same. The errors reported by {2} are: {3}.

PAM-CMN-1113 = Failed to start the cluster. Unable to check for consistent cluster configuration on member {0}. The remote errors reported are: {1}.

PAM-CMN-1114 = Failed to start the cluster. Unable to establish a connection to member {0}.

PAM-CMN-1115 = Failed to start the cluster. Configuring the replication interface on member {0} failed.

PAM-CMN-1116 = Failed to start the cluster. Unable to successfully ping cluster member {0}.

PAM-CMN-1117 = Failed to start the cluster. Unable to retrieve hostname data from cluster member {0}.

PAM-CMN-1118 = Failed to start the cluster. Unable to save hostname data on cluster member {0}.

PAM-CMN-1119 = Failed to stop the cluster on member {0}: {1}

PAM-CMN-1120 = Failed to stop the cluster due to configuration errors.

PAM-CMN-1121 = Failed to start the cluster. Unable to configure and start the cluster runtime.  
PAM-CMN-1122 = Failed to configure the cluster runtime on member {0}.  
PAM-CMN-1123 = Starting the cluster runtime has failed.  
PAM-CMN-1124 = Starting the cluster runtime on member {0} has failed.  
PAM-CMN-1125 = Unable to start cluster members {0}.

 PAM-CMN-3355 = Invalid host id specified.

## Session Manager Service Messages

PAM-CMN-1341 = This CA PAM appliance is in maintenance mode. Only admin users will be able to login.  
 PAM-CMN-4100 = Session log records must be in an array.  
 PAM-CMN-4101 = Session log record {0} is invalid.  
 PAM-CMN-4102 = Ignore session log level flag {0} is invalid. Value should be 1 for true, 0 for false.  
 PAM-CMN-4103 = Session log transaction type {0} is invalid. See documentation for a list of valid types.  
 PAM-CMN-4014 = Created timestamp {0} is invalid. It should be number of milliseconds since the epoch or empty.

## Upgrade, Backup, and Recovery Messages

PAM-CMN-1342 = Applied patch '{0}'. {1}  
 PAM-CMN-1343 = Upgrading to the same version could cause unexpected result  
 PAM-CMN-1344 = Problem applying the upgrade package. Details: {0}  
 PAM-CMN-1345 = Please stop the cluster before proceeding with the upgrade  
 PAM-CMN-1346 = Upgrade package has been applied successfully  
 PAM-CMN-1347 = Backup of the appliance takes time. Please be patient and wait until it reboots.<br/>The LCD will show the message <b>System backup! Please wait!</b> <br/> Wait until the normal operation message shows on the LCD then log in again and resume work in your browser.  
 PAM-CMN-1348 = Recover of the appliance takes time. Please be patient and wait until it reboots.<br/>The LCD will show the message <b>System backup! Please wait!</b><br/> Wait until the normal operation message shows on the LCD then log in again and resume work in your browser.  
 PAM-CMN-1349 = An error occurred while running the backup  
 PAM-CMN-1350 = An error occurred while running recovery  
 PAM-CMN-1351 = Configuration-Upgrade: Performing Backup

PAM-CMN-1352 = Configuration-Recovery: Performing Recovery

PAM-CMN-1353 = An error occurred while trying to delete the staging file

PAM-CMN-3278 = FAILED TO RESTORE DB. {0} is too big to restore the database safely!

PAM-CMN-3279 = DB can be restored successfully. Required DB size is less than Existing DB

PAM-CMN-3280 = FAILED TO RESTORE DB. {0} is too big to restore. Required SPACE={1} kb

PAM-CMN-3281 = DB can be successfully restored. Required Disk space={0}, HALF of Available Space={1}

PAM-CMN-3282 = {0} is not a writable directory.

PAM-CMN-3283 = A fatal error occurred while dumping the database.

PAM-CMN-3284 = Database dumped successfully to {0}

PAM-CMN-3285 = The database you are attempting to load is not compatible with the current version.

PAM-CMN-3286 = This database contains settings that are not compatible with FIPS mode. Turn off FIPS mode to continue restoring.

PAM-CMN-3287 = An error occurred while trying to load {0}.

PAM-CMN-3288 = Allows the use of the External API by {0}.

PAM-CMN-3335 = Cannot access patchinfo file. This patch must be an older package type, not installable on this version of CA PAM.

PAM-CMN-3336 = CA PAM cannot be upgraded while in cluster mode. Turn off clustering before upgrading.

PAM-CMN-3337 = Insufficient storage space for successful firmware upgrade.<br>Export your logs to free storage space and try again.

PAM-CMN-3338 = Problem unpacking the upgrade package.

PAM-CMN-3339 = This is an invalid FIPS patch. Please contact Broadcom Support.

PAM-CMN-3340 = Patch verification failed.

PAM-CMN-3341 = This is not an approved FIPS patch.

PAM-CMN-3342 = Insufficient storage for database update.<br>Export your logs and try to upgrade again.

PAM-CMN-3343 = Unable to check the upgrade package version.<br>The package seems to be older. CA PAM cannot be downgraded.

PAM-CMN-3344 = Cannot upgrade CA PAM.

PAM-CMN-3345 = Cannot upgrade because current<br>CA PAM version {0} must equal {1}.

PAM-CMN-3346 = Cannot upgrade because current<br>CA PAM version {0} must be between {2} and {3} (inclusive).

PAM-CMN-3347 = Could not export record of type "{0}" initiated by user "{1}". Error message: "{2}".

PAM-CMN-3349 = Cannot upgrade because patch is not HMAC signed. Please contact Broadcom Support.

PAM-CMN-3350 = Cannot upgrade because patch has invalid checksum. Please contact Broadcom Support.

PAM-CMN-3367 = Cannot upgrade because {0} cannot be installed on CA PAM {1}. <br>To upgrade from CA PAM {2}, please use CA PAM {3}. {4} once available.

PAM-CMN-3382 = The last full appliance backup failed on {0}

## CA Threat Analytics Related Messages

PAM-CMN-1028 = CA Threat Analytics server is inaccessible or its configuration is invalid.

PAM-CMN-1354 = CA Threat Analytics update failed. Message (if any) was {0}

PAM-CMN-1355 = CA Threat Analytics update succeeded in part and failed in part.

PAM-CMN-1356 = CA Threat Analytics get failed.

PAM-CMN-1357 = CA Privileged Access Manager is collecting and analyzing limited information about your client system and sessions

PAM-CMN-2032 = BAPService.getRiskLevels called when {0} was not configured. Request ignored.

PAM-CMN-2033 = BAPService.getUserRiskLevels called when {0} was not configured. Request ignored.

PAM-CMN-2034 = User Id {0} invalid for BAPService.getUserRiskLevel.

PAM-CMN-2035 = User {0} was assigned a risk level from {1}.

PAM-CMN-2036 = User {0} was assigned the default risk level.

PAM-CMN-2037 = Session id was not in proper format. Data was not sent to {0}.

PAM-CMN-2038 = Unexpected action {0} while trying to log a connect or disconnect. Expected values are connect or disconnect

PAM-CMN-2039 = Invalid connection id {0} when attempting to log a {1} event.

PAM-CMN-2040 = No connection found with sequence number {0}. {1} was not logged to {2}.

PAM-CMN-2041 = Unexpected reason {0} for disconnecting from client. Disconnection will not be logged.

PAM-CMN-2042 = Default risk level not found. A risk level of Good will be used.

PAM-CMN-2043 = Unexpected default risk level {0}. A risk level of Good will be used.

PAM-CMN-2044 = Missing required service identifier. Data was not reported to {0}.

PAM-CMN-2045 = Invalid url {0} for sending to {1}.

PAM-CMN-2046 = Unable to construct {0} URL. Message was {1}

PAM-CMN-2047 = extraData should be an array or empty

PAM-CMN-2048 = Warning: extra parameters supplied will be ignored because the url contains a query string

PAM-CMN-2049 = Invalid request type {0} - one of GET, POST, PUT, or DELETE should be used

PAM-CMN-2050 = Unable to find {0} Authorization token. Message was {1}.

PAM-CMN-2051 = Invalid administrative user id {0} when attempting to log a session logout

PAM-CMN-2052 = Invalid logout reason {0} when attempting to log a session logout

PAM-CMN-2053 = Session id was not in proper format. Data was not sent to {0}.

PAM-CMN-2054 = Unable to get user information for logout based on administrator userid: {0}.

PAM-CMN-2055 = Private IP address was not in proper format. Data was not sent to {0}.

PAM-CMN-2056 = Public IP address was not in proper format. Data was not sent to {0}.

PAM-CMN-2057 = Machine id was not in proper format. Data was not sent to {0}.

PAM-CMN-2058 = No session found for session {0} uplnit data will not be sent to {1}.

