<updateUser>admin</updateUser>
</TargetAccount>
</cr.result>
</CommandResult>

```

### 3. View the password. Use the ID provided by the output of the previous command:

Windows:

```

capam_command adminUserID=admin capam=mycompany.com cmdName=viewAccountPassword ^
TargetAccount.ID=1005 reason=Poweroutagereason reasonDetails=Recover Tuesday pm ^
PasswordViewRequest.requestPeriodStart="2010-11-16 16:58" ^
PasswordViewRequest.requestPeriodEnd="2010-11-16 17:05"

```

Linux:

```

capam_command adminUserID=admin capam=mycompany.com cmdName=viewAccountPassword \
TargetAccount.ID=1005 reason=Poweroutagereason reasonDetails=Recover Tuesday pm \
PasswordViewRequest.requestPeriodStart="2010-11-16 16:58" \
PasswordViewRequest.requestPeriodEnd="2010-11-16 17:05"

```

#### 4. Enter your password at the prompt.

Credential Manager immediately returns the requested password in the following XML command string. Internally, a retrospective approval request is generated and sent to the account owner for retrospective approval.

```
<CommandResult>
  <cr.itemNumber>0</cr.itemNumber>
  <cr.statusCode>400</cr.statusCode>
  <cr.statusDescription>Success.</cr.statusDescription>

</cr.result>
</CommandResult>

```

### **Acknowledge or Decline a Request Using the CLI**

Use the following procedure to acknowledge or decline a password view request from the CLI using the `updatePasswordViewRequestStatus` command.

#### **Follow these steps:**

1. Search target accounts to retrieve the target account ID:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=searchPasswordViewRequestByApprover
```

2. Enter your password at the prompt.

Credential Manager returns the following XML command string. Note the ID value. In this example, it is **4**.

```

<CommandResult>
  <cr.itemNumber>0</cr.itemNumber>
  <cr.statusCode>400</cr.statusCode>
  <cr.statusDescription>Success.</cr.statusDescription>
  <cr.result>
    <PasswordViewRequest>
      <endDate>Fri Nov 30 22:21:00 UTC 2018</endDate>
      <startDate>Fri Nov 30 22:21:00 UTC 2018</startDate>
      <ssoType></ssoType>
      <requestorID>1000</requestorID>
      <targetAccountID>1005</targetAccountID>
      <approverID>-1</approverID>
      <referenceCode></referenceCode>
      <reasonDescription>view</reasonDescription>
      <approvalReason></approvalReason>
      <approvalReasonDescription></approvalReasonDescription>
      <approverIPAddress></approverIPAddress>
      <viewStatus>1</viewStatus>
      <reason>view</reason>
      <status>11</status>
      <createTime>1543616479000</createTime>
      <createDate>Fri Nov 30 22:21:19 UTC 2018</createDate>
      <extensionType></extensionType>
      <updateDate>Fri Nov 30 22:21:19 UTC 2018</updateDate>
      <createUser>super</createUser>
      <updateTime>1543616479000</updateTime>
      <updateUser>super</updateUser>
      <hash>XtwwNcuGn4807UrSSekcq5g3Mlo=</hash>
      <ID>1059</ID>
    </PasswordViewRequest>
  </cr.result>
</CommandResult>

```

3. Change the status of the password view request to acknowledged or declined. Use the ID provided by the output of the previous command:

```

Windows:
capam_command adminUserID=admin capam=mycompany.com ^

```

```
cmdName=updatePasswordViewRequestStatus PasswordViewRequest.ID=4 ^
PasswordViewRequest.status=acknowledged
Linux:
capam_command adminUserID=admin capam=mycompany.com \
cmdName=updatePasswordViewRequestStatus PasswordViewRequest.ID=4 \
PasswordViewRequest.status=acknowledged
```

#### 4. Enter your password at the prompt.

Credential Manager returns the following XML command string.

```
<CommandResult>
  <cr.itemNumber>0</cr.itemNumber>
  <cr.statusCode>400</cr.statusCode>
  <cr.statusDescription>Success.</cr.statusDescription>
  <cr.result>
    <PasswordViewRequest>
      <endDate>Fri Nov 30 22:21:00 UTC 2018</endDate>
      <startDate>Fri Nov 30 22:21:00 UTC 2018</startDate>
      <ssoType></ssoType>
      <requestorID>1000</requestorID>
      <targetAccountID>1005</targetAccountID>
      <approverID>1000</approverID>
      <referenceCode></referenceCode>
      <reasonDescription>view</reasonDescription>
      <approvalReason></approvalReason>
      <approvalReasonDescription></approvalReasonDescription>
      <approverIPAddress></approverIPAddress>
      <viewStatus>1</viewStatus>
      <reason>view</reason>
      <status>9</status>
      <createTime>1543616479000</createTime>
      <createDate>Fri Nov 30 22:21:19 UTC 2018</createDate>
      <extensionType></extensionType>
      <updateDate>Fri Nov 30 22:36:23 UTC 2018</updateDate>
      <createUser>super</createUser>
      <updateTime>1543617383416</updateTime>
      <updateUser>super</updateUser>
      <hash>ouVRldocSDru0WMQ1Q/cXDmyRfg=</hash>
      <ID>1059</ID>
    </PasswordViewRequest>
  </cr.result>
</CommandResult>
```

### **Update the Acknowledge or Decline Reasons for a Request Using the CLI**

The reasons to be populated in the Reason drop-down list while acknowledging or denying the password view request using the GUI, can be updated using the `setSystemProperty` command.

To update the list of acknowledgement reasons, use:

```
Windows:
cspmservice_admin cmdName=setSystemProperty propertyName=ViewPasswordAcknowledgeReasons ^
propertyValues=reason1
Linux:
cspmservice_admin cmdName=setSystemProperty propertyName=ViewPasswordAcknowledgeReasons \
```

```
propertyValues=reason1
```

To update the list of denial reasons, use:

Windows:

```
cspmserver_admin cmdName=setSystemProperty propertyName=viewPasswordDeclineReasons ^
propertyValues=reason1|reason2
```

Linux:

```
cspmserver_admin cmdName=setSystemProperty propertyName=viewPasswordDeclineReasons \
propertyValues=reason1|reason2
```

The | character delimits multiple reasons.

## Require an Account Check-Out to View the Password

If an account has a Check-out/Check-in view policy, the account must be checked out to view the password. The person then has exclusive access to the password. While it is checked out, other persons cannot view the password nor can they change any aspect of the account in any way. Once the password is checked back in to Credential Manager, others can view it and can update it.

The Check-out/Check-in policy can have a time interval, after which the account is automatically checked back in.

Sometimes an administrator needs immediate access to a password that is checked out. The administrator can remove the restriction on the account by checking in the account on behalf of another user. By default, only the administrator role has permission to force a check-in operation. If necessary, you can configure other roles with this permission.

This topic describes the following procedures:

For the equivalent procedures using the CLI, see [Require a Password Check Out and Check using the CLI](#).

### Check Out a Password Using the UI

Follow these steps:

1. Select **Credentials, Manage Targets, Accounts**.
2. Select the blue View icon (which resembles an eye) in the **Action** column of the Account for which you want to request authorization. A Show Password pop-up window appears, prompting you for your password and the reasons for viewing the target password.
3. Enter your (Credential Manager administrator) password.

#### **NOTE**

The password field is displayed if the target account is authenticated.

4. Select your **Reason** for viewing the (target account) password.
5. (Optional) Enter the **Reason Description**.
6. Select **View**.  
The GUI displays the account User ID and the password. The GUI also notifies you that the account is checked out.
7. Select **OK**.

### Determine Who Has a Password Checked Out

Use the following procedure to find out how has a password that is checked out.

Follow these steps:

1. Select **Credentials, Manage Targets, Accounts**.
2. For the appropriate entry in the Target Accounts list, select the blue Checkout icon (which resembles an eye with an X across it) located in the Action column. A dialog appears showing who has checked out the password.

The Reference Code is shown only if the requestor has entered the reference code in View Account Password Request screen before viewing the account password.

### **Check In a Password Using the UI**

When you check out a password, no other user can view the password or can change the account until you select it back in again. Checking in the password removes this restriction and frees the account for use by others. In emergency situations, an administrator can check in a password on behalf of another user.

#### **NOTE**

Checking in passwords does not affect open access sessions. Users currently in active access sessions will remain logged in regardless of the password being checked in.

You can check in an account password from the following GUI locations:

- Credentials, Manage Targets, Accounts
- Credentials, Workflow, My Requests
- Access screen

Use the following procedure to check in a password from the **Credentials, Manage Targets, Accounts** screen.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**.
2. For the account password to be checked in, select the Check-In icon (a black right-facing arrow inside a box). The icon is in the Action column.  
A message confirms that the password has been checked in.

Use the following procedure to check in a password from the **Credentials, Workflow, My Requests** screen.

#### **Follow these steps:**

1. Select **Credentials, Workflow, My Requests**
2. Select the entry for the account (with status "Checked Out") whose password you want to check in and select **View**. The Password View Request Details screen appears.
3. In the Password View Request Details dialog, select **CHECK IN**.  
A message confirms that the password has been checked in.

Use the following procedure to check in a password from the **Access** screen.

#### **Follow these steps:**

1. If you are logged in as an administrator, select **Access** from the main menu. If you are not an administrator, the home screen *is* the Access screen (though it is not labeled).  
A list of checked out passwords is presented at the top of the screen.

#### **NOTE**

If you are not an administrator, you might need to log out and log back in again before checked-out passwords are visible.

2. Select **Check In** in the right-hand column of the password line item.

### **Force a Password Check In Using the GUI**

When an account password is checked out, other users cannot view the password nor can they change the account. Use this procedure to force a check-in of an account password on behalf of another user.

**NOTE**

Checking in passwords does not affect open access sessions. Users currently in active access sessions will remain logged in regardless of the password being checked in.

**NOTE**

When you perform a forced check in, any required activities that are associated with that operation also occur, for example, an update of the account password.

The administrator can check in an account on behalf of another user from the following screens:

- **Credentials, Manage Targets, Accounts**
- **Credentials, Workflow, All Requests**

User the following procedure to check in a password using the **Credentials, Manage Targets, Accounts** screen.

**Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**.
2. For the password to be checked in, select the Check-In icon (black right-facing arrow inside a box). The icon is in the Action column.  
A message confirms that the password has been checked in.

Use the following procedure to check in a password using the **Credentials, Workflow, All Requests** screen.

**Follow these steps:**

1. Select **Credentials, Workflow, All Requests**.
2. Select the account (with status "Checked Out") for which you want to view check out details and select **View**. The Password View Request Details screen appears.
3. Select the **FORCE CHECK-IN** button.  
The account password is checked in.

**Check Out An Account Using the CLI**

You can use the CLI to require that an account is checked out to view the password.

**Check Out an Account to View the Password**

Using the CLI, you can require an account check-out using the `addPasswordViewPolicy` command and the parameter `PasswordViewPolicy.checkinCheckoutRequired=true`.

Example:

```
capam_command capam=capamServer adminUserID=admin cmdName=addPasswordViewPolicy
PasswordViewPolicy.name=restrictedAccounts PasswordViewPolicy.changePasswordOnView=true
PasswordViewPolicy.checkinCheckoutRequired=true
PasswordViewPolicy.checkinCheckoutInterval=240
```

When a user views the password, message displays indicating that the account is checked out.

Use the following procedure to view an account password from the CLI.

**Follow these steps:**

1. Search target accounts to retrieve the target account ID:  

```
capam_command adminUserID=admin capam=mycompany.com cmdName=searchTargetAccount
TargetAccount.userName=account1
```

## 2. Enter your password at the prompt.

Credential Manager returns the following XML command string. Note the ID value. In this example, it is **1**.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetAccount>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.changePasswordAfterViewing>true</Attribute.changePasswordAfterViewing>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1</ID>
<createDate>Mon Nov 12 15:42:43 UTC 2007</createDate>
<updateDate>Mon Nov 12 15:42:43 UTC 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>q3/BaUy9uPvtbUkKgIrXvgseGt8=</hash>
<targetApplicationID>1</targetApplicationID>
<userName>account1</userName>
<password>l4adc6a1a720e58ee52032364b98f95b</password>
<accessType>A</accessType>
<cacheAllow>true</cacheAllow>
<cacheDuration>20</cacheDuration>
<privileged>false</privileged>
<synchronize>false</synchronize>
<passwordVerified>false</passwordVerified>
<lastVerified>Mon Nov 12 15:42:43 EST 2007</lastVerified>
</TargetAccount>
</cr.result>
</CommandResult>
```

## 3. View the password. Use the ID provided by the output of the previous command.

```
capam_command adminUserID=admin capam=mycompany.com cmdName=viewAccountPassword TargetAccount.ID=1
reason=Power Outage reasonDetail=Recovery
```

## 4. Enter your password at the prompt.

Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>

</CommandResult>

```

### **Check In an Account Password Using the CLI**

Use the following procedure to check in an account password using the `checkInAccountPassword` command.

#### **Follow these steps:**

1. Search target accounts to retrieve the target account ID of the account that was previously checked out:

```

capam_command adminUserID=admin capam=mycompany.com cmdName=searchTargetAccount
TargetAccount.userName=account1

```

2. Enter your password at the prompt.

Credential Manager returns the following XML command string. Note the ID value. In this example, it is **1**.

```

<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetAccount>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.changePasswordAfterViewing>>true</Attribute.changePasswordAfterViewing>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1</ID>
<createDate>Mon Nov 12 15:42:43 UTC 2007</createDate>
<updateDate>Mon Nov 12 15:42:43 UTC 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>q3/BaUy9uPvtbUkKgIrXvgseGt8=</hash>
<targetApplicationID>1</targetApplicationID>
<userName>account1</userName>
<password>14adc6a1a720e58ee52032364b98f95b</password>
<accessType>A</accessType>
<cacheAllow>>true</cacheAllow>
<cacheDuration>20</cacheDuration>
<privileged>>false</privileged>
<synchronize>>false</synchronize>
<passwordVerified>>false</passwordVerified>
<lastVerified>Mon Nov 12 15:42:43 EST 2007</lastVerified>
</TargetAccount>

```

```
</cr.result>
</CommandResult>
```

3. Check in the password. Use the ID provided by the output of the previous command.

```
capam_command adminUserID=admin capam=mycompany.com cmdName=checkInAccountPassword TargetAccount.ID=1
```

4. Enter your password at the prompt.

Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<PasswordViewRequest>
<status>1</status>
<targetAccountID>1</targetAccountID>
<startDate>Wed Sep 10 15:34:00 UTC 2008</startDate>

<ID>3</ID>
<createDate>Wed Sep 10 14:34:51 UTC 2008</createDate>
<createUser>admin</createUser>
<hash>fcWQRQVNDogOFxpvm/DLZGlu614=</hash>
<updateDate>Wed Sep 10 15:34:51 UTC 2008</updateDate>
<updateUser>admin</updateUser>
<extensionType/>
</PasswordViewRequest>
</cr.result>
</CommandResult>
```

### **Force an Account Check-In Using the CLI**

When you check out an account, this action restricts others from viewing the password and from changing the account. However, sometimes the administrator must override this restriction. If an administrator wants to access a checked-out account, the administrator can force a check-in of the account on behalf of another user. When the administrator forces a check-in, any required activities for that operation also occur, for example, an update of the account password.

**Follow these steps:**

1. Search target accounts to retrieve the target account ID of the account that was previously checked out:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=searchTargetAccount
TargetAccount.userName=account1
```

2. Enter your password at the prompt.

Credential Manager returns the following XML command string. Note the ID value. In this example, it is **1**.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetAccount>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.changePasswordAfterViewing>true</Attribute.changePasswordAfterViewing>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1</ID>
```

```

<createDate>Mon Nov 12 15:42:43 UTC 2007</createDate>
<updateDate>Mon Nov 12 15:42:43 UTC 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>q3/BaUy9uPvtbUkKgIrXvgseGt8=</hash>
<targetApplicationID>1</targetApplicationID>
<userName>account1</userName>
<password>14adc6a1a720e58ee52032364b98f95b</password>
<accessType>A</accessType>
<cacheAllow>true</cacheAllow>
<cacheDuration>20</cacheDuration>
<privileged>false</privileged>
<synchronize>false</synchronize>
<passwordVerified>false</passwordVerified>
<lastVerified>Mon Nov 12 15:42:43 EST 2007</lastVerified>
</TargetAccount>
</cr.result>
</CommandResult>

```

3. Check in the password. Use the ID provided by the output of the previous command.

```
capam_command adminUserID=admin capam=mycompany.com cmdName=forceCheckInAccountPassword TargetAccount.ID=1
```

4. Enter your password at the prompt.

Credential Manager returns the following XML command string.

```

<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<PasswordViewRequest>
<status>1</status>
<targetAccountID>1</targetAccountID>
<startDate>Wed Sep 10 15:34:00 UTC 2008</startDate>
<endDate>Wed Sep 10 19:34:00 UTC 2008</endDate>
<requestorID>1</requestorID>
<approverID>-1</approverID>

<createUser>admin</createUser>
<hash>fcWQRQVNDogOFxpvm/DLZGlu614=</hash>
<updateDate>Wed Sep 10 15:34:51 UTC 2008</updateDate>
<updateUser>admin</updateUser>
<extensionType/>
</PasswordViewRequest>
</cr.result>
</CommandResult>

```

## Enable Email Notifications for Viewed Passwords

The *email notification* option for a password view policy allows certain users to receive email notifications when another user views an account password. Emails are sent only for successful initial password view requests. For example, if the password is viewed for an already checked out account, no email is sent.

When adding or updating the policy, select a new set of users to receive email notification or select dual authorization approvers. You can also send the email notification only to the active users from the list of identified users.

#### NOTE

Dual authorization is not required for email notifications.

Enable email notifications in the password view policy.

#### Follow these steps:

1. Select **Credentials, Workflow, Password View Policies**. The Password View Policies page appears.
2. Select the password view policy for which Email Notification is to be enabled and select the **Update** button. The Update Password View Policy dialog appears.
3. Select the **Email Notification** tab and set the **Email Notification** option.
4. Optionally, to send emails to only active users, select **Active Users Only**. Active users can be dual authorization approvers or a new set of users.
5. Optionally, if dual authorization is enabled for this policy, and you want only approvers to receive emails, select **Dual Authorization Approvers Only**. Assign the users by moving them from the **Available Users** list to the **Selected Users** list.

#### WARNING

To receive email notifications, the selected users must have an account with the **Password Manager** role assigned. The email address that is associated with the user account is used.

6. Select **OK**.

#### Configure the Email Settings

The email server and email messages are configured in the Credential Manager email settings. Access these settings by selecting **Settings, Credential Manager**. For instructions on the email settings, see [Configure the Email Server and Email Templates](#).

### Track Account Movement Across Active Directory OUs

Credential Manager can track user accounts that move between different organizational units (OUs) in Active Directory.

When an account changes OUs, the account DN changes. Credential Manager account tracking can find the user account in Active Directory and successfully change the password. Password view policies and password rollover are not impacted by the change to an OU.

Credential Manager first tries to bind to Active Directory using the Distinguished Name (DN). If that binding fails, it tries to bind using the User Principal Name (UPN). If the UPN binding works, the DN is updated in the PAM database to match the DN in Active Directory.

#### Accounts that Do Not Use the UPN

Credential Manager might not be able to track the account change automatically under the following circumstances. Manual updates are required.

- If the Active Directory account does not include a UPN, manually update the DN in the target account. Without a UPN, there is no alternative to the DN.
- If the UPN changes in the Active Directory account, manually update the UPN in the PAM target account. The UPN between Active Directory and Credential Manager must be in sync. Credential Manager can still track an account using the DN. However, any subsequent OU change can alter the DN and the UPN is needed as an alternative.

#### NOTE

Changes only to the UPN do not change the DN.

## See a List of Password View Requests

You can see a list of all password view requests, provided you have the requisite permission. You can also see a list of only your own requests. Both options are available from the **Credentials**, **Workflow** menu. Follow these steps:

1. Go to **Credentials**, **Workflow**, **My Requests**, or **All Requests**.
2. The All Password View Requests or My Password View Requests page display.  
Both pages list the same columns, but the **All Requests** page has a **Delete** button to remove entries.
3. Select **View** to see details of a particular request.

## Make a Request to View a Password

With password view policies established, users and administrators with the required privileges can view passwords. Credential Manager administrators must have appropriate permissions to view passwords and password histories.

### Make a View Password Request Using the UI

Follow these steps:

1. Navigate to **Credentials**, **Manage Targets**, **Accounts**.
2. Do *one* of the following tasks.
  - **From the Target Accounts page:** Select the icon that resembles an eye in the **Action** column of the Account whose password you want to see. A Show Credential pop-up window appears, displaying the account name and credential.
  - **From the account Update page:** Select the name of the account and select the **Update** button. In the Update dialog that appears, select the icon that resembles an eye to the right of the **Credential** field.  
For compound accounts, a drop-down list of all target servers appears in a pop-up window. Select the target server whose password you want to view. Typically, the password is the same for all servers. However, if a password update fails, each server on which the subsequent rollback fails has an out-of-sync password.
3. Select the viewing interval. Times are given based on your local time zone, as set in the Preferences page.
4. Enter your password in the **Password** field.
5. Select the **Reason** for viewing the password from the drop-down list.  
Depending on your organizational policy, your reason can also require a **Reason Description** or a **Reason Code**.

#### **TIP**

Using the CLI, you can customize the list of reasons for viewing a password. See [Customize the Reasons for Viewing a Password](#).

The reference code is shown only if the requestor enters the reference code in the View Account Password Request screen before requesting password authorization.

6. Select **View**.

### View an Account Password from the Access Page

Active Target Applications and their associated Target Accounts are listed on the Access page. Every Target Application that is associated with a Device is identified in the drop-down list in the Target Applications column. Every Target Account that is associated with each application appears in a nested list.

After selecting a target account from the drop-down list, a pop-up window appears with a View Account Password Request window. After entering the password (for the currently logged-in user), the credentials are displayed.

## **View Password History from the UI**

### **Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**. The Target Accounts page appears with a list of existing accounts.
2. In the account list, select the account for which you want to view the password history. The Account Details page appears.
3. On the **Credential** tab, select the View History icon (a clock with a clockwise arrow) located to the right of the Credential field. The Password History page appears showing password change history.  
The Password History Compromised flag may be manually set within Credential Manager. The flag may be used to record whether a password has become known to an unauthorized individual. The flag may be set to true to indicate that a password should not be reused. The value of the flag does not affect Credential Manager processing.

## **Set Password History Compromised Flag from the UI**

### **Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**.
2. Select the account with the compromised password.
3. Select the **View History** icon located to the right of the **Credential** field. The **View History** icon resembles a clock with a clockwise arrow.
4. Select the date and time of the credential request. The Password History details page appears.
5. Select the **Compromised** check box.
6. Select **Save**.

## **View Target Passwords from the CLI**

### **Follow these steps:**

1. Search target accounts to retrieve the target account ID:  

```
capam_command adminUserID=admin capam=mycompany.com cmdName=searchTargetAccount
TargetAccount.userName=account1
```
2. Enter your password at the prompt. Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetAccount>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.changePasswordAfterViewing>true</Attribute.changePasswordAfterViewing>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1</ID>
<createDate>Mon Nov 12 15:42:43 EST 2007</createDate>
<updateDate>Mon Nov 12 15:42:43 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>q3/BaUy9uPvtbUkKgIrXvgseGt8=</hash>
<targetApplicationID>1</targetApplicationID>
<userName>account1</userName>
<password>14adc6a1a720e58ee52032364b98f95b</password>
<accessType>A</accessType>
<cacheAllow>true</cacheAllow>
<cacheDuration>20</cacheDuration>
```

```

<privileged>false</privileged>
<synchronize>false</synchronize>
<passwordVerified>false</passwordVerified>
<lastVerified>Mon Nov 12 15:42:43 EST 2007</lastVerified>
</TargetAccount>
</cr.result>
</CommandResult>

```

3. Request to view the password. Use the ID provided by the output of the previous command:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=viewAccountPassword TargetAccount.ID=1
reason=Power Outage reasonDetail=Recovery
```

For compound accounts, you can specify the `TargetServer.hostName` parameter to view the password for a specific server. This parameter is only required for compound server accounts.

4. Enter your password at the prompt. Credential Manager returns the following XML command string.