PAM-CMN-2790 = User must have configuration manager, manage devices and manage network services privileges to update the TAP configuration

PAM-CMN-2791 = Invalid address {0} supplied for TAP device. Update failed.

PAM-CMN-3615 = Created {0} Admin Group with group name {1}.

PAM-CMN-3616 = {0} group already exists, was not changed.

PAM-CMN-3617 = Threat Analytics special user group is deleted when Threat Analytics is no longer licensed, and may not be deleted otherwise.

PAM-CMN-3618 = Deleted {0} Admin Group {1}.

PAM-CMN-3619 = Threat Analytics special user group cannot be updated.

PAM-CMN-3621 = Threat Analytics special policy cannot be deleted.

PAM-CMN-3622 = Threat Analytics special policy cannot be updated.

PAM-CMN-3623 = Threat Analytics special user group should have super user as one of its members.

PAM-CMN-3624 = Only Users with Global Administrator privilege can be added to Threat Analytics special user group and vice versa.

## Active Directory Messages

PAM-CMN-2177 = The user must reset their password.

PAM-CMN-2178 = The user's password has expired.

PAM-CMN-2179 = The user entered an incorrect password.

PAM-CMN-2180 = The user's account is disabled in Active Directory.

PAM-CMN-2181 = The user's account has expired in Active Directory.

PAM-CMN-2182 = The user's account has been locked in Active Directory.

PAM-CMN-2183 = The user's account cannot be found in Active Directory.

PAM-CMN-2184 = The user is not permitted to login in Active Directory.

PAM-CMN-2185 = The user is not permitted to login on this workstation in Active Directory.

## SAML Related Messages

PAM-CMN-1360 = PAM received a request to issue an assertion for SAML service {0}, but the user is not authorized to access this service.

PAM-CMN-1361 = SAML assertion for service {0} will not be released because the subject name ID format was not specified in the policy for this user.

PAM-CMN-1362 = SAML assertion for service {0} will not be released because the following required attributes have not been mapped or resolved to a value: {1}

PAM-CMN-1363 = PAM SAML IdP issued an authentication failed response to SAML service {0} with entity ID {1} via {2}

PAM-CMN-1364 = PAM SAML IdP issued an authentication failed response to SAML service {0} with entity ID {1} via {2} authenticated via {3}

PAM-CMN-1365 = PAM SAML IdP has issued an assertion to SAML service {0} with entity ID {1} via {2} as subject {3}

PAM-CMN-1366 = PAM SAML IdP has issued an assertion to SAML service {0} with entity ID {1} via {2} as subject {3} authenticated via {4}

PAM-CMN-1367 = There is a SAML Subject Identifier Format policy conflict for user {0} for SAML service {1} involving the following policies: {2}

PAM-CMN-1368 = There is a SAML Subject Identifier Value policy conflict for user {0} for SAML service {1} involving the following policies: {2}

PAM-CMN-1369 = PAM SAML IdP request: Message did not meet security requirements. {0}

PAM-CMN-1370 = PAM received a request to issue an assertion for recorded SAML service {0}, but the user did not access the service using the PAM browser, as required for web session recording. The user must access the service using the PAM browser from the PAM Access page.

PAM-CMN-1520 = PAM SAML IdP request: {0}

PAM-CMN-1731 = SAML SSO Enabled

PAM-CMN-1732 = SAML SSO Disabled

PAM-CMN-1908 = PAM SAML IdP request: Message did not meet security requirements. Authentication request received from unknown SAML SP {0}

PAM-CMN-2158 = Error parsing the SAML metadata file.

PAM-CMN-2159 = Metadata file does not contain any SAML IdP entities.

PAM-CMN-2160 = SAML entity {0} does not contain a SingleSignOnService with a valid Post binding. Acceptable Post bindings are: {1}.

PAM-CMN-2161 = SAML entity {0} does not contain a SingleSignOnService with a Post or Redirect binding.

PAM-CMN-2162 = SAML entity {0} does not contain any key data.

PAM-CMN-2163 = There are no valid SAML 2.0 IdP descriptors in the metadata file.

PAM-CMN-2164 = SAML Remote IdP(s) added: {0}.

PAM-CMN-2186 = SAML user provisioned via Just In Time provisioning from Remote Identity Provider {0}

PAM-CMN-2747 = SAML configuration (except Fully Qualified Hostname) will be replicated to all cluster members

PAM-CMN-5388 = Refreshing the metadata for SAML identity provider %s failed. Please ensure the source URL is accessible and that if configured for validation, that the certificate fingerprint corresponds to the certificate used to sign the metadata.

PAM-CMN-5389 = Metadata refresh is enabled but there are no IdPs configured with a source URL for metadata refresh.

PAM-CMN-5390 = SAML metadata refresh for IdP %s completed successfully but there were no updates.

PAM-CMN-5391 = SAML metadata refresh for IdP %s completed successfully: %s certificates added, %s certificates removed.

PAM-CMN-5392 = Saving the updated certificates during SAML metadata refresh failed with the following error: %s

PAM-CMN-5393 = Specifying the fingerprint for the metadata refresh signing certificate requires the source URL where the metadata can be retrieved.

PAM-CMN-5394 = The metadata source URL is not a valid URL.

PAM-CMN-5395 = Specified metadata refresh certificate fingerprint is not a valid SHA-1 certificate fingerprint.

PAM-CMN-5396 = Invalid SP metadata refresh mode specified.

## SSL, FIPS, and Cryptography Messages

PAM-CMN-2724 = OpenSSL configuration error: {0}, {1}

PAM-CMN-2831 = PAM is currently provisioned to use OpenSSL and the password is not cached!  
PAM-CMN-2832 = PAM is re-encrypting the DB. Please try again later.

PAM-CMN-2837 = PAM is currently provisioned to use WolfSSL and the password is not cached!

PAM-CMN-2848 = Proper usage: useOpenSSL <provider>

PAM-CMN-2849 = password and confirmed password do not match!

PAM-CMN-2851 = PAM is currently provisioned to use non-FIPS mode cryptography provider

PAM-CMN-2852 = PAM is currently provisioned to use FIPS mode cryptography provider

PAM-CMN-3105 = Warning: client selects unsupported cipher.

## Other Common Messages

PAM-CMN-1359 = CA Single Sign-On disabled. Rebooting Apache...

PAM-CMN-1371 = Log records viewed

### NOTE

The PAM-CMN-1371 message appears twice when someone logs into the CA PAM UI. This is expected behavior as the UI queries the log to obtain information to appear under **Recent Events** and to populate the dashboard.

PAM-CMN-1372 = Downloaded log records

PAM-CMN-1373 = Failed to update status of log row {0}

PAM-CMN-1374 = Log report {0} successfully added

PAM-CMN-1375 = Log report {0} not added

PAM-CMN-1376 = Log report {0} updated

PAM-CMN-1377 = Update of log report {0} failed

PAM-CMN-1378 = Log report {0} was deleted

PAM-CMN-1379 = Log report {0} was not deleted

PAM-CMN-1380 = Unable to retrieve all device data for applet. Check device properties and terminal types for device.

PAM-CMN-1381 = Credential service is down, user must enter their own credentials

PAM-CMN-1382 = Credential not found for association

PAM-CMN-1383 = Missing session host data for device, unable to launch applet

PAM-CMN-1386 = Unable to find sequence number for device {0} service {1} protocol {2}

PAM-CMN-1387 = Check Conflicts require either a task or a service to check against.

PAM-CMN-1389 = Unable to find secondary login credential for transparent login

PAM-CMN-1390 = CSV {0} of type {1} initiated by user {2}.

PAM-CMN-1391 = CSV {0} of type {1} initiated by user {2} completed in {3}.

PAM-CMN-1392 = A CSV import/export job is already running and is at {0} percent completion. Please wait until it is complete before initiating another.

## Transparent Login Messages

PAM-TLGN-0060: CA PAM user who is transparently logged into RDP Application <ApplicationName> to <WindowsTitle> window as <Username> user, at <Device> device.

**ApplicationName** – The name of the RDP application defined in Privileged Access Manager

**WindowsTitle** – The title of the window that the end-user used to log in

**Username** – The name of the target account that was used

**Device** – The credential source

## PAM-CS: Cluster Status Messages

PAM-CS-0001 = Database Cluster Replication Status from PAM Instance {0}

PAM-CS-0002 = The following primary site cluster members are no longer participating in database replication: {0}

PAM-CS-0003 = Failed retrieving list of unavailable cluster replication members: {0}

PAM-CS-0004 = ONLINE

PAM-CS-0005 = OFFLINE

PAM-CS-0006 = RECOVERING

PAM-CS-0007 = UNREACHABLE

PAM-CS-0008 = ERROR

PAM-CS-0009 = MISSING

PAM-CS-0010 = The following primary site cluster members are no longer participating in database replication: {0}

PAM-CS-0011 = Database cluster replication status: {0}.