```

<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetAccount>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.changePasswordAfterViewing>true</Attribute.changePasswordAfterViewing>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1</ID>
<createDate>Mon Nov 12 15:42:43 EST 2007</createDate>
<updateDate>Mon Nov 12 15:42:43 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>q3/BaUy9uPvtbUkKgIrXvgseGt8=</hash>
<targetApplicationID>1</targetApplicationID>
<userName>account1</userName>
<password>123456</password>
<accessType>A</accessType>
<cacheAllow>true</cacheAllow>
<cacheDuration>20</cacheDuration>
<privileged>false</privileged>
<synchronize>false</synchronize>
<passwordVerified>false</passwordVerified>
<lastVerified>2007-11-12 15:42:43.0</lastVerified>
</TargetAccount>
</cr.result>
</CommandResult>

```

## Configure Just in Time (JIT) Provisioning for MSSQL User Accounts

This section describes how to configure Just in Time (JIT) provisioning to dynamically provision and deprovision Microsoft SQL Server (MSSQL) user accounts on demand.

JIT provisioning provides the following security enhancements for access to your SQL Server database:

- Zero-trust security where user identities only exist on SQL Server during the checkout period.
- On-demand identity and access management with dynamic privileges that is auditable and can be subject to third-party approval.

Key components introduced to support JIT dynamic provisioning are:

- *Custom workflows* that are used to define custom directives to execute when a PAM user checks out and checks in target account credentials
- *Provisioned accounts* that are used as a template for dynamically creating target accounts. These target accounts are provisioned when credentials are checked out and deleted when they are checked in.

### Prerequisites

- An Active Directory domain server that is configured as an LDAP directory in PAM and containing the users and user groups to be imported into PAM.
- A supported Microsoft SQL Server database on a server that is a member of the previously described LDAP domain.

### Configuration Steps

To configure JIT provisioning, complete the following procedures in order:

1. [Add the LDAP Domain Server Required for JIT Provisioning](#)
2. [Import LDAP User Groups for JIT Provisioning](#)
3. [Create a Device for the MSSQL Database That Requires JIT Provisioning](#)
4. [Create a Custom Workflow to Handle Just in Time Target Account Checkout and Check-in](#)
5. [Create a Target Application for the MSSQL Database Admin Account Used by JIT Provisioning](#)
6. [Create a Target Account for the MSSQL Database Administrator \(for JIT Provisioning\)](#)
7. [Configure a Provisioned Account for JIT Provisioning](#)
8. [\(Optional\) Restrict Users from Editing Azure User Name Values](#)
9. [Create an Access Policy for JIT LDAP Users](#)

## Add the LDAP Domain Server Required for JIT Provisioning

This procedure describes how to configure PAM to communicate with an LDAP domain server that contains the users and groups that require JIT provisioning.

### Follow these steps:

1. Do the following steps to create a target device for the LDAP domain server:
  - a. Navigate to **Devices, Manage Devices**
  - b. Select the **Add** button.
  - c. Complete the following fields in the **Add Device** pane that opens:
    - **Name**: A descriptive name for the device.
    - **Address**: The IP address of the LDAP domain server.
    - **Device type**: Set the **Access** and **Password Management** options.
2. Do the following steps to configure a target application for the domain server:
  - a. Navigate to **Credentials, Manage Targets, Applications**.
  - b. Select the **Add** button.
  - c. Complete the following fields on the **Application** tab of the **Add Target Application** pane that opens:
    - **Host Name**: The IP address or FQDN of the LDAP domain server.
    - **Device Name**: The name of the domain server.
    - **Application Name**: The name of the target application.
    - **Application Type**: Select **Active Directory** from the drop-down menu.
  - d. Select the **Active Directory** tab and enter the desired domain name (for example, examplead.com).
3. Do the following steps to configure a target account for the domain administrator:
  - a. Navigate to **Credentials, Manage Targets, Accounts**.
  - b. Select the **Add** button.
  - c. Complete the following fields on the **Account** tab of the **Add Target Account** pane that opens:

- **Host Name:** The IP address or FQDN of the LDAP domain server.
  - **Device Name:** The name of the domain server.
  - **Application Name:** The name of the domain server target application.
  - **Account Name:** The name of the domain administrator account.
  - **Password View Policy:** The required password view policy.
  - **Password:** Specify the password of the domain administrator account.
- d. Select the **Active Directory** tab and enter the DN of the domain administrator account in the **Distinguished Name** field. For example: CN=Administrator,CN=Users,DC=EXAMPLEAD,DC=com
4. Do the following steps to configure the LDAP domain for the LDAP server:
- a. Navigate to **Configuration, 3rd Party, LDAP**.
  - b. Select the **Add** button.
  - c. Complete the following fields on **Add LDAP Domain** pane that opens:
    - **Bind Server:** The IP address of the LDAP domain target server.
    - **Bind Application:** The domain server target application.
    - **Bind Account:** The domain administrator target account.
    - **Server:** Select the plus icon and specify the IP address and port number of the LDAP domain.

**TIP**

**Next step:** [Import LDAP User Groups for Azure SQL JIT Provisioning](#).

## Import LDAP User Groups for JIT Provisioning

This topic describes how to import LDAP user groups that contain the MSSQL users and groups that require JIT provisioning.

### Follow these steps:

1. Connect to PAM using the PAM client.
2. Navigate to **Users, Manage User Groups, Import LDAP Groups**. The LDAP Browser opens.
3. Select **File, Connect**.
4. In the **Connect to LDAP Domain** dialog that opens, select the LDAP domain that you configured to communicate with your LDAP domain server and select **OK**.
5. Locate and expand the **Users** folder from the LDAP tree in the left pane.
6. Locate and select the checkbox beside each user group that you want to import.
7. (Optional) Review the device groups that are selected for import:
  - a. Select **PAM Groups, Manage selected groups to register with the PAM appliance**.  
The list of the Distinguished Names for all selected groups displays.
  - b. Select and edit any group DN, or remove it from the staging list.
8. Select **PAM Groups, Register selected groups with the PAM appliance**. A window opens displaying a list of the staged groups from which you can monitor progress, and can display any messages that are associated with the actions.
 

**Note:** When you import a group, all the users that are members of that group are imported into PAM automatically.
9. Select **Register Groups** in the lower-left corner. PAM imports the groups in the order that they are listed. The browser provides feedback and cancellation options throughout the process
10. When the import is complete and verified, close the LDAP browser.
11. In the PAM UI, navigate to **Users, Manage User Groups**, and confirm that the imported user groups appear.
12. Navigate to **Users, Manage Users**, and confirm that the users in the imported user groups appear on the page.
13. Update the definition of each imported user to define an **RDP User Name** that specifies the LDAP domain name and the user name specified in the user information using the following format: *LDAP\_Domain\SAM\_Account\_Name*  
For example: JITDOMAIN\joe

**Note:** If you have imported a large number of users, we recommend that you use the External API to automate the RDP User Name update for those users.

14. Assign appropriate PAM roles to each user and group based on your organizational requirements.

**TIP**

**Next step:** [Create a Device for the MSSQL Database That Requires JIT Provisioning.](#)

## Create a Device for the MSSQL Database That Requires JIT Provisioning

This topic describes how to create a device for the Microsoft SQL Server (MSSQL) database on which you require Just in Time dynamic provisioning and deprovisioning of user accounts

**Follow these steps:**

1. Navigate to **Devices, Manage Devices**
2. Select the **Add** button.
3. Complete the following fields in the **Add Device** pane that opens:
  - **Name:** A descriptive name for the device (Provisioned Account, “SQL 2019”).
  - **Address:** The IP address of the SQL Server.
  - **Device type:** Set the **Access** and **Password Management** options.

**TIP**

**Next step:** [Create a Custom Workflow to Handle Just in Time Target Account Checkout and Check-in .](#)

## Create a Custom Workflow to Handle Just in Time Target Account Checkout and Check-in

Configure a Custom Workflow that defines the directives to execute when a PAM user checks out and checks in a target account using Just in Time (JIT) provisioning on an MSSQL or Azure SQL managed instance.

### Credential Manager Privileges Required to Work with Custom Workflows

Administrators responsible for creating, updating, and deleting custom workflows must be assigned a role with the following Credential Manager privileges (as appropriate):

- **Add Custom Workflow:** Required to create a new custom workflow.
- **Delete Custom Workflow:** Required to delete a custom workflow.
- **Update Custom Workflow:** Required to update a custom workflow.
- **Read Custom Workflow:** Required to view a custom workflow.
- **Search Custom Workflow:** Required to search for and list custom workflows.

For a complete list of Credential Manager roles and privileges, see [Add or Modify Credential Manager Roles.](#)

### Directives for MSSQL JIT Custom Workflows

Use the following directives when configuring actions to run on the target database when a user checks out or checks in a target account:

**Note:** Use the exact syntax used in the following samples.

Application Type	Required Operation	Directive
MSSQL	Create account	+Account
MSSQL	Remove account	-Account
MSSQL	Add a role	+Role:<role name>

MSSQL	Remove a role	-Role:<role name>
MSSQL	Add multiple roles	+Role:<role1 name>,<role2 name>
MSSQL	Remove multiple roles	-Role:<role1 name>,<role2 name>
MSSQL	Create Account and update roles	+Account;+Role:<role1 name>,<role2 name>

### Directives for Azure SQL Managed Instance JIT Custom Workflows

Use the following directives when configuring actions to run on the target database when a user checks out or checks in a target account:

**Note:** Use the *exact* syntax used in the following samples.

Application Type	Required Operation	Directive
MSSQL Azure Managed Instance	Create account	+Account
MSSQL Azure Managed Instance	Remove account	-Account
MSSQL Azure Managed Instance	Add a role	+Role:<role name>
MSSQL Azure Managed Instance	Remove a role	-Role:<role name>
MSSQL Azure Managed Instance	Add multiple roles	+Role:<role1 name>,<role2 name>
MSSQL Azure Managed Instance	Remove multiple roles	-Role:<role1 name>,<role2 name>
MSSQL Azure Managed Instance	Create Account and update roles	+Account;+Role:<role1 name>,<role2 name>

### Create and Configure a Custom Workflow

Follow this procedure to create and configure a custom workflow

**Follow these steps:**

1. Navigate to **Credentials, Workflow, Custom Workflows**.
2. In the **Custom Workflows** panel that opens, select the **Add** button to create a new custom workflow. The **Add Custom Workflow** pane opens.
3. Provide the high-level details of the custom workflow:
  - **Name:** The name of the custom workflow.
  - **Description:** Optionally, add some high level details about the directives that the workflow executes on check and check-in operations. Provisioned Account, "Create an account with roles on checkout; remove account on check-in."
  - **Application Type:** Select the appropriate application type: **MSSQL** or **MSSQL Azure Managed Instance**.
4. Do the following steps to create a custom workflow action for check-out operations:
  - a. Select the **Add** button. The **Add Custom Workflow Action** dialog opens.
  - b. Select **Check-Out** from the **Action** drop-down menu  
Enter an appropriate directive in the **Commands** field. Provisioned Account, to create a database login account with roles *dbcreator* and *diskadmin* on checkout enter the following directive: +Account;+Role:dbcreator,diskadmin
  - c. Select the **OK** button. You are returned to the **Add Custom Workflow** pane.

5. Do the following steps to create a custom workflow action for check-in operations:
  - a. Select the **Add** button. The **Add Custom Workflow Action** dialog opens.
  - b. Select **Check-In** from the **Action** drop-down menu
 Enter the –Account directive in the **Commands** field.  
 Select the **OK** button. You are returned to the **Add Custom Workflow** panel.
6. Select **OK** to submit the custom workflow.

**TIP**

**Next step:** One of the following, as appropriate:

- [Create a Target Application for the MSSQL Database Admin Account Used by JIT Provisioning](#)
- [Provide an Administrator Account to Use to Access the Azure SQL Managed Instance for JIT Provisioning](#)

## Create a Target Application for the MSSQL Database Admin Account Used by JIT Provisioning

This topic describes how to create a target application for the Microsoft SQL Server (MSSQL) database account required to implement Just in Time dynamic provisioning and deprovisioning of user accounts.

**Follow these steps:**

1. Navigate to **Credentials, Manage Targets, Applications**.
2. Select the **Add** button.
3. Complete the following fields on the **Add Target Application** pane that opens:
  - **Host Name:** Specify the device that you created for the SQL Server.
  - **Application Name:** Specify a name for the application.
  - **Application Type:** Select **MSSQL** from the drop-down menu.

**TIP**

**Next step:** [Create a Target Account for the MSSQL Database Administrator \(for JIT Provisioning\)](#).

## Create a Target Account for the MSSQL Database Administrator (for JIT Provisioning)

This topic describes how to create a target account for the MSSQL database administrator, which is used to access the MSSQL database.

**Follow these steps:**

1. Navigate to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.
3. Complete the following fields on the **Add Target Account** pane that opens:
  - **Host Name:** The IP address or FQDN of the MSSQL Server.
  - **Device Name:** The name of the MSSQL Server.
  - **Application Name:** The name of the MSSQL Server target application.
  - **Account Name:** The name of the MSSQL server administrator account, for example "sa".
  - **Password View Policy:** The name of the required password view policy, for example "default".
  - **Password:** Specify the password of the MSSQL Server administrator account.

**TIP**

**Next step:** [Configure a Provisioned Account for JIT Provisioning](#).

## Configure a Provisioned Account for JIT Provisioning

A *provisioned account* is a special target account used as a template for dynamic provisioning. The provisioned account is saved as a reference point but resolves as the personal account of the user. To comply with zero trust, the personal account does not exist in PAM or at the target server until it is required by the user.

Any action taken is based upon the directives configured in the associated custom workflow.

### NOTE

PAM currently supports checkout and check-in custom workflow operations.

Do the following procedures to configure a provisioned account for JIT Provisioning:

1. [Create a Password View Policy for the JIT Provisioned Account](#)
2. [Create a Target Application for the JIT Provisioned Account](#)
3. [Create a Target Account for the MSSQL JIT Provisioned Account](#)

## Create a Password View Policy for the JIT Provisioned Account

This topic describes how to configure a password view policy for the JIT provisioned account, which is used as a template for dynamic provisioning.

Follow these steps:

1. Navigate to **Credentials, Workflow, Password View Policies**.
2. Select the **Add** button.
3. Complete the following fields on the **Add Password View Policy** pane that opens:
  - **Name:** Specify a descriptive name for the password view policy.
  - **Description:** Optionally, provide a description for the password view policy.
  - **Check-Out/Check-In:** Set this option to enable the custom workflow that you configured to execute when a PAM user checks out and checks in a target account.
4. Optionally, configure other compatible options (see the following note) to comply with organizational requirements.

### IMPORTANT

Do not set any of the following options, which are incompatible with JIT provisioning:

- **Change Password on view**
- **Change Password On Connection End**
- **Re-authenticate For Auto Connect**
- **Reason Required For Auto Connect**
- **Change Password On Auto Connect**
- **Change Password On Session End**

### TIP

**Next step:** [Create a Target Application for the JIT Provisioned Account](#).

## Create a Target Application for the JIT Provisioned Account

This topic describes how to create a target application for the JIT Provisioned Account, which is used for dynamically creating user accounts.

Follow these steps:

1. Navigate to **Credentials, Manage Targets, Applications**.
2. Select the **Add** button.
3. Complete the following fields on the **Add Target Application** pane that opens:

- **Host Name:** Specify the device that you created for the SQL Server.
- **Application Name:** Specify a name for the application.
- **Application Type:** Select **MSSQL** from the drop-down menu.
- **Custom Workflow:** Select the Custom Workflow that you created earlier.

**TIP**

**Next step:** [Create a Target Account for the MSSQL JIT Provisioned Account.](#)

## Create a Target Account for the MSSQL JIT Provisioned Account

This topic describes how to configure a target account for the JIT Provisioned Account, which is used for dynamically creating user accounts.

### Follow these steps:

1. Navigate to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.
3. Complete the following fields on the **Account** tab on the **Add Target Account** pane that opens:
  - a. **Host Name:** The IP address or FQDN of the SQL Server.
  - b. **Device Name:** The name of the SQL Server.
  - c. **Provisioned Account:** (Located at the bottom of the listed options.) Set this option to configure this target account as a template for dynamically creating user accounts to support JIT provisioning.

**NOTE**

Setting the **Provisioned Account** option activates a search icon (  ) beside the **Account Name** field that is required to select an identity template.

- d. **Application Name:** The name of the MSSQL Server target application that you created for the provisioned account.
- e. **Password View Policy:** The name of the password view policy that you created for the provisioned account.
- f. **Account Name:** To specify the account name, follow these steps:
  - a. Select the search (  ) icon.
 

**NOTE**

If the search icon is not present, verify that the **Provisioned Account** option (located at the bottom of the listed options) is set.
  - b. Select the **RDP User Name** entry from the **Extended Identity Templates** dialog that opens.
  - c. Select **OK**.  
The **Account Name** field is populated with the value from the **Template** column on the **Extended Entity Templates** dialog ( `${User.rdpUsername}` ).
  - g. **Password:** Any text that matches the password composition policy for the target application (provisioned account passwords are not managed within PAM).
4. On the **MSSQL** tab, set the **Use the following account to administer changes** option, and use one of the following options to identify the target account that you created when configuring the connection to Azure:

- Enter the name of the target account in the text box.
- Select the **Search** icon (🔍) and choose the appropriate account from the **Target Accounts** dialog that appears, as shown in the following example

### Target Accounts

Column: Application Type Value: MSSQL 🔍 ↺

Account Name	Application Name	Application	Host Name	Device Name	Account Type	Owner User	Verified
\${User.userPrincipalName}	MSSQL JIT	MSSQL	10.252.5...	MSSQL	Privileged		
sa	MSSQL DB	MSSQL	10.252.5...	MSSQL	Privileged		✓

screenshot:

#### NOTE

When a user performs checkout and check-in operations using a provisioned account, their account name is replaced with the RDP User Name set in the User Information (Provisioned Account, *MYLDAP\TestUser1*) on the **Access** page.

#### TIP

**Next step:** [Create a Password View Policy for the JIT Provisioned Account.](#)

## (Optional) Restrict Users from Editing RDP User Name Values

Most users inherit the "Manage User RDP User Name" privilege that is required to edit the **RDP User Name** in user definitions from their assigned role.

The following roles provide the "Manage User the RDP Username" privilege:

- Standard user
- User/Group Manager
- Delegated Administrator
- Operational Administrator
- Global Administrator
- Server Control Administrator
- UNAB Manager

For a complete list of user roles and privileges, see [User Roles](#).

**To prevent users from editing the "RDP User name" field:** Create a custom role with user privileges that do not include or inherit the "Manage User RDP User Name" privilege. For more information, see [Add or Modify Credential Manager Roles](#).

#### TIP

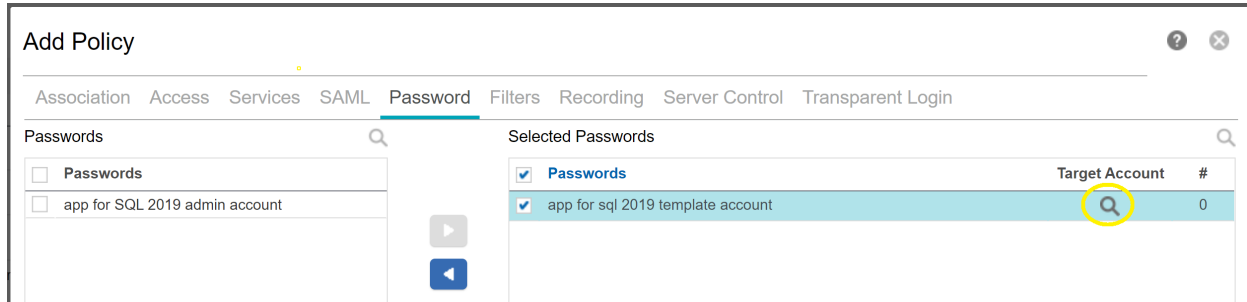

**Next step:** [Create an Access Policy for JIT LDAP Users.](#)

## Create an Access Policy for JIT LDAP Users

Create an access policy that defines the device that users imported from the LDAP domain server for Just in Time provisioning can access and the properties of that relationship.

1. Navigate to **Policies, Manage Policies**.
2. Select the **Add** button.

3. Complete the following fields on the **Association** tab of the **Add Policy** pane that opens:
  - **User or User Group:** Complete *one* of these fields with the Distinguished Name (DN) of the required user or group.  
**Tip:** Use the Search icon to display the list of choices, select the required user or group from the drop-down list, and then select **OK**.
  - **Device or Device Group Name:** Complete the **Device** field with the name of the device for which the policy controls access.
4. Do the following steps on the **Password** tab:
  - a. Select the target application that you created for the provisioned account in the **Passwords** column and move it to the **Selected Passwords** column.
  - b. Select the magnifying glass icon in the **Target Account** column (highlighted in the following screen capture):

- c. Select the target account that you created for the provisioned account and move it to the **Selected Target Account** column.
- d. Select **OK**.

## User Experience: Just in Time (JIT) Checkout and Check-in Operations

This section describes how a user from the LDAP domain server and configured in the JIT access policy checks out and checks in credentials.

1. Launch the PAM client, connect to PAM, and do the following steps to log in:
  - a. Enter your username and password in the corresponding fields.
  - b. Select **LDAP** from the **Authentication Type** drop-down menu
  - c. Select the name of the LDAP domain configured for JIT from the **Domain** drop-down menu.
2. To check out credentials for a device, do the following steps on the **Access** page:
  - a. Click the **Select** icon in the **Target Applications** column of the device entry. The name of the target application and your RDP account name appear.
  - b. Select the account name. A **Custom Workflow Checkout Status** pane opens, showing execution details, including messages related to the directives executed along with the status of the checkout operation.
3. To check in the credentials, return to the **Access** page and select the corresponding **Check-in** link available under the **Passwords currently in use** heading. A **Custom Workflow Check-in Status** pane opens showing execution details, including messages related to the directives executed and the status of the check-in operation.

## Configure Just in Time (JIT) Provisioning for Azure SQL Managed Instance User Accounts

This section describes how to configure Just in Time (JIT) provisioning to dynamically provision and deprovision Azure SQL Managed Instance user accounts on demand.

JIT provisioning provides the following security enhancements for access to your Azure SQL Managed Instance:

- Zero-trust security where user identities only exist on Azure SQL Managed Instance during the checkout period.
- On-demand identity and access management with dynamic privileges that is auditable and can be subject to third-party approval.

Key components introduced to support JIT dynamic provisioning are:

- Custom workflows that are used to define custom directives to execute when a PAM user checks out and checks in target account credentials
- Provisioned accounts that are used as a template for dynamically creating target accounts. These target accounts are provisioned when credentials are checked out and deleted when they are checked in.

### Prerequisites

- A supported Azure SQL Managed Instance (MI) Database on Azure.
- An Active Directory domain server.

### Configuration Steps

To configure JIT provisioning, complete the following procedures in order:

1. [Add the LDAP Domain Server Required for JIT Provisioning](#)
2. [Import LDAP User Groups for Azure SQL JIT Provisioning](#)
3. [Create a Device for the Azure SQL Managed Instance That Requires JIT Provisioning](#)
4. [Create a Custom Workflow to Handle Azure SQL Managed Instance JIT Target Account Checkout and Check-in](#)
5. [Provide an Administrator Account to Use to Access the Azure SQL Managed Instance for JIT Provisioning](#)
6. [Configure a Provisioned Account for Azure SQL Managed Instance JIT Provisioning](#)
7. [\(Optional\) Restrict Users from Editing Azure User Name Values](#)
8. [Create an Access Policy for Azure Managed Instance JIT LDAP Users](#)

## Add the LDAP Domain Server Required for JIT Provisioning

This procedure describes how to configure PAM to communicate with an LDAP domain server that contains the users and groups that require JIT provisioning.

### Follow these steps:

1. Do the following steps to create a target device for the LDAP domain server:
  - a. Navigate to **Devices, Manage Devices**
  - b. Select the **Add** button.
  - c. Complete the following fields in the **Add Device** pane that opens:
    - **Name:** A descriptive name for the device.
    - **Address:** The IP address of the LDAP domain server.
    - **Device type:** Set the **Access** and **Password Management** options.
2. Do the following steps to configure a target application for the domain server:
  - a. Navigate to **Credentials, Manage Targets, Applications**.
  - b. Select the **Add** button.
  - c. Complete the following fields on the **Application** tab of the **Add Target Application** pane that opens:
    - **Host Name:** The IP address or FQDN of the LDAP domain server.
    - **Device Name:** The name of the domain server.
    - **Application Name:** The name of the target application.
    - **Application Type:** Select **Active Directory** from the drop-down menu.
  - d. Select the **Active Directory** tab and enter the desired domain name (for example, examplead.com).
3. Do the following steps to configure a target account for the domain administrator:
  - a. Navigate to **Credentials, Manage Targets, Accounts**.

- b. Select the **Add** button.
  - c. Complete the following fields on the **Account** tab of the **Add Target Account** pane that opens:
    - **Host Name:** The IP address or FQDN of the LDAP domain server.
    - **Device Name:** The name of the domain server.
    - **Application Name:** The name of the domain server target application.
    - **Account Name:** The name of the domain administrator account.
    - **Password View Policy:** The required password view policy.
    - **Password:** Specify the password of the domain administrator account.
  - d. Select the **Active Directory** tab and enter the DN of the domain administrator account in the **Distinguished Name** field. For example: CN=Administrator,CN=Users,DC=EXAMPLEAD,DC=com
4. Do the following steps to configure the LDAP domain for the LDAP server:
- a. Navigate to **Configuration, 3rd Party, LDAP**.
  - b. Select the **Add** button.
  - c. Complete the following fields on **Add LDAP Domain** pane that opens:
    - **Bind Server:** The IP address of the LDAP domain target server.
    - **Bind Application:** The domain server target application.
    - **Bind Account:** The domain administrator target account.
    - **Server:** Select the plus icon and specify the IP address and port number of the LDAP domain.

**TIP**

**Next step:** [Import LDAP User Groups for Azure SQL JIT Provisioning](#).

## Import LDAP User Groups for Azure SQL JIT Provisioning

To allow users to use the same password to log into PAM and the Azure SQL Managed Instance (recommended), import LDAP Azure SQL Managed Instance users and groups into PAM.

### Follow these steps:

1. Connect to PAM using the PAM client.
2. Navigate to **Users, Manage User Groups, Import LDAP Groups**. The LDAP Browser opens.
3. Select **File, Connect**.
4. In the **Connect to LDAP Domain** dialog that opens, select the LDAP domain that you configured to communicate with your LDAP domain server and select **OK**.
5. Locate and expand the **Users** folder from the LDAP tree in the left pane.
6. Locate and select the checkbox beside each user group that you want to import.
7. (Optional) Review the device groups that are selected for import:
  - Select **PAM Groups, Manage selected groups to register with the PAM appliance**. The list of the Distinguished Names for all selected groups displays.
  - Select and edit any group DN, or remove it from the staging list.
8. Select **PAM Groups, Register selected groups with the PAM appliance**. A window opens displaying a list of the staged groups from which you can monitor progress, and can display any messages that are associated with the actions. **Note:** When you import a group, all the users that are members of that group are imported into PAM automatically.
9. Select **Register Groups** in the lower-left corner. PAM imports the groups in the order that they are listed. The browser provides feedback and cancellation options throughout the process
10. When the import is complete and verified, close the LDAP browser.
11. In the PAM UI, navigate to **Users, Manage User Groups**, and confirm that the imported user groups appear.
12. Navigate to **Users, Manage Users**, and confirm that the users in the imported user groups appear on the page.
13. For *each* imported user, do one of the following operations on the **Extended Identities** tab:

- (Optional) If the user principal name assigned to the user in LDAP (and imported into PAM) is the required username for the account, verify that the entry in the **Value** field in the **User Principal Name** row is correct.
- If the user principal name assigned to the user in LDAP is not specified or is not the correct username, enter the appropriate username in the **Value** field in the **Azure Username** row.

**NOTE**

If you have imported a large number of users, we recommend that you use the External API to automate the Azure username update for those users.

14. Assign appropriate PAM roles to each user and group based on your organizational requirements.

**TIP**

**Next step:** [Create a Device for the Azure SQL Managed Instance That Requires JIT Provisioning.](#)

## Create a Device for the Azure SQL Managed Instance That Requires JIT Provisioning

This topic describes how to create a device for the Azure SQL Managed Instance on which you require Just in Time dynamic provisioning and de-provisioning of user accounts

**Follow these steps:**

1. Navigate to **Devices, Manage Devices**
2. Select the **Add** button.
3. Complete the following fields in the **Add Device** pane that opens:
  - **Name:** A descriptive name for the device (For example, "Microsoft Azure Target Server").
  - **Address:** The hostname of the Azure SQL Managed Instance. For example, example-sqlmi-1.3e83051ceee4.database.windows.net.
  - **Device type:** Set the **Password Management** options.

**TIP**

**Next step:** [Create a Custom Workflow to Handle Azure SQL Managed Instance JIT Target Account Checkout and Check-in.](#)

## Create a Custom Workflow to Handle Just in Time Target Account Checkout and Check-in

Configure a Custom Workflow that defines the directives to execute when a PAM user checks out and checks in a target account using Just in Time (JIT) provisioning on an MSSQL or Azure SQL managed instance.

**Credential Manager Privileges Required to Work with Custom Workflows**

Administrators responsible for creating, updating, and deleting custom workflows must be assigned a role with the following Credential Manager privileges (as appropriate):

- **Add Custom Workflow:** Required to create a new custom workflow.
- **Delete Custom Workflow:** Required to delete a custom workflow.
- **Update Custom Workflow:** Required to update a custom workflow.
- **Read Custom Workflow:** Required to view a custom workflow.
- **Search Custom Workflow:** Required to search for and list custom workflows.

For a complete list of Credential Manager roles and privileges, see [Add or Modify Credential Manager Roles.](#)

### Directives for MSSQL JIT Custom Workflows

Use the following directives when configuring actions to run on the target database when a user checks out or checks in a target account:

**Note:** Use the *exact* syntax used in the following samples.

Application Type	Required Operation	Directive
MSSQL	Create account	+Account
MSSQL	Remove account	-Account
MSSQL	Add a role	+Role:<role name>
MSSQL	Remove a role	-Role:<role name>
MSSQL	Add multiple roles	+Role:<role1 name>,<role2 name>
MSSQL	Remove multiple roles	-Role:<role1 name>,<role2 name>
MSSQL	Create Account and update roles	+Account;+Role:<role1 name>,<role2 name>

### Directives for Azure SQL Managed Instance JIT Custom Workflows

Use the following directives when configuring actions to run on the target database when a user checks out or checks in a target account:

**Note:** Use the *exact* syntax used in the following samples.

Application Type	Required Operation	Directive
MSSQL Azure Managed Instance	Create account	+Account
MSSQL Azure Managed Instance	Remove account	-Account
MSSQL Azure Managed Instance	Add a role	+Role:<role name>
MSSQL Azure Managed Instance	Remove a role	-Role:<role name>
MSSQL Azure Managed Instance	Add multiple roles	+Role:<role1 name>,<role2 name>
MSSQL Azure Managed Instance	Remove multiple roles	-Role:<role1 name>,<role2 name>
MSSQL Azure Managed Instance	Create Account and update roles	+Account;+Role:<role1 name>,<role2 name>

### Create and Configure a Custom Workflow

Follow this procedure to create and configure a custom workflow

**Follow these steps:**

1. Navigate to **Credentials, Workflow, Custom Workflows**.
2. In the **Custom Workflows** panel that opens, select the **Add** button to create a new custom workflow. The **Add Custom Workflow** pane opens.
3. Provide the high-level details of the custom workflow:

- **Name:** The name of the custom workflow.
  - **Description:** Optionally, add some high level details about the directives that the workflow executes on check and check-in operations. Provisioned Account, “Create an account with roles on checkout; remove account on check-in.”
  - **Application Type:** Select the appropriate application type: **MSSQL** or **MSSQL Azure Managed Instance**.
4. Do the following steps to create a custom workflow action for check-out operations:
    - a. Select the **Add** button. The **Add Custom Workflow Action** dialog opens.
    - b. Select **Check-Out** from the **Action** drop-down menu  
Enter an appropriate directive in the **Commands** field. Provisioned Account, to create a database login account with roles *dbcreator* and *diskadmin* on checkout enter the following directive: +Account;+Role:dbcreator,diskadmin
    - c. Select the **OK** button. You are returned to the **Add Custom Workflow** pane.
  5. Do the following steps to create a custom workflow action for check-in operations:
    - a. Select the **Add** button. The **Add Custom Workflow Action** dialog opens.
    - b. Select **Check-In** from the **Action** drop-down menu  
Enter the –Account directive in the **Commands** field.  
Select the **OK** button. You are returned to the **Add Custom Workflow** panel.
  6. Select **OK** to submit the custom workflow.

**TIP**

**Next step:** One of the following, as appropriate:

- [Create a Target Application for the MSSQL Database Admin Account Used by JIT Provisioning](#)
- [Provide an Administrator Account to Use to Access the Azure SQL Managed Instance for JIT Provisioning](#)

## Provide an Administrator Account to Use to Access the Azure SQL Managed Instance for JIT Provisioning

The type of administrator account that you require to access the Azure SQL Managed Instance depends on the authentication method that is specified for that instance in Azure:

- **Use only Azure Active Directory (Azure AD) authentication:** If this option is specified, Azure uses the administrator account that is defined for a configured [Azure Active Directory target connection](#). [Proceed to the next step](#).
- **Use both SQL and Azure AD authentication:** If this option is specified, Azure can use either of the following options:
  - The administrator account that is defined for a configured [Azure Active Directory target connection](#).
  - An account that you define in the Azure SQL Managed Instance using the following procedure.
- **Use SQL authentication:** If this option is specified, Azure uses an account that you define in the Azure SQL Managed Instance using the following procedure.

**To define an administrator account in the Azure SQL Managed Instance, follow these steps:**

1. Navigate to **Credentials, Manage Targets, Applications**.
2. Select the **Add** button.
3. Complete the following fields on the **Add Target Application** pane that opens:
  - **Host Name:** Specify the device that you created for the Azure SQL Managed Instance.
  - **Application Name:** Specify a name for the application.
  - **Application Type:** Select **MSSQL Azure Managed Instance** from the drop-down menu.
4. Navigate to **Credentials, Manage Targets, Accounts**.
5. Select the **Add** button.
6. Complete the following fields on the **Add Target Account** dialog that opens:

- **Host Name:** The FQDN of the Azure SQL Managed Instance. **Tip:** Use the **Search** icon to select the device from the **Target Servers** dialog that opens.
- **Device Name:** The name of the Azure SQL Managed Instance.
- **Application Name:** The name that you specified in the **Application Name** field in Step 3.
- **Account Name:** The name of the Azure SQL Managed Instance administrator account (for example, "sa").
- **Password View Policy:** The name of the required password view policy, for example "default".
- **Password:** Specify the password of the Azure SQL Managed Instance administrator account.

**TIP**

**Next step:** [Configure a Provisioned Account for Azure SQL Managed Instance JIT Provisioning.](#)

## Configure a Provisioned Account for Azure SQL Managed Instance JIT Provisioning

A *provisioned account* is a special target account used as a template for dynamic provisioning. The provisioned account is saved as a reference point but resolves as the personal account of the user. To comply with zero trust, the personal account does not exist in PAM or at the target server until it is required by the user.

Any action taken is based upon the directives configured in the associated custom workflow.

**NOTE**

PAM currently supports checkout and check-in custom workflow operations.

**Do the following procedures to configure a provisioned account for JIT Provisioning::**

1. [Create a Password View Policy for the JIT Provisioned Account](#)
2. [Create a Target Application for the JIT Provisioned Account](#)
3. [Create a Target Account for the Azure SQL Managed Instance JIT Provisioned Account](#)

### Create a Password View Policy for the JIT Provisioned Account

This topic describes how to configure a password view policy for the JIT provisioned account, which is used as a template for dynamic provisioning.

**Follow these steps:**

1. Navigate to **Credentials, Workflow, Password View Policies**.
2. Select the **Add** button.
3. Complete the following fields on the **Add Password View Policy** pane that opens:
  - **Name:** Specify a descriptive name for the password view policy.
  - **Description:** Optionally, provide a description for the password view policy.
  - **Check-Out/Check-In:** Set this option to enable the custom workflow that you configured to execute when a PAM user checks out and checks in a target account.
4. Optionally, configure other compatible options (see the following note) to comply with organizational requirements.

**IMPORTANT**

Do not set any of the following options, which are incompatible with JIT provisioning:

- **Change Password on view**
- **Change Password On Connection End**
- **Re-authenticate For Auto Connect**
- **Reason Required For Auto Connect**
- **Change Password On Auto Connect**
- **Change Password On Session End**

**TIP**

**Next step:** [Create a Target Application for the JIT Provisioned Account.](#)

## Create a Target Application for the JIT Provisioned Account

This topic describes how to create a target application for the JIT Provisioned Account, which is used for dynamically creating user accounts.

### Follow these steps:

1. Navigate to **Credentials, Manage Targets, Applications**.
2. Select the **Add** button.
3. Complete the following fields on the **Add Target Application** pane that opens:
  - **Host Name:** Specify the device that you created for the Azure SQL Database.
  - **Application Name:** Specify a name for the application.
  - **Application Type:** Select **MSSQL Azure Managed Instance** from the drop-down menu.
  - **Custom Workflow:** Select the Custom Workflow that you created earlier.

**TIP**

**Next step:** [Create a Target Account for the Azure SQL Managed Instance JIT Provisioned Account.](#)

## Create a Target Account for the Azure SQL Managed Instance JIT Provisioned Account

This topic describes how to configure a target account for the Azure SQL Managed Instance JIT Provisioned Account, which is used for dynamically creating user accounts.

### Follow these steps:

1. Navigate to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.
3. Complete the following fields in the specified order on the **Account** tab of the **Add Target Account** pane that opens:
  - a. **Host Name:** The IP address or FQDN of the Azure SQL managed instance.
  - b. **Device Name:** The name of the Azure SQL managed instance.
  - c. **Provisioned Account:** (Located at the bottom of the listed options.) Set this option, which is required to configure this target account as a template for dynamically creating user accounts to support JIT provisioning.

**NOTE**

Setting the **Provisioned Account** option activates a search icon (🔍) beside the **Account Name** field that is used to select an identity template.

- d. **Application Name:** The name of the Azure SQL Managed Instance target application that you created for the provisioned account.
- e. **Account Name:** To specify the account name, follow these steps:

- a. Select the search (🔍) icon.

**NOTE**

If the search icon is not present, verify that the **Provisioned Account** option (located at the bottom of the listed options) is set.

- b. Select one of the following **Identity Names** from the **Extended Identity Templates** dialog that opens:
  - **User Principal Name:** Use this option if the user principal name assigned to the user in LDAP (and imported into PAM) was the correct name for the account.
  - **Azure User Name:** Use this option if the user principal name assigned to the user in LDAP is not specified or is not the correct username.
- c. Select **OK**.

The **Account Name** field is populated with the value from the **Template** column from the **Extended Entity Templates** dialog. For example, if you selected **User Principal Name**, the field is populated with the following value: `${User.userPrincipalName}`.

- f. **Password View Policy:** Enter the name of the password view policy that you created for the provisioned account.
  - g. **Password:** Enter a password that conforms to the password composition policy for the target application or select the **Generate Password** icon (🔑) to generate one automatically. (Provisioned account passwords are not managed within PAM.)
4. On the **MSSQL Azure Managed Instance** tab, set the **Use the following account to administer changes** option, and use one of the following options to identify the target account that you created when configuring the connection to Azure:
- Enter the name of the target account in the text box.
  - Select the **Search** icon (🔍) and choose the appropriate account from the **Target Accounts** dialog that appears, as shown in the following example

### Target Accounts

Column: 

Application Type

 Value: 

MSSQL Azure Manager

🔍 ↻

Account N	Application Name	Application Type	Host Name	Device Name	Account Type	Owner User	Verified
sa	Azure SQL MI DB	MSSQL Azure Managed Instance	bosto...	Azure ...	Privileg...		✓
\${User....}	Azure SQL MI JIT	MSSQL Azure Managed Instance	bosto...	Azure ...	Privileg...		
\${User....}	Azure SQL MI JIT	MSSQL Azure Managed Instance	bosto...	Azure ...	Privileg...		

screenshot

OK

Cancel

#### TIP

- Accounts from the Azure SQL Managed Instance have an Application Type of "MSSQL Azure Managed Instance" and are listed by default.
- Accounts from an Azure AD have an Application Type of "Azure Access Credentials." To view such accounts, change the selection filter value to "Azure Access Credentials."
- To list all accounts, select the **Reset** icon (↻).

#### NOTE

When a user performs checkout and check-in operations using a provisioned account, their account name is replaced with either the Azure Username or the User Principal Name set in the user Extended Identity on the **Access** page.

#### TIP

**Next step:** (Optional) [Restrict Users from Editing Azure User Name Values](#).

## (Optional) Restrict Users from Editing Azure User Name Values

Most users inherit the "Manage User Azure User Name" privilege that is required to edit the Azure User Name in user definitions from their assigned role.

The following roles provide the "Manage User Azure User Name" privilege:

- Standard user
- User/Group Manager
- Delegated Administrator
- Operational Administrator
- Global Administrator
- Server Control Administrator
- UNAB Manager

For a complete list of user roles and privileges, see [User Roles](#).

**To prevent users from editing the "Azure User name" field:** Create a custom role with user privileges that do not include or inherit the "Manage User Azure User Name" privilege. For more information, see [Add or Modify Credential Manager Roles](#).

**TIP**

**Next step:** [Create an Access Policy for Azure Managed Instance JIT LDAP Users](#).

## Create an Access Policy for Azure Managed Instance JIT LDAP Users

Create an access policy that defines the device that users imported from the LDAP domain server for Azure Managed Instance Just in Time provisioning can access and the properties of that relationship.

1. Navigate to **Policies, Manage Policies**.
2. Select the **Add** button.
3. Complete the following fields on the **Association** tab of the **Add Policy** pane that opens:
  - a. **User or User Group:** Complete *one* of these fields with the Distinguished Name (DN) of the required user or group. **Tip:** Use the Search icon to display the list of choices, select the required user or group from the drop-down list, and then select **OK**.
  - b. **Device or Device Group Name:** Complete the **Device** field with the name of the device for which the policy controls access. **Tip:** Use the Search icon to display the list of choices, select the required device from the drop-down list, and then select **OK**.
4. Do the following steps on the **Password** tab:
  - a. Select the target application that you created for the provisioned account in the **Passwords** column and move it to the **Selected Passwords** column.
  - b. Select the magnifying glass icon in the **Target Account** column.
  - c. Select the target account that you created for the provisioned account and move it to the **Selected Target Account** column.
  - d. Select **OK**.
5. Select **OK** to save the policy.

## User Experience: Just in Time (JIT) Checkout and Check-in Operations

This section describes how a PAM user that has been configured in the JIT access policy checks out and checks in credentials.

1. Log into the PAM UI
2. To check out credentials for a device, do the following steps on the **Access** page:
  - a. Click the **Select** icon in the **Target Applications** column of the device entry. The name of the target application appears.
  - b. Select the account name. A **Custom Workflow Checkout Status** pane opens, showing execution details, including messages related to the directives executed along with the status of the checkout operation.

3. To check in the credentials, return to the **Access** page and select the corresponding **Check-in** link available under the **Passwords currently in use** heading. A **Custom Workflow Check-in Status** pane opens showing execution details, including messages related to the directives executed and the status of the check-in operation.

**NOTE**

If you do not check in the credentials before the checkout time limit expires, the account is checked in and all associated workflow actions are executed automatically.

## Delegate Password Management Tasks to Groups

Credential Manager uses groups to separate password management duties and improve security. Credential Manager groups allow users, or groups of users to view and change passwords for only a specific set of resources. Credential Manager users are also grouped, which simplifies the design and implementation of the security policies that are used to manage them.

**NOTE**

Credential Manager groups and roles are separate from access user groups and roles. See [Credential Manager Group Terminology](#).

**WARNING**

When defining a user that is to have Credential Manager privileges – administering or viewing passwords – the user must be assigned a Credential Manager Group. Assign a Credential Manager group by adding or editing a user from the **Users, Manage Users** screen on the **Credential Manager Groups** tab.

**NOTE**

**Important!** With release 3.4.3, the Credential Manager Role only applies to the objects scoped by the Credential Manager Target Group in the same Credential Manager Group. Previously, all Credential Manager Roles applied to all Credential Manager Target Groups in all Credential Manager Credential Groups the user was a member of.

Privileged Access Manager is preconfigured with a Credential Manager Group named "System Admin Group". This might appropriately be used to provision a Global Administrator using the PM Groups setting.

Credential Manager uses two types of groups:

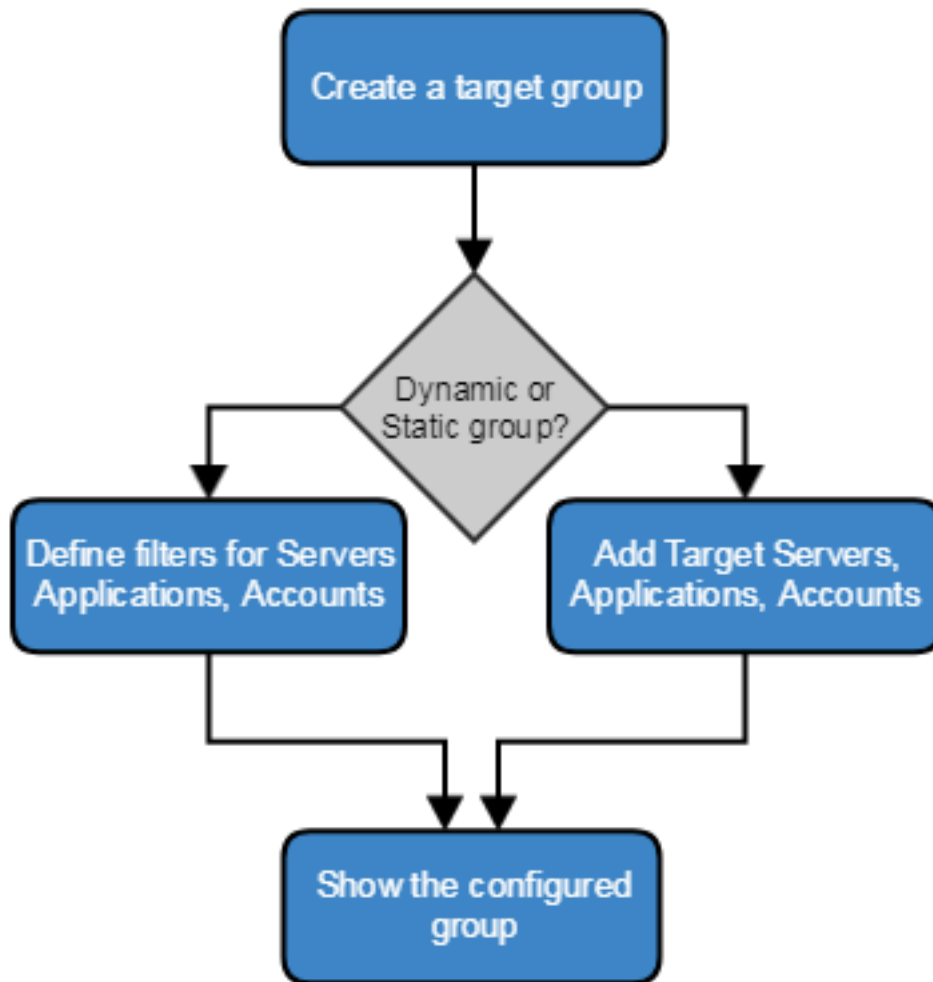

- **Static groups**

Static groups enable the direct assignment of specific resources to a particular user group. Static groups enforce the resource assignment and provide control over group membership. You can configure static target groups and A2A requestor groups.

- **Dynamic groups**

Dynamic groups use rules and filters to specify patterns for resource assignment. All entities that match the rules are assigned membership in the specified dynamic group. Any new entity that is added and that matches the pattern is automatically placed in all applicable groups, minimizing administrative burden. You can configure dynamic target groups and A2A requestor groups.

The process for defining target groups is:

**Figure 34: Credential Manager Group Configuration**

If there are no consistent standards for group attributes, names or addresses, use the Descriptor fields to create standards to support dynamic group assignment.

Authorization groupings do not apply to reports, metrics, or application-to-application credential requests.

See the following other articles in this section for more details:

- [Credential Manager Group Terminology](#)
- [Add Credential Manager Target Groups](#)
- [Add Credential Manager Requestor Groups](#)
- [Add Credential Manager Credential Groups](#)
- [Add or Modify Credential Manager Roles](#)
- [Configure Users with the Manage Credentials Privilege to View Passwords on the Access Screen](#)

## Credential Manager Group Terminology

A user or a request script can access a target account password.

- A user creates a password request from the UI, from the CLI, or from a program that uses the Java API.
- A request script executes a request to the A2A client.

To filter access to passwords, target accounts and request scripts can be organized into target groups and request groups. You can then configure credential groups to permit only selected operations on a target or request group.

### **Grouping Terminology**

The following table describes grouping terminology.

Term	Definition
Target Group	A target group is a collection of target servers, target applications, or target accounts that meet specific filter criteria. For example, all target servers that have the identifier <code>London</code> in the <code>Descriptor2</code> field. A single target can belong to multiple target groups. When a target group consists of target servers, all applications and accounts on that server are automatically contained within that target group.
Request Group	A request group is a collection of request servers (A2A Clients) or requests (scripts) that meet specific filter criteria. For example, all request servers that have the identifier <code>New York</code> in the <code>Descriptor1</code> field form a request group. A single request can belong to multiple request groups. When a request group consists of request servers, all applications on that server are automatically contained within that request group.
Roles	Each role is a collection of actions that can be performed in Credential Manager. You can build roles for each series of permissions you want to assign to users.
Credential Group	A credential group is a collection of all appliance users who are dynamically determined from a Credential Manager role, a target group, or a request group.  Credential groups are distinct and separate from Access user groups.  Specify the target group in a credential group. Then, members of the group can access any target servers, applications, or accounts. Specify the Request Group so members of the group have access to any A2A clients or scripts.
Users	Users refer to user accounts. Each Credential Manager user belongs to one or more credential groups. The credential groups define what targets and requests the user can see and what actions the user can perform on the appliance interfaces.
Filter	A condition that is assigned to a target group or request group. It determines which target or request objects are accessible by members of the target or request group.

### **Credential Manager Credential Groups and Roles**

Credential Manager credential groups and roles are distinct and separate from Access user groups and roles.

An Access user group is:

- A static association of specific users. Some user attributes, such as (Access) Roles and Access Time, can be assigned at the group level.
- Listed on the **Users, Manage Groups** page. Access user groups are created or edited from a template on that page.

A Credential Manager credential group is:

- A collection of all users who are dynamically determined from a Credential Manager role, a target group, or a request group.
- Listed on the **Credentials, Manage Credential Groups, Credential Groups** page. Credential groups are created or edited from a template that is opened on that page, or through CLI commands.

Similarly, access roles are configured with the Roles template on the **Users, Manage Roles** page. Credential Manager roles are configured on the **Credentials, Manage Credential Groups, Credential Roles** page. Credential Manager roles are created or edited from a template that is opened on that page, or through CLI commands.

**NOTE**

Be careful to avoid assigning conflicting privileges in the Credential Manager roles and Access roles for the same user or credential group. Configure segregation of duties in the Access policy, not with Credential Manager roles.

**Group Filters for Dynamic Groups**

Add filters to dynamic target and request groups to define which elements belong to the group. When using the UI to add a target or request group, you add filters from the Group List page. Filter attributes are displayed as checkboxes on the Group List page and filter types are selected from a drop-down list.

With the CLI, first add a dynamic target or request group then use the `addFilter` command to add filters.

The following table describes the filters that you can create:

Filter Object (Filter.objectClassId)	Filter Attribute (Filter.attribute)	Description
Target server (c.cw.m.ts)	Host name (hostName)	Host name for the target server.
	ipAddress (IPAddress)	IP address for the target server.
	descriptor1 (Attribute.descriptor1)	Descriptor for the target server.
	descriptor2 (Attribute.descriptor2)	Descriptor for the target server.
Target application (c.cw.m.tp)	Name (name)	Name of the target application.
	Type (type)	Type (target connector) of the target application.
	descriptor1 (Attribute.descriptor1)	Descriptor for the target application.
	descriptor2 (Attribute.descriptor2)	Descriptor for the target application.
Target account (c.cw.m.ac)	accountName (userName)	Account user name for the target account.
	accessType (accessType)	Access type for the target account.
	descriptor1 (Attribute.descriptor1)	Descriptor for the target account.
	descriptor2 (Attribute.descriptor2)	Descriptor for the target account.
request server (c.cw.m.rs)	Host name (hostName)	Host name for the request server.
	ipAddress (IPAddress)	IP address for the request server.
	descriptor1 (Attribute.descriptor1)	Descriptor for the request server.

	descriptor2 (Attribute.descriptor2)	Descriptor for the request server.
request application (c.cw.m.sc)	Name (name)	Script name for the request application.
	Type (type)	Script type for the request application.
	descriptor1 (Attribute.descriptor1)	Descriptor for the request application.
	descriptor2 (Attribute.descriptor2)	Descriptor for the request application.
	File path (filePath)	Path to the script file.
	Execution Path (executionPath)	Path from which the application is launched.

## Add Credential Manager Target Groups

A target group is a collection of target servers, target applications, or target accounts that meet specific filter criteria. For example, all target servers that have the identifier London in the Descriptor2 field. A single target can belong to multiple target groups. When a target group consists of target servers, all applications and accounts on that server are automatically contained within that target group. You can configure dynamic or static target groups.

### NOTE

**Important!:** Release 331 changed the behavior of the dynamic target group definition logic. Previously, if no filters were defined for target servers, all target servers were considered members of that filter. If neither target server nor target application filters were defined, all target applications were also considered members of the target group. For example, if you specified a filter only on an account, *all* applications and servers were added to the target group.

In 3.3.1 and future releases the following logic applies:

- If only an account filter is defined, then *only* matching accounts become members of the group; *no* servers or applications are added to the group. If you want servers or applications to belong to the group, you must *explicitly* define appropriate filters.
- If only an application filter is defined, matching applications and associated accounts are added to the group. *No* servers are added. If you want servers to belong to the group, you must *explicitly* define an appropriate filter.
- If both an account filter and an application filter are defined, matching applications and accounts from applications which match the account filter are added to the group. *No* servers are added. If you want servers to belong to the group, you must *explicitly* define an appropriate filter.

*The new logic also applies to existing dynamic target group definitions.* If this change invalidates an existing target group definition, you must manually redefine that definition so that the target group includes all the target servers, target applications, or target accounts that were previously implicitly included.

This topic covers the following contents:

### Target Group Filter Behavior Matrix

The following table shows how each combination of specified filters determines the contents of a dynamic or static target group:

Server Filter Specified	Application Filter Specified	Account Filter Specified	Objects Included in Target Group	
Yes	No	No	Matching servers, applications from the matching servers, and accounts associated with those applications.	
Yes	Yes	No	Matching servers, matching applications from the matching servers, and accounts associated with matching applications.	
Yes	Yes	Yes	Matching servers, matching applications from the matching servers, and matching accounts from the associated applications.	
Yes	No	Yes	Matching servers, applications from the matching servers, matching accounts from the included applications.	
No	No	Yes	Matching accounts only.	
No	Yes	No	Matching applications and accounts associated with those applications only.	
No	Yes	Yes	Matching applications and accounts associated with those applications only.	

### **Add Dynamic Target Groups**

Apply target group filters to target servers, target applications, or target accounts.

When you apply multiple filters to a dynamic target group, filters that use the same attribute are applied using a logical "or" relationship. For example, if a target group contains a server filter for the host name **Test** and a server filter for the host name **Production**. The group contains target servers with **Test or Production** in their host name.

Filters that use different attributes are applied using a logical "and" relationship. For example, if a group contains a server filter with the host name **Production**, and an account filter with the account name **siteAdmin**. The group contains only **siteAdmin** accounts running on servers with **Production** in the host name.

Credential Manager is preconfigured with the dynamic target group **All Targets**. The default Credential Manager Administrator account, **super**, is assigned to the All Targets group.

Credential Manager allows you to show all the targets that are associated with a specific target group. This capability allows you to validate that you have set your resource assignments and target filters appropriately.

### ***Add a Dynamic Target Group Using the UI***

Use this procedure to add a dynamic target group using the UI.

**Follow these steps:**

1. Select **Credentials, Manage Targets, Target Groups**.
2. Select **Add**.
3. Enter the group **Name**.
4. (Optional) Enter the group **Description**.
5. Select the **Dynamic** entry from the **Type** drop-down list.

**NOTE**

For AWS access accounts, the Dynamic filter does not support the Access Key Alias. The filter does support the Access Key ID.

6. Add filters to a server, application, or account. Repeat this procedure for each filter you want to add.
  - a. Select the **Not Specified** link for the filter that you want to apply. The Define Filters dialog appears.
  - b. Select **+** to add an expression.
  - c. Select the filter type (for example, contains) from the drop-down list in the **Operator** field.
  - d. Enter the filter expression (for example, 192.0.2) in the **Value** field.

When creating a filter for **Application Type**, use the following table to supply the filter expression.

**NOTE**

If you have implemented custom application types using the Target Connector Framework, those custom types will also be available from the **Application Type** drop-down menu.

Application Type	Enter the following text as the filter expression.
Active Directory	windowsDomainService
AS/400	AS/400
AWS Access Credentials Accounts	AwsAccessCredentials
AWS Proxy Credential Accounts	AwsApiProxyCredentials
Cisco	CiscoSSH
Juniper Junos	juniper
LDAP	ldap
MSSQL	mssql
MYSQL	mysql
Oracle	oracle
SPML v2.0	SPML2
UNIX	unixll
VMware ESX/ESXi	vmware
VMware NSX Controller	nsxcontroller
VMware NSX Manager	nsxmanager
VMware NSX Proxy	nsxproxy
WebLogic	weblogic10
Windows Proxy	windows

- e. Select **OK**. The Filter specification is listed.
7. After you add all your filters, select **OK** at the bottom of the page to commit the target group to Credential Manager.

**Add a Dynamic Target Group Using the CLI**

Use this procedure to add a dynamic target group using the CLI.

**Follow these steps:**

1. Add a target group. Remember to specify dynamic or static. For example:

```
Windows:
capam_command adminUserID=admin capam=mycompany.com cmdName=addGroup ^
Group.name=TokyoTargets Group.description="Targets in Tokyo" ^
Group.type=target Group.dynamic=true
Linux:
capam_command adminUserID=admin capam=mycompany.com cmdName=addGroup \
Group.name=TokyoTargets Group.description="Targets in Tokyo" \
Group.type=target Group.dynamic=true
```

2. Enter your password at the prompt. Credential Manager returns the following XML command string. Note the ID value, because it is the required Group.ID value in the addFilter command.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<Group>
<name>TokyoTargets</name>
<permissions>[]</permissions>
<type>target</type>
<readOnly>false</readOnly>
<description>Targets in Tokyo</description>
<dynamic>true</dynamic>
<ID>5</ID>
<createDate>Thu May 08 09:42:52 EDT 2008</createDate>
<createUser>admin</createUser>
<hash>eGuxUhVerHQile7mjKyW9b/ZJ04=</hash>
<updateDate>Thu May 08 09:42:52 EDT 2008</updateDate>
<updateUser>admin</updateUser>
<extensionType />
</Group>
</cr.result>
</CommandResult>
```

3. Add a filter. For example, adding a target server host name filter:

```
Window:
capam_command adminUserID=admin capam=mycompany.com cmdName=addFilter ^
Group.ID=5 Filter.objectClassId=c.cw.m.ts Filter.attribute=hostName ^
Filter.type=contains Filter.expression="mydomain"
Linux:
capam_command adminUserID=admin capam=mycompany.com cmdName=addFilter \
Group.ID=5 Filter.objectClassId=c.cw.m.ts Filter.attribute=hostName \
Filter.type=contains Filter.expression="mydomain"
```

4. Enter your password at the prompt. Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<Filter>
<type>contains</type>
```

```

<attributeName>hostName</attributeName>
<groupID>5</groupID>
<objectClassID>c.cw.m.ts</objectClassID>
<expression>mydomain</expression>
<ID>7</ID>
<createDate>Thu May 08 09:47:35 EDT 2008</createDate>
<createUser>admin</createUser>
<hash />
<updateDate>Thu May 08 09:47:35 EDT 2008</updateDate>
<updateUser>admin</updateUser>
<extensionType />
</Filter>
</cr.result>
</CommandResult>

```

### **Add Static Target Groups**

For static group assignments, define the specific servers, applications, and accounts that are members of the group. Static groups provide precise control over the accounts within the group.

If there are no target accounts defined for the static group, all target accounts associated with the target applications are managed.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, Target Groups**.
2. Select **Add**.
3. Enter the group **Name**.
4. (Optional) Enter the group **Description**.
5. Select the **Static** entry from the **Type** drop-down list.
6. Add the servers, applications, and accounts over which the group should have control.
  - a. Select **+** for the entity you want to add. A list of available resources appears. The following figure shows a typical page that appears when you select **+** for applications
  - b. Select the desired resources from the list.
  - c. Select **OK**.

#### **NOTE**

In previous releases, selecting a specific account populated the server and application filters with the associated server and application information for that account. In 3.3.1 and future releases, you must manually add the **associated server and application**.

7. Select **OK** to save your changes.

### **View All Targets Belonging to an Existing Target Group**

Use the following procedure to view all targets belonging to an existing target group from the UI.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, Target Groups**.
2. Select the target group that you want to view and select the **UPDATE** button.
3. Select **Show**. The list of targets matching the criteria within the group displays.
4. Select **OK**.

## Add Credential Manager Requestor Groups

Learn how to add PAM Credential Manager requestor groups.

Use the following procedures to add dynamic and static requestor groups and view all requestors belonging to an existing requestor group.

### Add Dynamic Requestor Groups

For dynamic group assignments, apply requestor group filters to requestor servers and requestors. Filters provide added flexibility for defining group members.

When you apply multiple filters to a dynamic target group, filters that use the same attribute are applied using a logical "or" relationship. For example, a requester group contains a server filter for the host name **Test** and a server filter for the host name **Production**. The group contains request servers with **Test** or **Production** in their host name. Filters that use different attributes are applied using a logical "and" relationship. For example, a group contains a server filter with the host name **Production**, and an account filter with the account name **siteAdmin**. The group contains only **siteAdmin** accounts running on servers with **Production** in the host name.

Credential Manager is preconfigured with the dynamic requestor group `Requestors`. The default Credential Manager Administrator account, `admin`, is assigned to the All Requestors group.

### Applying Scripts

If you have several scripts, you can eliminate the need to provision each script manually. Set the script filters to access all client applications having a particular file or execution path. If you define Path File or Execution File filters, then all scripts in the path that meet the criteria become members of the script group. The group includes scripts that are defined in the Credential Manager database and those scripts that are not.

A credential request (`GetScriptCredentials`) can be from a script that is not defined in the Credential Manager database. Even if the script matches an authorization mapping with a requestor group, which contains the filters `Type`, `Descriptor1`, and `Descriptor2`, the credential request fails. The data for these filters does not exist in the database until the script is provisioned.

### Add Dynamic Requester Groups using the UI

Use the following procedure to add a dynamic requestor group from the UI.

#### Follow these steps:

1. Select **Credentials, Manage A2A, Request Groups**.
2. Select **Add**.
3. Enter the group **Name**.
4. (Optional) Enter the group **Description**.
5. Select **Dynamic** from the **Type** drop-down list.
6. Add filters to a client or script. Repeat this procedure for each filter you want to add to the list.
  - a. Select the **Not Specified** link for the filter that you want to apply. The Define Filters dialog appears.
  - b. Select **+** to add an expression.
  - c. Select the filter type (for example, contains) from the drop-down list in the **Operator** field.
  - d. Enter the filter expression (for example, 10) in the **Value** field.
  - e. Select **OK**.
7. Select **OK** to save your changes.

### Add Dynamic Requester Groups using the CLI

Use the following procedure to add a dynamic requestor group from the CLI.

**Follow these steps:****1. Add a requestor group. For example:**

```
Windows:
capam_command adminUserID=admin capam=mycompany.com cmdName=addGroup ^
Group.name=NewYorkRequestors Group.description="Requestors in New York" ^
Group.type=requestor Group.dynamic=true
Linux:
capam_command adminUserID=admin capam=mycompany.com cmdName=addGroup \
Group.name=NewYorkRequestors Group.description="Requestors in New York" \
Group.type=requestor Group.dynamic=true
```

**2. Enter your password at the prompt. Credential Manager returns the following XML command string. Note the ID value, because it is the required Group.ID value in the addFilter command.**

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<Group>
<ID>4</ID>
<createDate>Tue Apr 08 10:21:21 EDT 2008</createDate>
<updateDate>Tue Apr 08 10:21:21 EDT 2008</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>jrLLJH7U5QUFjNux1GDlavKk/qc=</hash>
<name>NewYorkRequestors</name>
<description>Requestors in New York</description>
<type>requestor</type>
<dynamic>true</dynamic>
<readOnly>false</readOnly>
<permissions>[]</permissions>
</Group>
</cr.result>
</CommandResult>
```

**3. Add a filter. For example, adding a requestor server host name filter:**

```
Windows:
capam_command adminUserID=admin capam=mycompany.com cmdName=addFilter group.ID=4 ^
Filter.objectClassId=c.w.m.rs Filter.attribute=hostName Filter.type=contains ^
Filter.expression="mydomain"
Linux:
capam_command adminUserID=admin capam=mycompany.com cmdName=addFilter group.ID=4 \
Filter.objectClassId=c.w.m.rs Filter.attribute=hostName Filter.type=contains \
Filter.expression="mydomain"
```

**4. Enter your password at the prompt. Credential Manager returns the following XML command string.**

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<Filter>
<ID>7</ID>
<createDate>Tue Apr 08 10:23:02 EDT 2008</createDate>
```

```

<updateDate>Tue Apr 08 10:23:02 EDT 2008</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>
</hash>
<expression>mydomain</expression>
<type>contains</type>
<objectClassID>c.cw.m.rs</objectClassID>
<attributeName>hostName</attributeName>
<groupID>4</groupID>
</Filter>
</cr.result>
</CommandResult>

```

### **Add a Static Requestor Group**

Use the following procedure to add a static requestor group from the UI.

#### **Follow these steps:**

1. Select **Credentials, Manage A2A, Request Groups**.
2. Select **ADD**.
3. Enter the group **Name**.
4. (Optional) Enter the group **Description**.
5. Select **Static** from the **Type** drop-down list.
6. Add the clients and requestors over which the group should have control.
  - a. Select **+** for the entity (Client; Script) that you want to add. A list of available resources appears.
  - b. Select one or more resources from the list.
  - c. Select **OK**.
7. Select **OK** to save your changes.

### **View All Requestors Belonging to a Requestor Group**

Credential Manager allows you to show all the requestors that are associated with a specific requestor group. You can validate that you have set your resource assignments and requestor filters appropriately.

Use the following procedure to view all requestors belonging to an existing requestor group from the UI.

#### **Follow these steps:**

1. Select **Credentials, Manage A2A, Request Groups**.
2. Select the target group that you want to view and select the **UPDATE** button.
3. Select **Show**. The list of requestors matching the criteria within the group displays.
4. Select **OK**.

## **Manage Credential Manager Credential Groups**

PAM Credential Manager credential groups (also known as Credential Manager credential groups) map a single target group to a request group and role.

To allow for flexibility, each Credential Manager administrative user can belong to multiple credential groups.

**NOTE**

After an upgrade, you may see a new credential group called Base Users. The Base Users group is a container for users that are not associated to any other user group. We recommend that you associate any Base Users to other more meaningful user groups.

The following procedures describe how to add and delete credential groups using the PAM UI, CLI, or the External API:

- [Add a Credential Group](#)
- [Delete a Credential Group](#)
- [Manage Credential Groups Using the External API](#)

**Add a Credential Group**

You can add a credential group using the PAM UI, CLI, or the External API.

**NOTE**

Be careful to avoid assigning conflicting privileges in the Credential Manager roles and Access roles for the same user or user group. Configure segregation of duties in the Access policy, not using Credential Manager roles. Currently, PAM does not support assigning more than one credential group to any single PAM user account or user group.

**Add a Credential Group Using the PAM UI**

Use the following procedure to add a Credential Manager credential group using the PAM UI.

**Follow these steps:**

1. Select **Credentials, Manage Credential Groups, Credential Groups**.  
The **Credential Manager User Groups** page opens.
2. Select the **Add** button.  
The **Add Credential Manager User Group** page opens.
3. Enter a unique **Name** for the user group.
4. (Optional) Enter a **Description** for the user group.
5. Select a **Role** with the necessary privileges. For more information, see [Add or Modify Credential Manager Roles](#).
6. Select a **Target Group**. For more information, see [Add Credential Manager Dynamic and Static Target Groups](#).
7. Select a **Request Group**. For more information, see [Add Credential Manager Request Groups](#).
8. Add credential group members using one or both of the **Users** and **User Groups** tabs. (Only users and user groups that are assigned to roles with the Manage Credentials privilege are available for selection.)

**NOTE**

You can also assign credential groups when adding or editing users and groups. For more information, see [Create and Manage Users](#) and [Configure User Groups](#).

9. Select **OK**.

**Add a Credential Group Using the CLI**

Use the following procedure to add a Credential Manager credential group Using the CLI.

**Follow these steps:**

1. Use the [addUserGroup](#) command and appropriate parameters. For example:  

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addUserGroup UserGroup.name=LonUserGroup
UserGroup.description="London user group" UserGroup.roleID=11 UserGroup.groups=3,2
```
2. Enter your password at the prompt. Credential Manager returns the following XML command string.  

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
```

```

<cr.result>
<UserGroup>
<name>LonUserGroup</name>
<readOnly>false</readOnly>
<description>London user group</description>
<role />
<roleID>11</roleID>
<groups>[]</groups>
<groupIDs>[2, 3]</groupIDs>
<ID>2</ID>
<createDate>Thu May 08 08:57:16 EDT 2008</createDate>
<createUser>admin</createUser>
<hash>D8VjG143dB45/altCCiikvXebbw=</hash>
<updateDate>Thu May 08 08:57:16 EDT 2008</updateDate>
<updateUser>admin</updateUser>
<extensionType />
</UserGroup>
</cr.result>
</CommandResult>

```

### **Add a Credential Group Using the External API**

To learn how to use the External API to add Credential Manager user groups, see [Manage Credential Groups Using the External API](#).

### **Delete a Credential Group**

You can delete a credential group using the PAM UI, CLI, or the External API.

#### **IMPORTANT**

You cannot delete credential groups that contain users that do not belong to any other credential groups and would therefore be left without any Credential Manager privileges.

To delete such a group, do one of the following actions on each user or session manager user group that does not belong to another credential group:

- Add or move the user or group to another credential group.
- Remove all assigned Access Management roles with the Manage Credentials privilege from the user or group.

### **Delete a Credential Group Using the UI**

Use the following procedure to delete a Credential Manager credential group using the PAM UI.

#### **Follow these steps:**

1. Select **Credentials, Manage Credential Groups, Credential Groups**.  
The **Credential Manager User Groups** page opens.
2. Select the user group that you want to delete.
3. Select the **Delete** button.
4. Select the **Yes** button on the **Delete Item** dialog that appears.

#### **NOTE**

Users or access user groups with the Access Manager "Manage Credentials" privilege must belong to a credential manager user group. If deleting a Credential Manager user group would result in access users or groups no longer belonging to any user group, the deletion attempt fails with the following error message.

Error: PAM-UI-2417: Error deleting Credential Manager user group. Delete failed. The group cannot be deleted because it would leave some users of group 'example\_group' without any credential user group assigned.

## Delete a Credential Manager Credential Group Using the CLI

Use the following procedure to delete a Credential Manager credential group Using the CLI.

### Follow these steps:

1. Use the [deleteUserGroup](#) command and appropriate parameters. For example:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=deleteUserGroup UserGroup.name=LonUserGroup
```

2. Enter your password at the prompt. Credential Manager runs the command and, if successful, returns something like the following example command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<UserGroup>
<name>LonUserGroup</name>
<readOnly>>false</readOnly>
<description>London user group</description>
<role />
<roleID>11</roleID>
<groups>[]</groups>
<groupIDs>[2, 3]</groupIDs>
<ID>2</ID>
<createDate>Thu May 08 08:57:16 EDT 2008</createDate>
<createUser>admin</createUser>
<hash>D8VjG143dB45/altCCiikvXebbw=</hash>
<updateDate>Thu May 08 08:57:16 EDT 2008</updateDate>
<updateUser>admin</updateUser>
<extensionType />
</UserGroup>
</cr.result>
</CommandResult>
```

### NOTE

Users or access user groups with the Access Manager "Manage Credentials" privilege must belong to a credential manager user group. If deleting a Credential Manager user group would result in access users or groups no longer belonging to any user group, the deletion attempt fails with the following error message.

Error: PAM-UI-2417: Error deleting Credential Manager user group. Delete failed. The group cannot be deleted because it would leave some users of group 'example\_group' without any credential user group assigned.

## Delete a Credential Group Using the External API

To learn how to use the External API to delete Credential Manager user groups, see [Manage Credential Groups Using the External API](#).

## Manage Credential Groups Using the External API

Use the following External API **credentialUserGroups** methods to manage credential groups.

Operation	Method	Function
POST	/cspm/ext/rest/credentialUserGroups	Add a Credential Manager User Group without users or user groups. Either id or name may be specified for each attribute. If both are specified, they must match.
PUT	/cspm/ext/rest/credentialUserGroups/{id}/users	Replace the list of Session Manager Users associated with a Credential Manager User Group. If both ids and names are supplied, they are merged. Returns the new list of members of the group using GET eligibleUsers for members only.
PUT	/cspm/ext/rest/credentialUserGroups/name/{name}/users	Replace the list of Session Manager Users associated with a Credential Manager User Group. If both ids and names are supplied, they are merged. Returns the new list of members of the group using GET eligibleUsers for members only.
PUT	/cspm/ext/rest/credentialUserGroups/{id}/userGroups	Replace the list of Session Manager User Groups associated with a Credential Manager User Group. If both ids and names are supplied, they are merged. Returns the new list of members of the group using GET eligibleUsers for members only.
PUT	/cspm/ext/rest/credentialUserGroups/name/{name}/userGroups	Replace the list of Session Manager User Groups associated with a Credential Manager User Group. If both ids and names are supplied, they are merged. Returns the new list of members of the group using GET eligibleUsers for members only.
PUT	/cspm/ext/rest/credentialUserGroups/name/{name}	Update an existing Credential Manager User Group without modifying users or user groups. The name, role, and id of the group are required. You can specify the id, name, or both for each attribute. If both are specified, they must match.
PUT	/cspm/ext/rest/credentialUserGroups/name/{name}	Update an existing Credential Manager User Group without modifying users or user groups. The name, role, and ID of the group are required. Either ID or name may be specified for each attribute. If both are specified, they must match.
GET	/cspm/ext/rest/credentialUserGroups/userName	Return all the Credential Manager User Groups that a particular Session Manager User belongs to.
GET	/cspm/ext/rest/credentialUserGroups/{id}/eligibleUsers	Return all the Session Manager Users who could be assigned to a Credential Manager User Group, along with a flag that says if they are already part of the group.
GET	/cspm/ext/rest/credentialUserGroups/userName/{name}/eligibleUsers	Return all the Session Manager Users who could be assigned to a Credential Manager User Group, along with a flag that says if they are already part of the group.
GET	/cspm/ext/rest/credentialUserGroups/{id}	Get a specific Credential Manager User Group by ID.

Operation	Method	Function
GET	/cspm/ext/rest/credentialUserGroups/{id}/protectedUserGroups	Any Session Manager User Group which belongs only to the Credential Manager User Group specified may not be removed from that group.
GET	/cspm/ext/rest/credentialUserGroups/name{name}/protectedUserGroups	Any Session Manager User Group which belongs only to the Credential Manager User Group specified may not be removed from that group.
GET	/cspm/ext/rest/credentialUserGroups/{id}/protectedUsers	Any Session Manager User which belongs only to the Credential Manager User Group specified may not be removed from that group.
GET	/cspm/ext/rest/credentialUserGroups/name{name}/protectedUsers	Any Session Manager User which belongs only to the Credential Manager User Group specified may not be removed from that group.
GET	/cspm/ext/rest/credentialUserGroups/name/{name}/eligibleUserGroups	Return all the Session Manager User Groups who could be assigned to a named Credential Manager User Group, along with a flag that says if they are already part of the group.
GET	/cspm/ext/rest/credentialUserGroups/{id}/eligibleUserGroups	Return all the Session Manager User Groups who could be assigned to a Credential Management User Group, along with a flag that says if they are already part of the group.
GET	/cspm/ext/rest/credentialUserGroups	Search for Credential Manager User Groups.
GET	/cspm/ext/rest/credentialUserGroups/name/{name}	Search for Credential Manager User Groups Get a specific Credential Manager User Group by group name.
DELETE	/cspm/ext/rest/credentialUserGroups/{id}	Delete a Credential Manager User Group by ID.
DELETE	/cspm/ext/rest/credentialUserGroups/name/{name}	Delete a Credential Manager User Group by name.

**NOTE**

When using the **credentialUserGroups** methods, consider the following information:

- **eligibleUsers** are Session Manager users with the Manage Credentials privilege.
- **eligibleUserGroups** are Session Manager user groups with the Manage Credentials privilege
- **protectedUsers** are Session Manager users that belong to exactly one Credential Manager User group besides Secrets Management Users and so cannot be removed from that other group.
- **protectedUserGroups** are Session Manager user groups that belong to exactly one Credential Manager User group besides Secrets Management Users and so cannot be removed from that other group.
- You cannot add or remove users from the following read-only Credential Manager user groups:
  - System Admin Group
  - Standard Users
  - Base Users
  - Vault Administrators
  - Secret Management Users
  - Active MQ Group

To obtain detailed information about and, optionally, test the **credentialUserGroups** methods, do the following steps:

1. If necessary, enable and configure the API Docs. See [Use the External REST API \(Programmers\)](#) for details.

2. Select **Settings, API Doc** to access the API Docs.
3. Navigate to **credentialUserGroups** to see the details of and test the available methods.

## Add or Modify Credential Manager Roles

Credential Manager roles define the privileges that a user has to perform Credential Manager functions.

### NOTE

When selecting available privileges for a role, the Credential Manager requires the associated `get` and `list` privileges. For example, if you want a user to have `addAgent` or `deleteAgent`, you must also add privileges to `getAgent`.

These following sections describe Credential Manager roles and how to manage them using the PAM UI, CLI, and External API:

- [Preconfigured Roles](#)
- [Add a Credential Manager Role](#)
- [Get Credential Manager Roles Using the External API](#)

### Preconfigured Roles

Credential Manager is preconfigured with the following roles:

- **FirecallApprover:** This role provides a user with the ability to approve password-view requests only. This role is assigned to users with a view type of General User.
- **FirecallAutoConnect:** This role is deprecated. Do not use it.
- **FirecallUser:** This role provides a user with the ability to view target account passwords only. This role is assigned to users with a view type of General User.
- **ReadOnly:** This role allows read-only access to the Credential Manager pages. Users can view information but not make any changes. Users with this role can view target account passwords. This role is distinguished from a General User role, which can view a limited subset of the Credential Manager pages.
- **RequestorAdmin:** This role provides a user privilege to access and update requestor information only. Give this role to personnel doing requestor integration for A2A integrations. Users with this role cannot add script authorizations and do not have access to any target or user information.
- **ScriptAuthorizationAdmin:** This role allows a user to add script authorizations. Give this role to personnel doing requestor integration for A2A integrations.
- **ServerAdmin:** This role provides the User access to all Credential Manager administrative functions, except those functions in Targets, Applications; Targets, Aliases; A2A or Groups menus.
- **System Admin:** The System Admin is the default role. This role has access to all Credential Manager functionality. **Do not modify this role.**
- **TargetAdmin:** This role allows a user to access and update only target information. Give this role to database administrators that register and manage database accounts using Credential Manager. Users with this role can add and update password policies; however, they cannot delete password policies. Users with this role do not have access to any requestor or user information.

### CAUTION

The TargetAdmin role includes the `updateGroup` privilege, which can be exploited by an administrator that belongs to a credential group that has the TargetAdmin role to promote their own privileges. For example, say that a target administrator user belongs to a credential group that has the TargetAdmin role that is limited by a target group (such as if the administrator is only supposed to administer accounts that belong to applications of type Oracle). However, because they have the `updateGroup` privilege, they can edit the target group to expand its scope (say to cover all target servers with an IP address that contains the digit 1).

**To prevent promotion attacks on target groups:** Create a custom role based on the TargetAdmin role that does not include any 'group' related privileges (`addGroup`, `deleteGroup`, `getGroup`, `listTargetGroup`, `updateGroup`).

Administrators with that role cannot see or manipulate target groups in any way. Alternatively, leave the privileges that allow administrators to see target groups and delete addGroup, deleteGroup, and updateGroup, and they are able to view all target groups but not be able to edit them.

- **UserAdmin:** This role allows a user to administer Credential Manager Roles and Credential Manager User Groups. This role does not allow access to targets or requestor information, nor to individual User accounts or (regular) User Groups.
- **VaultAdmin:** This role allows an administrator to view, create, update, and delete vaults and secrets across the organization. Administrators assigned this role must first be assigned the SecretsManagementUser role.

**NOTE**

The VaultAdmin role includes the addVault privilege. Any credential group that is associated with this role must include *Vaults* as the target group. Any role that has the addVault privilege does not appear under the Roles dropdown menu in the Vaults Manager window in PAM.

- **ViewReports:** This role allows a user to run some but not all of the available Credential Manager reports. More privileges are required to run the other reports.

**NOTE**

For information about what reports a user with the ViewReports role can run and which privileges are required to run the other reports, see [Credential Manager Report Roles and Privileges](#).

- **BaseRole:** This role is used internally. **Do not modify this role.**

**NOTE**

Only the FirecallUser and System Admin roles include the privileges that are required to view passwords on the **Access** screen. For information on how to configure Credential Manager administrative users to view passwords, see [Configure Users with the Manage Credentials Privilege to View Passwords on the Access Screen](#)

## **Add a Credential Manager Role**

Use one of the following methods to add a Credential Manager role:

- [Add a Credential Manager Role Using the UI](#)
- [Add a Credential Manager Role Using the CLI](#)

### ***Add a Credential Manager Role Using the UI***

Modify a role in the UI.

Follow these steps:

1. Select **Credentials, Manage Credential Groups, Credential Roles**.  
The Credential Manager Roles page appears.
2. Select **ADD**.  
The Add Credential Manager Role page appears.
3. Supply a role **Name** and **Description**.
4. Add or remove privileges using the arrows.
5. Select **OK** to save.

### ***Add a Credential Manager Role using the CLI***

Use the following procedure to add a role with the Remote CLI.

Follow these steps:

1. Add a role. For example:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addRole Role.name=patchMgrRole
Role.description="Manages patches"
Role.privileges=activatePatch,activatePatchNow,addPatch,deletePatch,deletePatchDetail,getPatchDetail,listPatch,listPatchDetail,updatePatch,updatePatchDetail,updatePatchDetailList
```

For a complete list and description of the available roles for the role.privileges parameter, see [Credential Manager CLI User Interface Actions](#).