PAM-CS-0012 = Failed refreshing list of unavailable cluster replication members

PAM-CS-0013 = The database is out of sync with the primary site for the following secondary site members: {0}

PAM-CS-0014 = CA PAM Cluster Failure: Please check the status of each member in the primary site

PAM-CS-0015 = CA PAM instance {0} lost its connection to other members of the primary site, and has limited functionality. Please check the availability of other primary site members to ensure that they are online and reachable. Next, check their status by visiting their respective URLs: {1}. If you cannot access other members, visit https://{2} to repair the cluster.

PAM-CS-0016 = CA PAM Cluster is recovering

PAM-CS-0017 = CA PAM instance {0} can now communicate with all members of the cluster's primary site. To recover from a previous failure, we are rebooting the CA PAM instance.

PAM-CS-0018 = CA PAM Cluster is recovering the primary site

PAM-CS-0019 = We are rebooting all the members in the primary site of CA PAM Cluster to try to recover it from a previous failure.

PAM-CS-0020 = PAM appliance attempted to perform cluster operation on {0}, but is not part of its cluster list.

PAM-CS-0021 = The database is back online and participating in replication for the following primary site cluster members: {0}

PAM-CS-0022 = If the database is out of sync with the primary site for {0} more minutes, deactivation occurs.

PAM-CS-0023 = The database is back in sync with the primary site for the following secondary site members: {0}

PAM-UPD-0019 = Network storage for database backup does not have enough free space!  
PAM-UPD-0020 = There was a problem with the recording storage. This connection is continued in operationally-safe mode.

## Credential Manager Client Return Codes

Credential Manager clients generate these return codes and the associated messages. These clients include A2A (application to application), Windows Proxy, Windows Remote, client integrations, and their associated components.

## **Message Headers**

- `error.validation.header` =Validation Error:
- `error.exception` =Exception occurred {0} in {1}
- `error.loadingEntity` =Unable to load entity of type {0} with id {1}
- `error.entityDoesNotExist` =The entity of type {0} with id {1} does not exist
- `error.entityNotCorrectType` =The retrieved entity of type {0} does not match the expected type of {1}

## **Error Codes and Associated Messages**

### ***General Messages***

- `error.code.0`=Success.
- `error.code.1`=Application error occurred.
- `error.code.2`=Failed to connect to database.
- `error.code.3`=Database version does not match application version.
- `error.code.4`=A database error occurred.
- `error.code.5`=Request failed. The Xsuite cluster is in stopped mode.
- `error.code.10`=Invalid user ID.
- `error.code.11`=Invalid password.
- `error.code.12`=Login failed.
- `error.code.13`=User ID/password combination does not exist.
- `error.code.14`=User session has not been authenticated. Please log in.
- `error.code.15`=Account suspended.
- `error.code.16`=Missing login digest values.
- `error.code.17`=Missing login digest.
- `error.code.18`=Cannot log in to secondary site.
- `error.code.19`=User is authenticated, but credential must be reset.
- `error.code.20`=User ID must have 3 to 16 characters.
- `error.code.21`=Password must have 6 to 16 characters.
- `error.code.22`=Authorization failed. User {0} does not have permission for this action.
- `error.code.23`=Password must contain at least one alpha character (a-z, A-Z).
- `error.code.24`=Password must contain at least one numeric character (0-9).
- `error.code.25`=Password must contain at least one special character (~!@#\$%^&\*()\_+~`~:~|~/?~.,).
- `error.code.26`=Authorization failed. User {0} does not have permission for this entity.
- `error.code.27`=Invalid password specified.
- `error.code.30`=Invalid license has been registered. Unable to complete request.
- `error.code.31`=License limit has been exceeded. Unable to complete request.
- `error.code.32`=Success. {Warning: Approaching license limit; you may need to upgrade your license.}
- `error.code.33`=Unlimited license error.
- `error.code.34`=Limited license error.
- `error.code.35`=Failed to register error. Error code already defined.
- `error.code.36`=Not authorized for updating the license. Permission required: `setSystemProperty`

### ***Client Error Messages***

- error.code.400=Success.
- error.code.401=Failed to authenticate with the Password Authority service.
- error.code.402=Unable to establish connection with client daemon.
- error.code.403=Not authorized (for client daemon).
- error.code.404=Unable to establish connection with Password Authority Server.
- error.code.405=No data found for specified target alias.

- error.code.421=Invalid IP address specified.
- error.code.422=Invalid port number specified. Unable to connect.
- error.code.423=Invalid execution path specified.
- error.code.424=Invalid script type specified.
- error.code.425=Invalid script name specified.
- error.code.426=Invalid execution user ID specified.
- error.code.427=Cannot update a new target alias.
- error.code.428=Maximum length of target alias exceeded.
- error.code.429=Application already exists for this server.
- error.code.430=No patch found.
- error.code.431=Patch found, but must be applied manually.
- error.code.432=Patch has already been processed.
- error.code.433=Privileged account cannot be used to create target alias.
- error.code.434=Invalid username.
- error.code.435=Invalid or no extension/application type specified.
- error.code.436=Security exception. Script integrity check failed.
- error.code.437=Security exception. Data tampering detected. Request denied.
- error.code.438=Unauthorized request server. Fingerprint has changed.
- error.code.439=Invalid XML definition.
- error.code.440=Password Authority Windows Proxy operation failed.
- error.code.441=Invalid file path specified.
- error.code.442=Unsupported command specified.
- error.code.446=Authorization mapping validation error. Invalid execution path specified for request script.
- error.code.447=Authorization mapping validation error. Invalid file path specified for request script.
- error.code.448=Authorization mapping validation error. Missing request script information.
- error.code.449=Authorization mapping validation error. Missing hash value for request script.
- error.code.450=Unsupported OS platform specified.
- ~~error.code.451=Command cannot be executed because the primary site is unavailable~~
- error.code.452=Primary site is unavailable. Any workflow tasks associated with the account's password view policy (dual authorization, change password, or checkin/checkout) have not been performed. <sup>2598</sup>
- error.code.460=Data source has not been initialized.
- error.code.461=Data source is not configured for clustering.
- error.code.462=Connection with client daemon timed out

**Native Call Application Error Messages**

- error.code.1400=Application JNI error - maximum length exceeded.
- error.code.1401=Application JNI error - null value.
- error.code.1500=Maximum retries exceeded.
- error.code.1501=No data found.
- error.code.1502=A problem occurred during archive. Not all records were archived. Please run the command again.

**Target Manager Error Messages**

- error.code.1600=Failed to synchronize password with target. If this problem persists then, please ask your Administrator to investigate.
- error.code.1601=Failed to verify password with target. If this problem persists then, please ask your Administrator to investigate.
- error.code.1602=Target server application is not responding!
- error.code.1603=Insufficient permission to change password on target application.
- error.code.1604=Authentication failed.
- error.code.1605=Database driver class not found.
- error.code.1606=Account is unsynchronized.
- error.code.1607=Target Manager cannot store credential
- error.code.1650=Unable to establish connection with target application!
- error.code.1651=Remote host closed connection during handshake. Possible invalid SSL certificate or port.
- error.code.1652=Invalid SSL Certificate.
- error.code.1660=Lock timeout, unable to process request.
- error.code.1661=Account update in progress, unable to process request.
- error.code.1662=The view password module did not respond.

**Role Error Messages**

- error.code.1700=Invalid role specified.
- error.code.1701=Role is read-only.
- error.code.1702=User status cannot be null.

**Update User Password Error Messages**

- error.code.1703=Invalid user password specified.
- error.code.1704=Invalid user authentication type.

**Client Error Messages**

- error.code.1800=Client is unable to process the request.
- error.code.1801=Unable to connect to client.
- error.code.1802=Client internal error processing request.
- error.code.1900=Invalid metric ID.

**Batch Sequence Error Messages**

- error.code.1910=Invalid parameters.
- error.code.1911=Invalid batch command.
- error.code.1912=Unable to commit transaction in database.
- error.code.1913=Unable to rollback transaction in database.
- error.code.1914=Unable to start a transaction in database.

- error.code.1920=Invalid start date
- error.code.1921=Invalid end date
- error.code.1922=Invalid result limit
- error.code.1930=Unable to upgrade database. Unsupported minimum release.
- error.code.1940=Another archive operation is in progress.
- error.code.1950=Invalid file name.
- error.code.1951=Invalid file path.
- error.code.1952=Invalid file permissions.
- error.code.1953=Invalid file size.
- error.code.1954=Invalid version when running in FIPS mode.