2. Enter your password at the prompt. Credential Manager returns the following XML command string:

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<Role>
<ID>11</ID>
<createDate>Tue Apr 08 10:31:28 EDT 2008</createDate>
<updateDate>Tue Apr 08 10:31:28 EDT 2008</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>SD01a6QKWvtwUPILiY5eznW7I7I=</hash>
<name>patchMgrRole</name>
<description>Manages patches</description>
<privileges>[activatePatch, activatePatchNow, addPatch, deletePatch, deletePatchDetail, getPatchDetail,
listPatch, listPatchDetailSummary, updatePatch, updatePatchDetail, updatePatchDetailList]</privileges>
<readOnly>false</readOnly>
<hidden>false</hidden>
</Role>
</cr.result>
</CommandResult>
```

### Available Privileges for Roles

Use the following table to determine the privileges you can assign when adding or modifying a Credential Manager role.

#### NOTE

If a command is available in the CLI and the UI, the names are similar for each interface. For example, the command activatePatch is named Activate Patch in the UI. To see the complete list of UI privileges, go to [Credentials, Manage Credential Groups, Credential Roles](#). To see the complete list of CLI commands, go to [Credential Manager CLI Commands](#).

Command/Privilege Name	Interface	Description
activatePatch	UI	Sets the active flag for patches.
activatePatchDeployments	UI	Activates selected patches in the system
addAgent	UI	Adds a Credential Manager Windows Proxy.
addAuthorization	UI, CLI	Adds an authorization mapping.
addCustomWorkflow	UI, CLI	Required to create a custom workflow.
addFilter	UI, CLI	Adds a filter to a target group or request group.
addGroup	UI, CLI	Adds a target or request group.
addPasswordPolicy	UI, CLI	Adds password policies.
addPasswordViewPolicy	UI, CLI	Adds a password view policy.

addPatch	UI	Loads a Credential Manager client patch in the Credential Manager server.
addRequestScript	UI, CLI	Adds a request application.
addRequestServer	UI, CLI	Adds a request server.
addRequestServerDefaults	UI, CLI	Adds a request server default.
addRole	UI, CLI	Adds a role.
addScheduleJob	UI, CLI	Schedules a target account update or verify for later execution.
addSite	UI, CLI	Adds a site to a multisite configuration.
addSSHCertificatePolicy	UI, CLI	Adds an SSH certificate Policy to Privileged Access Manager.
addSSHKeyPairPolicy	CLI	Adds an SSH Key Pair Policy to Privileged Access Manager.
addTargetAccount	UI, CLI	Adds a target account.
addTargetAlias	UI, CLI	Adds a target alias.
addTargetApplication	UI, CLI	Adds target applications.
addTargetServer	UI, CLI	Adds a target server.
addUser	UI, CLI	Adds a user.
addUserGroup	UI, CLI	Adds a user group.
archiveAuditData	CLI	Archives audit data.
archiveMetricData	CLI	Archives metric data.
autoConnectTargetAccount	UI	Allows the user to auto-connect to a target account.
batchSequence	CLI	Provides bulk registration for CLI commands.
canGetCredentials	CLI	Validates a specified A2A request can retrieve credentials from Credential Manager.
checkConnectionStatus	UI, CLI	Checks the connection status of a client.
checkDelete	CLI (internal only)	Checks if a target server or request server can be deleted (or were previously deleted).
checkInAccountPassword	UI, CLI	Checks in an account that was previously checked out by a user viewing the password.
deleteAgent	UI	Deletes a Credential Manager Windows Proxy.
deleteAuthorization	UI, CLI	Deletes an authorization mapping.
deleteCustomWorkflow	UI, CLI	Required to delete a custom workflow.
deleteFilter	UI, CLI	Deletes a filter to a target group or request group.
deleteGroup	UI, CLI	Deletes a target or request group.
deletePasswordPolicy	UI, CLI	Deletes a password policy.
deletePasswordViewPolicy	UI, CLI	Deletes a password view policy.
deletePasswordViewRequest	UI, CLI	Deletes either a specific password view request or all expired password view requests.
deletePatch	UI	Removes a Credential Manager client patch from the Credential Manager server.
deleteRequestScript	UI, CLI	Deletes a request application.
deleteRequestServer	UI, CLI	Deletes a request server (Credential Manager client).

deleteRequestServerDefaults	UI, CLI	Deletes request server defaults.
deleteRole	UI, CLI	Deletes a role.
deleteScheduleJob	UI	Used to delete a scheduled job.
deleteSite	UI, CLI	Deletes a site from a multi-site configuration.
deleteSSHCertificatePolicy	UI, CLI	Deletes an SSH certificate policy.
deleteSSHKeyPairPolicy	UI, CLI	Deletes an SSH Key Pair policy.
deleteSystemProperty	CLI	Delete a system property (for example: set isDeleted = 1).
deleteTargetAccount	UI, CLI	Deletes a target account.
deleteTargetAlias	UI, CLI	Deletes a target alias.
deleteTargetApplication	UI, CLI	Deletes a target application.
deleteTargetServer	UI, CLI	Delete a target server.
deleteUser	UI, CLI	Deletes a user.
deleteUserGroup	UI, CLI	Deletes a user group.
disableCLIHostNameCheck	CLI	Disables Host Name verification when authenticating using the CLI.
disableFingerprinting	UI, CLI	Disables the Credential Manager client hardware fingerprinting feature.
enableCLIHostNameCheck	CLI	Forces host name checking when connecting with the CLI.
enableFingerprinting	UI, CLI	Enables the Credential Manager client hardware fingerprinting feature.
enableLicense	UI, CLI	Activates a Credential Manager license.
expirePasswordViewRequest	UI, CLI	expires a password view request.
forceCheckInAccountPassword	UI, CLI	Checks in an account that is checked out by another user.
generateEncryptedPassword	CLI	Generates an encrypted String from the value that is passed in.
generateReport	UI	Generates Credential Manager reports.
getAgent	UI	Retrieves a Credential Manager Windows proxy.
getAllScriptHash	UI, CLI	Refreshes the script hash for all the request applications on the specified request server (Credential Manager client).
getAuthorization	UI	Retrieves an authorization mapping.
getAwsManagementConsoleSessionUrl	CLI	Retrieves a URL to an authenticated Amazon Web Services Management Console federation session.
getErrorCodes	CLI	Retrieves the list of Credential Manager server error codes.
getEventProcessingMetrics	CLI	Gets metrics for notification event processing.
getGroup	UI	Retrieves a target group or request group.
getLocalProperty	CLI	Retrieves the property value which matches the property name.
getLogs	UI, CLI	Retrieves a ZIP file containing the logs from a siteServer or requestServer.
getMetric	UI	Retrieves metric data.
getMostRecentPasswordHistory	Internal	Retrieves the most recent password history for a target account.

getMSOLFederatedSessionCmd	CLI	Generates a federated session request for presentation to the MSOL portal. The request is returned as a web form that is automatically submitted by the browser. Submitting the form launches a federated session with MSOL.
getNumberOfAccounts	UI, CLI	Retrieves the number of target accounts that are registered in Credential Manager.
getPasswordHistory	UI	Retrieves the password history for a target account.
getPasswordViewPolicy	UI	Retrieves a single password view policy from the DB by ID or name
getReportData	UI	A command to retrieve data for a named report
getRequestServerDefaults	UI, CLI	Gets request server defaults.
getScheduleJob	UI	Gets a scheduled job.
getScript	UI	Retrieves a request application.
getScriptHashAsynchronous	UI, CLI	Refreshes the script hash for a specified request script on a request server (Credential Manager client).
getServiceStatus	CLI	Gets the status of services that are associated with a Windows Domain Service target account. This command assumes that the service information is stored in the extend attribute serviceInfo.
getSite	UI	Retrieves a site.
getSystemProperty	CLI	Retrieves the property value which matches the property name.
getTargetAccount	UI	Retrieves a target account.
getTargetAlias	UI	Retrieves a target alias.
getTargetApplication	UI	Retrieves a target application.
getTargetServer	UI	Retrieves a target server.
getUser	UI	Retrieves a user.
getUserGroup	UI	Retrieves a user group.
listAuthorization	UI	Lists authorization mappings.
listDBClusterMembers	UI, CLI	Lists database cluster members in the system.
listGroups	UI	Lists user groups.
listMetrics	UI	Retrieves metric data.
listPasswordHistory	UI	Lists the password history for target accounts.
listPasswordViewRequestByApproverSummary	UI, CLI	Returns a list of password view requests for an approver.
listPasswordViewRequestByRequestorSummary	UI, CLI	Returns a list of password view requests for a requestor.
listPasswordViewRequestSummary	UI	Returns a list of password view requests.
listPatch	UI	Lists the Credential Manager client patches loaded in the Credential Manager server.
listPatchDeploymentSummary	UI	Lists the patch deployments.
listReports	UI	Lists the available reports.
listRequestScript	UI	Lists request applications.

listRequestServerDefaults	CLI	Lists Request Server defaults.
listScheduleJob	UI	Lists scheduled password validation and updates.
listTargetAccounts	UI	Lists target accounts.
listTargetAliases	UI	Lists target aliases.
listTargetApplications	UI	Lists target applications.
listUsers	UI	Lists Credential Manager users.
readCustomWorkflow	UI, CLI	Required to read a custom workflow.
renameUser	CLI	Creates a copy of an existing user with a new name, and deletes the old user.
resetClientCache	CLI	Informs all active clients that their caches of saved passwords should be reset. Contact CA Support before using this command.
resetDBHash	UI, CLI	Resets the database hash for an object.
resetGroupCache	CLI	Resets the group cache for all groups, or a single group. This command is asynchronous.
searchAgent	CLI	Lists Credential Manager Windows Proxies.
searchAuditLog	UI	Lists audit log records.
searchAuthorization	CLI	Lists authorization mappings.
searchCustomWorkflow	UI, CLI	Required to search and list custom workflows.
searchFilter	UI, CLI	Lists filters.
searchGroup	CLI	Lists target groups or request groups.
searchPasswordPolicy	CLI	Lists Password Composition Policies.
searchPasswordViewPolicy	UI, CLI	Lists password view policies in the system.
searchPasswordViewRequest	UI, CLI	Lists the password view requests in the system.
searchPasswordViewRequestByApprover	UI, CLI	Lists the password view requests for a particular approver. The approver is the user executing the command.
searchPasswordViewRequestByRequestor	UI, CLI	Lists the password view requests for a particular requestor. The requestor is the user executing the command.
searchRequestScript	CLI	Lists request applications.
searchRequestServer	UI, CLI	Lists request servers.
searchRole	CLI	Lists roles.
searchServerKey	UI	Lists all the server keys.
searchSite	UI, CLI	Lists sites.
searchSSHCertificatePolicy	UI, CLI	Lists SSH certificate policies.
searchSSHKeyPairPolicy	CLI	Lists SSH Key Pair policies.
searchTargetAccount	CLI	Lists target accounts.
searchTargetAlias	CLI	Lists target aliases.
searchTargetApplication	CLI	Lists target applications.
searchTargetServer	UI, CLI	Lists target servers.
searchUser	CLI	Lists users.
searchUserGroup	CLI	Lists user groups.

setInitProperty	CLI	Sets the initialization property (database username and password) for DB2 databases.
setLocalProperty	CLI	Sets the site name in the site-local Credential Manager data store.
setPasswordViewReasons	CLI	Sets the password view reasons text for UI display.
setPasswordViewRequestDeleteInterval	UI, CLI	Sets the Password View Request Delete Interval.
setReportRowLimit	UI, CLI	Sets the maximum number of entries that reports display.
setSystemProperty	CLI	Sets a Credential Manager system property.
showGroup	UI	A command that retrieves the contents of a Requestor or Target group.
updateAgent	UI	Changes a Proxy.
updateAuthorization	UI, CLI	Changes an authorization mapping.
updateCompoundServers	UI	Changes a target compound server.
updateCustomWorkflow	UI, CLI	Required to update a custom workflow.
updateDBClusterMembers	UI, CLI	Update information about a database cluster member.
updateDBPassword	CLI	Changes the Credential Manager datastore administrator password on all databases except DB2.
updateFilter	UI, CLI	Updates a filter in a target group or request group.
updateGroup	UI, CLI	Changes target and request groups.
updatePasswordHistory	UI	Changes a password history item.
updatePasswordPolicy	UI, CLI	Updates password policies.
updatePasswordViewPolicy	UI, CLI	Updates a password view policy.
updatePasswordViewRequestStatus	UI, CLI	Updates the status of password view request to 'approved' or 'denied'.
updateRequestScript	UI, CLI	Changes a request application.
updateRequestServer	UI, CLI	Changes a request server.
updateRequestServerDefaults	UI, CLI	Updates a request server defaults.
updateRequestServerKey	UI, CLI	Changes a request server (Credential Manager client) encryption key.
updateRole	UI, CLI	Changes a role.
updateServerKey	CLI	Changes the Credential Manager server encryption key.
updateSite	UI, CLI	Changes site information.
updateSSHCertificatePolicy	UI, CLI	Updates an existing SSH certificate in Privileged Access Manager.
updateSSHKeyPairPolicy	CLI	Updates an existing SSH Key Pair Policy in Privileged Access Manager.
updateTargetAccount	UI, CLI	Changes a target account.
updateTargetAccountDescriptor	CLI	Changes a target account descriptor value.
updateTargetAccountPassword	UI, CLI	<p>Changes a target account password.</p> <p><b>Note:</b> To change passwords using the UI, this Role also requires the updateTargetAccount permission.</p> <p>The CLI only requires the updateTargetAccountPassword permission to change passwords.</p>

updateTargetAlias	UI, CLI	Changes target aliases.
updateTargetApplication	UI, CLI	Changes target applications.
updateTargetServer	UI, CLI	Changes target servers.
updateUser	UI, CLI	Changes user information.
updateUserGroup	UI, CLI	Changes a user group.
updateUserPassword	CLI	Changes a user password.
updateUserStatus	UI, CLI	Enable or disable access of a Credential Manager user to the system.
verifyAccountPassword	UI, CLI	Verifies a synchronized account password or all synchronized accounts in a target group (optionally excluding verified or non verified accounts).
verifyDBHash	CLI	Verifies the hash value of most BaseModel objects that are stored in DB.
viewAccountPassword	UI, CLI	Allows the user to view an account password.

### Get Credential Manager Roles Using the External API

Use the External API **credentialRoles** method to get Credential Manager roles.

Operation	Method	Description
GET	/cspm/ext/rest/credentialRoles	Get Credential Manager roles.

To obtain detailed information about and, optionally, test the **credentialRoles** method, do the following steps:

1. If necessary, enable and configure the API Docs. See [Use the External REST API \(Programmers\)](#) for details.
2. Select **Settings, API Doc** to access the API Docs.
3. Navigate to **credentialRoles** to see the details of and test the method.

## Configure Users with the Manage Credentials Privilege to View Passwords on the Access Screen

By default, users with Credential Manager administrative privileges do *not* have privileges to view passwords on the **Access** screen. This article describes how to create and assign a Credential Manager group with password viewing privileges.

### NOTE

**Background:** By default, users are assigned to the "[Standard User](#)" role and are *silently* assigned to the "Standard Users" Credential Manager group. ("Standard Users" is not shown on the **Credential Manager Groups** tab). Membership of the "Standard Users" Credential Manager group provides privileges to view account passwords on the **Access** page. However, when a user is assigned any role with the "Manage Credentials" privilege (for example, "Password Manager"), that user is removed from the "Standard Users" Credential Manager group and cannot view passwords on the **Access** page.

### Follow these steps:

1. Do the following steps to create the Credential Manager role:
  - a. Open **Credentials, Manage Credential Groups, Credential Roles**.
  - b. Select **ADD**.
  - c. Enter a **Name** for the new role. For example, "ViewPasswords."

- d. Move the following privileges from the **Available Privileges** column to the **Selected Privileges** column:

- Get Password View Policy
- Get Target Account
- View Account Password

The following screenshot shows an example:

**Add Credential Manager Role**

Name:

Description:

**Available Privileges**

- ☐ Name
- ☐ Update Server Key
- ☐ Update Site
- ☐ Update Target Account
- ☐ Update Target Account Descriptor
- ☐ Update Target Account Expired Password
- ☐ Update Target Account Password
- ☐ Update Target Alias
- ☐ Update Target Application
- ☐ Update Target Server
- ☐ Update User
- ☐ Update User Group
- ☐ Update User Password
- ☐ Update User Status
- ☐ Verify Account Password
- ☐ Verify DB Hash

**Selected Privileges**

- ☒ Name
- ☒ Get Password View Policy
- ☒ Get Target Account
- ☒ View Account Password

**OK** **CANCEL**

- e. Select **OK** to save the role and exit.
2. Do the following steps to create a Credential Manager group with the "ViewPasswords" role that you created in Step 1:
- Open **Credentials, Manage Credential Groups, Credential Groups**.
  - Select **ADD**.
  - Enter a **Name** for the new group. For example, "View Passwords."
  - Select the "ViewPasswords" role that you created in Step 1 from the **Role** drop-down list.
  - Add a **Target Group**. Note that if user A is assigned a credential manager group with the "Target Administrator" role and "Targets" as the target group, that user sees only the assigned "Targets" group in the display, not other target groups. User A can add a new target group, but it does not appear in the display because user A does not have the permissions to view it. To see other groups, assign the user A with the Credential Manager group with the "Target Administrator" role only.
  - Optionally, add a **Request Group** for A2A.

The following screenshot shows an example:

## Update Credential Manager User Group View Passwords

?
✕

---

Requestors

🔍

OK

CANCEL

- g. Select **OK** to save the group and exit.
3. Do the following steps to add the "View Passwords" group that you created in Step 2 to the user account with Credential Manager administrative privileges:
  - a. Open **Users, Manage Users**.
  - b. Select the user account with Credential Manager administrative privileges and select **UPDATE**.
  - c. Select the **Credential Manager Groups** tab.
  - d. Move the "View Passwords" group that you created in Step 2 from the **Available Groups** column to the **Selected Groups** column.

The following screenshot shows an example user with Report Viewer and View Passwords Credential Manager groups:

**Update User Pat**

Basic Info Administration Roles Access Times Groups **Credential Manager Groups** API Keys

Available Groups

- ☐ Name
- ☐ AWS Proxy Accessors
- ☒ Base Users

- ☐ View Passwords

MANAGE POLICY

OK CANCEL

e. Select **OK** to save the user and exit.

The user can now see passwords on the **Access** screen.

## Configure a PAM User to View the Password History of Target Accounts

Use this procedure to learn how to view the Target Account's password credential history.

**Follow these steps:**

1. [Add a new Credential Manager Role](#) named **CredentialHistory**.

2. Add the following privileges: **Get Password History**, **Get Target Account**, **List Password History**, **List Target Accounts**, and **Search Target Account**.

### Update Credential Manager Role CredentialHistory

Name: \*

Description:

Available Privileges

- ☐ Name
- ☐ Activate Patch
- ☐ Activate Patch Deployments
- ☐ Add A2A Client
- ☐ Add A2A Client Defaults
- ☐ Add A2A Script
- ☐ Add Agent
- ☐ Add Authorization
- ☐ Add Filter
- ☐ Add Group
- ☐ Add Password Policy
- ☐ Add Password View Policy
- ☐ Add Patch
- ☐ Add Policy
- ☐ Add Role

Selected Privileges

- ☐ Name
- ☒ Get Password History
- ☐ Get Target Account
- ☐ List Password History
- ☐ List Target Accounts
- ☐ Search Target Account

OK

3. [Add a new Credential Manager Group](#) named **Credential History Accessors** with the **CredentialHistory** role, and the appropriate **Target Group**. **Note:** *Targets* by default provides access to credentials across all Target Devices. To restrict viewing credentials to certain Target Devices, create a new Target Group that only

includes the desired Target Devices. A **Request Group** is not needed.

4. [Create a new user.](#)
5. Under **Roles**, remove the automatically assigned **Standard User Role**. This prevents the **Access** page from loading on login.
6. Add the **Password Manager** role.

7. Under the **Credential Manager Groups** tab, add the **Credential History Accessors CM Group**, and click OK to complete and confirm this page.

8. **Note:** At this point, **log in** as the newly-created user to view credential history directly from the **Target Accounts** page.
9. Select the desired **Target Account** to view its credential history.

Account Name	Application Name	Application Type	Host Name	Device Name	Account Type	Owner User Name	Verified	Action
CA7apApUser...	ApiKey	XsaultApiKey	apikeyxcedu...	apikeyxcedu...	AQA		✓	
MCapiKey-1001	ApiKey	XsaultApiKey	apikeyxcedu...	apikeyxcedu...	AQA		✓	
nimadmin	CA Normaliza...	CalimSM	nim.pam.ca.c...	nim.pam.ca.c...	Privileged			
nimadmin	CA Normaliza...	CalimJM	nim.pam.ca.c...	nim.pam.ca.c...	Privileged			
root	SSHDevice-76	ssh	10.17.45.199	SSHDevice	Privileged			

- **To view the Target Account's password history**, select the **Credential History** icon located next to the Password field. **Note:** Such a user can perform NO OTHER action on this page, as the user only

has privileges to view password history. For example, clicking the magnifying glass by the **Host Name**, **Application Name**, or **Password View Policy** fields displays a permission error, as the user does not have the proper privileges. Lack of permissions also disallows viewing the current credential of the Target Account.

- The **Password History** is a list of all previous credentials for this Target Account, ordered by **Date**

Date Changed	Changed By	Compromised
2020/04/01 11:21:34 GMT-0000	super	<input type="checkbox"/>
2020/04/01 11:21:22 GMT-0000	super	<input type="checkbox"/>
2020/03/26 13:10:37 GMT-0000	super	<input type="checkbox"/>
2020/03/25 13:04:35 GMT-0000	super	<input type="checkbox"/>
2020/03/25 13:04:06 GMT-0000	super	<input type="checkbox"/>
2020/03/25 13:03:58 GMT-0000	super	<input type="checkbox"/>

Changed.

- To view the actual historical password for the Target Account at a particular date, select the desired entry in the Password History list.

."/>

## Manage Credentials Between Applications (A2A)

The A2A (Application to Application) feature lets you manage credential requests from automated request servers. After Credential Manager provides the password, the request server submits them to access the target. *Request scripts* are applications that require credentials for target accounts on password management target devices. These scripts request the managed credentials by way of the A2A Client, which runs on a request server. This request server is treated like a target server but is an A2A device type.

The A2A feature uses an A2A Client that you install on a host in the customer environment. The A2A Client then has to integrate with the appliance.

This topic describes the following tasks:

### A2A Terminology

The following terms are specific to A2A configurations:

- **Request Server:** A host server where the requestor application resides and where you install the A2A Client.
- **A2A Client:** A program that is installed on the request server. The A2A is the intermediary that communicates between the requestors and PAM.
- **Requestor:** A program or script that requests credentials that are stored as part of an A2A target account at PAM. To obtain credentials, the requestor communicates to the A2A Client, which then fetches the credentials from PAM. When PAM receives the credential request, it evaluates attributes of the request server, the requesting program/script, and the user executing the requesting program. If authorized, PAM sends the credentials to the requestor. A requester can use credentials for any task that requires credentials, such as opening connections to databases.
- **Target Alias:** A unique name that identifies an A2A target account. An A2A target account might have multiple aliases.
- **Authorization Mapping:** A mapping defines which requesting application or scripts can access which target accounts. Mappings implement A2A security.

## **Configuration Overview**

This section provides a high-level overview of the process to configure A2A credential management:

### **NOTE**

You do not have to complete the A2A tasks in any specific order. The only exception is for A2A deployments on an AWS AMI in an Amazon Virtual Private Cloud.

1. Add target devices that host target accounts for use by request servers. These targets use the device type Privileged Management.
2. Install the A2A Client on a remote host.
3. Use the PAM UI to register the A2A Client with a PAM server or a site VIP in a clustered environment.
  - a. Add the A2A Client as an A2A device.
  - b. Activate the Device.
4. Integrate the A2A request scripts on the A2A Client host
5. Use the UI and integrate the request server with the appliance server:
  - a. Specify the A2A request scripts
  - b. Specify authorization mappings

## **Configure A2A for High-Availability in Multisite Clustered Environments**

You can configure your A2A implementation to provide varying levels of availability in a multisite clustered environment by configuring the PAM nodes at which sites to which each request server can connect. The more PAM nodes to which a request server can connect, the higher the availability.

At a minimum, configure each request server to be able connect to all the PAM nodes at its site by taking the following actions:

- Register all request servers with their local site VIP, not an individual PAM node.
- Configure your network and firewall rules to provide all PAM nodes at a site with a clear network path to all locally registered request servers.

### **NOTE**

The previous configuration is considered the default solution and is used in all associated procedures in this documentation.

Example configurations for higher A2A availability:

- **For additional A2A availability:** Configure your environment so that each request server has a clear network path to every PAM node at its local site *and* the primary site.
- **For maximum A2A availability:** Configure your environment so that each request server has a clear network path to every PAM node in your cluster

**IMPORTANT****High-Availability vs. Security and Performance**

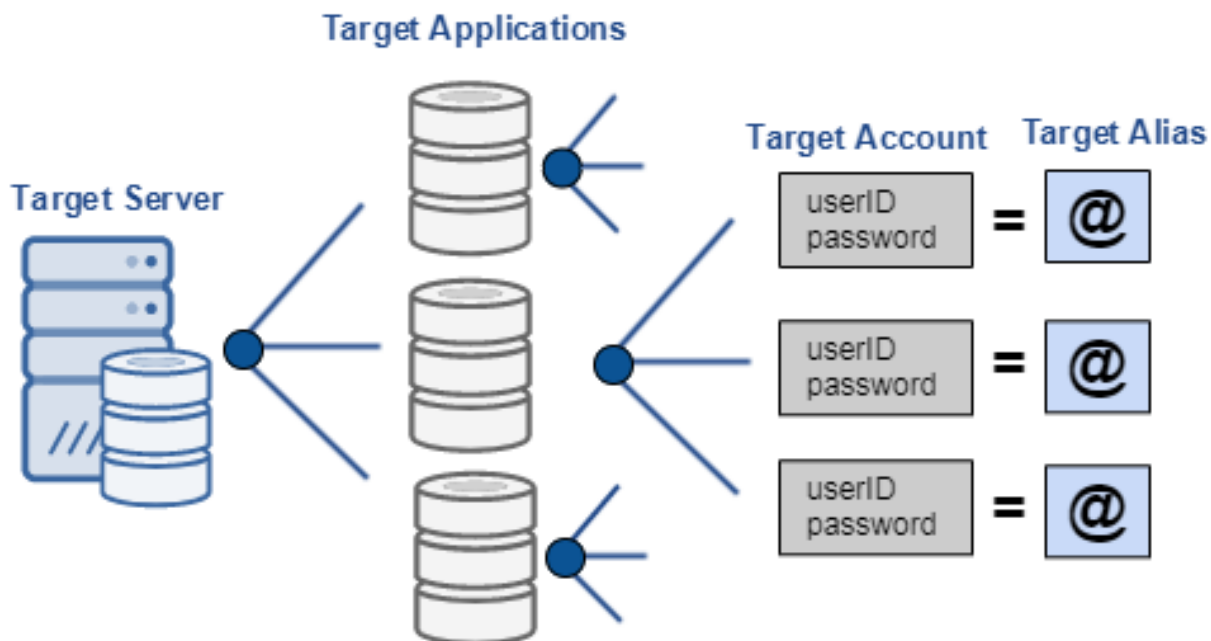

Because higher availability configurations require more connections between request servers and PAM nodes, some at remote sites, there is a corresponding impact on network security and performance. Configuring network and server firewall rules to allow the associated connections affects network security. The additional network traffic affects network performance. You must therefore consider these trade offs when determining your availability strategy.

**Identify Targets Using Target Aliases**

To manage A2A passwords, assign one or more target aliases for each target account. A target alias is a unique name that links a target server, a target application on that server, and a target account for that application. A script that is integrated with Credential Manager, uses the alias to retrieve the target account credentials from the database. The credentials enable access to the target system. With a target alias defined, target credentials are not hard-coded into scripts, allowing Credential Manager to handle password changes automatically.

The following figure shows the hierarchical structure of target accounts.

**Figure 35: Target Aliases for A2A Communication**

Requesting programs also identify a target account by specifying a target alias. Target aliases are global to the appliance. The aliases differ from target account names because target names can be duplicated on many hosts. An example of a duplicated name is the root account on UNIX systems.

Target aliases and groups are also used in authorization mappings.

Specifying a target alias is identical to the target alias specified by the requesting program.

If the mapping is to a target group, all accounts in the group represent the target. Grouping targets lets the requesting program/script obtain the target aliases for each target account without you configuring multiple mappings. Target groups are the most scalable way of specifying targets. However, some requesting programs might get credentials for target accounts that are not needed. To prevent this issue, configure mappings to individual aliases or set up target groups with the smallest scope possible.

**TIP**

See the following related content for more information about configuring A2A to allow PAM to manage credential requests from automated request servers:

- [Install and Activate an A2A Client on a Request Server](#)
- [Target Aliases for A2A Target Accounts](#)

- [Configure an A2A Client to Use Another Server](#)
- [Configure the A2A Client Multi-Home Feature](#)
- [Configure A2A Client Event Polling](#)

## Install and Activate an A2A Client on a Request Server

The A2A Client manages the connection between Privileged Access Manager and a request server. The A2A Client runs on a request server and allows requestors to communicate securely with the appliance.

This topic describes the requirements and installation procedures for an A2A Client.

### **A2A Client Hardware Requirements**

The following table details the hardware requirements for the A2A Client.

A2A Client	Hardware Requirements
A2A Client (32-bit)	32-MB RAM 120-MB hard drive space
A2A Client (64-bit)	32-MB RAM 170-MB hard drive space

50 MB must also be reserved for the A2A Client log file.

### **A2A Client Operating System Requirements**

The A2A Client runs as a daemon or service and requires a Java Virtual Machine (JVM). The A2A Client can be installed on 32-bit and 64-bit operating systems.

**NOTE**

The 32-bit installation is no longer supported on Linux or Solaris Sparc systems. However, the 32-bit **libcwjcafips.so** file is preserved as **libcwjcafips32.so** so that you can still run your applications using a 32-bit JRE if necessary.

To use the 32-bit **libcwjcafips32.so** file, follow these steps:

1. Navigate to **/citech/cspmclient/lib**.

2. Copy **libcwjcafips32.so** to a different folder.
3. Rename **libcwjcafips32.so** to **libcwjcafips.so**.
4. Set the **java.library.path** to point to the folder that contains your new **libcwjcafips.so** file before pointing to the **/catech/cspmclient/lib** folder.

### **Prepare the Request Server System for A2A Client Installation**

Before you install the A2A Client, do the following tasks:

- **Important!** Verify that no A2A Client is already installed on the host system. If there is, uninstall it. For more information, see [Uninstall the A2A Client](#).
- Verify that all A2A Client hardware and software requirements are met.
- Ensure that firewalls do not block the necessary communication ports. See [Default Port Settings](#) for details.
- Verify that the A2A Client correctly resolves the PAM appliance name using DNS. If DNS resolution fails, correct the issue. If it cannot be corrected, place the name in the A2A Client host file:
  - **On UNIX:** `/etc/hosts`
  - **On Windows:** `C:\Windows\System32\drivers\etc\hosts`
- Verify that the appliance resolves the DNS name of the A2A Client host. From the UI, select **Configuration, Tools**. Try to resolve the name of the A2A Client host. If it does not resolve, then correct the issue.

#### **TIP**

You can also verify DNS resolution after the A2A Client is started using the following procedure in the PAM UI:

1. Select **Credentials, Manage A2A, Mappings**.
  2. Select **Add** then use the magnifying glass for the **Request** field to display a list of A2A Clients.
  3. Verify that your A2A Client is displayed.
- The default installation directory for the A2A Client is one of the following:
    - **Windows:** `C:\cspm`
    - **Standard UNIX install:** `/opt/cloakware`
    - **RPM-based install for RHEL:** `/opt/Broadcom/PAM/A2A`
- If you do not want to use the default directory, create an alternate installation directory.

### **Download the A2A Client Software**

Download the A2A Client software from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

### **Install the A2A Client**

You can install the A2A Client on a UNIX or Windows host.

- [Install the A2A Client on a Windows Host](#)
- [Install the A2A Client on a UNIX or Linux Host Using the Install Script](#)
- [Install the A2A Client on a RHEL Host Using the RPM Package](#)
- [Install the A2A Client on an AIX Host](#)
- [Deploy an A2A Client on an AWS AMI](#)

#### ***Install the A2A Client on a Windows Host***

Install a single A2A Client on the Windows host. Multiple Clients on the same host are not supported. If there is an existing A2A Client, uninstall it before proceeding.

If the A2A Client host is a 64-bit platform, you can install the 32-bit or the 64-bit A2A Client. Install the 64-bit client to integrate with 64-bit applications or the 32-bit client to integrate with 32-bit applications.

### NOTE

The A2A Client installation on Windows is performed by InstallAnywhere software. If you execute the installation from an account that contains special characters, the InstallAnywhere wizard fails. To avoid this problem, start the installation by right-clicking on the executable file and selecting the **Run As** option. The **Run As** dialog opens and prompts for an alternate username and password for the installation. Specify the account credentials and continue with the installation.

### Follow these steps:

1. Open a Command window and navigate to the `clients/win` subdirectory in the unzipped installation package.
2. Start the installation wizard by double-clicking  
`setup_windows32_java.exe`  
or  
`setup_windows64_java.exe`  
An InstallAnywhere window informs you that the installation preparation has started.  
When the preparation completes, the A2A Client Welcome window followed by the **Introduction** window. Select Next.
3. In the **Choose Install Folder** window, enter, or select the folder where you want to install A2A Client.  
Do not use a space in the installation folder names.
4. In the **Server Information** window, specify one of the following options in the **Server Name** field:
  - **Clustered environment:** The IP address or fully qualified domain name (FQDN) of a node at the nearest site or the site VIP if there is one. If you specify the FQDN, it must match the name in the appliance SSL certificate.
  - **Unclustered environment:** The IP address or fully qualified domain name (FQDN) of the PAM server.

### NOTE

#### Important Information:

- In a clustered environment, always specify the address of the site VIP, if available. The VIP provides automatic load-balancing and failover between all the nodes at that site.
  - The specified `server_address` value is written to the A2A Client configuration file (`CSPM_CLIENT_HOME/cspmclient/config/cspm_client_config.xml`).
  - In a multisite cluster, add alternate site VIPs or node addresses to the A2A Client configuration file to configure A2A Client failover. For more information, see [Configure A2A Client Failover upon Connection Failure in a Cluster](#).
5. Optionally enable IPv6 by checking the **IPV6 Enabled** checkbox.
  6. In the **Choose Log Directory** window, enter a specific path name for the installation log file directory or use the default path name.
  7. In the **Pre-Installation Summary** window, validate the installation information then select **Install**.  
The **Installing Password Authority Client** window appears and shows the progress of the installation.
  8. When the installation finishes, the **Install Complete** window appears. Select **Done**.
  9. Do *one* of the following tasks to auto-register the A2A Client by starting the PAM software component service:
    - Open a command window and enter: `net start cspmclientd`
    - Open the Windows Services tool and start the `cspmclientd` service.

After the installation is complete and the client is started, the Client registers with PAM.

### **Install the A2A Client on a UNIX or Linux Host Using the Install Script**

Run the install script on *each* request server to install the A2A Client.

### NOTE

This release also includes an RPM package for use with Red Hat Enterprise Linux (RHEL) hosts. For more information, see [Install the A2A Client on a RHEL Host Using the RPM Package](#).

Install and configure the A2A Client on all request servers, but install only one A2A Client on each host. If there is an existing A2A Client, uninstall it before proceeding.

#### NOTE

Before you install the A2A Client on a Linux system, ensure that your system has the correct 32-bit or 64-bit libidn installed. If you try to install the Client without the correct libidn. The installation stops and an error message is displayed.

#### Follow these steps:

1. Open a shell window and navigate to the location of the unzipped A2A Client installation package:

```
cd unzip_location/
```

2. Enter the following command:

```
chmod u+x setup_unix
```

3. Start the installation script by entering the following command and options:

```
./setup_unix host_type A2A_client_install_dir  
server_address [true|false]
```

Where:

- *host\_type*: The type of UNIX host. Enter `Linux` or `SolarisSparc`
- *A2A\_client\_install\_dir*: The complete pathname of the installation directory for the A2A Client software. Relative path names (that is, paths beginning with `./`) are not acceptable.
- *server\_address*: One of the following options:
  - **Clustered environment**: The IP address or fully qualified domain name (FQDN) of a node at the nearest site or the site VIP if there is one. If you specify the FQDN, it must match the name in the appliance SSL certificate.
  - **Unclustered environment**: The IP address or fully qualified domain name (FQDN) of the PAM server.
- *[true/false]*: Optionally enable IPv6

#### NOTE

##### Important Information:

- In a clustered environment, always specify the address of the site VIP, if available. The VIP provides automatic load-balancing and failover between all the nodes at that site.
- The specified *server\_address* value is written to the A2A Client configuration file (`CSPM_CLIENT_HOME/cspmclient/config/cspm_client_config.xml`).
- In a multisite cluster, add alternate site VIPs or node addresses to the A2A Client configuration file to configure A2A Client failover. For more information, see [Configure A2A Client Failover upon Connection Failure in a Cluster](#).

4. Auto-register the A2A Client (request server) in the GUI by starting the daemon. Enter the following command:

```
cspmclientd start
```

After the installation is complete and the client is started, the client registers with PAM.

#### (Optional) Install the A2A Client on a Red Hat Enterprise Linux Host Using the RPM Package

You can install Red Hat A2A Clients using the standard UNIX install script. However, using the available RPM package with a Red Hat native package manager (YUM or DNF) to install the client provides the following benefits:

- To support efficient installation of the A2A Client on multiple request servers, you can place the RPM package in a central repository of a package handler rather than download it to each host.
- Package handlers can identify from the RPM that the A2A Client requires the **libidn** library and can resolve this dependency by installing the correct version automatically, if necessary. (You have to do this manually when using the standard UNIX install script.)
- Package handlers can identify an existing A2A Client that was installed from an RPM package and can upgrade it automatically. A2A Clients that are installed using the UNIX install script do not support upgrades and must be **manually uninstalled before installing the new version**.

#### NOTE

You can also obtain the same benefits using a more sophisticated software automation tool, such as Ansible or Jenkins.

The following content assumes that you are familiar with your choice of package manager or software automation tool and therefore only provides the information that you require.

- The RPM file name is `LinuxA2A-version-1.x86_64.rpm`.

#### NOTE

If you are using a package manager repository, add the `LinuxA2A-version-1.x86_64.rpm` to that repository.

- Use one of the following options to specify the address (FQDN or IP address) that the A2A Client uses to communicate with PAM:
  - Set a **PAM\_SERVER** environment variable before installation. The corresponding value in the A2A Client configuration file is populated automatically.
  - Edit the `<cspmserver>server_address</cspmserver>` parameter in the A2A Client configuration file (`/opt/Broadcom/PAM/A2A/cspmclient/config/cspm_client_config.xml`).
  - Copy a correctly configured A2A Client configuration file to the `/opt/Broadcom/PAM/A2A/cspmclient/config` directory on all A2A Client hosts after installing them from local files or a repository.

In either case, specify the appropriate address for your environment:

- **Clustered environment:** The IP address or fully qualified domain name (FQDN) of a node at the nearest site or the site VIP if there is one. If you specify the FQDN, it must match the name in the appliance SSL certificate.
- **Unclustered environment:** The IP address or fully qualified domain name (FQDN) of the PAM server.
- Optionally (a default value of 28088 is preconfigured), use one of the following options to specify the port that the A2A Client uses to listen for incoming requests:
  - Set a **PAM\_D1\_PORT** environment variable before installation. The corresponding value in the A2A Client configuration file is populated automatically.
  - Edit the `<cspmserver>daemonserver1_port</cspmserver>` parameter in the A2A Client configuration file (`/opt/Broadcom/PAM/A2A/cspmclient/config/cspm_client_config.xml`).
  - Copy a correctly configured A2A Client configuration file to the `/opt/Broadcom/PAM/A2A/cspmclient/config` directory on all A2A Client hosts after installing them from local files or a repository.
- Optionally (a default value of 28888 is preconfigured), use one of the following options to specify the port that the A2A Client uses to communicate with the PAM server:
  - Set a **PAM\_D2\_PORT** environment variable before installation. The corresponding value in the A2A Client configuration file is populated automatically.
  - Edit the `<cspmserver>daemonserver2_port</cspmserver>` parameter in the A2A Client configuration file (`/opt/Broadcom/PAM/A2A/cspmclient/config/cspm_client_config.xml`).
  - Copy a correctly configured A2A Client configuration file to the `/opt/Broadcom/PAM/A2A/cspmclient/config` directory on all A2A Client hosts after installing them from local files or a repository.
- Optionally enable IPv6:

- Set a **PAM\_ENABLE\_IPV6 [true|false]** environment variable before installation. The corresponding value in the A2A Client configuration file is populated automatically.
- To enable IPv6, edit the `<enableipv6>true</enableipv6>` parameter in the A2A Client configuration file (`/opt/Broadcom/PAM/A2A/cspmclient/config/cspm_client_config.xml`).
- Copy a correctly configured A2A Client configuration file to the `/opt/Broadcom/PAM/A2A/cspmclient/config` directory on all A2A Client hosts after installing them from local files or a repository.
- In a multisite cluster, add alternate site VIPs or node addresses to the A2A Client configuration file to configure A2A Client failover. For more information, see [Configure A2A Client Failover upon Connection Failure in a Cluster](#).
- The A2A Client is installed in the `/opt/Broadcom/PAM/A2A` directory. To see the version of the currently installed client, see the `A2A.version` file.
- Run the following command to start the A2A Client:  

```
/opt/Broadcom/PAM/A2A/cspmclient/bin/cspmclientd start
```

After the installation is complete and the client is started, the A2A Client registers with PAM.

### ***Install the A2A Client on an AIX Host***

#### **NOTE**

Before you install the A2A Client on an AIX system, ensure that your system has the correct 64-bit libidn installed. AIX only supports 64 bit. If you try to install the Client without the correct libidn, the installation stops and an error message is displayed. Also make sure to examine the User Resource Limit.

### **User Resource Limit**

The recommended data segment size for user resource limit (`ulimit -d`) is 1 GB. You have three options.

To **temporarily** increase the data segment size to 1 GB to meet OpenJDK requirements:

#### **NOTE**

If you do not make a more permanent change as shown in the following options, you must run these commands each time before you start the A2A client.

1. Before starting the A2A client, run the following command.

```
ulimit -d 1000000
```

2. Run the following command to start the A2A client (Use your real path if A2A is not installed in `/opt/catech`):

```
/opt/catech/cspmclient/bin/cspmclientd start
```

To make the data segment size change **permanent for the specified user**, modify the user setting via the AIX `chuser` command.

#### **NOTE**

The unit is represented in the number of 512-byte blocks.

```
chuser -d 2000000 root
```

To make a **system-wide change**, edit `/etc/security/limits` to increase the value.

### ***Install the A2A Client on an AIX Host***

#### **NOTE**

Before you install the A2A Client on an AIX system, ensure that your system has the correct 64-bit libidn installed. AIX only supports 64 bit. If you try to install the Client without the correct libidn, the installation stops and an error message is displayed. Also make sure to examine the User Resource Limit.

### **User Resource Limit**

The recommended data segment size for user resource limit (`ulimit -d`) is 1 GB. You have three options.

To **temporarily** increase the data segment size to 1 GB to meet OpenJDK requirements:

**NOTE**

If you do not make a more permanent change as shown in the following options, you must run these commands each time before you start the A2A client.

1. Run the following command before starting the A2A client:

```
ulimit -d 1000000
```

2. Run the following command to start the A2A client (Use your real path if A2A is not installed in /opt/catech):

```
/opt/catech/cspmclient/bin/cspmclientd start
```

To make the data segment size change **permanent for the specified user**, modify the user setting via the AIX chuser command.

**NOTE**

The unit is represented in the number of 512-byte blocks.

```
chuser -d 2000000 root
```

To make a **system-wide change**, edit **/etc/security/limits** to increase the value.

**How to Install the A2A Client on an AIX Host**

Install and configure the A2A Client on all request servers, but install only one A2A Client on a single host. Multiple Clients on the same host are not supported. If there is an existing A2A Client, uninstall it before proceeding.

**Follow these steps:**

1. Open a shell window and navigate to the location of the unzipped A2A Client installation package:

```
cd unzip_location/
```

2. Enter the following commands:

```
chmod u+x setup_aix
```

3. Start the installation script by entering the following command and options:

```
./setup_aix A2A_client_install_dir server_address [true|false]
```

Where:

- **A2A\_client\_install\_dir**: The complete pathname of the installation directory for the A2A Client software. Relative path names (that is, paths beginning with ".") are not acceptable.
- **server\_address**: One of the following options:
  - **Clustered environment**: The IP address or fully qualified domain name (FQDN) of a node at the nearest site or the site VIP if there is one. If you specify the FQDN, it must match the name in the appliance SSL certificate.
  - **Unclustered environment**: The IP address or fully qualified domain name (FQDN) of the PAM server.
- **[true/false]**: Optionally enable IPv6

**NOTE****Important Information:**

- In a clustered environment, always specify the address of the site VIP, if available. The VIP provides automatic load-balancing and failover between all the nodes at that site.
- The specified **server\_address** value is written to the A2A Client configuration file (**CSPM\_CLIENT\_HOME/cspmclient/config/cspm\_client\_config.xml**).
- In a multisite cluster, add alternate site VIPs or node addresses to the A2A Client configuration file to configure A2A Client failover. For more information, see [Configure A2A Client Failover upon Connection Failure in a Cluster](#).

4. Auto-register the A2A Client (request server) in the GUI by starting the daemon. Enter the following command:

```
A2A_client_install_dir/catech/cspmclient/bin/cspmclientd start
```

After the installation is complete and the client is started, the Client registers with PAM.

## ***Deploy an A2A Client on an AWS AMI***

### **Follow these steps:**

1. Create the instance in AWS. Do not add the device before installing the A2A Client.
2. Import the AWS AMI automatically into the appliance.  
During the import, the appliance recognizes the AWS internal IP address of the device.
3. Install the A2A Client. The A2A Client registers with the appliance using the AWS internal IP address.

### **To process credential requests, follow these steps:**

1. Activate the request server (A2A Device). This step is not required when the A2A Device has already been provisioned.
2. Associate the request script.
3. Add the authorization mapping.

## ***A2A Client Host (Request Server) Registration***

After you install the A2A Client and start it for the first time, the client sends a registration request to PAM. PAM registers the A2A Client and automatically configures an A2A device. The appliance names the device using the fully qualified domain name or the A2A Client host IP address.

To re-register the A2A Client, modify the A2A device record in the UI. Clear the **A2A** option for the **Device Type** setting. If you make change, the A2A Client responds by reregistering.

### **NOTE**

If you change the device address without changing the device name, the re-registration fails. The **Sessions**, **Logs** screen displays an error that the request server cannot register because the device name already exists.

The A2A Client is registered in an inactive state. For the A2A Client to receive credentials, activate the request server, as described in the following procedure.

## **Activate and Deactivate the A2A Request Server**

The A2A Client is registered in an inactive state. Activate the request server with the installed A2A Client.

This procedure assumes that you have:

- Installed the A2A Client software
- Started the A2A Client (CSPMClient service)

### **Follow these steps:**

1. Select **Devices**, **Manage Devices**.
2. From the Devices list, select the A2A Client and select **Update**.
3. On the **Basic Info** tab, select the **Active** option in the Request Client section
4. Select **OK** to activate the A2A Client.

To deactivate a request server, repeat the previous procedure but clear the **Active** option.

## **Uninstall the A2A Client**

This content describes how to uninstall a A2A Client on Windows and UNIX clients.

### **Uninstall an A2A Client on UNIX**

#### **Follow these steps:**

1. Stop the A2A Client:  
`$CSPM_CLIENT_HOME/cspmclient/bin/cspmclientd stop`

where `$CSPM_CLIENT_HOME` is your installation directory, for example `/opt/cloakware`

2. Run the uninstall script by entering:

```
$CSPM_CLIENT_HOME/cspmclient/bin/cspmclient_uninstall
```

This script removes all A2A Client files. However, it retains the `cloakware` directory that the installation script creates and the configuration file, if you created one during installation.

3. (Optional) If it is empty, remove the `cloakware` directory by entering the following command:

```
rmdir cloakware
```

## Uninstall an A2A Client on Windows

### Follow these steps:

1. Stop the A2A Client using one of the following steps:
  - Stop the `cspmclientd` service using the Windows Services tool.
  - Open a Command Prompt window and type the following text:
 

```
net stop cspmclientd
```
2. Use one of the following methods to launch the uninstall executable:
  - Use the Control Panel Add/Remove Programs option: Select the **PAM A2A Client** or **Password Authority Client** entry (as appropriate, depending on the version of the existing client).
  - Navigate to:
 

```
%CSPM_CLIENT_HOME%\cspmclient\Uninstall_Password_Authority,
```

 where `CSPM_CLIENT_HOME` is the A2A Client installation directory, for example, `C:\CSPM\Cloakware`. Double-click `Uninstall_Password_Authority.exe` or `Uninstall PAM A2A Client.exe` (as appropriate, depending on the version of the existing client).
 

The greeting window appears followed by the **Uninstall** window.
3. **Select Uninstall.**

When the uninstall finishes, the **Uninstall Complete** window appears. You might need to remove files manually. If so, the uninstaller identifies the files that must be manually removed.
4. Select **Done**.
5. (Optional) Remove the empty `cspm` folder.

## Target Aliases for A2A Target Accounts

A target alias enables an A2A requestor to request credentials from a specific account without transmitting the account user name and password. Target aliases are account-specific and are generated when the account is created. Privileged password accounts do not use target aliases.

The Aliases page lists aliases already created during target account set up. To add an alias, follow the instructions on the [Add Target Accounts to Target Applications](#) page.

## Start or Stop an A2A Client

You can start and stop the A2A Client from the command line or, for Windows systems, from the Windows Administrative Tools.

### Start and Stop the A2A Client on UNIX

To start the A2A client on UNIX, enter the following command:

```
cspmclientd start
```

To stop the A2A client on UNIX, enter the following command:

```
cspmclientd stop
```

## Start and Stop the A2A Client on Windows

To start the A2A client on Windows, do *one* of the following steps:

- From the **Windows Administrative Tools**, select **Component Services**. Locate and start the **cspmclientd** service. The steps for using the Windows Services Administrative tool depend on your version of Windows.
- Open a command line window and enter the following command:  

```
net start cspmclientd
```

To stop the A2A client on Windows, do *one* of the following steps:

- From the **Windows Administrative Tools**, select **Component Services** and stop the **cspmclientd** service. The steps for using the Windows Services Administrative tool depend on your version of Windows platform.
- Open a command line window and enter the following command:  

```
net stop cspmclientd
```

## A2A Client Connection Security

When an A2A Client authenticates with PAM, the PAM server identifies the client using the following data in the given order:

- Hardware fingerprint:** Uniquely identifies the client using a combination of data about the hardware characteristics of the request server. For example, CPU serial numbers and network IDs. The A2A Client generates a hardware fingerprint and passes it to the PAM server during initial registration. For subsequent client requests, the server dynamically calculates the fingerprint to validate the machine ID of the credential requestor.

### NOTE

The hardware fingerprint only changes if the hardware configuration of the request server significantly changes. When a hardware change occurs, the PAM client generates a new fingerprint. Because the fingerprint no longer matches the data on the PAM server, further client requests are refused.

To update the hardware fingerprint of an A2A Client in the PAM server, do the following steps:

- Verify that the **Enable Hardware Fingerprinting** option on the **Request Server Settings** tab on the **Settings, Credential Manager** page is enabled.
- Open the corresponding **View A2A Client** dialog and select the **Get Fingerprint** button.
- Client token:** A unique request server identifier that identifies the client in the appliance database. When an A2A Client initially registers, the server generates a unique token for the client. For subsequent client requests, the server uses the token to retrieve credentials from the database.
- Domain Name Servers (DNS):** Credential Manager uses the client host name as part of the client authentication process. Reverse IP lookup is also possible.

When a requestor application requests credentials, the credentials remain encrypted as they are transferred over the network. The A2A Client decrypts the credentials before passing them to the requestor.

## Integrity Verification

To support Integrity Verification, register the following information:

- File name
- File path
- Execution path for the client operating system and the integration method (Java, executable, DLL, or shared object)

The following table lists the details for each integration method:

Integration Method	Registered Data
Java (CSPMClient class)	<p><b>Script name:</b> The fully qualified name (including the package name) of the Java class that contains the <code>CSPMClient</code> instantiation and <code>getScriptCredentials</code> call, without the class extension.</p> <p><b>File path:</b> The absolute file path to the class file.</p> <p><b>Execution path:</b> The absolute file path to the class file. UNIX file paths cannot contain symbolic links.</p> <p><b>Example:</b> <code>com.cloakware.cspm.client.CSPMClient</code></p>
UNIX executable ( <code>cspmclient</code> , <code>cspmclient64</code> )	<p><b>Script name:</b> The name of the requestor file that contains the Credential Manager executable call.</p> <p><b>File path:</b> The absolute path to the requestor file.</p> <p><b>Execution path:</b> The absolute path from which the requestor is launched. UNIX file paths cannot contain symbolic links.</p>
UNIX shared object library ( <code>libcspmclientc.so</code> , <code>libcspmclientc64.so</code> )	<p><b>Script name:</b> The name of the requestor file that contains the shared object call.</p> <p><b>File path:</b> The absolute path to the requestor file.</p> <p><b>Execution path:</b> The absolute path from which the requestor is being launched. UNIX file paths cannot contain symbolic links.</p>
Windows executable ( <code>cspmclient.exe</code> , <code>cspmclient64.exe</code> )	<p><b>Script name:</b> The name of the requestor file that contains the executable call, including the file extension.</p> <p><b>File path:</b> The absolute path to the application file that contains the executable call.</p> <p><b>Execution path:</b> The absolute path from which the application is launched.</p>
Windows DLL	<p><b>Script name:</b> The name of the requestor file that contains the call <code>toGetCredentials</code>, including the file extension.</p> <p><b>File path:</b> The absolute path to the requestor file containing the DLL call.</p> <p><b>Execution path:</b> The absolute path from which the application is launched.</p>

The absolute file path is the complete path without symbolic links. To print the absolute file path in UNIX, use the `commandpwd-P`.

### **Refresh A2A Script Hashes**

A2A Client script hashes are used during integrity verification of A2A request scripts or applications. If you update or change an A2A request script or application, refresh the script hashes to avoid false integrity violations.

You can refresh the script hash for all the request applications on the specified request server (A2A Client).

#### **Follow these steps using the UI:**

1. Select **Credentials, Manage A2A, Clients**. The Client List page appears.
2. Select the server where the A2A client whose logs you want to view is installed and select **VIEW**. The Client Details page appears.  
When the A2A client is not reachable from the site server, you must log into the site where the A2A client is registered.
3. Select the **Get All Script Hash** button.

#### **For the CLI:**

Refresh the script hash by running the `getAllScriptHash` CLI command. For further details, see [getAllScriptHash](#).

## Add A2A Requestors

To implement A2A scripts, you add requestors in Privileged Access Manager. This procedure assumes that you have registered the request server and set it to the active status. (See [Example Requestors](#) provide registration data for the examples.

You can add scripts using the UI or the CLI:

### Add A2A Scripts using the UI

To add requestors using the UI, follow these steps:

1. Select **Credentials, Manage A2A, Scripts**.  
The Scripts list page appears.
2. Select **ADD**.  
The Add Script page appears.
3. To find an existing client, select the magnifying glass
4. Enter the **Script/App Name**, **Execution Path**, **File Path**, and script **Type**.  
**File Path** - The fully qualified path to where the executable file or script file is located.  
**Execution Path** - If the application itself is an executable file, then the Execution Path and the File Path are the same. If the application is a script, the two paths can be different.

#### NOTE

You can use standard Windows path formats, such as C:\Windows\System, or UNC (Uniform Naming Convention) paths.

5. If you use target groupings, enter descriptors for the target application.
6. Select **OK**.  
The page is updated with the registered request scripts.

To retrieve the script hash from the UI, follow these steps:

1. Select **Manage A2A, Scripts**.
2. Select the script that you want to retrieve the hash for and select **UPDATE**.  
The Script Details page appears.
3. Select **Get Script Hash**. If PAM cannot retrieve the script hash, ensure that nothing is blocking communication to the appliance. Possible causes might be the server hosting the A2A Client or a network device, such as a firewall. By default, A2A Client listens on port 28888.
4. Select **OK**.

### Add A2A Scripts Using the CLI

Use the following procedure to add requestors using the CLI.

Follow these steps:

1. Add a request server:  

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addRequestServer
RequestServer.hostName=Vienna-Lab4.cloakware.com RequestServer.ipAddress=11.2.0.4
RequestServer.active=true RequestServer.type=CLIENT Attribute.descriptor1=Vienna
Attribute.descriptor2=Lab
```
2. Enter your password at the prompt. Credential Manager returns the following XML command string.  