**Extension Manager: General Error Messages**

- error.code.2001=The password change process was not specified. The value assigned to the 'useOtherAccountToChangePassword' attribute must be 'true' or 'false'.
- error.code.2002=An invalid port number was specified.
- error.code.2003=An invalid Target Account ID was assigned to the 'otherAccount' attribute.
- error.code.2006=An invalid Target Account ID was assigned to the 'otherPrivilegedAccount' attribute.
- error.code.2007=The value assigned to the 'useOtherPrivilegedAccount' attribute must be 'true' or 'false'.

**Extension Manager: Oracle Error Messages**

- error.code.2011=Invalid database name.

**Extension Manager: UNIX Error Messages**

- error.code.2031=The specified other account has an incompatible protocol

**LDAP Error Messages**

- error.code.2041=No LDAP DN specified.

**Database Password Change Error Messages**

- error.code.2101=Invalid database username.
- error.code.2102=Invalid database password.
- error.code.2103=Invalid database host name.
- error.code.2104=Invalid database user type.
- error.code.2150=Failed to update database admin account.

**Enable Change-Password-On-View Error Messages**

- error.code.2201=Invalid interval parameter.

**Scheduling Error Messages**

- error.code.2301=Invalid schedule time.
- error.code.2302=This job will never run, the specified start date/time is in the past.
- error.code.2303=Failed to save job.
- error.code.2304=A Job already exists with this name.

**Constraint Error Messages**

- error.code.3000=Constraint manager parse error.
- error.code.3100=Invalid target server parameters.
- error.code.3200=Invalid target application parameters.
- error.code.3201=Cannot add a target application of a deprecated type.

### **Account Error Messages**

- error.code.3300=Invalid parameters.
- error.code.3301=Exceeded maximum length of access type parameter.
- error.code.3302=Account username may not contain whitespace characters.
- error.code.3303=Exceeded maximum length for username parameter.
- error.code.3304=Exceeded maximum length for password parameter.
- error.code.3305=The specified password view policy has "change password on view" enabled, but the account is unsynchronized.
- error.code.3306=The specified password view policy ID is invalid.
- error.code.3307=Duplicate compound servers are not allowed for compound account.
- error.code.3308=Circular reference. Account cannot refer to itself for "other account".
- error.code.3309=Target Server is not allowed to be added as compound server.
- error.code.3310=Compound account must be added as unsynchronized.
- error.code.3311=Servers are not specified for compound account.
- error.code.3312=Target server cannot be specified as a compound server.
- error.code.3313=Invalid target account ID.
- error.code.3314=User does not have `listOtherAccounts` permission.
- error.code.3315=The specified password view policy has "change password on SSO" enabled, but the account is unsynchronized.
- error.code.3316=Cannot use a password view policy with change on connection end with unsynchronized account.
- error.code.3317=Cannot use a password view policy with change on session end with unsynchronized account.
- error.code.3350=Password and confirm password do not match.
- error.code.3351=Account not specified.
- error.code.3360=Cannot update account password of unsynchronized account.

### **Target Alias Error Messages**

- error.code.3400=Invalid parameters.
- error.code.3401=Target alias name must consist only of characters [a-z A-Z 0-9 ~ \! @ \# \$ % ^ . \: \_ - + = \ / ].
- error.code.3500=Invalid request server parameters.
- error.code.3501=Request Server does not exist or has never connected to Password Authority Server.
- error.code.3502=Connection status checking is not supported on light clients.
- error.code.3503=Event polling is enabled or client port is invalid.
- error.code.3504=Invalid status code received from client ping.
- error.code.3505=Connection status checking is not supported on proxies.
- error.code.3506=Proxy cannot be deleted because it is in use.
- error.code.3507=Adding windows agent via CLI command is not supported in Xsuite.
- error.code.3508=Add request server failed.
- error.code.3600=Invalid script parameters.
- error.code.3700=Invalid script authorization parameters.
- error.code.3701=Invalid script authorization execution user maximum length exceeded.
- error.code.3702=Invalid script. It is on a different client than the one specified.
- error.code.3800=Invalid user parameters.

### **Role Error Messages**

- error.code.3900=Invalid parameters.
- error.code.3901=Exceeded maximum length of role name.
- error.code.3902=Role name must consist of characters [a-z, A-Z, 0-9].
- error.code.3903=Invalid role name.
- error.code.3904=Exceeded maximum length of role description.
- error.code.3905=Role description must consist of characters [a-z, A-Z, 0-9].
- error.code.3906=Invalid role ID.
- error.code.3907=Role is read-only.

**Group Error Messages**

- error.code.3950=Invalid parameters.
- error.code.3951=Exceeded maximum length of group name.
- error.code.3952=Group name must consist of characters [a-z, A-Z, 0-9].
- error.code.3953=Invalid group name.
- error.code.3954=Exceeded maximum length of group description.
- error.code.3955=Group description must consist of characters [a-z, A-Z, 0-9].
- error.code.3956=Invalid group ID specified.
- error.code.3957=Invalid permission specified.
- error.code.3958=Invalid object class ID.
- error.code.3959=Group is read-only.
- error.code.3960=Invalid group type.

**User Group Error Messages**

- error.code.3970=Invalid parameters.
- error.code.3971=Exceeded maximum length of user group name.
- error.code.3972=User group name must consist of characters [a-z, A-Z, 0-9].
- error.code.3973=Invalid user group name.
- error.code.3974=Exceeded maximum length of user group description.
- error.code.3975=User group description must consist of characters [a-z, A-Z, 0-9].
- error.code.3976=Invalid user group ID.
- error.code.3977=Invalid group IDs.
- error.code.3978=Invalid role ID.
- error.code.3979=User group is read-only.
- error.code.3980=Invalid read only.

**Report Error Messages**

- error.code.4000=Invalid parameters.

**System Property Error Messages**

- error.code.4100=Invalid property name specified.
- error.code.4101=Exceeded maximum length of property name.
- error.code.4102=Property name must consist of characters [a-z, A-Z, 0-9].
- error.code.4103=Invalid property value specified.

**E-mail Properties Validation Error Messages**

- error.code.4105=Invalid e-mail target account.
- error.code.4106=Invalid e-mail server host name.
- error.code.4107=Invalid e-mail server port.
- error.code.4108=Invalid e-mail address.
- error.code.4109=Invalid e-mail subject.
- error.code.4110=Invalid e-mail body.
- error.code.4111=Invalid e-mail subject for update.
- error.code.4112=Invalid e-mail body for update.
- error.code.4113=Target account not specified.
- error.code.4114=Requesting user not specified.
- error.code.4115=Password view policy not specified.
- error.code.4116=Password view request not specified.
- error.code.4117=Approver not specified.

### ***US 121 Messages***

- error.code.4118=Invalid e-mail subject for Password View.
- error.code.4119=Invalid e-mail body for Password View.

### ***US 120 Messages***

- error.code.4120=Invalid e-mail subject for Expired Password View Request.
- error.code.4121=Invalid e-mail body for Expired Password View Request.
- error.code.4122=Invalid e-mail subject for External Password Approvals.
- error.code.4123=Invalid e-mail body for External Password Approvals.

### ***US 91 Messages***

- error.code.4124=Invalid e-mail subject for Report Results.
- error.code.4125=Invalid e-mail body for Report Results.
- error.code.4126=Max User Group Limit cannot be more than 25.

### ***Initial Property Error Messages***

- error.code.4150=Invalid property name specified.

### ***Patch Error Messages***

- error.code.4200=Invalid patch ID.
- error.code.4201=Invalid request server ID.
- error.code.4202=Invalid patch detail ID.
- error.code.4203=Invalid activate all flag.
- error.code.4204=Patch already exists.
- error.code.4205=Patch deployment disabled.
- error.code.4206=Invalid Request Server connection status.
- error.code.4207=Release now only supported for request servers of version 4.5.2 and up.

### ***Password Policy Error Messages***

- error.code.4300=Invalid password policy ID.
- error.code.4301=Invalid password policy name.
- error.code.4302=Invalid password policy name.
- error.code.4303=Exceeded maximum length of password policy name.
- error.code.4304=Password policy name must consist of characters [a-z, A-Z, 0-9].
- error.code.4305=Exceeded maximum length of password policy description.
- error.code.4306=Password policy description must consist of characters [a-z, A-Z, 0-9].
- error.code.4307=Invalid password policy type, this is a required value.
- error.code.4308=Invalid password policy type value. Valid values [passwordPolicy].
- error.code.4309=Password policy special characters cannot contain XML characters (> < & ' ").
- error.code.4310=Password policy minimum length is too small.
- error.code.4311=Password policy maximum length is too small.
- error.code.4312=Minimum length must be less than the maximum length.
- error.code.4313=Policy validation error.
- error.code.4314=Password policy cannot be null.
- error.code.4315=Repeats cannot be allowed if duplicates are disallowed.
- error.code.4316=Select at least one character set in the 'Must Contain' category.
- error.code.4317=Select at least one character set in the 'First Must Contain' category.
- error.code.4318=First upper case character conflicts with no upper case characters anywhere.
- error.code.4319=First lower case character conflicts with no lower case characters anywhere.
- error.code.4320=First numeric character conflicts with no numeric characters anywhere.

- error.code.13507=Could not log into HP Service Manager server.
- error.code.13508=HP Service Manager server specified in the password view policy could not be found.
- error.code.13509=HP Service Manager application specified in the password view policy could not be found.
- error.code.13510=HP Service Manager account specified in the password view policy could not be found.
- error.code.13511=The CA NIM SM target server could not be found.
- error.code.13512=The CA NIM SM target application could not be found.
- error.code.13513=The CA NIM SM target account could not be found.
- error.code.13514=Could not retrieve the ticket from the HP Service Manager system.

**Custom View Password Module Error Code Messages (14000 - 14999)**

- error.code.14000=The specified CA Normalized Integration Management account is in use and can't be deleted.
- error.code.14001=The requested operation is not allowed on the CA Normalized Integration Management Target Account.
- error.code.14002=The requested operation is not allowed on the CA Normalized Integration Management Target Application.
- error.code.14003=The requested operation is not allowed on the '[nim.pam.ca.com](http://nim.pam.ca.com)' Target Server.
- error.code.14004=The requested operation is not allowed on the selected application type.
- error.code.15000=An invalid issuer URL was specified.
- error.code.15001=An invalid console URL was specified.
- error.code.15002=An invalid sign-in URL was specified.
- error.code.15003=Exceeded maximum length for URL parameter.
- error.code.15004=The specified URL is not formatted correctly.
- error.code.15005=An invalid session duration was specified; the allowed range is 3600 - 129600 seconds.
- error.code.15006=An invalid policy was specified.
- error.code.15007=Exceeded maximum length for policy parameter.
- error.code.15008=The specified policy is not formatted correctly.
- error.code.15009=The AWS client reports that corrupted data was received from the AWS server; the error message is: {0}
- error.code.15010=The AWS client reports that communications with the AWS server failed; the error message is: {0}
- error.code.15011=An invalid session URL encoding option was specified.
- error.code.15012=The AWS service reported a problem; the error message is: {0}
- error.code.15013=The requested operation is not allowed on the AWS Access Credentials Target Application.
- error.code.15014=The requested operation is not allowed on the '[xceedium.aws.amazon.com](http://xceedium.aws.amazon.com)' Target Server.
- error.code.15015=The requested command cannot be invoked from a remote host.
- error.code.15016=The specified federated user name is incompatible with AWS; it contains too few characters.
- error.code.15017=The specified federated user name is incompatible with AWS; it contains too many characters.
- error.code.15018=The federated user name is missing from the request.
- error.code.15019=The specified federated user name is incompatible with AWS.
- error.code.15020=The specified AWS access account is in use and can't be deleted.
- error.code.15021=The requested operation is not allowed on the AWS API Proxy Credentials Target Account.
- error.code.15022=The requested operation cannot be performed by user with the specified target application type.
- error.code.15023=The requested operation is not allowed
- error.code.15099=The specified VMware access account is in use and can't be deleted.
- error.code.15100=Delete Check: the requested operation would delete an existing Target Server with ID: {0}
- error.code.15101=Delete Check: the specified host name corresponds to one or more deleted Target Server(s): {0}
- error.code.15102=Delete Check: the specified host name does not correspond to any existing or deleted Target Server(s): {0}
- error.code.15103=Delete Check: the specified ID corresponds to a deleted Target Server: {0}
- error.code.15104=Delete Check: the specified ID does not correspond to an existing or deleted Target Server: {0}
- error.code.15105=Delete Check: the requested operation would delete an existing Request Server of type CLIENT or AGENT with ID: {0}
- error.code.15106=Delete Check: the specified host name corresponds to one or more deleted Request Server(s) of type {1}: {0}
- error.code.15107=Delete Check: the specified host name does not correspond to any existing or deleted Request Server(s) of type {1}: {0}
- error.code.15108=Delete Check: the specified ID corresponds to a deleted Request Server of type CLIENT or AGENT: {0}
- error.code.15109=Delete Check: the specified ID does not correspond to an existing or deleted Request Server of type CLIENT or AGENT: {0}
- ~~error.code.15110=Delete Check: the specified ID corresponds to one or more deleted Target Server(s): {0}~~
- error.code.15111=Delete Check: the specified ID does not correspond to any existing or deleted Target Server(s): {0}

**Extension Manager: Common Channel and Processor Target Connector API (15200 - 15299)**

- error.code.15200=Failed to process a target connector script. Refer to the log file for further information.
- error.code.15201=Failed to store an object in script processor memory.
- error.code.15202=Failed to retrieve an object from storage in script processor memory.
- error.code.15203=Failed to reset the script processor.
- error.code.15204=An error occurred while processing a target connector script. The Target Account specifies an unrecognized password change method.
- error.code.15205=An error occurred while processing a target connector script. The Target Account specifies an unsupported protocol.
- error.code.15206=An error occurred while configuring the communications channel. The Target Account specifies an unsupported protocol.
- error.code.15207=Failed to find {0} pattern(s) while reading from the communications channel: {1}
- error.code.15208=An error occurred while configuring the script processor. Failed to retrieve a Target Account with ID {0}.
- error.code.15209=An error occurred while configuring the script processor. The Target Account specifies another account should be used for authentication and/or verification but no value is assigned to the other account attribute.
- error.code.15210=An error occurred while configuring the communications channel. The specified and calculated known host key fingerprints do not match.
- error.code.15211=An error occurred while configuring the communications channel. Failed to decode the known host key.
- error.code.15212=Failed to establish a communications channel to the remote host.
- error.code.15213=An error occurred while configuring the script processor. An invalid pattern was specified for the password entry prompt.
- error.code.15214=An error occurred while configuring the script processor. An invalid pattern was specified for the password confirmation prompt.
- error.code.15215=An error occurred while configuring the script processor. An invalid pattern was specified for the password change prompt.
- error.code.15216=An error occurred while configuring the script processor. An invalid pattern was specified for the user name entry prompt.
- error.code.15217=Failed to remove an object from storage in script processor memory.
- error.code.15218=An error occurred while configuring the script processor. Failed to retrieve a Target Account with ID {0}.
- error.code.15219=An error occurred while configuring the script processor. The Target Account specifies another privileged account should be used but no value is assigned to the other privileged account attribute.
- error.code.15220=A problem occurred while executing the script processor. Please try your request again or contact your Administrator.
- error.code.15221=A problem occurred while executing the script processor. Failed to automatically derive a public key. Specify the public key and try again or else contact your Administrator.

**Extension Manager: Common Channel and Processor Target Connector UI (15300 - 15399)**

- error.code.15300=Cannot read the revised update script file. Verify the filename and ensure the patch obtained from Customer Support has been applied.
- error.code.15301=Cannot read the revised verify script file. Verify the filename and ensure the patch obtained from Customer Support has been applied.
- error.code.15302=An invalid filename was specified for the revised update script file. Verify the filename or else contact Customer Support to obtain the correct filename.
- error.code.15303=An invalid filename was specified for the revised verify script file. Verify the filename or else contact Customer Support to obtain the correct filename.
- error.code.15304=Must choose the filename of the revised update script if any are available. Only use this field if instructed to do so by Customer Support.
- error.code.15305=Must choose the filename of the revised verify script if any are available. Only use this field if instructed to do so by Customer Support.
- error.code.15306=An invalid regular expression was specified to match the Password Change prompt.
- error.code.15307=An invalid list of server host key types was specified.
- error.code.15308=An invalid list of inbound compression methods was specified.
- error.code.15309=An invalid list of key exchange algorithms was specified.
- error.code.15310=An invalid list of outbound compression methods was specified.
- error.code.15311=An invalid list of inbound hashes was specified.
- error.code.15312=An invalid list of outbound hashes was specified.
- error.code.15313=An invalid list of inbound ciphers was specified.
- error.code.15314=An invalid list of outbound ciphers was specified.
- error.code.15315=Must specify a replacement update script. Only use this field if instructed to do so by Customer Support.
- error.code.15316=Must specify a replacement verify script. Only use this field if instructed to do so by Customer Support.
- error.code.15317=An invalid list of ciphers to detect was specified.
- error.code.15318=An invalid regular expression was specified to match the Password Confirmation prompt.
- error.code.15319=An invalid regular expression was specified to match the Password Entry prompt.
- error.code.15320=An invalid regular expression was specified to match the User Name Entry prompt.