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
```

```

<cr.result>
<RequestServer>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1</ID>

</RequestServer>
</cr.result>
</CommandResult>

```

### 3. Add a request script:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addRequestScript
RequestServer.hostName=Vienna-Lab4.cloakware.com RequestScript.name=example.pl
RequestScript.executionPath=/opt/cloakware/cspmclient_v.3.5.0/examples RequestScript.type=Perl
RequestScript.filePath=/opt/cloakware/cspmclient_v.3.5.0/examples Attribute.descriptor1=Vienna
Attribute.descriptor=Lab
```

### 4. Enter your password at the prompt. Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<RequestScript>
<ID>1</ID>
<createDate>Mon Nov 12 15:47:35 UTC 2007</createDate>
<updateDate>Mon Nov 12 15:47:35 UTC 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>/14qoJ1SI63KgaTIKDZD8J5lWvs=</hash>
<name>example.pl</name>
<filePath>/opt/cloakware/cspmclient_v.3.5.0/examples</filePath>
<executionPath>/opt/cloakware/cspmclient_v.3.5.0/examples</executionPath>
<type>Perl</type>
<requestServerID>1</requestServerID>
<scriptHash>
</scriptHash>
</RequestScript>
</cr.result>
</CommandResult>
```

## Example Requestors

Each Privileged Access Manager A2A Client includes example applications. The examples are located in the `$CSPM_CLIENT_HOME/cspmclient/examples` directory.

The UNIX version of the A2A Client supports symbolic links in the File Path field only.

Example	Integration Method	Registration Data
<b>Executable:</b> example.pl <b>Source file:</b> example.pl	cspmclient	<b>Script name:</b> example.pl <b>File path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Execution path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Script type:</b> Perl
<b>Executable:</b> example.ps1, example64.ps1 <b>Source file:</b> example.ps1, example64.ps1	cspmclient	<b>Script name:</b> example.ps1 <b>File path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Execution path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Script type:</b> PowerShell

<b>Executable:</b> Run_example,Example.class <b>Source file:</b> Example.java	Java	<b>Script name:</b> Example <b>File path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Execution path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Script type:</b> Java
<b>Executable:</b> example_c_interface_java <b>Source file:</b> example.c	cspmclient	<b>Script name:</b> example_c_interface_java <b>File path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Execution path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Script type:</b> C
<b>Executable:</b> example.ksh <b>Source file:</b> example.ksh	cspmclient	<b>Script name:</b> example.ksh <b>File path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Execution path:</b> \$CSPM_CLIENT_HOME / cspmclient/examples <b>Script type:</b> ksh

When entering Credential Manager request script data, you must enter the actual value for \$CSPM\_CLIENT\_HOME.

Example	Integration Method	Registration Data
<b>Executable:</b> VB_Sample <b>Source directory:</b> VB_Sample	Credential Manager MFC DLL	<b>Script name:</b> VB_Sample.exe <b>File path:</b> \$CSPM_CLIENT_HOME \cspmclient\examples\VB_Sample <b>Execution path:</b> \$CSPM_CLIENT_HOME \cspmclient\examples\VB_Sample <b>Script type:</b> VB
<b>Executable:</b> VC_Sample <b>Source directory:</b> VC_Sample	Credential Manager MFC DLL	<b>Script name:</b> VC_Sample.exe <b>File path:</b> \$CSPM_CLIENT_HOME \cspmclient\examples\VC_Sample <b>Execution path:</b> \$CSPM_CLIENT_HOME \cspmclient\examples\VC_Sample <b>Script type:</b> C
<b>Executable:</b> VBScriptSample.html <b>Source directory:</b> VB_Script_Sample	Credential Manager ATL DLL	<b>Script name:</b> VBScriptSample.html <b>File path:</b> \$CSPM_CLIENT_HOME \cspmclient\examples\VB_Script_Sample <b>Execution path:</b> \$CSPM_CLIENT_HOME \cspmclient\examples\VB_Script_Sample <b>Script type:</b> VB
<b>Executable:</b> JavaScriptSample.htm <b>Source directory:</b> Java_Script_Sample	Credential Manager ATL DLL	<b>Script name:</b> JavaScriptSample.htm <b>File path:</b> \$CSPM_CLIENT_HOME \cspmclient\examples\Java_Script_Sample <b>Execution path:</b> \$CSPM_CLIENT_HOME \cspmclient\examples\Java_Script_Sample <b>Script type:</b> Java

For more information, see [Integrate A2A Applications](#).

## Configure A2A Authorization Mappings

To ensure target credential security, PAM must authorize requestors to retrieve the target credentials. Authorization mappings associate requestors and request servers with a target alias or a target group.

This topic describes how to map A2A requestors to targets and how to add an Authorization mapping.

### Mapping A2A Requestors to Targets

Before a requestor can obtain credentials for a target, you must define an A2A mapping. A mapping links requestors to targets.

You can configure authorization mappings for the following registered components:

- A requestor (script) and a target alias
- A request server and a target alias
- A request group and a target alias
- A requestor (script) and a target group
- A request server and a target group
- A request group and a target group

A mapping to a target group includes all aliases for all accounts in the group. A mapping from a request server can include all applications (scripts) on the server or you can restrict the mapping to a specific script. A mapping from a request group includes all applications (scripts) in the group.

A requestor is defined by several attributes, not all of which are necessarily used by a mapping. A mapping can use the following attributes to identify a requestor:

- **Request server (required):** The host name or IP address and associated descriptors. A mapping must specify a single request server or a request group
- **Application or script name:** The name of the program or script (for example, myProgram.exe)
- **Application or script execution path:** The path to the program on the request server
- **Application or script file path:** The path that invokes the program (for example, ./)
- **Execution user id:** The user ID that executes the program
- **Application or script hash:** A hash of the requesting program or script. This value can ensure that the program or script is not modified

A mapping must specify a request server. The other attributes are optional. If a mapping uses only a request server (or a request server group; not programs), any program on the request server can access account passwords. The program can be executed by any user. To restrict access to specific programs or users, you can configure a mapping and a script for each request server.

### ***Specifying Requestors in a Mapping***

Mappings can specify requestors as follows:

- Request group. A request group is a collection of requestors. The group identifies a collection of request servers and request scripts.
- All requesting programs on a request server
- A specific registered Request Script

Also, you can restrict each mapping to apply only when the requesting program is run as a user ID in a specific list of Execution User IDs. The mapping can specify that the execution, file path, and hash be verified. This condition implies that the requesting program has an associated registered Request Script.

### **Request Group**

If a requestor group includes a Request Server but not any Request Scripts, it implicitly includes all request programs on those request servers. If a request group specifies only request scripts, it implicitly allows them from any request server. Static request groups can only reference request servers or registered request scripts. Dynamic request groups can also reference unregistered request scripts (based on their name, file path, or execution path).

Large organizations find that dynamic request groups can scale easily.

### **All Requesting Programs on a Request Server**

A mapping can also be made to allow any requesting program on a given request server. This method does not permit any checking of the requesting program. However, as with all mappings the user ID the program is running under can be checked.

This method is useful when A2A is first deployed because it eliminates authorization as a failure reason. This feature can make it easier to develop of A2A programs.

### **Registered Request Script**

Registered Request Scripts are always associated with a specific request server. A Request Script specifies the Request Server that it runs on, its name, and an execution path.

This method gives great control but requires the creation of many mappings. This method is not as scalable as using a Request Group.

### **Request Validations**

For each mapping, request validations are done. The following table shows the scope of the validations:

Option	Scope
Request server	Validated for every application
Application name	Validated for every application
Application location	Validated only if file path is checked.
Application hash (script integrity)	Validated only if script integrity validation is checked.
Execution user ID	Validated only if execution user ID is checked.
Execution path	Validated only if execution path is checked.

### **Add an Authorization Mapping**

#### ***Prerequisite***

Before you add an authorization mapping, add the target alias or group, request server or request server group. If necessary, also add any request script for a request group mapping. If there is no verification of the script, such as integrity verification or execution path, a request script is not required.

#### ***Guidelines for Mapping Script Groups***

When you create a dynamic requestor script group, the group contains all scripts in the path that satisfy the filter criteria. The group includes scripts that are defined in the PAM database and scripts that are not.

When you map a script group that is created with filters, be aware how you set the **Check Execution Path** and **Check File Path** checkboxes:

- If you select one or both checkboxes, the authorization mapping is restricted to only those scripts that are in the database. Any scripts that are not in the database are excluded from the authorization mapping.
- If you clear the checkboxes, all scripts in the group are included in the authorization mapping.

#### ***Add a Mapping Using the UI***

**Follow these steps:**

1. Select **Credentials, Manage A2A, Mappings**.  
The Authorization Mappings page displays with a list of existing authorizations.
2. Select **ADD**.
3. For the **Target** setting, select **Group** or **Alias**.
4. Enter the target group or alias name or search for a target group or alias using the magnifying glass.
5. For the **Request** setting, select **Group** or **Client**.
6. Enter the requestor group or client name or search for an A2A requestor group or client using the magnifying glass.
7. For the **Script** setting, select whether the mapping applies to **All** applications (scripts) on the request server or an **Individual** application (script). For an individual script, enter the script name or search for the script. For A2A requestor groups, the mapping applies to all scripts.
8. Set the **Check Execution User** option.
9. Enter one or more **Execution User** IDs. Separate multiple user IDs with commas.
10. To restrict the authorization to provisioned scripts only, set one of both of the following settings:
  - **Check Execution Path**
  - **Check File Path**
11. Set the **Perform Script Integrity Validation** option. If you cannot select this validation option, no valid script hash is available. Complete the following steps:
  - a. Add the authorization mapping without selecting the validation option.
  - b. Run a query from the requestor.
  - c. Update the mapping and select this validation option.
12. Select **OK** to save the mapping.

**Add a Mapping Using the CLI****Using the CLI, follow these steps**

1. Add an authorization mapping by entering the following command:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addAuthorization
  TargetAlias.name=ViennaAlias5 RequestServer.hostName=Vienna-Lab4.cloakware.com
  RequestScript.name=example.pl RequestScript.executionPath=/opt/cloakware/cspmclient_v.3.3.0/examples
  Authorization.checkExecutionID=true Authorization.executionUser=root Authorization.checkPath=true
  Authorization.checkScriptHash=true
```

2. Enter your password at the prompt. Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<Authorization>
<ID>1</ID>
<createDate>Mon Nov 12 15:51:06 EST 2007</createDate>
<updateDate>Mon Nov 12 15:51:06 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>XOPh+2zvQDphQ0M4LPzLfyTPoiw=</hash>
<executionUser>root</executionUser>
<targetAliasID>1</targetAliasID>
<scriptID>1</scriptID>
<requestServerID>1</requestServerID>
<checkPath>false</checkPath>
```

```
<checkExecutionUser>true</checkExecutionUser>
<checkScriptHash>false</checkScriptHash>
<checkFilePath>false</checkFilePath>
</Authorization>
</cr.result>
</CommandResult>
```

## View Unsuccessful A2A Client Requests

All requests that are made to Credential Manager are stored in the Credential Manager database. You can view unsuccessful A2A client requests from the **Dashboard Overview Tab** in the **Credential Management** panel.

You can also select the **Credentials, Reports, Activities Credential Manager Activities** panel.

To view the list of the failed items on the **Credential Manager Activities** panel, select **Failed A2A Client Request In Last 30 Days**. If the **Failed A2A Client Request In Last 30 Days** item does not appear, select **Configure**, and then select the item from the configuration panel.

## Run an Example Application

This section describes running an example application on either a UNIX A2A client or a Windows A2A client.

### Run an Example Application on a UNIX Client

Follow these steps:

1. Launch the example with the target alias and the bypass cache flag set `true`. The local credential cache is bypassed and the query goes directly to the Privileged Access Manager server:

```
/opt/catech/cspmclient/examples/example.pl SydneyAlias1 true
```

#### NOTE

When using Integrity Verification in UNIX, you must use the complete path to invoke the requestor script.

2. A successful query provides the user name and password that is associated with the target alias. For example, running the Java example on a UNIX-based A2A Client yields the following result:

```
/opt/catech/cspmclient/examples/Run_example testAlias1 true
Status Code: 400
UsedId:      someaccount
Password:    q6YIbGECF0C261Xo
PASSED
```

### Run an Example Application on a Windows Client

The Windows A2A Client contains example projects that you can compile in Visual Basic, C, and C#. (Compiled programs are no longer provided.) The examples also include Java, Python, PHP, Perl, VBScript, and PowerShell scripts. The examples are in the `$CSPM_CLIENT_HOME\cspmclient\examples` folder.

#### NOTE

The PowerShell example (`example.ps1`) has an error in version 3.2. Update Line 15 to include the `-Command` parameter:

```
$output = Invoke-Expression -Command $command
```

## Modify the A2A Client Configuration File

You can edit the A2A Client configuration file for the following reasons:

- To change a configuration that is not included in the installer, such as port numbers.
- To apply a configuration change after installation, such as changing the log file location.
- To modify the log level to debug a problem.

### Modify the File

Use this procedure to modify the A2A client configuration file.

#### Follow these steps:

1. Stop the A2A Client service by entering the appropriate command:
  - **UNIX:** `cspmclientd stop`
  - **Windows:** `net stop cspmclient`
2. Navigate to the A2A client configuration file, **cspm\_client\_config.xml**. The configuration file is in one of the following directories:
  - **UNIX:** `$CSPM_CLIENT_HOME/cspmclient/config/cspm_client_config.xml`
  - **Windows:** `%CSPM_CLIENT_HOME%\cspmclient\config\cspm_client_config.xml`
 Where `CSPM_CLIENT_HOME` is the A2A Client installation directory.
3. Edit the `cspm_client_config.xml` file in a text editor then save your changes.
4. Start the A2A Client service by entering the appropriate command:
  - **UNIX:** `cspmclientd start`
  - **Windows:** `net start cspmclient`

### A2A Client Configuration Settings

The following table describes the XML tags in the A2A Client configuration file:

XML Tag	Description
<code>&lt;applicationtype&gt;</code>	Valid values are <code>cspm</code> or <code>cspm_agent</code> . Default: <code>cspm</code>
<code>&lt;cacheallow&gt;</code>	Enables or disables credential caching on the A2A Client. Default: <code>true</code> .  This setting overrides the PAM <code>cacheBehavior</code> setting. If the <code>&lt;cacheallow&gt;</code> tag is <code>true</code> , then the Client follows the <code>cacheBehavior</code> setting. If the <code>&lt;cacheallow&gt;</code> tag is <code>false</code> , then the <code>cacheBehavior</code> setting is ignored.
<code>&lt;loglevel&gt;</code>	Specifies the log level. The following entries are valid levels (in descending order): <ul style="list-style-type: none"> <li>• OFF</li> <li>• SEVERE</li> <li>• WARNING</li> <li>• INFO</li> <li>• CONFIG</li> <li>• FINE</li> <li>• FINER</li> <li>• FINEST</li> <li>• ALL</li> </ul> The default level is OFF. Entry is case insensitive.

<cspmserver>	Specifies the host name of the PAM appliance. The installer sets this value.
<cspmserver_port>	The default port on which the appliance listens. The default is blank. For HTTPS, the default is 443. If the server port is changed from 443, you must modify this value.
<daemonserver1_port>	The A2A Client uses this port to listen for local requests from client stubs. The daemon validates that the request is local. The default value is 28088.
<daemonserver2_port>	Identifies the port that the A2A Client listens for local requests from PAM. Default port: 28888 If the value is 1, the A2A client does not listen for external requests. Instead, the A2A client polls the appliance for event information.
<eventpolling_interval>	(Optional) Specifies the interval, in seconds, after which the A2A Client polls the appliance for events. If no value is specified, the Client uses the default polling interval of 120 seconds.
<logfile>	Specifies the location of the log file that is used by the A2A Client. The installer sets this value.
<c_logfile>	The log file that is used by the service and stateless client interface stubs. <ul style="list-style-type: none"> <li>Windows default: C:\WINDOWS\TEMP\cspm_c_client_log.txt</li> <li>UNIX/LINUX default: /tmp/cspm_c_client_log.txt</li> </ul> All users of the A2A Client must have write access to the log file directory. The c_loglevel setting controls the detail in the log file. The syntax is case-sensitive: <c_loglevel>LEVEL</c_loglevel> LEVEL is one of the following values, in descending order: <ul style="list-style-type: none"> <li>OFF</li> <li>SEVERE</li> <li>WARNING</li> <li>INFO</li> <li>CONFIG</li> <li>FINE</li> <li>FINER</li> <li>FINEST</li> <li>ALL</li> </ul> The default level is OFF.
<patch>	Specifies patch management attributes, as in the following XML tags: frequency, starthour, and endhour.
<frequency>	Specifies the frequency at which the A2A Client polls the appliance for an update. Valid values are daily or weekly. The default value is daily.
<startHour>	Determines the interval at which the A2A Client randomly polls the appliance for a version check. Valid values are 0 -23. The default value is 0 (12 A.M.).
<endHour>	Determines the interval by which the A2A Client randomly polls the appliance for a version check. Valid values are 0 -23. The default value is 5 (5 A.M.).
<operation>	For internal use only.

<preserveCacheBetweenRestarts>	Enables caching to local storage. before release 3.0.1, A2A Clients maintained the credential cache in memory <i>and</i> on local storage by default. Beginning with release 3.0.1, the default behavior is to maintain the cache <i>only</i> in memory. To enable local storage, set the <preserveCacheBetweenRestarts> tag to true . Caching credentials locally reduces network traffic and increases reliability. The A2A Client can use the cached credentials instead of accessing PAM to process the credential requests. The A2A Client, like the appliance, provides credentials only in response to authorized credential requests. When a password change for a target account is triggered, the appliance notifies any A2A Client that is caching the password. This notification ensures that A2A Clients do not cache target passwords that are out of date.
<c_connection_timeout>	Indicates the value of connection timeout (in seconds) from A2A Client to A2A Daemon
<c_read_timeout>	Indicates the value of read timeout (in seconds) from A2A Client to A2A Daemon.
<cspmserver_connection_timeout>	Indicates the value of connection timeout (in seconds) from A2A Daemon to the PAM Server.
<cspmserver_read_timeout>	Indicates the value of read timeout (in seconds) from A2A Daemon to the PAM Server.

## How the A2A Client Configures Cache Credentials to Local Storage

To reduce network traffic and increase reliability, the A2A Client locally caches credentials as specified in the target account details. When target credentials are cached, the A2A Client does not need to access Privileged Access Manager to process the target credentials request. The A2A Client uses the same application logic as Privileged Access Manager to ensure that it provides credentials only in response to authorized credential requests.

When a user or a scheduled update triggers a change of target account passwords, Credential Manager sends notification of the change to any A2A Client that might be caching the password. This process ensures that A2A Clients do not cache target passwords that are out of date.

## View A2A Client Logs

You can view A2A Client logs with the GUI, so you can troubleshoot client issues. This feature is not available for clients with event polling enabled.

### Follow these steps:

1. Select **Credentials, Manage A2A, Clients**. The Client List page appears.
2. Select the server where the A2A client whose logs you want to view is installed and select **VIEW**. The Client Details page appears.  
When the A2A client is not reachable from the site server, you must log into the site where the A2A client is registered.
3. Select the **Get Logs** button. A zip file containing the Tomcat logs directory is downloaded to your browser. The default maximum file size is 20 MB. You can configure the maximum file size using the `getLogsMaxSize` {SystemProperty.SYSTEM\_PROPERTY\_MAX\_LOG\_SIZE} property setting. For further details, see the description of the `setSystemProperty` CLI command.

## Update an A2A Client Key

The A2A Client key is used to encrypt communication between the A2A Client and the Privileged Access Manager appliance. As an added layer of security, you can update the A2A Client key regularly to mitigate possible detection and misuse of the key.

### Follow these steps:

1. Select **Credentials, Manage A2A, Clients**. The Client List page appears.

2. Select the server where the A2A client whose logs you want to view is installed and select **VIEW**. The Client Details page appears.  
When the A2A client is not reachable from the site server, you must log into the site where the A2A client is registered.
3. Select the **Change Key** button.

## View A2A Client Status and Troubleshoot Connection Issues in a Cluster

This content describes how to view the status of the connection between PAM and an A2A Client and troubleshoot issues with that connection. The content also describes how to generate a hardware fingerprint for the request server.

### Verify A2A Client Connection Status

Use the following procedure to verify the status of the connection between an A2A Client and the PAM node or PAM site (represented by a VIP) with which it is registered.

#### Follow these steps:

1. Log into the PAM UI on the PAM server on which the A2A Client was originally registered (the *owning* PAM server).
2. Select **Credentials, Manage A2A, Clients**. The **Client List** page opens.
3. Select the request server where the A2A Client whose status that you want to view is installed and select **VIEW**.  
The **View A2A Client** dialog opens.

#### NOTE

The name and address of the PAM node with which the A2A Client is registered are indicated by the **Owning PAM Member** and **Owning PAM Member Address** fields.

In a multisite cluster, the name and address of the VIP of the site with which the A2A Client is registered are indicated by the **Owning PAM Site** and **Owning PAM Site Address** fields.

The **Connection Status** field displays an icon that indicates the status and time of the last connection attempt from PAM to the A2A Client. The following table provides details about the connection status values that are indicated by the colored status icon.

Icon Color	Status	Condition
Green	Online	The owning PAM node or other member of the same site has successfully connected to the A2A Client within the configured threshold.
Orange	Unknown	The state of the A2A Client is unknown. The owning PAM node or no PAM nodes in an owning site were unable to connect to that client within the configured threshold. Event processing for that client is therefore stopped.
Red	Offline	The A2A Client service <code>cspmcliclientd</code> is stopped.

4. To refresh the information in the **Connection Status** field to provide updated data, select the **Check Connection Status** button.

If the **Connection Status** field still shows orange, the status of the A2A Client is unknown because neither the owning PAM node nor any PAM nodes in an owning site can connect to it.

Event processing for this A2A Client is therefore stopped on all PAM nodes and the A2A Client cannot receive event notifications or obtain user credentials. To resolve this issue, see [Troubleshoot Outbound A2A Client Connections](#) and [Troubleshoot Inbound A2A Client Connections](#) later in this topic.

### Troubleshoot Outbound A2A Client Connections

Use this procedure to attempt to establish an *outbound connection* from a node at another site in the cluster to allow PAM to send event notifications.

**NOTE**

This procedure does *not* reestablish an *inbound* connection from the A2A Client connection, which is required to obtain user credentials. For more information, see *Troubleshoot Inbound A2A Client Connections* later in this topic.

**Follow these steps:**

1. Log into the UI of a PAM node at any other site in the cluster and navigate to one of the following locations:
  - On a primary node: **Credentials, Manage A2A, Clients**
  - On a secondary node: **Credentials, A2A Clients**
2. Select the problem request server (identified by the orange bubble in the **Connection Status** field) from the list and select the **View** button. The **View A2A Client** dialog opens.
3. Select the **Check Connection Status** button. If any operational node in the cluster has a clear network path to the A2A Client, the **Connection Status** field should now be green.
4. If the **Connection Status** field is still orange, no node in the cluster has a clear network path to the A2A Client. Do the following operations in order to attempt to restore outbound connectivity:
  - a. Check that the A2A Client (cspmclientd) process is still running on the request server.
  - b. Restore operation of the owning member or site.
  - c. Reconfigure your network to provide a clear network path to the A2A Client from another node or site.

**Troubleshoot Inbound A2A Client Connections**

The A2A Client requires an *inbound* connection to obtain credential information. By default, such a connection can only be established with the owning node or a member of the owning site. To reestablish credential processing, do one of the following operations:

- Restore operation of the owning member or site.
- Temporarily register the A2A Client with another site.
- [Configure A2A Client failover](#) by adding the addresses of alternate PAM nodes or VIPs in the cluster to the A2A Client configuration. If a connection to the first defined location fails, the A2A Client attempts to connect to the next defined location, and so on.

**Generate a Hardware Fingerprint for the Request Server**

If [hardware fingerprinting is enabled](#), Credential Manager can use generated hardware fingerprints to uniquely identify request servers. Hardware fingerprints combine hardware characteristics of the request server, such as CPU serial numbers and network IDs.

To generate a hardware fingerprint for a request server, select the **Get Fingerprint** button.

**NOTE**

The **Get Fingerprint** button only appears if hardware fingerprinting is enabled.

To see the date and time that the current hardware fingerprint was generated, select the **Fingerprint** tab.

**Configure an A2A Client to Use Another Server**

If you have previously used your A2A Client installation for one server and are now pointing it to a different server, delete the following cache file before starting the A2A Client daemon or service again:

```
$CSPM_CLIENT_HOME/cspmclient/config/data/.cspmclient.dat
```

where `$CSPM_CLIENT_HOME` is the location and name of your installation directory. Example: `/opt/cloakware`.

Use the following procedure to reconfigure an A2A Client to use a different Privileged Access Manager appliance.

**Follow these steps:**

1. Stop the A2A Client. See [Stop the A2A Client](#).
2. Navigate to `$CSPM_CLIENT_HOME/cspmclient/config/data/`.
3. Delete the `.cspmclient.dat` file.
4. Update the `<cspmserver>` entry in the A2A Client configuration with your new server name. Example:  
`<cspmserver>new_server.company.com</cspmserver>`  
 The configuration file is located at `$CSPM_CLIENT_HOME/cspmclient/config/cspm_client_config.xml`.
5. Restart the A2A Client. See [Start the A2A Client](#).

## Configure A2A Client Failover in a Multisite Cluster

*A2A Client failover* enables A2A Clients in a multisite cluster to connect to nodes at other sites if their current connection has failed.

**NOTE**

A2A Client failover was previously known as the *multi-home* feature.

To enable A2A Client failover, add the addresses of one or more alternate PAM nodes or site VIPs to the A2A Client configuration file. When a connection to the owning node or site fails, the A2A Client attempts to connect to the other specified addresses in sequential order. If no attempts are successful, an error code is returned.

**Follow these steps:**

1. Open the A2A Client configuration file in a text editor:  
`$CSPM_CLIENT_HOME/cspmclient/config/cspm_client_config.xml`  
 where `$CSPM_CLIENT_HOME` is your installation directory, for example, `/opt/cloakware`.
2. Add `cspmserver` and `cspmserver_port` XML entry pairs for each alternate node or site *below* the existing entry pair, which defines the original node or VIP specified during installation.  
 The following example includes three `cspmserver/cspmserver_port` entry pairs. The first pair represents the original PAM node or site VIP. The second two pairs specify the alternate nodes or site VIPs. The order of the entries in the file determines the connection order.

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <applicationtype>cspm</applicationtype>
  <cacheallow>true</cacheallow>
  <loglevel>WARNING</loglevel>
  <cspmserver>cspm1.cloakware.com</cspmserver>
  <cspmserver_port></cspmserver_port>
  <cspmserver>cspm2.cloakware.com</cspmserver>
  <cspmserver_port></cspmserver_port>
  <cspmserver>cspm3.cloakware.com</cspmserver>
  <cspmserver_port>80</cspmserver_port>
  <daemonserver1_port>27088</daemonserver1_port>
  <daemonserver2_port>28888</daemonserver2_port>
  <logfile>C:\cspm\cloakware\cspmclient\log\cspm_client_log.txt</logfile>
  <c_logfile>C:\WINDOWS\Temp\cspm_c_client_log.txt</c_logfile>
  <patch>
    <frequency>daily</frequency>
    <starthour>0</starthour>
    <endhour>5</endhour>
  </patch>
  <operation>production</operation>
</configuration>
```

3. Save your changes.

## Configure A2A Client Event Polling

If you disable event listening for an A2A Client, you must configure the Client to poll PAM for event messages. Event information includes messages, such as **get script hash** or **get fingerprint**.

When you enable event polling, the A2A Client contacts and queries the PAM server for event data at a regular polling interval. The PAM server places the events in a queue, and they remain in the queue until the A2A Client sends a request to retrieve event data.

### WARNING

Enabling event polling increases network traffic between the appliance and A2A Client. If too many A2A Clients run event polling, it impacts performance at the appliance.

### Prerequisite Steps for A2A Clients Previously Configured to Listen for Events

If the A2A Client is already registered with PAM as device of type **A2A** on the **Devices** screen (as shown in the following screen capture), do this procedure before registering that client as a polling device.

#### Follow these steps:

1. Open the PAM UI on the PAM server with which the A2A Client is registered.
2. Navigate to **Devices, Manage Devices**.
3. On the **Devices** screen that opens, select the request server from the list and select the **Update** Button. The **Update Device** dialog opens, showing how the A2A Client is configured in the **Device Type** section as shown in the following screen capture:

The screenshot shows the 'Update Device' dialog box. Under the 'Device Type' heading, there are three radio button options: 'Access', 'Password Management', and 'A2A'. The 'A2A' option is selected. Below these options is the text 'Request Client'. There are two text input fields labeled 'Description 1:' and 'Description 2:'. The 'Description 1' field contains the text 'A2A Client'. At the bottom of the dialog, there are two checkboxes: 'Active:' which is checked, and 'Preserve Hostname:' which is unchecked.

4. Do one of the following steps depending on the **Device Type** selection:
  - If either or both of the **Access** and **Password Management** options are set, unset the **A2A** option and select the **OK** button.
  - If only the **A2A** option is set, do the following steps:
    - a. Select the **Cancel** button to exit the **Update Device** screen.
    - b. Back on the **Devices** screen, select the **Delete** button to remove the existing device entry.

## Enable Event Polling

To enable event polling, modify the A2A Client configuration file.

### Follow these steps:

1. Open the A2A Client configuration file in a text edit. The file is in the directory:  
`$CSPM_CLIENT_HOME/cspmclient/config/cspm_client_config.xml`  
where `$CSPM_CLIENT_HOME` is the installation directory, for example, `/opt/cloakware`.
2. Set the external listening port (`daemonserver2_port`) to 1, as shown:  
`<daemonserver2_port>1</daemonserver2_port>`
3. Optionally, change the default polling interval of 120 seconds. For example, change it to 180 seconds:  
`<eventpolling_interval>180</eventpolling_interval>`
4. Save your changes.

---

# Implementing Secrets Management

---

The topics in this section provide end-to-end instructions for configuring Secrets Managements. See [Secrets Management Overview](#) for details about Secrets Management.

- [About Secrets Management and Roles](#)
- [Administering Users, Vaults, and Secrets](#)
- [Configuring Secrets Authorization](#)

## About Secrets Management and Roles

PAM includes specific roles and privileges that are specific to secrets management.

PAM provides granular permissions over vaults and secrets. These granular permissions let administrators securely provide the appropriate access to authorized users. For example, some users should only be able to view or use secrets (access). Others may be able to manage secrets and assign vaults (administration).

- **Secret Viewer:** Can view secrets. Secret Viewers can be assigned to one or more vaults.
- **Secret Owner:** Can manage (create, update, and delete) secrets. Secret Owners can be assigned to one or more vaults.
- **Vault Owner:** In addition to Secret Owner capabilities, Vault Owners can manage vaults. They can assign Secret Owners or other Vault Owners and can delete the vaults.
- **Vault Administrator:** In addition to Vault Owner capabilities, Vault Administrators can create vaults and can assign the initial users as Secret Owners or Vault Owners.

Secret Viewers, Secret Owners, and Vault Owners are scoped, meaning that these users only see the vaults to which they are assigned and the secrets that are stored within those vaults. The Vault Administrator role is not scoped, so it has visibility across all vaults.

Users assigned to a vault as a Secret Viewer, Secret Owner, or Vault Owner have access to view all secret values stored in the vault (and manage them, if assigned an owner role). If shared access is undesirable or if a narrower scope is required, you should separate the secrets into separate vaults.

In addition, Global Administrators and Delegated Administrators have all required privileges by default. Global Administrators and Delegated Administrators can perform secret management tasks with full Vault Administrator privileges.

### **Considerations for Secrets Management and Roles**

One of the goals of Secrets Management is to retain governance and oversight with a Security Team, while distributing management and day-to-day maintenance to others within the user community. This segregation of duty model enables oversight, while still allowing select users the necessary control to add and manage their own secret content.

When assigning roles to key users, consider the level of granularity and least-control principles that each user requires to perform their required tasks. Assign those users enough control to complete those tasks, but no more than is required. Base your decision on how to assign roles on your organizational needs, your users, and the tasks that they perform. This decision has no right or wrong answer.

For example, when assigning the Vault Administrator role, consider the following items:

- Who in the organization should control how and when Vaults are created and initially assigned?
- Should this Vault Administrator be a single person, a select few throughout the organization, or maybe some or all of the members of the Security Team?

Another way to determine which roles to assign to users is to consider the “span of control”. This consideration also has implications for vault and secret management, and for role management. For example, vaults contain a collection of secrets. Vault Owners are able to view and manage all of the secrets within the vaults that are assigned to them. Assigning the Vault Owner role to someone for vaults that encompass a large division or organization can over-expose information among the Vault Owners.

Similarly, Secret Viewers are able to view the secrets within the vaults that are assigned to them. Secret Owners are able to view and manage the secrets within the vaults that are assigned to them. Assigning the Secrets Viewer or Secrets Owner role to users for secrets that encompass a large division or organization can over-expose information to these users.

#### NOTE

If there are two Secret Viewers or Secret Owners that are assigned to a vault, they can see (and Secret Owners can manage) the secrets of each other. If this shared access is undesirable, assign one vault per user.

Creating vaults and assigning Vault Owners (or secrets and Secret Viewers or Secret Owners) that are narrowly focused gives cleaner data segregation. However, this initial configuration requires more effort to set up. Symantec recommends that you consider starting with a small span of control, such as a product or application team that must manage secrets. Assign the Secret Viewer or Secret Owner role to a single manager or devops person and assign the Vault Owner role to another individual, as appropriate. Ultimately, you decide the balance between the level of security and the ease of convenience. Again, there is no right or wrong answer to this decision.

### Assigning Users the Secrets Management Role and Granular Roles

Before you can assign the Secret Viewer, Secret Owner, Vault Owner, or Vault Administrator role to users or user groups, you must first assign the *Secrets Management* role. The Secrets Management role provides the user or user group access to the Secrets Management functionality. A user or user group can only be assigned to a vault after they have been assigned this role.

Note: The Secrets Management role lets users and user groups access the Secrets menu in PAM. However, they are unable to see or manage any vaults or secrets until they are assigned a Vault Owner, Secrets Owner, or a Secret Viewer role for a vault.

A Global Administrator or Designated Administrator can assign the initial Secrets Management role.

You assign the Secrets Management role from the User or User Group details window.

1. Select the Roles tab.
2. Click the plus (+) icon.
3. Select the **Secrets Management** entry and add it.
4. After selecting the role on this tab, a User Group row appears on the list. Click the plus (+) icon in this row, click the pencil icon, and then select **All Users**.

See [Configure Users](#) for procedures on adding and updating users.

After assigning the Secrets Management role to a user or user group, that user can log in and will see the Secrets PAM menu option. Assign the users more granular roles:

- To assign the Vault Administrator role:
  - a. In the User or User Group edit page, click on the **Credential Manager Groups** tab.
  - b. Select the Vault Administrator entry on the left side under Available Groups.
  - c. Click the arrow to move the administrator to the right side.
- To assign the Secret Viewer, Secret Owner, or Vault Owner roles:
  - a. When creating or editing a vault, select the **Vault Managers** tab
  - b. Select a Secrets Management user on the left side.
  - c. Click the arrow to move the user to the right side.
  - d. Select **Secret Viewer**, **Secret Owner**, or **Vault Owner** for this user in the drop-down menu.

See [Managing Vaults](#) for procedures on adding or updating a Vault.

Global Administrators and Delegated Administrators have all required roles by default.

## Administering Users, Vaults, and Secrets

Once you have assigned your initial roles and provided access to the Secrets Management functionality, you can begin creating and managing vaults and secrets using the appropriate procedures. See [About Secrets Management and Roles](#) for procedures on assigning roles.

- [Managing Vaults](#)
- [Managing Secrets](#)
- [Managing Secret Types](#)

You can also perform many of these operations using the PAM API or a command line interface (CLI):

- For information on using the PAM API to perform these operations, see [PAM External REST API](#).
- For information on using the Remote CLI to perform these operations, see [Remote CLI and Credential Manager Java API](#).

## Managing Vaults

This section describes how to add, update, delete, and import or export Vaults.

### Adding or Updating a Vault

To add or update a Vault:

1. As a Global Administrator or Vault Administrator, select **Secrets, Manage Vaults**.
2. On the Vaults page:
  - To add a new Vault, click **Add**. The Add Vault modal appears
  - To update an existing Vault, select the Vault from the list to be updated and click **Update**. The Update Vault modal window appears

The resulting modal window has a few tabs:

- On the Vault Info tab, enter a Name and Description to identify this vault and click **OK**. The vault name must be unique.
- On the Vault Managers tab, set the users or groups that have access to this vault:

#### **TIP**

Adding a user group to a vault gives all of the users in that group the same access to the vault, as defined by the role assigned to the group.