**Error Messages for Microsoft Office 365 (Online Portal) (15400 - 15499)**

- error.code.15400=The portal URL is missing from the request.
- error.code.15401=The specified portal URL is invalid.
- error.code.15402=The Security Token Service endpoint URL is missing from the request.
- error.code.15403=The specified Security Token Service endpoint URL is invalid.
- error.code.15404=The Security Token Service endpoint reference URI is missing from the request.
- error.code.15405=The specified Security Token Service endpoint reference URI is invalid.
- error.code.15408=The context (`wctx`) parameter is missing from the request.
- error.code.15409=The specified context (`wctx`) parameter is invalid.
- error.code.15410=Failed to load the token request template.
- error.code.15411=Failed to initiate federated session.
- error.code.15412=Failed to retrieve token request response from the Security Token Service.
- error.code.15413=Failed to load the federated session request template.
- error.code.15414=Failed to retrieve target account password.
- error.code.15415=The target account ID is missing from the request.
- error.code.15416=The specified target account ID is invalid.
- error.code.15419=The reason parameter is missing from the request.
- error.code.15421=The specified start date is invalid.
- error.code.15423=The specified end date is invalid.
- error.code.15424=The specified compound server ID is invalid.
- error.code.15425=Failed to encode the specified context (`wctx`) parameter.

#### **Error Messages for SSH Key Pair Policy (15500 - 15599)**

- error.code.15500=The SSH Key Pair Policy ID is missing.
- error.code.15501=The specified SSH Key Pair Policy ID is invalid; it must be an integer greater than zero.
- error.code.15502=The SSH Key Pair Policy name is missing.
- error.code.15503=The specified SSH Key Pair Policy name is invalid; it must consist of characters [a-z, A-Z, 0-9].
- error.code.15504=The specified SSH Key Pair Policy name is too long; reduce the number of characters that it contains.
- error.code.15505=The SSH Key Pair Policy description is missing.
- error.code.15506=The SSH Key Pair Policy description is invalid; it must consist of characters [a-z, A-Z, 0-9].
- error.code.15507=The SSH Key Pair Policy description is too long; reduce the number of characters that it contains.
- error.code.15508=The SSH Key Pair Policy key type is missing.
- error.code.15509=The specified SSH Key Pair Policy key type is invalid; it must be ECDSA or RSA or DSA.
- error.code.15510=The SSH Key Pair Policy key length is missing.
- error.code.15511=The specified SSH Key Pair Policy key length is invalid.
- error.code.15512=Failed to add SSH Key Pair Policy due to error: {0}
- error.code.15513=Failed SSH Key Pair generation test due to error: {0}
- error.code.15514=The specified SSH Key Pair type and length are not compatible.
- error.code.15515=An SSH Key Pair Policy ID or Name must be specified.
- error.code.15516=Failed to load an SSH Key Pair Policy having the specified ID or Name.
- error.code.15517=Must specify either an SSH Key Pair Policy ID or a Name but not both.
- error.code.15600=Invalid subnet x.x.x.x. Format should be in CIDR notation (xxx.xxx.xxx.xxx/xx)

- error.code.15601=Cannot change host name. Device in use by LDAP Domain Configuration.
- error.code.15602=Cannot change host name. Application in use by LDAP Domain Configuration.
- error.code.15603=Cannot change application. Account in use by LDAP Domain Configuration.
- error.code.15604=Failure updating LDAP configuration
- error.code.15605=Cannot change host name. Device in use by RADIUS and TACACS+ Configuration.
- error.code.15606=Cannot change application type. Application in use by RADIUS and TACACS+ Configuration.
- error.code.15607=Cannot change application. Account in use by RADIUS and TACACS+ Configuration.

**Remote Agent Error Codes (15608 - 15622)**

- error.code.15608=Remote Agent other account
- error.code.15609=Cannot change application. Account in use by another Windows Remote Agent account.
- error.code.15610=Cannot change account type. Account in use by another Windows Remote Agent account.
- error.code.15611=Cannot change application. Account in use for discovery by an Active Directory account.
- error.code.15612=Cannot change account type. Account in use for discovery by an Active Directory account.
- error.code.15613=Not a Remote Agent admin
- error.code.15614=Remote Agent I/O error
- error.code.15615=Remote Agent process interrupted
- error.code.15616=Remote Agent process abnormal exit
- error.code.15617=Remote Agent logon failed
- error.code.15618=Remote Agent access denied
- error.code.15619=Remote Agent connection error
- error.code.15620=No Remote Agent admin
- error.code.15621=Remote Agent cannot clean up
- error.code.15622=No Remote Agent admin ID
- error.code.15623=Account is in use by Azure Configuration.
- error.code.15624=Operation is not permitted on Azure access credentials target server

**Error messages for CA NIM SM target manager connector (15700 - 15719)**

- error.code.15701=Change process not specified.
- error.code.15702=Internal target connector error.
- error.code.15703=Failed to synchronize password with target.
- error.code.15704=Failed to verify password with target.

**Error Code Messages for CA NIM UM Target Manager Connector (15720 - 15739)**

- error.code.15721=Change process not specified.
- error.code.15722=Internal target connector error.
- error.code.15723=Failed to synchronize password with target.
- error.code.15724=Failed to verify password with target.

**Error Code Messages for ServiceNow Target Manager Connector (15740 - 15759)**

- error.code.15741=Change process not specified.
- error.code.15742=Internal target connector error.
- error.code.15743=Failed to synchronize password with target.
- error.code.15744=Failed to verify password with target.
- error.code.15745=A ServiceNow URL must be specified.
- error.code.15746=A `ServiceNowClientURL` must be specified.
- error.code.15747=Could not log into ServiceNow server.

**Basic error messages for Service Desk connector (15760 - 15779)**

- error.code.15760=Error retrieving Service Desk user credentials.
- error.code.15761=The CA NIM UM target server could not be found.
- error.code.15762=The CA NIM UM target application specified in the password view policy could not be found.
- error.code.15763=The CA NIM UM target account specified in the password view policy could not be found.
- error.code.15764=Failed to synchronize password with target.
- error.code.15765=Failed to verify password with target.

***Error messages for HP Service Manager target manager connector (15780 - 15799)***

- error.code.15780=Change process not specified.
- error.code.15781=Internal target connector error.
- error.code.15782=Failed to synchronize password with target.
- error.code.15783=Failed to verify password with target.
- error.code.15784=A port must be specified.
- error.code.15785=A `HPSMClientURL` must be specified.
- error.code.15786=An Enabled Protocol must be specified.
- error.code.15787=Could not log into HP Service Manager server.

***Error Code Messages for CA SDM Target Manager Connector (15800 - 15819)***

- error.code.15800=Change process not specified.
- error.code.15801=Internal target connector error.
- error.code.15802=SOAP Protocol must be specified.
- error.code.15803=SOAP Port must be specified.
- error.code.15804=REST Protocol must be specified.
- error.code.15805=REST Port must be specified.
- error.code.15806=Could not log into CA SDM server.

***SSH Certificate Policy Error Messages***

- error.code.18000=The SSH Certificate Policy ID is missing.
- error.code.18001=The specified SSH Certificate Policy ID is invalid; it must be an integer greater than zero.
- error.code.18002=The SSH Certificate Policy name is missing.
- error.code.18003=The specified SSH Certificate Policy name is invalid; it must consist of characters [a-z, A-Z, 0-9].
- error.code.18004=The specified SSH Certificate Policy name is too long; reduce the number of characters that it contains.
- error.code.18005=The SSH Certificate Policy description is missing.
- error.code.18006=The SSH Certificate Policy description is invalid; it must consist of characters [a-z, A-Z, 0-9].
- error.code.18007=The SSH Certificate Policy description is too long; reduce the number of characters that it contains.
- error.code.18008=The SSH Certificate Policy force command is too long; reduce the number of characters that it contains.
- error.code.18009=The specified SSH Certificate Policy permit-x11-forwarding is invalid; it must be true or false.
- error.code.18010=The specified SSH Certificate Policy permit-pty is invalid; it must be true or false.
- error.code.18011=The specified SSH Certificate Policy permit-port-forwarding is invalid; it must be true or false.
- error.code.18012=The specified SSH Certificate Policy permit-user-rc is invalid; it must be true or false.
- error.code.18013=An SSH Certificate Policy ID or Name must be specified.
- error.code.18014=Failed to load an SSH Certificate Policy having the specified ID or Name.
- error.code.18015=Must specify either an SSH Certificate Policy ID or a Name but not both.
- error.code.18016=Failed to add an SSH Certificate Policy having the specified ID or Name.
- error.code.18017=The SSH Certificate Policy permit-x11-forwarding is missing.
- error.code.18018=The SSH Certificate Policy permit-pty is missing.
- error.code.18019=The SSH Certificate Policy permit-port-forwarding is missing.
- error.code.18020=The SSH Certificate Policy permit-user-rc is missing.
- error.code.18021=Cannot delete Default policy.
- error.code.18022=Cannot update Default policy's name.