- a. Add or remove individual users or user groups by dragging them to the appropriate column.
  - b. Add or remove multiple users or user groups by selecting them and using the arrows to move them to the appropriate column.
  - c. Once added to the right side, set the Secret Roles for the user or user group for this vault and click **OK**. See [About Secrets Management and Roles](#) for details about the available roles.
- On the Secrets tab, add, copy, update, or delete the secrets for this vault and click **OK**. Go to System Info, Licenses to see the number of secrets used.

#### **NOTE**

You can also add a secret to an existing vault without editing any other information about the vault. See [Managing Secrets](#).

## **Deleting a Vault**

Deleting a Vault removes it permanently from PAM. You can only delete an empty vault. You must delete all secrets from a vault before you can delete it.

You cannot restore a deleted Vault. However, deleting the vault does not delete the users or user groups that are assigned to them.

As Global Administrator or Vault Administrator, to delete a Vault:

1. Select **Secrets, Manage Vaults**.
2. Select the Vault to update and click **Delete**.
3. When prompted to confirm the action, click **Yes** to delete the Vault.

## **Importing and Exporting Vaults**

Vault Administrators can export and import vaults in PAM. For example, you might import a vault as an alternative to manually or programmatically creating a vault. You import vaults using a CSV file.

You can also export all current vaults. All vaults and vault details (users, user groups, and a list of secrets) are exported to a CSV file. The secrets contained in the vault are not exported.

To import a vault:

1. Select **Secrets, Manage Vaults**.
2. Click **Import**. The Import/Export Vaults modal appears.
3. Click **Choose file** to navigate to a CSV file containing the vault information to import (or type the file location directly into the **File** field).
4. Click **Import Vaults**.

To export a vault:

1. Select **Secrets, Manage Vaults**.
2. Click **Export**. PAM generates a CSV file containing the information for all existing vaults.

### ***Vault CSV file format***

The file that contains vault information must be a CSV file containing the following information for each vault. The first line must be a header containing Type,Vault Name,Description,Users,User Roles,User Groups,User Group Roles.

- Type: Always *Vault*.
- Vault Name: A unique name for the vault.
- Description: A description of the vault.
- Users: The users that have access to this vault. Separate multiple users with the vertical bar symbol (|).
- User Roles: The Secrets Management role that is assigned to the corresponding user in the Users column. Each user in the User column must be assigned a Secrets Management role. If multiple users are listed in the User column, separate User Roles with the vertical bar symbol (|).
- User Groups: The user groups that have access to this vault. Separate multiple user groups with the vertical bar symbol (|).
- User Group Roles: The Secrets Management role that is assigned to the corresponding user group in the User Groups column. Each user group in the User Group column must be assigned a Secrets Management role. If multiple user groups are listed in the User Groups column, separate User Group Roles with the vertical bar symbol (|).

All fields are required except for the Description field. You must include either the Users and User Roles fields or the User Groups and User Group Roles fields, or both.

From the Import/Export Vaults modal, click Download Sample File to see an example of a valid vault CSV file. You can download this file, edit it, and use it to import your vaults.

## Managing Secrets

A secret can be any type of information that your organization regards as secret and proprietary, and to which you want to control access. For example, a secret might be an SSL certificate, database credential in a configuration file, a JSON object, an API, or a password for user access.

Secrets are stored using a plain-text format, such as JSON, XML, or TXT. Binary formats are not supported.

This section describes how to view, copy, add, update, and delete secrets. It also describes how to manage Secret Types and Secret Formats. This section is designed for secret administrators (users with the Vault Administrator, Vault Owner, Secret Owners, or Global Administrator or Designated Administrator roles).

Secret consumers (users or processes that require secrets to perform tasks) can obtain access to secrets through the PAM Access Policy or through the A2A Mapping Policy.

### NOTE

By default, secret administrators do not have an ability to view nor manage PAM Access Policies nor A2A Mapping used for authorization.

### Adding or Updating a Secret

When adding or updating a secret, you select the vault information, assign Secret Types, and define any future actions.

To add or update a secret:

1. Select **Secrets, Manage Vaults**.
2. Select the vault to update and click **Add Secret**.
3. You can manually add or update a secret or you can upload a file containing the secret:
  - To upload a secret, click **Upload Secret** and browse to the file that contains the secret. The secret file must be a text-based file (such as a .txt, .json, or .xml file) up to a maximum of 8,000,000 characters.
  - To manually add or update your secret, enter the following information:
    - Secret Name: Set a unique name to identify this secret.
    - Aliases: Enter how the entity using the secret is identified in the authentication source (for example, username or client ID).
    - Secret Type: Select the type of secret from the drop-down list. The Secret Type must exist before you can add it to a vault. See [Managing Secret Types](#).
    - Secret Format (optional): Once a Secret Type is selected, all available formats display. Select a Secret Format and click **Insert Format** to populate the secret value with the selected format.
    - Descriptor 1 and Descriptor 2 (optional): PAM can use the descriptor fields to identify the secret. Descriptors are also by dynamic rules, which is useful when granting programmatic access using an A2A client.
    - Future Actions: Select what actions should apply to the secret and the time that the action should occur. Time is based on GMT:
      - Expire Secret: The secret expires after the date and time set, and users can no longer use them. However, expiring a secret does not remove it from the system. Enter the time in the format HH:MM:SS.
      - Delete Secret: PAM deletes the secret at the date and time set. Note that you cannot restore a deleted secret. Select a time for deletion from the drop-down menu (PAM only deletes secrets at the top of the hour).

### NOTE

If a secret is expired or deleted, then no user nor process can access it. PAM treats these secrets as if they do not exist.

4. Click **OK**.

## **Deleting a secret**

Deleting a secret removes it permanently from the vault and from PAM. You can neither restore nor recover a deleted secret.

To delete a secret:

1. Select **Secrets, Manage Secrets**.
2. Select the secret to delete and click **Delete**.
3. When prompted to confirm the action, click **Yes**. PAM deletes the secret at the top of the hour.

## **Viewing or Copying a Secret**

To view a secret or copy a secret into your clipboard as a Vault Administrator, Vault Owner or Secrets Owner:

1. Select **Secrets, Manage Secrets**.
2. Select the secret to view or copy and click **View**. The View Secret modal appears. The secret is obscured in this view. Click the eye icon to view the unobscured secret value.

From this modal, you can:

- Copy the secret value into your clipboard by clicking the clipboard icon.
- View the secret by clicking the pencil icon.

## **Automatically Expiring or Deleting a Secret**

When you add or update a secret you have the option to make it expire or be deleted after a specified number of days. An expired secret is not removed from PAM, but a user or a client can no longer access the secret. A deleted secret is removed from PAM. In both cases, PAM treats these secrets as if they do not exist. No user nor process can access it. However, you can manually extend the secret expiration or deletion date after it is set. You can also set the maximum number of days that can be specified before the secret is expired or deleted. Additionally, you can configure the timing and the content of the email that PAM sends to the secret owner when a secret is about to expire or be deleted.

### ***Extending the Expiration or Deletion Date***

Complete the following steps to manually extend the expiration or deletion date of a secret. The secret must be set to expire or be deleted and be eligible for extension.

1. Select **Secrets, Manage Secrets**.
2. Select the secret or secrets to extend and click **Extend**.
3. In the Extension (Days) box, set the number of days to extend the secret expiration.
4. Click **Yes**.

### ***Setting the Maximum Numbers of Days to Set for Expiration or Deletion***

By default, the maximum number of days that you can specify before a secret is expired or deleted is 365. You can configure the maximum number of days in PAM.

To set the maximum number of days that you can specify before a secret is expired or deleted:

1. As a PAM administrator with the appropriate privileges, select **Global Settings, Secrets Management**.
2. Under Maximum Secret Extension (Days), set the maximum number of days that can be specified before the secret is expired or deleted, up to 365 days.
3. Click **Ok** to confirm the setting.

### ***Configure the Expiration and Deletion Notification***

By default, PAM notifies the secret owners that their secrets are expiring or are being deleted seven days before the event. You can modify the content of the notification email and the number of days before the event that PAM sends the notification email.

To modify the secret expiration or deletion notification email:

1. As a PAM administrator with the appropriate privileges, select **Settings, Credential Manager**.
2. Click the Email Templates tab.
3. For the Notify of Upcoming Secret Expirations email template, configure the following settings:
  - Secret Expiration (Days): Set how many days before the event that this email notification is sent.
  - Secret Expiration Subject: Enter the text to display in the subject line of the notification email.
  - Secret Expiration Body: Enter the text to display in the body of the notification email.
  - Click **Ok** to confirm the setting.

## Managing Secret Types

A secret type is a way to categorize and label different types of secrets, such as tokens, certificates, or db connection strings. PAM administrators have the ability to build this list as they see fit for their organization. Only Global Administrators and Vault Administrators can manage secret types. Vault owners and secret owners cannot edit secret types.

Optionally, you can give a secret type one or more different secret formats (or templates) for further clarity. Think of the secret format as a hint that is provided to someone adding this secret type. To make secret creation easier, you can apply an existing secret format or create custom formats.

PAM also lets you upload an example payload.

### NOTE

PAM does not do any kind of format validation or checking on the information supplied. A secret value is a plain text field.

Some examples of secret types and secret formats include (but are not limited to):

Secret Type	Possible Secret Formats
Token	JWT, OAuth, Access, HomeGrown
DB Connection	JDBC, ODBC
KubeConfig	Kube v1.22, Kube v1.23

PAM provides editable samples for some of these secret types and formats that you can use, modify, add to or delete, as needed.

### Adding a Secret Type

To add a secret type:

1. Select **Secrets, Manage Secret Types**.
2. Click **Add**. The Add Secret Type modal appears.
3. Enter a unique name to identify the secret type and click **Add**.
4. Manually add a secret format or upload a file containing the expected structure, format, or contents.
 

Note: PAM does not validate the secrets against the Secret Format. Secret Formats do not need to match the expected format

  - To upload a secret format, click **Upload Format** and browse to the file that contains the secret format. The secret format file must be a valid .txt, .json, or .xml file, up to a maximum of 2048 characters.
  - To manually add a secret format:
    - Enter a unique name to identify the Secret Format
    - Enter the secret format. The secret format can be up to 2048 characters.
5. Click **OK**.

## **Updating a Secret Type**

You can update the secret format associated with a secret type.

To update a secret type:

1. Select **Secrets, Manage Secret Types**.
2. Select the secret type for the format that you want to update and click **Update**. The Update Secret Type modal appears.
3. Select the format type that you want to update and click **Update**.
4. Manually update the secret format or upload a file containing the secret format:
  - To upload a secret format, click **Upload Format** and browse to the file that contains the secret format. The secret format file must be a valid .txt, .json, or .xml file, up to a maximum of 2048 characters.
  - To manually update a secret format:
    - Enter a unique name to identify the secret format.
    - Enter the secret format. The secret format can be up to 2048 characters.
5. Click **OK**.

## **Deleting a Secret Type**

Deleting a secret type removes it and its associated Secret Format permanently from PAM. You cannot restore a deleted Secret Type.

Note: You cannot delete a secret type if it is actively in use by a secret. You also cannot delete the Generic Secret Type.

To delete a secret type:

1. Select **Secrets, Manage Secret Types**.
2. Select the secret type that you want to delete and click **Delete**. The Update Secret Type modal appears.
3. When prompted to confirm the action, click **Yes**.

## **Copying a Secret Format**

To copy a secret format into your clipboard:

1. Select **Secrets, Manage Secret Types**.
2. Select the secret type for the format that you want to copy and click **Update**. The Update Secret Type modal appears.
3. Select the format type that you wish to copy and click **Copy**.
4. Modify the data as required and click **OK** to save this as a new format type.

# **Configuring Secrets Authorization**

Secret administrators (Vault Administrators, Vault Owners, and Secret Owners) are responsible for creating and managing vaults and secrets in PAM. However, secret consumers (users, user groups, and processes) also need access to these secrets to perform day-to-day or automated tasks, without being able to change or delete them. Also, secret consumers should be able to see only those secrets to which they are authorized to see.

PAM allows for authorized access through multiple sources:

- PAM Client (Desktop)
- PAM Agent (Windows Desktop)
- A2A Agent (Programmatic Access)

## Managing Secret Authorizations (Mappings)

In PAM, authorizations are required as an additional layer of control to allow a specific A2A Agent running on a specific Request Server to request a specific secret. These authorizations are referred to as *mappings*.

Mappings are a type of authorization policy that apply to the programmatic access use cases.

There are two types of mappings:

- Credential mappings authorize Request Servers to access traditional credentials.
- Secret mappings authorize a Request Server or Request Group (a group of Request Servers) to access a secret or secret group.

This section describes secret mappings. See [Configure A2A Authorization Mappings](#) for information on credential mapping.

Before you add a secret mapping, ensure that your secrets and Request Servers are created and set up in PAM.

### Adding or Updating a Secret Mapping

To add or update a Secret Mapping, complete the following procedures as the PAM Administrator:

1. Select **Secrets, Manage Secret Authorizations**
2. The Secret Authorizations page lists the existing mappings. If an entry shows as a plain name then it is a single secret. If the entry shows () around the name, then it is a secret group. See [Using Groups for Authorization](#) for information about secret groups.
  - a. To add a new mapping, click **Add**. The Add Secret Authorization Mapping modal appears
  - b. To update an existing mapping, select the map from the list to be updated and click **Edit**. The Update Secret Authorization Mapping modal window appears.
3. Select whether to add a secret group (Group) or a single secret (Alias). Then, enter the target group or alias name, or search for a target group or alias using the magnifying glass.
4. Select a Requestor Server Group (Group) or Requestor Server (Client). Then, enter the requestor group or client name, or search for an A2A requestor group or client using the magnifying glass.
5. The mapping can perform a series of additional security checks to further lock down what processes on the Request Server can access the secret. These are optional. See [Configure A2A Authorization Mappings](#) for more information.
6. Select **OK** to save the mapping.

### Deleting a Secret Mapping

Deleting a secret mapping removes it permanently from PAM. You cannot restore a deleted secret mapping. However, the secrets and the Request Server assigned to the secret mapping are not deleted.

To delete a secret authorization mapping:

1. Select **Secrets, Manage Secret Authorizations**.
2. Select the secret mapping that you want to delete and click **Delete**.
3. When prompted to confirm the action, click **Yes**.

## Using Secret Groups for Authorization

Authorizing a Request Server to access a single secret is a fine-grained way to manage authorizations using secret mappings. Although PAM supports this use scenario, it can become cumbersome and difficult to manage. For ease of management, a PAM administrator may choose to group a set of secrets (a secret group), a group of Request Servers (a request group), or both. Using groups lets the administrator apply authorization policies to multiple secrets and Request Servers more easily.

A group is a collection of secrets or Request Servers that meet specific filter criteria; for example, all secrets that have the identifier SSL in the Descriptor2 field. A single secret or Request Server might belong to multiple groups.

PAM supports two types of groups:

- Static groups allow PAM Administrators to choose explicitly what is in the group. Group contents do not change over time.
- Dynamic groups allow PAM Administrators to choose a set of rules which the request references to determine if something is in or out of the group.

Dynamic secret groups apply a logical *or* relationship for filters that use the same attribute. For example, if a group contains a vault filter with the Description1 “Test” and a vault filter for the Description1 “Production”, the resulting group contains all secrets with either *Test* or *Production* in their description.

Filters that use different attributes are applied using a logical *and* relationship. For example, if a group contains a vault filter for the Description1 “Production”, and a Secret filter in Description2 with “SSL”. The resulting group contains only secrets with *Production* in Description1 and *SSL* in the Descriptor2 field.

On the pages where groups are defined, there is a **Show** button that provides a preview of the resulting data. This preview gives PAM Administrators the ability to check the results before saving.

### **Guidelines for Mapping Secret Groups**

When you create a Dynamic Secret Group, the group contains all Secrets that satisfy the filter criteria. When you map a Secret Group that includes filters, be aware of how you set the Check Execution Path and Check File Path check boxes:

- If you select one or both check boxes, the authorization mapping is restricted to only those secrets that are in the database. The authorization mapping excludes any secrets that are not in the database.
- If you clear the check boxes, all secrets in the group are included in the authorization mapping.

### **Adding or Updating a Secret Group**

1. Select **Secrets, Manage Secret Groups**.
2. On the Secret Groups page:
  - To add a new secrets group, click **Add**. The Secret Group modal appears.
  - To update an existing secret group, select the group to update and click **Update**. The Update Secret Group modal appears.
3. Enter a Name and optionally a Description to identify this secret group and click **OK**. The group name must be unique.
4. Select whether the group is dynamic or static from the Type drop-down.
5. Add filters to the group. Repeat this procedure for each filter you want to add.
  - a. Select the **Not Specified** link for the filter that you want to apply. The Define Filters dialog appears.
  - b. Select the plus icon (+) to add an expression.
  - c. Select the filter type (for example, *contains*) from the drop-down list in the Operator field.
  - d. Enter the filter expression (for example, *SSL*) in the Value field.
6. Select **OK** to save your changes.

### **View All Secrets Belonging to an Existing Secret Group**

Use the following procedure to view all secrets belonging to an existing secret group:

1. Select **Secrets, Manage Secret Groups**.
2. On the Secret Groups page, select the target group that you want to view and select **Update**.
3. Select **Show**. The list of groups matching the criteria within the group displays.
4. Switch between the Vaults, Secret Types, and Secrets tabs to view detailed information about the secrets that are assigned to this group.

5. Select **OK**.

### **Copying a Secret Group**

To copy a secret group into your clipboard:

1. Select **Secrets, Manage Secret Groups**.
2. Select the secret group that you want to copy and click **Update**. The Copy Secret Type modal appears.
3. Modify the secret group as required and click **OK** to save this secret group as a new secret group.

### **Deleting a Secret Group**

Deleting a secret group removes it permanently from PAM. You cannot restore a deleted secret group. However, the secrets that are assigned to the group are not deleted.

To delete a secret group:

1. Select **Secrets, Manage Secret Groups**.
2. Select the secret group that you want to delete and click **Delete**.
3. When prompted to confirm the action, click **Yes**.

## Implementing PAM SC

---

The topics in this section provide end-to-end instructions for configuring the unified PAM Integrated Server Control functionality, with a strong emphasis on migration from existing PIM or PAM SC implementations:

- [PAM SC Unification Overview](#)
- [PAM SC Guided Workflows](#)
- [Install And Configure PAM SC Utility Appliances](#)
- [Migrate From PIM or PAM SC to PAM](#)
- [Upgrade and Migrate PIM and PAM SC Endpoints](#)
- [Associating PAM SC Devices with PAM Devices](#)
- [Install PAM SC Endpoints](#)
- [Server Control Configuration Settings](#)
- [High Availability](#)
- [Configure PAM SC to Protect Your Endpoints](#)
- [Administrate PAM SC](#)
- [Troubleshoot PAM SC](#)
- [PAM SC reference](#)

### PAM SC Unification Overview

This content introduces the features and benefits of unifying the PIM and PAM Server Control (formerly the standalone Privileged Access Manager Server Control product) into Privileged Access Manager.

#### **Privileged Access Manager (PAM)**

PAM enables centralized management of local and remote high-risk users over traditional physical hardware, virtual, and cloud environments.

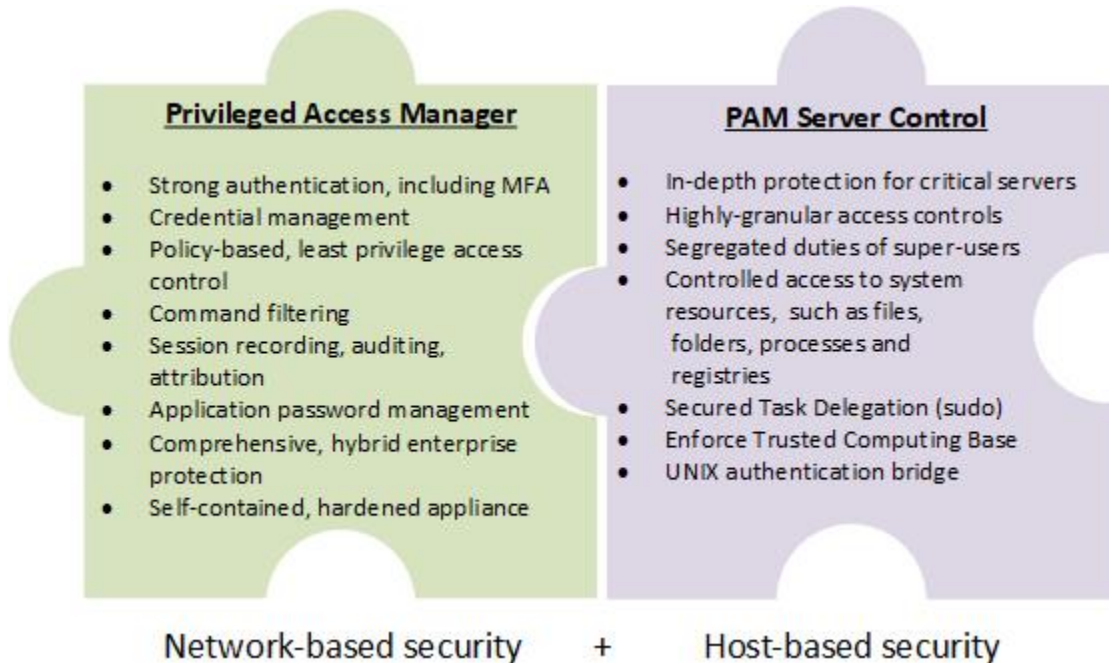

#### **Privileged Identity Manager (PIM) and Privileged Access Manager Server Control (PAM SC)**

The PIM and PAM SC products provide comprehensive solutions for protecting the most critical business assets — your mission-critical servers. These products provide powerful, fine-grained protection over operating system-level access and privileged user actions. PIM and PAM SC are system-level, host-based solutions that:

- Control, monitor, and audit privileged user activity to improve security.
- Reduce administrative costs.
- Simplify audit and compliance processes across physical and virtual environments.

#### **Unification Overview**

The PAM server now includes a *Server Control Module* that unifies the capabilities of PIM and PAM SC, adding powerful host-based security to its existing comprehensive network-based security. This combination of capabilities is shown in the following diagram:

### **Unification Highlights**

The following sections describe the unification-related functionality in more detail:

#### ***Migration Utility to Migrate PIM or PAM SC DMS Data to PAM***

This release includes a Migration Utility wizard that migrates DMS data (Devices, Device Groups, Policies, and Deployments) from existing PIM and PAM SC environments to PAM. Migration involves the following tasks:

- Extraction
- Validation
- Backing up PAM
- Migrating the PIM or PAM SC data
- Finalizing the process

#### ***New PAM Distribution Server Utility Appliance***

This release provides a new hardened *Distribution Server Utility Appliance* that runs the software necessary to deploy and support PIM and PAM SC Distribution Server functionality.

#### ***PIM and PAM SC Policy Deployment Integrated Into the PAM UI***

Policy deployment functionality allows you to deploy fine-grained access policies to the Endpoint Agents from the PAM UI. The following lists show the operations that you can perform:

#### **Policy CRUD Functionality**

- Add
- Copy
- Update
- Delete

#### **Policy Management Functionality**

- Assign
- Unassign
- Upgrade
- Downgrade

### ***UNIX Authentication Broker (UNAB)***

The UNIX Authentication Broker (UNAB) consists of several components that manage and control access to the UNIX host by Active Directory users. You can manage the following UNAB functions through PAM:

- **UNAB Login Authorization - Host or Host Group**

From the PAM UI, you can control users and groups access to the UNIX hosts and can configure your UNAB host. You can also control user and group access to the UNIX host by granting access to only those users and groups that are permitted to log into that host.

- **Configure a UNAB Host or Host Group**

From the PAM UI, you can change the configuration files of a UNAB host or hosts (belonging to a host group) by deploying UNAB configuration policies.

### ***Role-Based UI Allows Segregation of Duties***

In the PAM UI, you assign privileges to users and administrators by assigning admin and privileged access roles. A role contains tasks that correspond to application functions in PAM.

Roles simplify privilege management. Instead of associating a user with each task that they perform, you can assign a role to the user. The user can perform all the tasks in their assigned role. Every user who has the role can now perform the new task.

When a user logs in to PAM, the user sees only the tabs and tasks that are assigned to their role. You can assign separate roles to different users to prevent one user being able to complete every task. This feature allows your organization comply with separation of duties requirements.

List of available roles:

- Server Control Administrator
- Server Control Policy Editor
- Server Control Deploy Manager
- UNAB Manager

### ***Agent Status Dashboard***

The **Agent Status Dashboard** allows users to check the status (Active, Inactive, and warning) of PIM and PAM SC devices (Agent, UNAB, and PUPM). Once the devices are migrated to PAM, the exact count of existing PIM and PAM SC devices that are displayed in the **PAM Device Agent** summary under **Uninitialized** is accurate. Once the cutover is done, the device count is always shown under the corresponding agent type.

### ***API-Based Policy Management***

Use PAM APIs to automate management of CA PAM/PIM policies (Policy CRUD and Policy Manage) without the need to use the PAM UI.

### ***(SIEM) Track User Behavior Activities on Server Control Devices on PAM***

Use this functionality to track all the activities and events that are performed on all Server Control Devices. These events can be viewed through a third-party tool such as Splunk and ArcSight.

### ***Login Integration With the New Virtual Appliance Distribution Server***

Login integration assists you to audit the actual user of your server, not just the shared local privileged user name. Privileged Access Manager Server Control Login Integration allows PAM to integrate the login process and

information with Server Control. When activated, it allows the use of the actual user name for auditing in Privileged Access Manager Server Control.

### ***Simplifies Agent Installation and Upgrades***

Unified Server Control allows you to simplify PIM and PAM SC Endpoint installations, upgrades, and patches with *no* downtime and provides a rollback mechanism if there is failure. This simplification reduces the time to deploy from several months to days.

Simplified agent installation is supported on all Linux implementations, as shown in the following list:

- YUM Package Manager: OEL, SLES, RHEL
- APT-GET Package Manager: DEBIAN, UBUNTU

### **Introducing the Utility Appliance (Which Replaces Distribution Servers)**

In the PAM environment, PAM SC Distribution Servers are replaced by *Utility Appliances*. These Utility Appliances are VMware, AWS, or Azure virtual machines that you can freely download and deploy. Utility Appliances host preloaded Distribution Server software that is backwards-compatible with the PIM and PAM SC endpoint agents that are currently installed on endpoints.

#### **NOTE**

#### **Why was the Distribution Server replaced by the Utility Appliance?**

First, each PAM SC Distribution Server held a full copy of all information from across *all* endpoints, causing a noisy and data-intensive communication paradigm.

By contrast, the Utility Appliance only caches information about the Server Control devices to which it is connected. When data changes (for example, a new device is assigned), the cache for that device is invalidated and the next request by the device fetches updated information.

This model reduces the overall traffic between the components and streamlines data delivery. These features allow you to configure a more frequent polling time and therefore deliver policies more quickly to the devices.

Second, the adjusted communication method provides the opportunity to support larger sets of Server Control devices. Third, with the new Utility Appliances, you can deploy, configure, and run Distribution Software within minutes, significantly reducing the time and effort to expand capacity.

Like PIM and PAM SC Distribution Servers, Utility Appliances sit between PAM and the *devices* (formerly known as endpoints) that are under Server Control management, maintaining scale and Endpoint load distribution. The PAM implementation also provides optimized communication between PAM and the Utility Appliance, and between the Utility Appliance and the endpoints. The following diagram shows the basic architecture.

- [Server Control Components in PAM](#)
- [PAM Unified Server Control Functional Overview and Business value](#)
- [Technical Specifications](#)

:

## Server Control Components in PAM

This content describes the Server Control-related components in the unified PAM solution.

### PAM Server

The Server Control module makes the PAM Server the central management server for all Server Control functions. The Server Control module replaces the Enterprise Management Server in the standalone PIM and PAM SC products. The Server Control module includes components and tools that allow you to:

- Deploy policies to endpoints
- Define resources
- Define accessors
- Define access levels

### **Utility Appliances**

In the PAM environment, PIM and PAM SC Distribution Servers are replaced by *Utility Appliances*. The Utility Appliances are VMware, AWS, or Azure virtual machines that you can freely download and deploy. Utility Appliances host preloaded Distribution Server software that is backwards-compatible with PAM SC Endpoint Agents that are currently installed on endpoints. Like the PAM appliances, the Utility Appliances are hardened. PAM protects and controls access to these appliances.

#### **NOTE**

##### **Why was the Distribution Server replaced by the Utility Appliance?**

Each PAM SC Distribution Server held a full copy of all information from across *all* endpoints, causing a noisy and data-intensive communication paradigm.

By contrast, the Utility Appliance only caches information about the Server Control devices to which it is connected. When data changes (for example, a new device is assigned), the cache for that device is invalidated and the next request by the device fetches the updated information.

This model reduces the overall traffic between the components and streamlines data delivery. These features allow you to configure a more frequent polling time and therefore deliver policies more quickly to the devices.

Like PIM and PAM SC Distribution Servers, Utility Appliances sit between PAM and the endpoints that are under Server Control management, maintaining scale and Endpoint load distribution. The PAM implementation also provides optimized communication between PAM and the Utility Appliance, and between the Utility Appliance and the endpoints. The following diagram shows the basic architecture:

**NOTE**

For failover purposes, deploy multiple Utility Appliances in your enterprise. You can place a load balancer between the Server Control Devices and the Utility Appliances under a Source IP algorithm. Load balancers are not provided as part of the PAM infrastructure.

**Server Control Agent**

The Server Control Agent is a powerful tool for managing security for your native platforms, allowing you to set up the following capabilities:

- Implement a customizable security policy to meet the security requirements of the enterprise
- Provide security for users, groups, and resources beyond what is available in native operating systems
- Centrally manage security across the organization and integrate your Windows and UNIX security policies in a heterogeneous environment

## **UNIX Authentication Broker (UNAB)**

UNIX Authentication Broker (*UNAB*) allows you to log in to UNIX computers using an Active Directory data store. This functionality means that you can use a single repository for all your users. Your users can log in to all platforms with the same username and password.

Integrating UNIX accounts with Active Directory enforces strict authentication and password policies and transfers the rudimentary UNIX user and group properties to Active Directory. This integration allows you to manage UNIX users and groups in the same location that you manage Windows users and groups.

In the unified PAM solution, you manage your UNAB hosts from the PAM UI, from where you can:

- Control Active Directory users' access to every UNAB host in the enterprise.
- Manage hosts' login authorizations.
- Resolve hosts' migration conflicts.
- Generate reports.
- Create login authorization and configuration policies for UNAB devices and device groups. Login authorization policies permit or revoke authorization to Active Directory users and user groups on UNAB devices and device groups.

UNAB consists of two components that manage and control access to UNIX hosts by Active Directory users:

- **UNAB Authentication Agent:** Services and maintains a secure connection with Active Directory to provide the following functionality:
  - User authentication and login authorization
  - Host registration with Active Directory
  - User and group migrations
  - Administering local access files
- **uxconsole:** A UNAB management console to register the UNIX host with Active Directory, migrate users and groups and to register and activate UNAB.

## **Endpoint Software**

PAM SC provides software for two types of Endpoint agents:

- **Endpoint Agents**  
Install PAM SC Endpoint Agent software on Windows and UNIX servers that you want to secure with PAM SC.
- **UNAB Authentication Agent**  
Install the UNAB Authentication Agent on UNIX servers with an Active Directory data store that you want to act as a single repository for all of your users.

## PAM Unified Server Control Functional Overview and Business value

This topic provides a detailed functional overview and presents the business value of PAM with unified Server Control functionality.

Problem Statement	Solution
<p>Many data breaches happen because of compromises in privileged user accounts, such as UNIX/Linux superuser account (root) and Windows administrator accounts. Privileged user accounts provide full, unauthorized access to all applications, data, and audit logs for exploitation. As a result, malicious insiders and external hackers specifically target these accounts.</p> <p>Unfortunately, these superuser accounts cannot be disabled because systems administrators need the privileges to perform necessary and legitimate maintenance of critical servers. Extra protections that audit all access, identify, and prevent unauthorized activities, while still allowing legitimate actions, are key to defending mission-critical servers. Just one improperly authorized privileged account usage can cause widespread, irreparable damage to the infrastructure, intellectual property, and brand equity for exploitation of your organization.</p> <p>You need a proven privileged access management solution that provides powerful controls over privileged users on your most critical systems.</p>	<p><b>Use PAM</b></p> <p>Integration of CA Privileged Access Manager Server Control with PAM is a comprehensive and mature solution that is designed to protect your most sensitive systems whether they are physical, virtual, or cloud.</p> <p>CA Privileged Access Manager is a scalable solution capable of deploying fine-grained access controls, auditing, and UNIX authentication bridging across servers from a single PAM control plane. PAM is also uniquely capable of deploying policies that enforce access kernel-level controls on any account, such as UNIX root and Windows administrator.</p>
<p>The Security Administrators in two different divisions of a company have come to you for assistance in developing consistent security policies across the divisions.</p>	<p><b>Deploy Policies</b></p> <p>The three Security Administrators have decided to deploy a PAM 4.0 environment to establish centralized propagation of vaulting and security rules. With PAM 4.0, you can create and deploy a policy to the agents distributed across your entire company or enterprise.</p>
<p>You are a Security Administrator for the Manufacturing Division of Example.com. Now that management has decided to implement an enterprise-wide security solution, your task is to install the application.</p>	<p><b>Install PAM</b></p> <p>Set up the system for installation. Install PAM 4.0 Appliance. Verify the installation.</p>
<p>You are the Security Administrator for PIM and PAM SC, and management has decided to consolidate security tools into a single platform: PAM. As the owner of this application and project, and to cause minimal business disruptions, you want:</p> <ul style="list-style-type: none"> <li>• An automated way to transfer the data into PAM</li> <li>• A controlled way to roll out this change.</li> </ul> <p>You should still be able to access all existing fine grained policies, devices, devices groups, and deployments from the PAM UI.</p>	<p><b>Use the Migration Utility</b></p> <p>The Migration Utility allows you to migrate the DMS data (Devices, Device Groups, Policies, and Deployments) from the existing PIM environment to PAM. Migration does the following tasks:</p> <ul style="list-style-type: none"> <li>• Extraction</li> <li>• Validation</li> <li>• Backup PAM</li> <li>• Migrate Data</li> <li>• Finalize Process</li> </ul>
<p>You are a Security Administrator. Now that you want to deploy Server Control or fine-grained policies across multiple agents, you need Distribution Server software which is easy to install and scalable.</p>	<p><b>Utility Appliance</b></p> <p>The new Utility Appliance is a hardened all-in-one virtual appliance that provides all Distribution Server functionality.</p>

<p>The Example.com security policy requires least privilege and separation of duties, requiring the following restrictions:</p> <ul style="list-style-type: none"> <li>Each user has only the access that is required to perform their job.</li> <li>No single user has access to all security functional areas.</li> </ul> <p>Your primary concern is policy management functionality. When you log into PAM as a user with Server Control privileges, you should see the aspects of the UI and functionality that is related to your role. Similarly, users should see only the tabs and tasks that are assigned to their role.</p>	<p><b>Role-based UI</b></p> <p>You can assign users in PAM entitlements in privileges, which are known as roles, that enable and can disable different options within the PAM UI.</p> <p>Roles simplify privilege management. Instead of associating a user with each task that they perform, you can assign a role to the user. The user can perform all the tasks in their assigned role. Every user who has the role can now perform the new task.</p> <p>When a user logs in to PAM, the user sees only the tabs and tasks that are assigned to their role. You can assign separate roles to different users to prevent one user being able to complete every task. This feature allows your organization to comply with separation-of-duties requirements.</p> <p>List of roles:</p> <ul style="list-style-type: none"> <li>Server Control Administrator</li> <li>Server Control Policy Editor</li> <li>Server Control Policy Manager</li> <li>UNAB Manager</li> </ul>
<p>You are a Security Administrator of Example.com. As a Security Administrator, you would like to know and understand the health and status of your different agents.</p>	<p><b>Agent Status Dashboard</b></p> <p>Agent Status Dashboard only applies to Server Control-based devices. The Agent Status Dashboard allows users to check the Status (Active, Inactive, Warning) across each of the different Agent types (Server Control, UNAB, PUPM).</p> <p><b>Note:</b> During a migration from PIM/PAM SC, Agents might be listed as "Uninitialized". This status is expected until the final cutover occurs, and then PAM starts managing this data.</p>
<p>As a Security Administrator, you want to automate the policy deployment without having to log in to the PAM UI.</p>	<p><b>Policy Management through API</b></p> <p>The PAM APIs for Server Control policy management functionality (Policy CRUD and Policy Manage) allow Security Administrators to automate without using the PAM UI.</p>
<p>You are a Security Administrator, and you want to track and audit the actual user of your server, not the shared local privileged user name.</p>	<p><b>Login Integration</b></p> <p>Login integration helps you to audit the actual user of your server, not the shared local privileged user name. Privileged Access Manager Server Control Login Integration allows Privileged Access Manager to integrate the login process and information with Server Control. When activated, it allows the use of the actual user name for auditing in Privileged Access Manager Server Control.</p>
<p>As a Security Administrator for the Manufacturing Division of Example.com, you have a deadline to upgrade from existing PIM endpoints to PAM SC/PIM, but you have a concern that it might take several months.</p>	<p><b>Simplified Agent Installation and Upgrades</b></p> <p>This functionality allows you to simplify endpoint installations, upgrades, and patches with NO downtime. This functionality includes rollback mechanism in case failures occur. This simplification reduces the time to deploy from several months to days.</p> <p>This functionality supports all Linux variants:</p> <p>YUM Package Manager: OEL, SLES, RHEL</p> <p>APT-GET Package Manager: DEBIAN, UBUNTU</p>
<p>The Example.com corporate security policy mandates a daily audit to monitor critical hosts for user activity security breaches and attempted security breaches. As a security Administrator, you want to see all the Audit events in a centralized UI.</p>	<p><b>(SIEM) Track User Behavior Activities on Server Control Devices</b></p> <p>As System Administrator, you decide to log in to the PAM server to configure the SIEM tool information. Next, you log in to the Server Control device to run the Report Agent. The agent then sends the snapshot to Splunk, where you can view the User Activity reports.</p>

Example.com, wants to consolidate user stores across windows and UNIX hosts. Their goal is to enable Active Directory-based UNIX logins.

#### UNAB

PAM offers the UNIX Authentication Broker to authenticate UNIX users against Active Directory. UNAB must be installed and configured for UNIX users to be able to log in with their AD credential. With AC UNAB Authorization, the administrators can authorize users and groups to host or host groups. With AC UNAB configuration, the administrators can manage UNAB configuration settings. Host or host groups can be managed using this feature.

## Server Control Concepts

In the PAM-integrated solution, Server Control refers to fine-grain control enforcement.

To establish fine-grain control, assign a Server Control policy to a device or group of devices.

- **Server Control Policy:** A Server Control Policy is a set of rules that are enforced within the kernel of the device. Server Control Policies are authored and managed in PAM using the UI and API. Versions of Policies are managed within PAM; however, once a policy is finalized, it cannot be changed.
- **Device and Device Group:** In PAM, devices can be grouped into Devices and Device Groups, saving management overhead for authorization. Similarly, for Server Control functionality, individual devices or groups of devices can be assigned Server Control policies. As in previous versions of PAM, device group membership can be managed directly in PAM or imported from an external source.
- **Assignment:** An Assignment is an instruction stating that a version of a policy is assigned to a device or device group. A device or device group is often assigned one or more policies.

## PIM/PAM SC Component Changes in PAM 4.0

The following table compares the key components and functions in PIM and PAM SC to their functional equivalents in PAM 4.0.

PIM/PAM SC	PAM 4.0	Notes
Enterprise Manager (ENTM) centralized management platform	PAM Server	PAM facilitates policy and deployment changes.
Distribution Server	Utility Appliance	The Utility Appliance is a black-box, PAM-managed device that runs the Distribution Server software. The Utility Appliance handles communication between PAM and the endpoints. For scalability and to manage endpoints that are located behind firewalls, install more Distribution Servers in your enterprise.
Policy Model Database (PMDb)	Utility Appliance	In PIM/PAM SC, the PMDB plays a critical role in distributing data to endpoints connected to it. In PAM 4.0, the functionality in the Utility Appliance significantly changes the role of the PMDB. <b>Direct access to PMDB on the Utility Appliance is not allowed in PAM 4.0.</b>
Endpoint Agents	Endpoint Agents	No software changes needed. In PAM 4.0, endpoint agents can be deployed using package managers (for example, yum or apt).
	Migration Tool	A multi-staged utility to extract data out of PIM/PAM SC and add that data into PAM.