## Credential Manager Terms and Concepts

The following terms and concepts are used regarding Credential Manager.

- **Application-to-application (A2A) accounts:** A2A accounts are accessed by applications in addition to users. For example, database accounts are used by web pages to retrieve information from the database.
- **Batch processing:** The Credential Manager CLI feature that lets you read an XML formatted file as input to a registration activity.
- **Credentials:** User name and password or RSA key that is associated with an account
- **Master account:** A target account that is used to change another account. This account must have the ability to change another account password, such as `root` or `sudo` -enabled accounts in UNIX. See also Slave account.
- **Privileged accounts:** Accounts that have elevated privileges; for example, UNIX root accounts and database administrator accounts. Attended privileged accounts are associated with people. Unattended privileged accounts are associated with automated applications or machines. Privileged accounts can usually affect multiple users. Privileged accounts are often used for access and password viewing. See also Unprivileged accounts.
- **Remote account:** An account on or accessible by a remote host. Some accounts can be considered to be on multiple hosts. For example, an account is stored in a directory, such as AD or LDAP. The account can be managed in the directory server or on a remote host when the account is typically used, such as a user desktop. There can be multiple

target application types that manage a given remote account although typically not. This situation usually occurs for Windows accounts or account in a directory server.

- **Remote application:** An application on a remote host, such as the OS or a Database Management System (DBMS)
- **Remote host:** A computing platform other than the Privileged Access Manager appliance. Examples include servers, laptops, desktops, and routers.
- **Roles:** A collection of actions that can be performed on the GUI and CLI. Roles can be built for each series of permissions you want to assign to Credential Manager administrators. Credential Manager roles are distinct and separate from Privileged Access Manager roles. See [Credential Manager Group Terminology](#).
- **Slave account:** A target account whose password is changed by a master account. See also Master account.
- **Synchronized credentials:** The ability of Credential Manager to renew credentials on target applications using a predetermined process to keep the Privileged Access Manager appliance and requestor synchronized.
- **Target:** General term for a target account, target application, and target server.
- **Target account:** An account that is located on a remote host and is managed by Credential Manager.
- **Target applications:** Applications on a remote host that require credentials for access. Examples include a databases or the remote host OS. A target application can contain one or more target accounts. Multiple target application types exist, each corresponding to a different target connector.
- **Target connector:** Code and extensions that are applied to the Credential Manager target application and target account details pages that communicate with a given type of remote application. Each target connector is associated with a target application.
- **Target group:** A collection of target servers, target applications, or target accounts that meet specific filter criteria; for example, all target servers that have the identifier `London` in the descriptor field. A single target can belong to multiple target groups. When a target group consists of target servers, all applications and accounts on that server are automatically within that target group.
- **Target server:** A server hosting one or more target applications. In the *Privileged Access Manager* appliance, it is configured as a Device of type **Password Management**.
- **Unprivileged accounts:** Accounts that have restricted privileges, usually allowing a user to read or affect only their own data. See also privileged accounts. See also Privileged accounts.
- **User group:** A collection of one target group, one requestor group, and one role. Credential Manager user groups are distinct and separate from Privileged Access Manager User Groups. See [Credential Manager Group Terminology](#).
- **Users:** Users are people that access and operate Credential Manager. Each user belongs to one or more user groups. The user groups define what targets and requestors the user can see and what actions the user can perform on the Credential Manager interfaces.

## **A2A Terminology**

In addition, the following terms and concepts apply when referring to Application-to-application (A2A) functionality:

- **Client:** A program that identifies information about the invoking program or script (such as its name, path, hash, and `userId`). For UNIX and Linux, the client stub is `cspmclient`. For Windows, the client stub is `cspmclient.exe`. For Java programs, the client stub is `cspmclient.jar`.
- **Client daemon or service:** A UNIX daemon or Windows service that caches credentials from the Privileged Access Manager appliance. The A2A Client requests credentials from it. If the credentials are not cached, it requests the credentials from the Privileged Access Manager appliance. It then caches them before returning the credentials to the client.
- **Requestor application:** Applications that initiate communications with target applications using target credentials. Requestor applications invoke a client stub to communicate to the Privileged Access Manager appliance to get the required credentials.
- **Requestor group:** A collection of requestors or requestor servers that meet specific filter criteria; for example, all requestor servers that have the identifier `London` in the descriptor field. A single requestor can belong to

multiple requestor groups. When a requestor group consists of requestor servers, all requestors on that server are automatically within that requestor group.

- **Requestor script:** A Perl, Python, PHP, sh, ksh, or csh script that invokes a client stub to get credentials.
- **Requestor server:** A server hosting one or more requestors

## Windows Shortcut Keys for the RDP Client

The following table lists the shortcut keys for the Privileged Access Manager RDP Client and their comparison to standard shortcut keys supported by native Windows RDP Client (mstsc):

Key	Action	Mstsc (non full screen mode)	Mstsc (full screen mode)	PAM RDP Client
Alt+Delete	Opens the Windows menu.	Yes	No	The Content Menu appears
Alt+Esc	Cycles through programs in the order that they were started.	No	Yes	No
Alt+Home	Opens the Start menu.	Yes	No	Yes
Alt+Insert	Cycles through programs in the order that they were started.	Yes	No	Yes
Alt+Page Down	Switches between programs from right to left.	Yes	No	Yes
Alt+Page Up	Switches between programs from left to right.	Yes	No	Yes
Alt+Shift+Home	Opens the Task Manager	Yes	No	Yes
Alt+Space	Opens the Windows menu.	No	Yes	No
Alt+Tab	Switches between programs from left to right.	No	Yes	No
Ctrl+Alt+Break	Switches the client between full-screen mode and window mode.	Yes	Yes	No
Ctrl+Alt+Minus Sign (-)	Places a snapshot of the active window, within the client, on the Remote Desktop Session Host (RD Session Host) server Clipboard. This provides the same functionality as pressing Alt+Print Screen on the local computer.	Yes	No	No
Ctrl+Alt+Plus Sign (+)	Places a snapshot of the entire client windows area on the RD Session Host server Clipboard. This provides the same functionality as pressing	Yes	No	No

	PRINT SCREEN on the local computer.			
Ctrl+Break	Breaks the execution of a console application.	Yes	Yes	No
Ctrl+Esc	Opens the Start menu.	No	Yes	No
Ctrl+Shift+Esc	Opens the Task Manager	No	Yes	No

In addition, the Privileged Access Manager RDP Client handles this key combination in the following way:

Key	Action
Alt+Enter	Switch to full screen mode.

## Upgrade

These general instructions describe the function of the Upgrade page on the product UI. For upgrade instructions pertaining to specific upgrades, patches, or hotfixes, see the Upgrading section for that version on [Techdocs](#).

### **Backup and Recovery**

Backup and Recovery is offered as a precaution you take before upgrading your appliance. The Backup and Recovery tab functions only on a physical appliance.

- For virtual machines, take a "snapshot" using a product such as VMware vSphere.
- See [AWS AMI Backup and Recovery](#) for backup and recovery information for AWS instances.

### **Perform Full Appliance Backup**

This button provides a full system backup, including OS, firmware, configuration settings of the appliance, and the provisioning data of managed users and devices. The backup is saved to the appliance internal secondary drive. Note these characteristics of system backups:

- Only a single backup is maintained. Because the secondary drive stores up to an entire primary drive capacity, it can contain only the most recently executed Backup.
- Upgrades automatically back up the appliance. As part of any upgrade, or any hotfix that requires a reboot, Privileged Access Manager performs the backup process automatically and silently.
- A full copy is made. During the backup process, the secondary drive makes a complete copy of the primary drive.
- The product reboots automatically. After it copies the primary drive, the appliance will automatically reboot.

### **Recover Appliance from Latest Backup**

Perform recovery only with the assistance of CA Support.

A Privileged Access Manager backup on the internal secondary drive can be restored by clicking the Recover button. If the system has become inaccessible from the network, Recover is also possible from the Console.

### **NOTE**

Patch binaries use HMAC (Hash-based Message Authentication Code), a FIPS 140-2 requirement, and SHA 256. Privileged Access Manager verifies HMAC-SHA-256 on all appliances (FIPS or not). Upgrade patches and diagnostic patches that are supplied by Broadcom Support are all included.

### **Upgrade**

1. Navigate to **Configuration, Upgrade**.

2. In the **Upgrade History** section, confirm that your currently installed upgrades include all necessary patches to enable upgrade to the current release.
3. Select **Choose File** and select the upgrade file in the file browser. Do not select the payload file.
4. Select **Upload And Apply**. The UI and the LCD display show messages as the upgrade progresses. These messages might display for several minutes.