## Server Control Roles in PAM

Server Control user roles support separation-of-duties requirements. As with any capability or role within PAM, you can choose to combine them for a desired operational state.

The following list describes the Server Control roles and the privileges that they provide:

- **Server Control Policy Editor:**
    - Full access to Server Control policy features, including create, update, version, and finalization process.
  - **Server Control Deploy Manager:**
    - Full access to policy deployment features, including assign, unassign, upgrade, and downgrade.
    - Read-only access to devices/device groups and server control policies.
  - **Server Control Administrator:**
    - Access to the Dashboard Overview, Device Agent Status, Session Logs, Device / Device Groups, Device Tags, Server Control Policy, Policy Deployment, and Deployment audit.
- NOTE**  
The Dashboard System Tab is not available for users with the Server Control Administrators role.
- Full access to UNAB policy management, UNAB Configuration, and token management capabilities on devices and device groups. Access to users and user groups.
  - **UNAB Manager:**
    - Full Access to UNAB host login policy management and UNAB configuration token management on devices and device groups.

## How Server Control Works

This content describes how the existing PAM and new PAM SC components work together.

### PAM Server

The PAM Server is the central source of information. Server Control information is shared across the PAM cluster and is available from wherever PAM is accessible.

Policies can be drafted, saved, and edited as often as needed on the PAM Server. However, when a policy is *finalized*, it cannot be changed.

Assignments indicate that a policy or policies are consigned to a device or a device group.

### Endpoint

The endpoint software running on a device requests for and receives assignments and corresponding policy details and instructions. The agent incorporates these instructions into its processing engine, where they become the enforcement rules.

### Utility Appliance with Distribution Server Software

To help with the scale and regional distribution, PAM provides a hardened virtual Utility Appliance that hosts improved Distribution Server software. The Distribution Server software helps distribute the load and improve the communication traffic.

The Distribution Server software is backwards-compatible, so no upgrade of any currently installed endpoint agent is required.

## Technical Specifications

### Recommendations for single-site or small environment production workloads:

#### NOTE

These suggested numbers depend on the eventual size of your deployment. See the Sizing Guide for additional information.

Count	Type	RAM	Disk	Cores
3	PAM	16 GB	120 GB	8
N	PAM Utility Appliance	16 GB	40 GB	8

### Recommendations for multi-site environment production workloads:

Count	Type	RAM	Disk	Cores
6	PAM (2 sites)	16 GB	120 GB	8
N	PAM Utility Appliance	16 GB	40 GB	8

## PAM SC Guided Workflows

The topics in this section contain high-level guided workflows.

Use the table of contents to access the individual workflows.

### Guided Workflow: Migrate a PIM or PAM SC Environment to PAM

This guided workflow provides a high-level overview of how PIM and PAM SC administrators can adopt PAM. This content also summarizes the technical and business value from your point of view, where applicable.

	Step	Description
1	Complete prerequisites before migrating from PIM or PAM SC to PAM	Required preparation for migrating from PIM or PAM SC to PAM. See <a href="#">Prepare to Migrate to PAM</a> for details.
2	Upgrade existing PAM servers to 4.x or deploy new PAM 4.x servers.	All the PAM servers in your cluster must be running version 4.x. Upgrade existing PAM servers to 4.x or deploy new PAM 4.x servers. See <a href="#">Upgrading</a> or <a href="#">Deploying</a> for details.
4	License PAM to support Server Control.	Server Control is a separately licensed PAM component. See <a href="#">License PAM to Support Server Control</a> for details.
3	Download and Deploy Utility Appliances.	Utility Appliances are VMware virtual machines that host the Distribution Server software that stands alone in PIM and PAM SC. Download and deploy at least one Utility Appliance before proceeding with the adoption process. See <a href="#">Download and Deploy a New Utility Appliance</a> for details.
5	Add and activate Utility Appliances in PAM	To configure PAM to communicate with and activate Utility Appliances, do the following steps: <ol style="list-style-type: none"> <li><a href="#">Create Utility Appliance devices.</a></li> <li><a href="#">Add the Utility Appliance devices to Utility Groups.</a></li> </ol> PAM creates a cluster from the Utility Appliances in a Utility Group, starts the Utility Appliances, which then start communicating with PAM.
6	Migrate data from CA PIM to PAM.	Install and run the Migration Utility on an Enterprise Management Server to migrate the PIM or PAM SC data to PAM. See <a href="#">Migrate Data from PIM or PAM SC to PAM on Windows</a> or <a href="#">Migrate Data from PIM or PAM SC to PAM on Linux</a> for details.

7	Verify that all your PIM/ PAM SC endpoint agents are present in the PAM environment.	Once your devices are migrated to PAM, verify that the exact count of existing PIM or PAM SC endpoint devices is shown in the <b>Agent Status Summary</b> screen as Uninitialized. Once the cutover is complete, each agent is listed under its respective agent type. See <a href="#">View Server Control Endpoint Agent Status on the Device Agent Status Screen</a> for more details.
8	Configure endpoints to connect to Utility Appliances, manage endpoints with PAM.	Configuring endpoints to connect to Utility Appliances and managing endpoints with PAM enables the cutover of server control devices from PIM or PAM SC to PAM. See <a href="#">Post Migration Steps</a> for details.
9	Troubleshoot extraction and validation errors.	If you have extraction or validation errors, and the problem is not immediately obvious, see <a href="#">Troubleshooting and Maintenance</a> and <a href="#">Troubleshoot Orphaned Data, Records, and Validation Errors</a> for information about how to solve these issues: <ul style="list-style-type: none"> <li>• Identify extraction errors</li> <li>• Fix orphan data</li> <li>• Identify validation errors</li> <li>• Review the reasons for failures</li> <li>• Fix records in the JSON File</li> </ul>
10	Assign user roles to specify segregation of duties.	To perform Server Control operations in PAM, a user must be assigned one or more of the following roles, which were designed to support separation of duties, if desired. <b>Server Control Policy Editor</b> Full access to Server Control policy creation, updates, version, and finalization process Read-only Access to device and device groups, policy deployment, and deployment audit features <b>Server Control Deploy Manager</b> Full access to policy deployment features, including assign, unassign, upgrade, and downgrade. Read only Access to device/device groups and server control policies <b>Server Control Administrator</b> Full access to Device/Device groups, Device tags, Server Control Policy, policy deployment and deployment audit Full access to UNAB policy management, UNAB configuration, and token management capabilities on devices and device groups. Access to users and user groups <b>UNAB Manager</b> Full Access to UNAB Host Login policy management and UNAB configuration token management on devices and device groups For more information, see <a href="#">Identify User Roles and Privileges</a> .
11	Use the Server Control Policy Editor	Create, copy, update, and delete Server Control Policies that may or may not be sent to and enforced on a Server Control Device or Server Control Device Group. For more information, see <a href="#">Manage and Troubleshoot Server Control Policies</a> .
12	Assign, unassign, upgrade, and downgrade Server Control Policies.	To implement the policy rules, assign the latest, finalized policy version to specific Devices or Device Groups. Assigned policies are automatically deployed. Once deployed, you can then monitor the policy's deployment status. You can also unassign a specified policy from one or more hosts or host groups. New policy versions are not automatically sent to assigned hosts or to hosts with a deployed policy. You must manually upgrade hosts where the policy is deployed to the latest policy version. If you either inadvertently assign the wrong policy version to one or more hosts, or if you want to go back to an older version of a policy on specific hosts, you can downgrade a policy. For more information, see <a href="#">Advanced Server Control Policy Management</a> .
13	Policy Management using the PAM External API	Use the PAM External API to manage your Server Control policies programmatically, which allows you to automate the process without using the PAM UI. For more information, see <a href="#">PAM External REST API</a> .

14	Configure PAM to track user activities on Server Control devices or viewing in a SIEM Tool.	To track all activity and events that are performed on your Server Control devices for IT governance purposes, configure PAM to report them to a <i>Security information and event management (SIEM)</i> tool such as Splunk or ArcSight. For more information, see <a href="#">Track User Behavior Activities on Server Control Endpoints Using an SIEM Tool</a> .
15	Login integration with new Distribution Server	Login integration helps customers to audit the actual user of your server, not the shared local privileged user name. PAM Server Control Login Integration allows PAM to integrate the login process and information with Server Control. When activated, it allows the use of the actual user name for auditing in PAM Server Control. For more information, see <a href="#">Configure Login Integration for a Server Control Endpoint</a> .

## Guided Workflow: Migrate a PIM or PAM SC Environment with UNAB to PAM

This guided workflow provides a high-level overview of how PIM and PAM SC administrators whose PIM or PAM SC deployments include UNAB can adopt PAM 4.0. This content also summarizes the technical and business value from your point of view, where applicable.

Your UNAB host should be the same host on which you install PAM SC.

	Step	Description
1	Install and configure the PAM SC UNIX Attributes plug-in	Install and configure the PAM SC UNIX Attributes plug-in on your UNAB host. The plug-in lets you manage UNIX attributes for UNAB users on Active Directory: <ul style="list-style-type: none"> <li><a href="#">Install the CA Privileged Access Manager Server Control UNIX Attributes Plug-in</a></li> <li><a href="#">Configure UNIX Attributes for an Active Directory User</a></li> </ul>
2	Configure your Active Directory (AD)	Configure your AD to work with your UNAB host: <ul style="list-style-type: none"> <li>Configure your AD with forward and reverse lookups for your UNAB endpoint.</li> <li>Your AD must have existing users. At least one user must have account membership in a group that permits that user to perform administrative tasks.</li> </ul> See the documentation that came with your Active Directory for details.
3	Install UNAB Agents (Standalone)	Install and configure the UNAB Agents: Install a UNAB Agent on the PAM server to get granular access to AD users. <ul style="list-style-type: none"> <li><a href="#">Install and Configure UNAB Agent</a></li> <li><a href="#">UNAB Agent Post Installation Configuration</a></li> </ul>
4	Upgrade or install PAM SC Endpoint Agents	If not already installed, install the PAM SC Endpoint Agents: <ul style="list-style-type: none"> <li><a href="#">Install a CA PIM or PAM SC Endpoint Windows</a></li> <li><a href="#">Install a Server Control Agent on a UNIX Endpoint</a></li> <li><a href="#">Installing and Uninstalling Endpoint Agents Using YUM</a></li> </ul> Otherwise, upgrade your PAM SC Endpoint Agents. See <a href="#">Upgrade and Migrate PIM and PAM SC Endpoints</a>
5	Verify that users can access the UNAB host	Verify that users can access the UNAB host. With a user in a group that permits that user to perform administrative tasks, run the following command: <pre>uxconsole -manage -show -user &lt;username&gt;</pre>
6	Complete prerequisites for migrating from PIM or PAM SC to PAM	Required preparation for migrating from PIM or PAM SC to PAM. See <a href="#">Prepare to Migrate to PAM</a> for details.
7	Upgrade existing PAM servers to 4.0 or deploy new PAM 4.0 servers.	All the PAM servers in your cluster must be running version 4.0. Upgrade existing PAM servers to 4.0 or deploy new PAM 4.0 servers. See <a href="#">Upgrading</a> or <a href="#">Deploying</a> for details.
8	License PAM to support Server Control.	Server Control is a separately licensed PAM component. See <a href="#">License PAM to Support Server Control</a> for details.

9	Download and Deploy Utility Appliances.	Utility Appliances are VMware virtual machines that host the Distribution Server software that stands alone in PIM and PAM SC. Download and deploy at least one Utility Appliance before proceeding with the adoption process. See <a href="#">Download and Deploy a New Utility Appliance</a> for details.
10	Add and activate Utility Appliances in PAM	To configure PAM to communicate with and activate Utility Appliances, do the following steps: 1. <a href="#">Create Utility Appliance devices</a> . 2. <a href="#">Add the Utility Appliance devices to Utility Groups</a> . PAM creates a cluster from the Utility Appliances in a Utility Group, starts the Utility Appliances, which then start communicating with PAM.
11	Migrate data from CA PIM to PAM.	Install and run the Migration Utility on an Enterprise Management Server to migrate the PIM or PAM SC data to PAM. See <a href="#">Migrate Data from PIM or PAM SC to PAM on Windows</a> or <a href="#">Migrate data from PIM or PAM SC to PAM on UNIX</a> for details.
12	Verify that all your PIM/PAM SC agents are present in the PAM environment.	Once your devices are migrated to PAM, verify that the exact count of existing PIM or PAM SC devices is shown in the <b>Agent Status Summary</b> screen as Uninitialized. Once the cutover is complete, each agent is listed under its respective agent type. See <a href="#">View Server Control Agent Status on the Device Agent Status Screen</a> for more details.
13	Import Active Directory users	Import Active Directory users and groups into PAM, to let PAM discover the selected users and groups from Active Directory. Once discovered, they appear in the PAM UI, letting you manage UNAB login authorization policies. For more information, see <a href="#">Import PIM and PAM SC Active Directory Users into PAM</a> .
14	Assign user roles to specify segregation of duties.	To perform operations in Privileged Access Manager, each user must be assigned one or more user roles, which define sets of privileges that are related to different product functions. This feature allows your organization to comply with separation of duties requirements. Assign one or more of the following roles to each Server Control administrator to specify which operations they can perform: <b>Server Control Policy Editor</b> Full access to Server Control policy creation, updates, version, and finalization process. Read-only access to device and device groups, policy deployment, and deployment audit features <b>Server Control Deploy Manager</b> Full access to policy deployment features including assign, unassign, upgrade, and downgrade. Read-only access to device/device groups and server control policies <b>Server Control Administrator</b> Full access to Device/Device groups, Device tags, Server Control policy, policy deployment, and deployment audit. Full access to UNAB policy management, UNAB configuration, and token management capabilities on devices and device groups. Access to users and user groups <b>UNAB Manager</b> Full Access to UNAB Host Login policy management and UNAB configuration token management on devices and device groups For more information, see <a href="#">Identify User Roles and Privileges</a> .
15	Manage UNAB Login Authorization - Host or Host Group	To control user logins to UNAB hosts or host groups, you create a list of users or groups who are granted access. The list is then formulated into a policy that Symantec PAM assigns and deploys to the selected host or host group. For more information, see <a href="#">Manage UNAB Login Authorization for Devices and Device Groups</a> .
16	Configure a UNAB Host or Host Group	You can define the configuration settings that govern UNAB hosts and host groups. Symantec PAM helps you set the value of the settings in the UNAB configuration file (uxauth.ini) or the configuration file (accommon.ini). After you finish assigning values to the configuration settings, Symantec PAM creates a configuration policy. The policy contains the updated settings values and assigns it to the host or host group. For more information, see <a href="#">Configure a UNAB Host or Host Group</a> .

17	Verify policy deployment from UNAB endpoint	Once policies are deployed from the PAM UI, the same can be verified from the UNAB endpoint. For more information, see <a href="#">Verify Policy Deployment from a UNAB Endpoint</a> .
18	UNAB Policy Management by API	This feature lets you use the APIs for the UNAB management functionality (Login Authorization and configuration) so that they can automate without the need to use the PAM UI. For more information, see <a href="#">Manage Server Control UNAB Policies Using the PAM External API</a> .

## Guided Workflow: Add a New PAM Server Control Implementation to PAM

This guided workflow provides a high-level overview of how to add a PAM Server Control implementation to a new or existing PAM 4.x installation. This content also summarizes the technical and business value from your point of view, where applicable.

	Step	Description
1	If you are not already running PAM 4.x (or later), upgrade an existing installation to 4.x or deploy a fresh one, as appropriate. If you already have an operational PAM 4.x installation, skip this step and proceed to Step 2.	Upgrade an existing PAM installation to 4.x or deploy a new one. For more information, see the <a href="#">Upgrading</a> or <a href="#">Deploying</a> section, as appropriate. All the PAM servers in your cluster must be running the same 4.x version. Once installed, log into the PAM server ( <a href="https://&lt;ip&gt;/cspm/home">https://&lt;ip&gt;/cspm/home</a> ).
2	Download and Deploy PAM SC Utility Appliances.	Utility Appliances are VMware virtual machines that host the Distribution Server software. Download and deploy at least one Utility Appliance. See <a href="#">Download and Deploy a New Utility Appliance</a> for details.
3	License PAM to support Server Control.	Server Control is a separately licensed PAM component. See <a href="#">License PAM to Support Server Control</a> for details.
5	Add and activate Utility Appliances in PAM	To configure PAM to communicate with and activate Utility Appliances, do the following steps: 1. <a href="#">Configure PAM to Communicate with Utility Appliances</a> . 2. <a href="#">Add the Utility Appliance devices to Utility Groups</a> .  PAM creates a cluster from the Utility Appliances in a Utility Group and starts the Utility Appliances, which then start communicating with PAM.
6	Install your PAM SC agents.	Install the PAM SC endpoint agents. See <a href="#">Agent Install or Upgrade</a> .
7	Verify that all your PAM SC agents are present in the PAM environment.	Verify that the exact count of PAM SC devices is shown in the <b>Agent Status Summary</b> screen. Each agent is listed under its respective agent type. See <a href="#">View Server Control Endpoint Agent Status on the Device Agent Status Screen</a> for more details.

10	Assign user roles to specify segregation of duties.	<p>To perform operations in Privileged Access Manager, each user must be assigned one or more user roles, which define sets of privileges that are related to different product functions. This feature allows your organization to comply with separation of duties requirements.</p> <p>Assign one or more of the following roles to each Server Control administrator to specify which operations they can perform:</p> <p><b>Server Control Policy Editor</b> Full access to Server Control policy creation, updates, version, and finalization process. Read only Access to device and device groups, policy deployment, and deployment audit features</p> <p><b>Server Control Deploy Manager</b> Full access to policy deployment features including assign, unassign, upgrade, and downgrade. Read only Access to device/device groups and server control policies</p> <p><b>Server Control Administrator</b> Full access to Device / Device groups, Device tags, Server Control Policy, policy deployment and deployment audit Full access to UNAB policy management, UNAB configuration, and token management capabilities on devices and device groups. Access to users and user groups</p> <p><b>UNAB Manager</b> Full Access to UNAB Host Login policy management and UNAB configuration token management on devices and device groups For more information, see <a href="#">Identify User Roles and Privileges</a>.</p>
11	Create, copy, update, and delete Server Control Policies.	<p>Create a policy to deploy it on any Server Control device or Server Control device group. Copy an existing policy to quickly add a policy with the same properties and then update it as required.</p> <p>Update a policy and create versions only if the previous version of the policy was finalized.</p> <p>For more information, see <a href="#">Manage and Troubleshoot Server Control Policies</a>.</p>
12	Assign, unassign, upgrade, and downgrade Server Control Policies.	<p><i>Assign</i> the latest finalized policy version to specific hosts or to host groups to implement the policy rules. Once assigned, the policy is automatically deployed and you can monitor the policy status from PAM. You can also <i>unassign</i> a specified policy from one or more hosts or host groups.</p> <p>New policy versions are not sent automatically to assigned hosts or to hosts where the policy is deployed. You must manually <i>upgrade</i> hosts where the policy is deployed to the latest policy version.</p> <p>If you inadvertently assign the wrong policy version to one or more hosts, or if you want to go back to an older version of a policy on specific hosts, you can also downgrade a policy.</p> <p>For more information, see <a href="#">Advanced Server Control Policy Management</a>.</p>
13	Policy Management using the PAM External API	<p>Use the PAM External API to manage your Server Control policies programmatically, which allows you to automate the process without using the PAM UI.</p> <p>For more information, see <a href="#">PAM External REST API</a>.</p>
14	Configure PAM to track user activities on Server Control devices or viewing in a SIEM Tool.	<p>To track all activity and events that are performed on your Server Control devices for IT governance purposes, configure PAM to report them to a <i>Security information and event management (SIEM)</i> tool such as Splunk or ArcSight.</p> <p>For more information, see <a href="#">Track User Behavior Activities on Server Control Endpoints Using an SIEM Tool</a>.</p>
15	Configure login integration with a new Utility Appliance.	<p>Login integration helps customers to audit the actual user of your server, not the shared local privileged user name. Server Control Login Integration allows PAM to integrate the login process and information with Server Control. When activated, it allows the use of the actual user name for auditing in PAM Server Control.</p> <p>For more information, see <a href="#">Configure Login Integration for a Server Control Endpoint</a>.</p>

## Install And Configure PAM SC Utility Appliances

The following topics provide end-to-end instructions for installing and configuring PAM SC Utility Appliances (which replace Distribution Servers in the PAM integration).

- [License PAM To Support Server Control](#)
- [Download and Deploy a New Utility Appliance](#)
- [Add Utility Appliances to an Existing Environment](#)
- [Utility Appliance Ports for Network Connectivity](#)
- [Configure PAM to Communicate with Utility Appliances](#)
- [License PAM To Support Server Control](#)
- [View Utility Group Status](#)

### License PAM To Support Server Control

This procedure describes how to license PAM to support Server Control.

#### Follow these steps:

1. Log in into the PAM UI ([https://pam\\_server\\_address/cspm/home](https://pam_server_address/cspm/home)).
2. If you have not already done so, do the following tasks:
  - a. Accept the terms and conditions.
  - b. Log in as super with the default local password.
  - c. Change the default local password.
3. Select **Configuration, Licensing**
4. Copy the Hardware ID.
5. if you do not already have one, obtain a license file with Server Control support from Broadcom support.
6. Do the following tasks to install the license file:
  - a. Navigate to the **Configuration, Licensing** page and select the **Install New License** tab.
  - b. Choose the appropriate license file and select **Upload file**.
  - c. Verify the new license and select **Save New License**.

### Download and Deploy a New Utility Appliance

Use this procedure to download and deploy a new Server Control Utility Appliance VMWare OVA for major (X.x) release.

#### Follow these steps:

1. Download the Utility Appliance software from the Broadcom Support site. For more information, see [Download PAM Installation Media](#).
2. Import the PAM Utility Appliance OVA into VMWare or a VMWare-compatible infrastructure.
3. Read and accept the license.
4. Select **Properties** of the imported OVA.
  - a. Set network and disk specifications as required.
  - b. Take a snapshot of the image before starting.
5. Start the VM.

#### TIP

The Utility Appliance can take several minutes to load upon its initial boot. The Blue Console screen appears in VMWare when the initial deployment process is complete and the Utility Appliance VM is ready to use.

6. Select **Network Interfaces** and take note of the IP address that is assigned to the Utility Appliance VM.
7. Stop the Utility Appliance VM and do the following steps before configuring the Utility Appliance in PAM:
  - a. Take a snapshot of the Utility Appliance VM.

- b. Clone the Utility Appliance VM. The Utility Appliance is shipped with a default SSH key that is known to PAM. Once the Utility Appliance is added to PAM, that key is rotated and cloning of that Utility Appliance is no longer recommended.

## Add Utility Appliances to an Existing Environment

This content describes how to add Utility Appliances to an existing PAM SC environment.

### Follow these steps:

1. [Deploy the new Utility Appliances.](#)
2. [Add the Utility Appliances to PAM.](#)
3. [Add the Utility Appliances to a Utility Group.](#)
4. [Apply the update patches deployed on the existing Utility Appliances to the new Utility Appliances.](#)

## Utility Appliance Ports for Network Connectivity

This content lists the default ports that must be open in the firewall of the Utility Appliance (UA) host for it to establish network connectivity to the PAM server and endpoint agents.

### Assign IP Addresses for the Utility Appliance

Before you configure your network, assign and allocate IP addresses for each Utility Appliance.

### Review Port Assignments

The following table lists the ports required to be open in the host instance firewall for connectivity between .

Port(s)	Protocol	Source	Destination	Notes
443	TCP	UA	PAM	Required in case of PAM cluster primary site failover. Ports need to be open between UAs and <i>all</i> PAM nodes at the primary site and all secondary sites.
22	TCP	PAM	UA	Required for PAM to securely manage Utility Appliances using SSH.
6443	TCP/SSL	PAM	UA	Required for PAM to manage micro services running inside Utility Appliance over TLS.
2379-2380	TCP	PAM	UA	Required to manage the Kubernetes cluster. Ports need to be open between UAs and all the PAM nodes in the Primary Site and all Secondary Sites (in case of primary failover)
2379-2380	TCP	UA	UA	Ports need to be open between all UAs within the same utility group. For example, if you have a utility group named "UG_US_East" containing UAs named "UA1," "UA2," and "UA3" these ports need to be open between UA1, UA2, and UA3.
10250	TCP	PAM	UA	Required to manage the Kubernetes cluster.
10259	TCP	PAM	UA	Required to manage the Kubernetes cluster.
10259	TCP	UA	UA	Required to manage the Kubernetes cluster.
10257	TCP	PAM	UA	Required to manage the Kubernetes cluster.
10255	TCP	PAM	UA	Required to manage the Kubernetes cluster.

28089	TCP	PAM	UA	PAM to A2A; but no filtering on PAM IPs open to all. PAM and A2A have mutual handshake.
5249	TCP	SC Agent	UA	Required by PAM to manage Server Control policies on SC Agents when SSL mode is enabled.
8891	TCP	SC Agent	UA	Required by PAM to manage Server Control policies on SC Agents when SSL mode is not enabled.
61616	TCP/SSL	SC Agent	UA	Required by SC Agents, PUPM Agents, Report Agent, and UNAB Agents running on Endpoint to transfer messages to and from the Utility Appliance
8161	TCP/SSL	Browser	UA	Required only when debugging and diagnosing activemq message queues, if necessary. Otherwise, you can leave it closed.
9095	TCP/SSL	PAM	UA	Required for UNAB policy management and login integration.
7243	TCP/SSL	SC Agent	UA	Required for legacy v12.x PAM SC agents that require Report Agent and UNAB functionality

## Configure PAM to Communicate with Utility Appliances

Distribution Server software is now hosted on Utility Appliances, which are virtual machine instances that you download and deploy. This content describes how to configure PAM to communicate with Utility Appliances by creating corresponding devices and placing them in device groups.

### NOTE

For information about downloading and deploying Utility Appliances, see [Download and Deploy a New Utility Appliance](#).

- [Configure PAM Devices for Utility Appliances](#)
- [Add Utility Appliance Devices to Utility Groups](#)
- [Locate Utility Appliance Devices and Utility Groups](#)
- [Export and Import PAM SC Utility Appliance Devices and Device Groups](#)
- [Replace a Utility Appliance](#)

## Configure PAM Devices for Utility Appliances

### NOTE

#### Prerequisites:

- A PAM server that is licensed for Server Control
- At least one deployed and running Utility Appliance

To configure PAM to communicate with a Utility Appliance VM, create a corresponding Utility Appliance device. PAM then automatically creates and configures all the other objects that are required to enable integration of the Utility Appliance.

### NOTE

This procedure describes how to add Utility Appliance using the PAM UI. You can also add devices using the External API or by uploading an appropriately formatted CSV file.

#### Follow these steps:

1. Navigate to the **Devices, Manage Devices** screen.
2. Select **Add** to create a new device for your utility appliance.  
The **Add Device** dialog opens.

3. Complete the following fields on the **Basic Info** tab.
  - **Name:** Specify the Utility Appliance name to be displayed on the Access page. You can enter double-byte characters.
  - **Address:** Enter the IP address or FQDN of the Utility Appliance.
  - **Operating System:** Select **Utility Appliance**.
4. Select **OK**.
5. Wait while PAM completes configuration of the Utility Appliance, which can take several minutes.

**NOTE**

When configuration is complete, PAM rotates the Utility Appliance target account private and public keys. Both keys are then rotated every time that someone logs into the Utility Appliance.

**CAUTION**

Do not change any of the properties that PAM configures; doing so breaks the integration of the PAM server and the Utility Appliance.

- Device configuration fields and options:

**Basic Info** tab:

- **Device Type:** Sets the following options:
- **Access:** Designates the Utility Appliance as a potential endpoint for access management
- **Password Management:** Designates the Utility Appliance as a target device for credential management
- **A2A:** Sets this option to provide A2A credential management for the Utility Appliance:
  - **Description 1:** Describes the device (specifically *Utility\_Appliance*)
  - **Active:** Allows the A2A Client to receive credentials

**Access Method** tab: Adds the **SSH** access method and configures it for communication with the Utility Appliance

- A corresponding target application with the following properties:
  - **Host Name:** The IP address or FQDN of the Utility Appliance device
  - **Device Name:** The name of the Utility Appliance device
  - **Application Name:** "Utility Appliance Application"
  - **Application Type:** UNIX
- A corresponding target account with the following properties:
  - **Host Name:** The IP address or FQDN of the Utility Appliance device
  - **Device Name:** The name of the Utility Appliance device
  - **Application Name:** "Utility Appliance Application"
  - **Account Name:** "root"
  - **Password View Policy:** The UtilityAppliancePVP policy rotates the Utility Appliance credentials at the end of each connection.
  - **Protocol:** SSH-2 Public Key Authentication"
  - **Private Key:** A generated private key
  - **Public Key:** A generated public key

**TIP**

**Troubleshooting Tip:** If a message appears stating that the device was defaulted to a Linux OS Type, there was likely a communication error. Information can be found on the **Sessions Logs** screen.

## Add Utility Appliance Devices to Utility Groups

A Utility Group consists of a set of Utility Appliance devices that are associated together in a cluster. An end user can assign and deploy policies on:

- A single Utility Appliance device
- Different Utility Groups
- A combination of a Utility Appliance device and a Utility group

Note the following guidance:

- Each Utility Appliance can only be assigned to one Utility Group at any time.
- The Utility Appliances grouped in a Utility Group run orchestration software to coordinate with each other. As such, these Utility Appliances should be co-located within the same network region, firewalled area, or Datacenter.
- PAM is unable to determine the location of Utility Appliances in relation to each other. As a result, you must know and set up the information in PAM appropriately.

To create a Utility Group, add Utility Appliance devices to Utility Groups with a provision type of `Utility Group` to make them operational.

#### NOTE

Each Utility device can belong to only one Utility Group.

**To add Utility Appliance devices to Utility Groups, follow these steps:**

1. Navigate to **Devices, Manage Device Groups**.
2. Select **Add** to create a new device group for your Utility Appliances. The **Add Device Group** dialog opens.
3. Enter a name for the Utility Group in the **Name** field.
4. Select **Utility Group** from the **Provision Type** drop-down.
5. On the **Devices** tab, move the desired Utility Appliance devices from the **Available Devices** list to the **Selected Devices** column.
6. Select **OK**.

PAM creates a cluster from the Utility Appliances in a Utility Group, starting the Distribution Server software on the Utility Appliances, which then start communicating with PAM.

To verify that the operation was successful, navigate to **Credentials, Manage A2A, A2A Clients** and check the status indicator beside the listed Utility Appliances.

#### IMPORTANT

When updating a Utility Group, *do not* remove *all* current members and add a new member or members in a single update operation.

Instead, use multiple updates as shown in the following procedure:

1. Remove all members from the Utility Group and commit the change.
2. Add the required new members to the Utility Group and commit the change.

## Locate Utility Appliance Devices and Utility Groups

This content describes how to locate configured Utility Appliance Devices and Utility Groups in the PAM UI.

### Locate Utility Appliance Devices

Use this procedure to locate all configured Utility Appliance devices.

**Follow these steps:**

1. Navigate to the **Devices, Manage Devices** screen.
2. Open the **Column** drop-down and select **Operating System**.
3. Select the **Value** field. The **Select Operating System** dialog appears.
4. If any Utility Appliances exist, `Utility Appliance` appears in the **Available Operating System** column.
5. Move the `Utility Appliance` entry to the **Selected Operating System** column.

6. Select **OK**.
7. Select **Filter**.

### **Locate Utility Groups**

Use this procedure to locate all configured Utility Groups.

#### **Follow these steps:**

1. Navigate to the **Devices, Manage Device Groups** screen.
2. Open the **Column** drop-down and select **Provision Type**.
3. Select the **Value** field. The **Select Provision Type** dialog appears.
4. If any Utility Groups exist, *Utility Group* appears in the **Available Provision Type** column.
5. Move the *Utility Group* entry to the **Selected Provision Type** column.
6. Select **OK**.
7. Select **Filter**.

## **Export and Import PAM SC Utility Appliance Devices and Device Groups**

As a Privileged Access Manager administrator, you can export a list of Utility Appliance devices or Utility Appliance device groups in CSV format. These files can optionally be modified and later be imported, preventing the need to add the devices or groups individually.

### **IMPORTANT**

To use the Import/Export functions with Internet Explorer (IE), verify that the following security settings are configured:

1. Open Internet Explorer.
2. Select **Tools, Internet Options**.
3. In the Internet Options pop-up window, select the **Security** tab.
4. Select the slider zone
5. Select **Custom level**. Scroll to **Downloads**. For **File download**, select the **Enable** option.
6. Select **OK** to save changes.

### **Export Utility Appliance Devices to a CSV file**

Use this procedure to download a CSV list of all configured Utility Appliance devices.

#### **Follow these steps:**

1. Navigate to the **Devices, Manage Devices** screen.
2. Open the **Column** drop-down and select **Operating System**.
3. Select the **Value** field. The **Select Operating System** dialog appears.
4. If any Utility Appliances exist, *Utility Appliance* appears in the **Available Operating System** column.
5. Move the *Utility Appliance* entry to the **Selected Operating System** column.
6. Select **OK**.
7. Select **Filter**.
8. Select **Import/Export**.
9. On the **Import/Export** dialog that opens, select **Export Devices**. This exported file can optionally be used to make a revised version and then imported back into Privileged Access Manager.

### **Export Utility Appliance Device Groups to a CSV file**

Use this procedure to download a CSV list of all configured Utility Appliance device groups.

#### **Follow these steps:**

1. Navigate to the **Devices, Manage Device Groups** screen.
2. Open the **Column** drop-down and select **Provision Type**.
3. Select the **Value** field. The **Select Provision Type** dialog appears.
4. If any Utility Groups exist, **Utility Group** appears in the **Available Provision Type** column.
5. Move the **Utility Group** entry to the **Selected Provision Type** column.
6. Select **OK**.
7. Select **Filter**.
8. Select **Import/Export**.
9. On the **Import/Export** dialog that opens, select **Export Devices**. This exported file can optionally be used to make a revised version and then imported back into Privileged Access Manager.

### **Import Utility Appliance Devices or Utility Appliance Device Groups from a Previously Exported CSV file**

This procedure describes how to import Utility Appliance devices or device groups from an exported CSV file.

#### **Follow these steps:**

1. Go to **Devices, Manage Devices**.
2. Select **Import/Export**.  
The **Import/Export Devices** window appears.
3. In the **Import/Export Devices** window, select **Choose File** to select the file, and select **Import Devices**.  
The content of the file is added to the existing device database. The new content does not replace the current database.
4. Navigate to **Devices, Manage Devices**, and confirm that the import was successful by inspecting the device list.

### **Replace a Utility Appliance**

This content describes how to replace a Utility Appliance with another, for example, to move the Utility Appliance to a more powerful server.

#### **Follow these steps:**

1. Navigate to the **Devices, Manage Device Groups** screen.
2. Select the Utility Group that contains the Utility Appliance that you want to replace and select the **Update** button.
3. Remove the Utility Appliance from the Utility Group by moving it from the **Selected Devices** column to the **Available Devices** column.
4. Select **OK**.
5. Navigate to the **Devices, Manage Devices** screen.
6. Select the Utility Appliance that is being replaced and select the **Delete** button.
7. [Download and deploy a new Utility Appliance](#).
8. [Configure the new Utility Appliance device](#) with the same IP address as the one that you deleted.

#### **IMPORTANT**

Because Endpoints are registered to the Utility Appliance by IP address, it is important to assign the new Utility Appliance the same IP address as the old one that it is replacing.

9. [Add the new Utility Appliance to the Utility Group](#) from which you removed the old one.

## Deploy and Manage Utility Appliance Update Patches

Utility Appliance update patches provide updates for new PAM releases, periodic fixes, new functionality, or both. This content describes how to deploy and manage Utility Appliance update service patches from the PAM UI.

### IMPORTANT

You must apply the same patch versions to all the active Utility Appliances (that is, members of Utility Groups) in your environment.

### Deploy a Utility Appliance Service Patch

Use the following procedure to deploy a Utility Appliance patch to all active Utility Appliances.

#### Follow these steps:

1. Download the required patch archive (for example, `pam-utility-appliance-1.0.0.6.p.zip`) from [Broadcom Support](#) and extract its contents (a `.bin` and a `.sha256` file) to a local drive.

### IMPORTANT

Do not discard downloaded patch files. If you later add Utility Appliances to a new or existing Utility Group, these patch files are required to reupload and restage each patch (unless you must change the existing Patch Level).

2. Open the PAM UI and navigate to **Configuration, Utility, Patches, Utility Appliance Patches**.
3. On the **Available Patches** tab, select **Upload**.
4. On the dialog that opens, select **Choose File**, locate, and select the patch executable (`.bin`) file, and then select **Upload**.
5. Verify that the file information is correct and select **Save**.  
The patch is uploaded to the PAM server and the service updates that it contains are added to the list of patches that are available to stage.
6. Do the following steps for each listed Utility Appliance service patch.
  - a. Select the patch and select **Stage**.
  - b. On the dialog that opens, verify that the patch information is correct and select **Yes**.

### NOTE

Take a note of the name of each patch that you stage to identify which services to update in Step 7.

7. Select the **Patch Level** tab and do the following steps to update each service that you staged in Step 6:
  - a. Select the appropriate entry from the following list of displayed services and select **Update**.
    - `pam-dh`
    - `pam-loginintegration`
    - `pam-activemq`
    - `pam-config`
    - `pam-eventforwarder`
    - `reloader`
    - `pam-a2a`
    - `activemq-config`
    - `pam-policyorchestrator`
  - b. On the dialog that opens, select the new patch version from the drop-down box and select **OK**. The version number of the patch may be later or earlier than your existing version number.

### NOTE

If no patch is staged for this service, the drop-down box is empty, and you cannot continue.

The service is updated on each Utility Appliance in the Utility Group and the new patch version is displayed in the patch level list.

## **Delete a Utility Appliance Patch**

Use this procedure to delete a patch that has not yet been staged or deployed.

### **NOTE**

You cannot delete a patch that has been staged or deployed. However, you can change which patch is deployed to your Utility Appliance on the **Patch Level** tab.

### **Follow these steps:**

1. On the **Available Patches** tab, select the patch that you want to delete. You cannot delete a patch that has been staged or deployed. However, you can change which patch is deployed to your Utility Appliance on the **Patch Level** tab.
2. Select **Delete**. You can only delete a patch that has not yet been staged.  
Once the patch has been deleted, it is removed from the list on this tab.

## **View information About Deployed Patches**

Select the **Patch Activity** tab to view the following information about each deployed patch:

- **Service:** To which service the patch was deployed.
- **From Version:** The patch level before the current patch was deployed.
- **To Version:** The patch level after the current patch was deployed.
- **Start Time:** When the current patch was deployed.
- **User:** The system administrator that deployed the patch.
- **Notes:** Any additional information about the patch that is provided with the patch. This field may be blank if no information is included with the patch.

Select a service in the list and then select **View** to see the following detailed information about a deployed patch:

- **Utility Group:** The name of the utility group to which this service belongs.
- **Devices Complete:** The number of devices that are in the utility group and to which the update has been deployed.
- **Status:** The progress of the latest update.
- **Last Status Time:** When the utility group was last updated.
- **Notes:** Any additional information about the service update that is provided with the patch. This field may be blank if no information about the service update is included with the patch.

## **View Utility Group Status**

The Utility Group Status panel provides comprehensive status information about the Utility Appliances that are configured in Utility Groups in your environment.

### **Access the Utility Group Status Panel**

To access the Utility Group Status panel, navigate to **Configuration,Utility, Status** in the PAM UI.

The **Utility Group Status** panel lists all the Utility Groups in your environment. Select the **Name** or **Description** column headers to sort the list.

### **Obtain the Status of a Utility Group**

To obtain the status of a listed Utility Group, double-click that group or select the entry and select the **View** button in the top right-hand corner.

The **View Utility Group** dialog opens, displaying the **Devices** tab.

## View Utility Group Tab Descriptions

The **View Utility Group** dialog provides comprehensive information about the corresponding Utility Group in the following tabs:

### Basic Info Tab

Provides the Utility Group name and description

### Devices Tab

The **Devices** tab provides information about the status of each Utility Appliance in the Utility Group and the services running on it.