**Important!** Keep your browser open until you see the final reboot message. Do not interrupt the upgrade process.

5. Optionally, select **Show Checksums**. This option recomputes the downloaded file's checksum value to verify that the file was not corrupted during the upload process. Compare this newly generated value with the value of the checksum file included in the downloaded zip file to make sure they match. Specifically, the checksum value appears the file with the sha256 file extension. If the values do not match, the file has been corrupted somehow.

**NOTE**

Running the **Show Checksums** option may take several minutes, depending on the number and size of the patches.

6. Following these steps to confirm that the upgrade has been successfully applied:
  - a. Navigate to **Configuration, Upgrade**, and confirm that the **Upgrade History** section shows the file name that you uploaded, with the current time and date.
  - b. Navigate to **Sessions, Logs** and confirm that you can see entries for the successful upgrade and reboot of the appliance.
7. Log in to the appliance and confirm that all data is restored.

## Third-Party License Acknowledgments

---

This product includes the following third-party components. To review a complete list of these third-party components, their subcomponents, and associated license agreements, select [this link](#).

- Activation 1.1.1
- adal4j 1.1.2
- Adoptium (Temurin) Java JDK 1.8.0\_402-b06
- Adoptium (Temurin) Java JDK 11.0.22+7
- Adoptium (Temurin) Java JDK 17.0.10\_7
- Aespipe 2.4e aespipe
- Amazon AWS SDK for PHP 3.263.2
- animal-sniffer-annotations 1.1.4
- animal-sniffer-annotations 1.17
- Antlr 2.7.6
- aopalliance-repackaged 2.5.0-b42
- Apache ActiveMQ 5.16.7
- Apache ActiveMQ 5.18.3
- Apache Commons Text 1.9
- Apache Directory LDAP API 1.0.0-M20
- Apache HTTP Web Server 2.2.9
- ASM 3.1
- AutoIT 3.3.10
- AWS SDK for Java 1.12.440
- backo-java 1.0.0
- Bcpkix-jdk15on-151.jar 1.5.1
- Beanshell 2.0b6
- Boost 1.68.0
- Boost 1.73.0

- SUN License

## Product Accessibility Features

---

Broadcom is committed to ensuring that all customers, regardless of ability, can successfully use its products and supporting documentation to accomplish vital business tasks.

You can use the following accessibility features with Privileged Access Manager:

### **Product Enhancements**

Privileged Access Manager offers accessibility enhancements in the following areas:

- Display
- Sound
- Keyboard
- Mouse
- Custom Controls (if any)

#### ***Display***

To increase visibility on your computer display, you can adjust the following options:

- **Font style, color, and size of items** Defines font color, size, and other visual combinations.
- **Screen resolution** Defines the pixel count to enlarge objects on the screen.
- **Cursor width and blink rate** Defines the cursor width or blink rate, which makes the cursor easier to find or minimize its blinking.
- **Icon size** Defines the size of icons. You can make icons larger for visibility or smaller for increased screen space.
- **High contrast schemes** Defines color combinations. You can select colors that are easier to see.

#### ***Sound***

Use sound as a visual alternative or to make computer sounds easier to hear or distinguish by adjusting the following options:

- **Volume** Sets the computer sound up or down.
- **Text-to-Speech** Sets the computer's hear command options and text read aloud.
- **Warnings** Defines visual warnings.
- **Notices** Defines the aural or visual cues when accessibility features are turned on or off.
- **Schemes** Associates computer sounds with specific system events.
- **Captions** Displays captions for speech and sounds.

#### ***Keyboard***

You can make the following keyboard adjustments:

- **Repeat Rate** Defines how quickly a character repeats when a key is struck.
- **Tones** Defines tones when pressing certain keys.
- **Sticky Keys** Defines the modifier key, such as Shift, Ctrl, Alt, or the Windows Logo key, for shortcut key combinations. Sticky keys remain active until another key is pressed.

#### ***Mouse***

You can use the following options to make your mouse faster and easier to use:

- **Click Speed** Defines how fast to click the mouse button to make a selection.
- **Click Lock** Sets the mouse to highlight or drag without holding down the mouse button.
- **Reverse Action** Sets the reverse function that is controlled by the left and right mouse keys.
- **Blink Rate** Defines how fast the cursor blinks or if it blinks at all.
- **Pointer Options** Lets you complete the following actions:
  - Hide the pointer while typing
  - Show the location of the pointer
  - Set the speed that the pointer moves on the screen
  - Select the size and color of the pointer for increased visibility
  - Move the pointer to a default location in a dialog

### **Keyboard Shortcuts**

The PAM Client login dialog supports the following keyboard shortcuts:

Keyboard	Description
Tab or Ctrl+Tab	Move forward through options
Shift+Tab or Ctrl+Shift+Tab	Move backward through options
Arrow keys	Move focus or selection in a group of controls, items, or tabs
Space	Locate new selection and anchor for the item.
Enter	Carry out the default command of the dialog or command of the selected control

The Privileged Access Manager UI supports the following keyboard shortcuts:

Keyboard	Description
Ctrl+X	Cut
Ctrl+C	Copy
Ctrl+V	Paste
Ctrl+F	Search

## Important Links

---

This content provides links to the following important information:

- The latest documentation for all supported versions of PAM is available online at <http://techdocs.broadcom.com/pam>. The site opens at the latest product version. Use the **Version** drop-down menu in the title bar near the top of the screen to access the documentation for other supported PAM versions
- [Privileged Access Manager solutions and patches](#) web page
- Free PAM education videos are available from the [IMS Software Academy](#) site.
- The 4.1 third-party license acknowledgments are available at: <https://techdocs.broadcom.com/us/en/symantec-security-software/identity-security/privileged-access-manager/4-1-1/third-party-license-acknowledgments.html>

## Telemetry Data

Broadcom uses a unique Portfolio License Agreement (PLA) model that enables customers to derive a value from the adoption and usage of the Broadcom product portfolio. Telemetry serves as the foundational data for Broadcom to measure portfolio consumption by a customer under a PLA. Telemetry is mandatory for customers participating in the PLA subscription model to enable the telemetry service and transmit usage information to the Broadcom data warehouse. This can be accomplished by using the Broadcom standalone **Product Usage Reporter** utility that is equipped with the telemetry usage reporting capabilities. The utility is a browser-based application that can be installed as a service on a Windows or a Linux machine.

For information about the Product Usage Reporter utility and its installation procedure, see [Product Usage Reporter Overview](#) and [Installing Product Usage Reporter](#).

### What Usage Data Do We Collect?

The Product Usage Reporter utility collects the following PAM data.

Data	Description
<b>Instance ID</b>	The instance ID of the product.
<b>Product usage</b>	Reports the number of devices, by type, in use on a particular day. Device types include: Access, Password Management, and A2A. If you have a cluster, the product usage data must be only from the primary site.
<b>System configuration</b>	Specifies the product version.
<b>Date when the data is collected</b>	The date when the product usage data is captured.

#### WARNING

The utility does not collect Personally Identifiable Information (PII). For more information, see [Privacy Policy](#).

### How to Configure PAM to Collect and Submit Usage Data to Us

As an administrator, configure telemetry after installing or upgrading the product.

#### Follow these steps:

1. In the UI, select **Configuration, Licensing, Telemetry Data**.
2. Complete the following fields:
  - **Is this install or upgrade related to a new or additional planned usage related to a portfolio license agreement (PLA):** If the product is installed or upgraded as part of a portfolio license agreement (PLA), select Yes. Otherwise, select No.
  - **Company Domain:** Enter your company domain name, for example, `forwardinc.com`.
  - **Enterprise Site ID:** Enter the assigned numeric ID for your organization. You can find this number on your PLA or on the [Broadcom Support site](#). To locate the number on the Support site:
    - a. Sign in to your Support account.
    - b. Select **My Account, Profile**.

- c. Under **Support Access Information**, refer to the **Site ID**.
  - **Internal Identifier:** Enter a label that identifies which group is reporting usage. Your company might have different divisions, each with their own product installations. This field enables you to indicate which division is sending data.
  - **Manually upload telemetry data:** Leave the default setting (**Yes**), to manually collect and submit the product usage data to Broadcom. A report is *not* sent automatically from the appliance.
  - **Use a proxy to send usage data:** If your appliance sits behind a proxy server, identify the server so that data can reach the telemetry service. Specify the URI of the proxy server and its associated credentials. To review proxy errors, go to Sessions, Logs page.
3. Select **Save** to complete the configuration. If you modify the telemetry configuration, always save your changes.

### **How to View and Download Usage Data for Manual Reporting**

The product usage data is saved in a file once it is submitted to Broadcom. For information about viewing and downloading the file, see [Dashboard](#).

For additional information about using or troubleshooting the utility, see [Product Usage Reporter](#).

### **How do you know if the usage data was successfully sent to us?**

View the submitted product usage data in the **Dashboard** page of the Product Usage Reporter utility. For information about viewing the usage data, see [Dashboard](#).