## View UG-45

**NOTE**

The services are [explained in a table](#) later in this topic.

The top row of the Devices tab provides controls that allow you to:

- Filter on a specific service name.
- Download a JSON file containing comprehensive information about the Utility Group and its members.
- Expand or collapse all entries in the table.
- Recycle all Utility Appliance services. Recycling a service kills it, forcing PAM SC to reschedule the service on the same or another host (depending on its configuration).

**NOTE**

Recycling can be useful when services do not start correctly, clearing the issue and allowing the services to start successfully.

Status Icons for **Devices** and **Service** tabs:

Each row in the following table provides status information and options for a Utility Appliance or a service running on a Utility Appliance.

Status Icon	Meaning for a Utility Appliance	Meaning for a Service
Green check mark	Utility Appliance is healthy to run services. No Disk, RAM, CPU pressure.	The service is deployed and running. (This status does not report the health of the service functionality – only that it is running.)
Yellow bell	N/A	Attempt to deploy the service on this Utility Appliance was made, but the service does not start.
Red stop sign	Utility Appliance is not reachable or not ready to run services on this device.	Either the Utility Appliance is unreachable (see the previous row) or the service cannot run for some other reason.

Functional Icons for **Devices** and **Service** tabs:

The following table describes the status and functional icons that appear beside each entry on the **Devices** and **Services** tabs:

Icon	Meaning
Information icon (  )	Returns detailed information about the associated Utility Appliance or service.
View service logs icon (  )	Returns the logfile for the associated service.
Recycle service icon (  )	Kills the service, forcing PAM SC to reschedule the service on the same or another host (depending on its configuration). Recycle can be useful when the service did not start correctly. Recycling can clear the issue and result in the service starting successfully.

**Services Tab**

The **Services** tab provides an alternative view of devices and services, grouping the list by service and showing the utility appliances on which each service is running.

(The Services tab uses the same status and functional icons as the Devices tab described previously.)

The following table describes all available services:

Service Name	Description	
pam-config	Sends the PAM configuration map to the Utility Group.	Changes when the
reloader	A utility within the Utility Group that watches for configuration changes. The reloader utility knows which other services to recycle when a specific configuration is changed.	Only one is needed per Appliance.
pam-a2a	Communicates with PAM to service Utility Appliance information that is stored when a Policy assigned or finalized.	One required for each

Service Name	Description	
pam-policy-orchestrator	Communicates between the Utility Appliance and PAM A2A. Facilitates device registration for Server Control, Login Integration, and UNAB.	One required for e
pam-dh	Allows Server Control endpoints to communicate with the DH for policy information.	One required for e
activemq-config	Configuration values that are used by ActiveMQ and other dependent services like eventforwarder.	Updates if the PA
pam-activemq	Endpoints connect to ActiveMQ for Login Integration, UNAB, and Event Forwarder.	One required for e
pam-eventforwarder	Syslog/Splunk consumer from ActiveMQ to an external server	If the PAM Syslog on each Utility Ap
pam-loginintegration	Service that listens for calls from PAM to process a login integration transaction	One required for e
pam-tibco	Service required to support the optional Tibco component (which is available as a patch that can be applied from <b>Configuration, Utility, Patches.</b> )	If the Tibco patch once per Utility Ap

### Config Map Tab

The **Config Map** tab displays the values of *Config Map* objects (key-value pairs) which determine the behavior of the Utility Appliances in the Utility Group.

## View pam.utilityappliance.group

### Basic Info Devices Services Config Maps

•			+	-	↺
Configuration	Key	Value			
- activemq-config	tibco-enabled	true			
	activemq-pwd-alias	activemq-pwd-alias1619098036			
	evenforwarder-enabled	true			
- pam-config	pamurl	10.17.45.16			
- syslog-config	syslog	syslog=TENANT;;TENANT=1;ENABLE=TRUE;FORMAT=AUDIT_FORMAT_CEF;TENANT_TYPE=AUDIT_SYSTE M_SIEM;HOST=10.17.47.16:6131			

### NOTE

The data on the Config Map tab is read-only. Select the links in the following descriptions for information about how to change the settings.

- **activemq-config**: Displays the following configuration information that is related to ActiveMQ and other dependent components in the utility group:
  - [Whether the Utility Group is TIBCO-enabled \(to support older PIM agents\)](#)
  - [ActiveMQ password changes](#)
  - [Whether the Event Forwarder is enabled](#)
- **pam-config**: [The VIP address of the cluster](#).
- **syslog-config**: [Syslog information](#) that is used by the Event Forwarder component (only displayed when eventforwarder is enabled).

#### NOTE

When the value of any Config Map object is updated, PAM recycles all services that use that value running on Utility Group members. Therefore, services on Utility Appliances always run with the latest configuration information.

## Migrate From PIM or PAM SC to PAM

This section describes the process of migrating from Privileged Identity Manager or Privileged Access Manager Server Control to Privileged Access Manager.

**Use the table of contents to access the topics in this section.**

### Migrate Policy Management Data

The procedures in this section describe how to migrate Policy Management Data.

**Use the table of contents to access the topics in this section.**

### Prepare to Migrate to PAM

This section contains the prerequisite steps and preparatory procedures for migration from PIM or PAM SC to PAM.

**Use the table of contents to access the topics that described these prerequisite steps and preparatory procedures.**

### Deployment Architecture Changes During Migration

This content illustrates how the architecture of a PIM or PAM SC deployment changes during the migration process. Review this content before starting your migration.

#### For PIM and PAM SC Deployments

This section illustrates how your deployment architecture changes during the migration process.

**Pre-migration:** Existing PIM or PAM SC logical deployment. PAM 4.0 is not yet deployed.

**Stage 1:** Deploy PAM 4.0 and Utility Appliances, but devices and endpoints are still managed by PIM or PAM SC.

**Stage 2:** Devices transition from management by the Distribution Server to management by the Utility Appliance.

### **For PAM-Only Deployments Adding Server Control Functionality**

If you currently only have a PAM deployment, you need only review the left side of Stage 3 and then complete the following procedures:

- Deploy Utility Appliances.
- Install Endpoint Agents on the devices.
- Configure the Endpoint Agents to point to a Utility Appliance.

### **Gather required information from the PIM or PAM SC ENTM Server**

This content describes how to gather required information from the PIM or PAM SC ENTM server.

#### **Follow these steps:**

1. Log on to the PIM or PAM SC ENTM server.
2. Take a note of policies, devices, device groups, deployments, and audit information.
3. Navigate to **Worldview, Hosts** and verify that at least two endpoints are configured against ENTM. Refer to the given environment details and provide proper search criteria in the Host Name.
4. Check the pre-migrated data like **hosts, policies, and host groups**

## Deploy or Upgrade an Existing PAM Deployment to 4.x

Deploy and configure a new 4.x PAM environment or upgrade an existing pre-4.0 PAM environment to PAM 4.0.

For more information, see the following resources:

- If you have no existing PAM environment, see [Deploying](#).
- If you have an existing pre-4.0 PAM environment, see [Upgrading](#).

## Migrate Data from PIM or PAM SC to PAM on Windows

Complete the following procedures to migrate your data from PIM or PAM SC to PAM on Windows.

### Prepare to Install the Migration Utility

1. Verify that you have PAM version 4.0 or later.
2. Log in to the PAM UI.
3. Complete the following steps to configure API keys for the user:
  - a. Select **Users, Manage Users**.
  - b. Select the Super User for which you want to enable the API keys and select **Update**.
  - c. On the **API Keys** tab, add an API key name.
  - d. Select **OK**.
4. Complete the following steps to configure API keys (password) for the user:
  - a. Select **Credentials, Manage Targets, Accounts**.
  - b. Select the API key name that you created in the previous step and select **Update**.
  - c. Set a password for the API key and select **OK**.
5. If your PIM or PAM SC environment includes UNAB policy data, do the following steps to configure and import groups and users from an LDAP server:
  - a. Do the following steps to configure a device and target application for the LDAP server:
    - a. Navigate to **Devices, Manage Devices** and select the **Add** button.
    - b. Provide the details of the LDAP server and verify that the **Password Management** device type option is set.
    - c. Select the **Save and Add Target Applications** button.
    - d. Enter an **Application Name** and select **Active Directory** from the **Application Type** drop-down menu.
    - e. Select the **Active Directory** tab that appears, provide the **Domain Name** and select the **OK** button to save your changes.
  - b. Do the following steps to create a target account to manage the Active Directory target application that you created:
    - a. Navigate to **Credentials, Manage Targets, Accounts**.
    - b. Select the **Add** button.
    - c. Enter the administrator **Account Name** and **Password**.
    - d. Enter or select the **Application Name** of the target application that you created. The **Host Name** and **Device Name** fields are populated and an **Active Directory** tab appears.
    - e. Select the **Active Directory** tab and enter the appropriate **Distinguished Name**. For example:  
CN=Administrator,CN=Users,DC=warriors,DC=com.
  - c. Navigate to **Configuration, 3rd Party, LDAP**, select the **Add** button, and enter the LDAP domain information.
  - d. Connect to PAM using the PAM client and import the groups and users (required for UNAB login policies).
6. Navigate to the PAM SC install location, C:\Program Files\CA\AccessControlServer\APMS\AccessControl\bin.
7. If you already have Server Control policies or device groups that are defined in PAM with the same names as policies or device groups that are defined in PIM/PAM SC, do one of the following steps to avoid migration errors:

- To retain the Server Control policies or device groups that are defined in PIM/PAM SC, delete the similarly named objects from PAM.
  - To retain existing Server Control policies or device groups that are defined in PAM, delete the similarly named objects from PIM/PAM.
8. Turn off access control on the PAM SC Server using the following command:
- ```
secons -s
```

### **Install the Migration Utility**

1. On the PAM SC server, locate and launch the Migration Utility installer, `MigrationUtility.exe`.
2. When the installer opens, follow the prompts:
  - a. On the **Choose Install Folder** panel, specify an install location.
  - b. On the **Pre Check Migration or Migration** panel do one of the following steps:
    - To perform end-to-end migration into PAM (Data Extraction, Validation, and Import data in to PAM), select **Migration**.
    - To perform only data extraction and validation to prepare the data for import in to PAM, select **Pre Check Migration**.
  - c. . On the **Launch Migration Utility** panel, select the **Launch Migration Utility** option if you want the installer to launch the Migration Utility directly after installation.
  - d. On the **Installation Complete** panel, select **Done**.

### **Run the Migration Utility**

This procedure describes how to run the migration utility to move your data from PIM/PAM SC to PAM.

#### **Follow these steps:**

1. If you set the **Launch Migration Utility** option during installation, the **PIM to PAM Migration Utility** starts. If not, navigate to `Migration_Installation_location/bin` and start **Migration.bat** to launch the utility manually. The utility opens at a home panel that displays all the steps that are involved in the migration process.
2. Specify the **DMS location**.  
The default values for PIM 12.8 and PIM 14 are:
  - Windows: `C:\Program Files\CA\AccessControlServer\APMS\AccessControl\Data\DMS`
  - UNIX: `/opt/CA/AccessControlServer/APMS/AccessControl/Data/DMS`
 The default values for PAM SC 14.0 and PAM SC 14.1 are:
  - Windows: `C:\Program Files\CA\PAMSCServer\APMS\PAMSC\Data\DMS`
  - UNIX: `/opt/CA/PAMSCServer/APMS/PAMSC/Data/DMS`
3. Specify a **Staging directory**, an empty folder where all the PIM/PAM SC data is extracted and stored for processing and validation.
4. Select the **Initialize** button to begin the extraction process. The utility sets up the staging location, and prepares for the data migration.
 

**NOTE**

If you have previously completed some migration on the provided staging location, the utility takes you directly to the phase where you stopped in the previous run. If you want to restart the migration from scratch, create a staging directory.
5. Select **Extract** to extract all the PIM or PAM SC data and deployment records from the ENTM DMS to the specified staging location.  
The live status of the records that are being extracted is shown in the utility.
6. When data extraction is successfully completed, select **Validate**.  
The utility scans all the PIM/PAM SC records, validating and creating relational mapping of the entities to be compatible with PAM. Validation progress is shown on the **Validate Data** page. If errors occur during migration that are

not an issue, select **Ignore Errors** and then select **OK** in the **Confirmation** dialog that appears. If errors that are an issue occur, see [Troubleshoot Orphaned Data, Records, and Validation Errors](#) for information about how to resolve them.

7. When validation is complete, select **Backup** to take a backup of the PAM server. Complete the following fields on the **PAM Server Details** dialog that appears and then select **OK**:

- **PAM Server Address**: The IP address of the PAM server to which the data is to be migrated.
- **API Key**: The complete API Key name that you set previously in these procedures.
- **API Password**: The API Key password that you set previously in these procedures.

**NOTE**

Make a note of the backup file name.

8. Select **Migrate** to initiate the data migration to the PAM server.

Migration progress is shown on the **Migrate Data** page.

During migration, you can take the following steps to verify that the migration is occurring correctly:

- Select **Pause** to verify the migrated data on the PAM Server. Select **Resume** to continue migration or select **Rollback** to restore the PAM database to the premigration state.
- Check the PAM environment in parallel to verify that the data (Devices, Device Groups, Policies, and Deployments) are loading correctly.

9. When the data migration to PAM is completed, select **Finalize** to commit the migration.

10. Select **Exit** to close the Migration Utility.

## **Postmigration Steps**

This procedure describes how to cut over from your existing PIM/PAM SC distribution server to a new Utility Appliance configured in PAM.

### **Follow these steps:**

1. Verify that the data (PIM/PAM SC Policies, Devices, Device Groups, Deployment Audit) is successfully migrated to PAM.
2. Check the **Agent Status** page to verify that the Uninitialized count should be equal to the number of migrated but not initialized devices.
3. Complete the following steps to re-configure PIM/PAM SC devices to communicate with the new PAM Utility Appliance:
  - a. Navigate to the PIM/PAM SC Access Control Server location. For example, `/opt/CA/AccessControlServer/APMS/AccessControl/bin/` or `/opt/CA/PAMSCServer/APMS/PAMSC/bin/`
  - b. Turn on access control on the PIM/PAM SC server.
  - c. Do the following steps to create a PIM/PAM SC policy:
    - a. Open the PIM/PAM SC ENTM user interface.
    - b. Navigate to **Policy Management, Policy, Create Policy**.
    - c. Enter the following commands to run a deployment script that creates a server control policy:
 

```
so dh-
so dh+(DH__@<UtilityServer>)
```
  - d. Assign the previously created policy on PIM/PAMSC devices that you want to configure to communicate with the new PAM Utility Appliance.
  - e. Restart the policyfetcher process on each endpoint (for immediate policy deployment) or wait for a scheduled job to restart the policyfetcher.
4. Complete the following steps to re-configure the PIM/PAM SC UNAB agent to communicate with the new PAM Utility Appliance:
  - a. Open the PIM/PAM SC ENTM user interface.
  - b. Navigate to **Policy Management, UNIX Authentication Broker, Host, Configure a UNAB Host**.
  - c. Select the UNAB device to configure.

- d. In the **Communication** section, select the token **Distribution\_Server** and set the following values:
  - ssl://<Utility Server name or ip address>:61616 for ActiveMQ based devices (for example, pamsc141)
  - ssl://<Utility Server name or ip address>:7243 for Tibco based devices (or example: PIM128)
- e. Submit the config policy.
- f. To configure a group of UNAB devices to work with the new Utility Server, you can choose **Configure a UNAB host group** under **Unix Authentication Broker**.
- g. Go to the UNAB device and set the message queue password:
 

```
<UNAB install dir>/bin/acuxchkey -t -pwd <Communication password of Utility Server>
```

All the PIM/PAM SC migrated devices are now pointed at a PAM Utility Appliance. You can now perform Policy Management activities using the PAM UI.

## Migrate Data from PIM or PAM SC to PAM on Linux

The following procedures describe how to migrate data from PIM or PAM SC to PAM on Linux:

### Prepare to Install the Migration Utility

**Complete the following steps on the PIM SC/PIM server to prepare for migration:**

1. Open a shell window.
2. Navigate to the Access Control Server location. For example, /opt/CA/AccessControlServer/APMS/AccessControl/bin/ or /opt/CA/PAMSCServer/APMS/PAMSC/bin/.
3. Turn off the access control PAM SC/PIM server by entering the following command: `./secons -sk`

**Complete the following steps on the PAM server to prepare for migration:**

1. Log in to the PAM UI.
2. Do the following steps to configure API keys for the user:
  - a. Verify that you are running version 4.0 or later.
  - b. Select **Users, Manage Users**.
  - c. Select the user for which you want to enable the API keys and select **Update**.
  - d. Navigate to the **API keys** tab and add an API key name.
3. Do the following steps to configure API keys (Password) for the user.
  - a. Click **Credentials, Manage Targets, Accounts** in the PAM UI.
  - b. Select the API key name that you created in the previous step, and click **Update**.
  - c. Set a password for the API key and select **OK**.
4. Verify that a Utility Server is installed and configured in PAM.
5. If your PIM or PAM SC environment includes UNAB policy data, do the following steps to configure and import groups and users from an LDAP server:
  - a. Do the following steps to configure a device and target application for the LDAP server:
    - a. Navigate to **Devices, Manage Devices** and select the **Add** button.
    - b. Provide the details of the LDAP server and verify that the **Password Management** device type option is set.
    - c. Select the **Save and Add Target Applications** button.
    - d. Enter an **Application Name** and select **Active Directory** from the **Application Type** drop-down menu.
    - e. Select the **Active Directory** tab that appears, provide the **Domain Name**, and select the **OK** button to save your changes.
  - b. Do the following steps to create a target account to manage the Active Directory target application that you created:
    - a. Navigate to **Credentials, Manage Targets, Accounts**.
    - b. Select the **Add** button.

- c. Enter the administrator **Account Name** and **Password**.
- d. Enter or select the **Application Name** of the target application that you created. The **Host Name** and **Device Name** fields are populated and an **Active Directory** tab appears.
- e. Select the **Active Directory** tab and enter the appropriate **Distinguished Name**. For example:  
CN=Administrator,CN=Users,DC=warriors,DC=com.
- c. Navigate to **Configuration, 3rd Party, LDAP**, select the **Add** button, and enter the LDAP domain information.
- d. Connect to PAM using the PAM client and import the groups and users (required for UNAB login policies).

## **Install the Migration Utility**

Complete the following steps to install the Migration Utility:

1. Open a shell window.
2. Navigate to the location where you downloaded the **MigrationUtility.bin** file.
3. Run the Migration Utility by entering the following command:  
./MigrationUtility.bin  
The Migration Utility installer starts.
4. Follow the prompts, entering the following information when prompted:
  - Enter **Y** to accept the License Agreement.
  - Specify the folder where you want to install the migration utility, then enter it again to confirm the folder.
  - Specify the installed location of the Access Control Server.
  - Enter **2** to install the utility in Migration mode.

The Migration Utility installs.

## **Run the Migration Utility**

Complete the following steps on the PAM SC/PIM server to run the migration utility and complete the migration:

1. Open a shell window.
2. Create a staging directory for all data processing and validation to take place. Create a different staging directory for each installation.  
For example:
  - /opt/CA/AccessControlServer/APMS/AccessControl/policies/DMS\_\_
  - /opt/CA/PAMSCServer/APMS/PAMSC/policies/DMS\_\_
3. Navigate to migration\_utility\_installation\_dir/bin
4. Type the following command to start the Migration Utility: ./Migration.sh  
The Migration Utility starts. The utility displays detailed metrics during each phase of the migration process.
5. Type `start` to initialize the migration process.
6. Verify the displayed Deployment Map Server (DMS) directory location and change it if necessary.
7. Specify the location of the Staging directory that you created earlier in these procedures.
8. Press **Enter**. The utility sets up the staging directory and prepares for data migration.
9. Type `extract` to extract all the PAM SC/PIM data and deployment records from the PAM SC/PIM Access Control Server to the Staging directory that you created earlier in these procedures.  
The live status of the records that are being extracted and the time that is taken are displayed. A progress bar indicates the percentage of records that have been extracted.  
If errors occur during extraction, see [Troubleshoot Orphaned Data, Records, and Validation Errors](#).
10. Upon successful completion of the extraction phase, type `validate` to start the validation phase of the migration process.

In the validation phase, the utility scans the PAM SC/PIM records, validates them, and creates relational mapping of the entities, to be compatible with PAM. A progress bar indicates the percentage of records being validated. If there are errors during Validation, see Validation Errors in [Troubleshoot Orphaned Data, Records, and Validation Errors](#).

- If you selected **Pre Check Migration** during installation of the Migration Utility, only extraction and validation are performed to check the health and readiness of PAMSC/PIM data for migration. No data is migrated. After validation, a success message of *The data is all set for migration to PAM* is displayed and you can quit the Migration Utility.
  - If you selected **Migration** during installation, then proceed with the following steps.
11. When validation is complete, select **Backup** to take a backup of the PAM server. Complete the following fields on the **PAM Server Details** dialog that appears and then select **OK**:
    - **PAM Server IP**: The IP address of the PAM server to which the data is to be migrated.
    - **API Key**: The complete API key name that you set previously in these procedures.
    - **API Password**: The API key password that you set previously in these procedures.

When complete, make a note of the backup filename for future use. The Migration Utility notifies you if PAM is unreachable or if incorrect API Key credentials are provided.
  12. Select **Migrate** to initiate the data migration to the PAM server.  
 Migration begins, and a progress bar indicates the percentage of records migrated.  
 During migration, you can take the following steps to verify that the migration is occurring correctly:
    - Select **Pause** to verify the migrated data on the PAM Server. Select **Resume** to continue migration or select **Rollback** to restore the PAM database to the premigration state.
    - Check the PAM environment in parallel to verify that the data (Devices, Device Groups, Policies, and Deployments) are loading correctly.

Errors, if any, are displayed on the console. See [Troubleshoot Orphaned Data, Records, and Validation Errors](#) for error details.
  13. When the data migration to PAM is completed, select **Finalize** to commit the migration.
  14. Select **Quit** to close the Migration Utility.

### Postmigration Steps

This procedure describes how to cut over from your existing PIM/PAM SC Distribution Server to a new Utility Appliance configured with PAM:

1. Navigate to the PIM/PAM SC Access Control Server location. For example, `/opt/CA/AccessControlServer/APMS/AccessControl/bin/` or `/opt/CA/PAMSCServer/APMS/PAMSC/bin/`.
2. Start access control on the PAM SC/PIM Server by doing the following steps:
  - a. Open two windows under root (superuser) authority.
  - b. In either window, enter the command:  
`seload`  
 Wait while the seload command starts three PIM or PAM SC daemons: Engine, Agent, and Watchdog.
  - c. After you have started the daemons, go to the other window and enter the command:  
`secons -t+ -tv`  
 PIM or PAM SC accumulates a file of messages reporting operating system events. The `secons -tv` command displays the messages on the screen as well.
  - d. In the first window, where you gave the seload command, enter the following command:  
`who`  
 Watch the second window, where PIM or PAM SC is writing the trace messages, to see whether it intercepts the execution of the who command and reports on it. PIM or PAM SC is correctly installed on your system if it reports interception of the who command.
  - e. If you want, enter more commands to see how PIM or PAM SC reacts to them.

The database does not yet contain any rules for blocking access attempts. Nevertheless, PIM or PAM SC monitors the system so that you can see how the system behaves with PIM or PAM SC installed and running, and which events it intercepts.

- f. Shut down the seosd daemon, by entering the following command:

```
secons -s
```

The following message displays on the screen:

```
CA ControlMinder is now DOWN !
```

3. Do the following steps to create a PIM/PAM SC policy:

- a. Open the PIM/PAM SC ENTM user interface.
- b. Navigate to **Policy Management, Policy, Create Policy**.
- c. Enter the following commands to run a deployment script that creates a server control policy:

```
so dh-
```

```
so dh+(DH__@<UtilityServer>)
```

4. Assign the previously created policy on PIM/PAMSC devices that you want to configure to communicate with the new PAM Utility Appliance.
5. Restart the policyfetcher process on each endpoint (for immediate policy deployment) or wait for a scheduled job to restart the policyfetcher.
6. Complete the following steps to re-configure the PIM/PAM SC UNAB agent to communicate with the new PAM Utility Appliance:
  - a. Open the PIM/PAM SC ENTM user interface.
  - b. Navigate to **Policy Management, UNIX Authentication Broker, Host, Configure a UNAB Host**.
  - c. Select the UNAB device to configure.
  - d. Select the **Communication** section, and then select the token "Distribution\_Server" and set the values as follows:
    - ssl://<Utility Server name or ip address>:61616 for ActiveMQ-based devices (for example, pamsc141)
    - ssl://<Utility Server name or ip address>:7243 for Tibco-based devices (for example, PIM128)
  - e. Submit the config policy.
  - f. To configure a group of UNAB devices to work with the new Utility Server, you can choose "Configure a UNAB host group" under Unix Authentication Broker.
  - g. Go to the UNAB device and set the message queue password:

```
<UNAB install dir>/bin/acuxchkey -t -pwd <Communication password of Utility Server>
```

All the PIM/PAM SC migrated devices are now pointed at a PAM Utility Appliance. You can now perform Policy Management activities using the PAM UI.

## How to Change the Migration Utility Timeout Value

By default, the Migration Utility timeout value is set to 120 seconds. You can configure the timeout timeout. For example, to set the timeout to 300 seconds, add the timeout attribute **--http.readtimeout=300** in the corresponding migration batch (for Windows) or sh (for Linux) file. Use the procedure that fits your system:

### Windows

Follow these steps to change the Migration Utility timeout value on Windows systems:

1. Browse to the following location: **<Migration Utility Install Folder>\bin**
2. Open the **Migration.bat** file at this location.
3. Add the timeout attribute to the **JAVA\_EXE** variable, as demonstrated in the following before and after sample:

**Before Modification:**

```
%JAVA_EXE% %JAVA_OPTS% -jar DataProcessor-0.1-SNAPSHOT.jar --install.dir="C:\Program Files
\MigrationUtility" --customer.validation=false --apms.home="C:\Program Files\CA\PAMSCServer\APMS\PAMSC"
%MU_OPTS%
```

#### After Modification:

```
%JAVA_EXE% %JAVA_OPTS% -jar DataProcessor-0.1-SNAPSHOT.jar --install.dir="C:\Program Files
\MigrationUtility" --customer.validation=false --http.readtimeout=300 --apms.home="C:\Program Files\CA
\PAMSCServer\APMS\PAMSC" %MU_OPTS%
```

4. After modifying the **Migration.bat** file, re-run the utility.

## Linux

Follow these steps to change the Migration Utility timeout value on Linux systems:

1. Browse to the following location: **<Migration Utility Install Folder>\bin**
2. Open the **Migration.sh** file at this location.
3. Add the timeout attribute to the **JAVA\_EXE** variable, as demonstrated in the following before and after sample:

#### Before Modification:

```
"$JAVA_EXE" $JAVA_OPTS -jar DataProcessor-0.1-SNAPSHOT.jar --install.dir="/root/MigrationUtility" --
customer.validation=false --apms.home="/opt/CA/PAMSCServer/APMS/PAMSC" $MU_OPTS
```

#### After Modification:

```
"$JAVA_EXE" $JAVA_OPTS -jar DataProcessor-0.1-SNAPSHOT.jar --install.dir="/root/MigrationUtility" --
customer.validation=false --http.readtimeout=300 --apms.home="/opt/CA/PAMSCServer/APMS/PAMSC" $MU_OPTS
```

4. After modifying the **Migration.sh** file, re-run the utility.

## How to Configure the Migration Utility to Work with a Copy of DMS Data

How to configure the Migration Utility to work with a copy of DMS data.

Normally, working with live DMS (Devices, Device Groups, Policies, and Deployments) data requires you to shut down the Access Control Services, which might bring down your production environment for a period of time. However, you can create a process to regularly maintain a *copy* of DMS data so you do not need to shut down the Access Control Services.

This topic shows you how to perform these steps for Windows and Linux.

### How to Configure the Migration Utility to Work with a Copy of DMS Data on Windows

1. Browse to the following location: **<Migration Utility Install Folder>\bin**
2. Open the **Migration.bat** file and update the **CHECK\_AC\_SERVICES** value to **false**, as demonstrated in the following before and after sample:

#### Before Modification:

```
set CHECK_AC_SERVICES=true
set "MU_OPTS=--check.ac.services=%CHECK_AC_SERVICES%"
```

#### After Modification:

```
set CHECK_AC_SERVICES=false
set "MU_OPTS=--check.ac.services=%CHECK_AC_SERVICES%"
```

**NOTE**

If CHECK\_AC\_SERVICES is set to false, then you must also copy the **seos.msg** file. For example: if you have copied DMS\_\_ folder to the C:\backup folder, then you need to copy the seos.msg file **from** C:\Program Files\CA\PAMSCServer\APMS\PAMSC\Data or C:\Program Files\CA\AccessControlServer\APMS\AccessControl\Data **to** c:\backup\DMS\_\_ folder.

3. After modifying the migration batch file, re-run the utility.
4. When prompted for the DMS location, provide the backup folder, that is, either **C:\backup\DMS\_\_** or **/work/backup/DMS\_\_**.

**How to Configure the Migration Utility to Work with a Copy of DMS Data on Linux**

1. Browse to to the following location: **<Migration Utility Install Folder>\bin**
2. Open the **Migration.sh** file and update the **CHECK\_AC\_SERVICES** value to **false**, as demonstrated in the following before and after sample:

**Before Modification:**

```
CHECK_AC_SERVICES=true
MU_OPTS="--xref href="http://check.ac/">check.ac.services=$CHECK_AC_SERVICES"
```

**After Modification:**

```
CHECK_AC_SERVICES=false
MU_OPTS="--xref href="http://check.ac/">check.ac.services=$CHECK_AC_SERVICES"
```

**NOTE**

If CHECK\_AC\_SERVICES is set to false, then you must also copy the **seos.msg** file. For example: if you have copied DMS\_\_ folder to the /work/backup folder, then you need to copy the seos.msg file **from** either /opt/CA/PAMSCServer/APMS/PAMSC/data **or** /opt/CA/AccessControlServer/APMS/AccessControl/data **to** /work/backup/DMS\_\_ folder.

3. After modifying the migration sh file, re-run the utility.
4. When prompted for the DMS location, provide the backup folder, that is, either **C:\backup\DMS\_\_** or **/work/backup/DMS\_\_**.

**View Server Control Endpoint Agent Status on the Device Agent Status Screen**

Select **Devices**, **Device Agent Status** to access the Device Agent Status screen, which shows the status, version, and other information about PAM SC Endpoint Agents of all types:

- Server Control Agents
- UNAB Agents
- PUPM Agents

The following screen shot shows an example **Device Agent Status** screen, which contains the following two panels:

- **Device Agent Summary**
- **Device Agent Status**

Dashboard
Access
Sessions
Users
Services
Devices
Credentials
Policies
Settings
Configuration

### Device Agent Summary

## Device Agent Summary Section Details

The Device Agent Summary section summarizes counts and status of all Server Control, UNAB, and PUPM agents on endpoint devices.

There are three possible agent statuses, represented by respective boxes:

- **Active:** The agent is active; PAM received the agent heartbeat within the warning status interval.
- **Warning:** PAM has not received the agent heartbeat within the warning status interval.
- **Inactive:** PAM has not received the agent heartbeat within the failure status interval.

### NOTE

The **Uninitialized** box displays agents on devices that are not yet registered or configured with PAM. This state occurs for migrated devices and server control devices that are imported from a CSV file using the Import/Export option.

To filter the agents that are displayed in the **Device Agent Summary** section by type or status, select the corresponding box.

For example, if you select the **Active** box under the **UNAB** box, only UNAB Agents that are in the Active state are listed in the **Device Agent Status** section.

## Device Agent Status Section Details

The Device Agent Status section shows the following status information about agents on endpoint devices:

- **Name:** The hostname of the system on which the agent is installed.
- **Address:** The IP address of the system on which the agent is installed.
- **Operating System:** The operating system of the system on which the agent is installed.
- **Server Control Agent Version:** The status and version of the Server Control Agent, if applicable
- **UNAB Agent Version:** The status and version of the UNAB Agent, if applicable
- **PUPM Agent Version:** The status and version of the PUPM Agent Version, if applicable

Agent status is indicated by the colored icon beside each agent version entry:

- **Green:** The agent is active; PAM received the agent heartbeat within the warning status interval.
- **Yellow:** PAM has not received the agent heartbeat within the warning status interval.
- **Red:** PAM has not received the agent heartbeat within the failure status interval.
- **N/A:** The agent has not been registered with PAM. This state occurs when devices have been migrated from PIM or PAM SC.

Click **Export** to download the status information for all the listed agents (as constrained by any configured filters, if applicable) as a comma-separated value (CSV) file.

### How Agent Status Changes and Agent-Related Actions Are Reflected

The following table shows how agent status changes and agent-related actions are reflected on the **Device Agent Status** screen.

| Agent Status or Agent-related Action                                                                                                                                 | What to expect on the Device Agent Summary screen                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Configure an access control endpoint.                                                                                                                                | Server Control Agent Status: Active<br>The AC Version, OS, and address details are updated.                                                                                                                  |
| PAM does not receive the next heart beat within the <b>Warning Status Interval</b>                                                                                   | Server Control Agent Status: <b>Warning</b> is updated.                                                                                                                                                      |
| PAM does not receive the next heart beat within the <b>Failure Status Interval</b>                                                                                   | Server Control Agent Status: <b>Inactive</b> is updated.                                                                                                                                                     |
| Migrate an access control endpoint from PIM or PAM SC to PAM.                                                                                                        | Status of Server Control Agent: N/A<br>The Server Control Agent Version, OS, and address are updated.<br>Status and version of PUPM and UNAB are empty.                                                      |
| Delete a <code>pamsc</code> device (in both the UI and in the Device API).                                                                                           | The record related to the device is removed.                                                                                                                                                                 |
| Double-click or select a row in the Agent Status table.                                                                                                              | A dialog opens with the Agent status details.                                                                                                                                                                |
| Configure an access control endpoint to multiple Utility Appliances (UA1 and UA2). Simulate a failover of the UA and check for the details in Agent Status.          | The Agent Status details (Model Window) show the UA info as UA1 as long as UA1 is up and running. When the UA1 goes down and the endpoint is working with UA2, the Agent Status details show UA info as UA2. |
| Change the Utility Appliance configuration from UA1 to UA2, and check for UA info in Agent Status.                                                                   | The UA info shows UA1 initially and then changes to UA2.                                                                                                                                                     |
| Activate the PUPM Agent on an access control endpoint, and configure Utility Appliance in <code>accommon.ini</code> .                                                | The PUPM Agent Status: Active<br>The version, OS, and address are updated. The Utility Appliance Info updates in the Model Window.                                                                           |
| PAM does not receive the next PUPM Agent heartbeat within the <b>Warning Status Interval</b> .                                                                       | PUPM Agent Status updates to <b>Warning</b> .                                                                                                                                                                |
| PAM does not receive the next PUPM Agent heartbeat within the <b>Failure Status Interval</b> .                                                                       | PUPM Agent Status updates to <b>Inactive</b> .                                                                                                                                                               |
| Change the Utility Appliance Configuration from UA1 to UA2 on the endpoint.                                                                                          | The UA info in the model window changes from UA1 to UA2.                                                                                                                                                     |
| Activate a PUPM Agent on the 128 access control endpoint, and configure a Utility Appliance in <code>accommon.ini</code> . Activation requires a TIBCO bridge in UA. | The PUPM Agent Status: Active<br>The version, address, and OS are updated. The Utility Appliance Info is also updated in the Model Window.                                                                   |
| Deploy a Utility Appliance and configure it in PAM.                                                                                                                  | The device details updates in the Agent Status and Model Window.                                                                                                                                             |

## **PAM SC Agent Summary Details**

The following table provides specific information for the different PAM SC Agent types.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Server Control Agent | <p>The total number of agents includes Active, Warning, Inactive, and Uninitialized (Migrated) agents:</p> <ul style="list-style-type: none"> <li>• SC Agent Active count should match the data in the Agent status details table.</li> <li>• SC Agent Warning count should match the data in the Agent status details table.</li> <li>• SC Agent Inactive count should match the data in the Agent status details table.</li> </ul>                         |
| UNAB Agent           | <p>The total number of agents includes Active, Warning, and Inactive agents:</p> <ul style="list-style-type: none"> <li>• UNAB Agent Active count should match the data in the Agent status details table.</li> <li>• UNAB Agent Warning count should match the data in the Agent status details table.</li> <li>• UNAB Agent Inactive count should match the data in the Agent status details table.</li> </ul>                                             |
| PUPM Agent           | <p>The total number of agents includes Active, Warning, and Inactive agents:</p> <ul style="list-style-type: none"> <li>• PUPM Agent Active count should match the data in the Agent status details table.</li> <li>• PUPM Agent Warning count should match the data in the Agent status details table.</li> <li>• PUPM Agent Inactive count should match the data in the Agent status details table.</li> </ul>                                             |
| Uninitialized        | <ul style="list-style-type: none"> <li>• Count should be equal to the number of migrated and imported devices, but should not include initialized devices.</li> <li>• The Uninitialized section should not be displayed in the summary when the count is 0.</li> <li>• Migrated devices count should match the data in the Agent status details table.</li> <li>• Imported devices count should match the data in the Agent status details table.</li> </ul> |

## **UNAB Agent Summary Details**

The following table provides specific information for UNAB Agents.

|                                                                                      |                                                                                                                     |
|--------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| UNAB Agent Status                                                                    | <p>UNAB Agent Status: Active,<br/>The AC Version, OS, and Address details are updated.</p> <p><b>Figure 36:</b></p> |
| PAM does not receive the next heart beat within the <b>Warning Status Interval</b> . | <p>UNAB Agent Status: <b>Warning</b> is updated.</p> <p><b>Figure 37:</b></p>                                       |
| PAM does not receive the next heart beat within the <b>Failure Status Interval</b> . | <p>UNAB Agent Status: <b>Inactive</b> is updated.</p>                                                               |

## **Post Migration Steps**

This content describes procedures that are required after completing migration.

1. Navigate to Access Control Server location:
  - For 12.x.x: /opt/CA/AccessControlServer/APMS/AccessControl/bin/
  - For 14.x.x: /opt/CA/PAMSCServer/APMS/PAMSC/bin/
2. Turn on the access control on the PIM Server and start the PAM SC endpoint services by using the appropriate command:
  - For Windows, enter:
 

```
seosd -start
```
  - For Linux, enter:
 

```
seosd
```
3. Move the PIM Access Control Devices to One PAM:

- Log in to the PIM ENTM.
  - Click on **Policy Management, Policy, Policy, Create Policy**.
  - Enter a Policy Name, such as MigrationPolicy854.
  - Provide the deployment script by clicking the **Policy Script** tab and entering the following:
 

```
So dh-
So dh+ (DH__@<One PAM DS>)
```
  - Click **Submit** to save changes.
4. Click on **Policy Management, Policy, Assignment**.
  5. Check the Agent status summary page:
    - Server Control Agent Status should show Active in the summary.
    - AC Version, OS, and Address details should be updated in the Status table.
    - If PAM does not receive the next heart beat for more than "Warning Status Interval," the Server Control Agent Status shows **Warning** and the count is updated in the summary.
    - If PAM does not receive the next heart beat for more than "Failure Status Interval," the Server Control Agent Status shows **Inactive** and the count is updated in the summary.
  6. Under **Policy Selection**, select the policy that you created when you moved the PIM Access Control Devices to One PAM in an earlier step.
  7. Select the Policy and click **Next**.
  8. Move the Server Control Devices to One PAM:
    - Under **Host Selection**, click **Add** and select the Server Control Devices that you would like to move to One PAM.
    - Select the Hosts and click **Next**.
    - Click on **Finish** to assign the Policy to the hosts.
  9. For testing purposes, restart the policyfetcher on the endpoint. Policyfetcher pulls the policy from the DH and executes it.
  10. Verify both the endpoints are configured against the PAM 4.0 DH by navigating to `selang` and running `so list`.
  11. Restart the policyfetcher on the endpoints so that it sends a heartbeat to PAM.
  12. Log in to PAM and verify that both endpoints are shown in the Device list.
  13. Now that you can manage the endpoints from PAM, deploy a policy on the migrated endpoints. For example:
 

Policy Name: PostMigrationPolicy

Policy Script: eu PostMigrationUser

    - To deploy a policy on demand, **restart** the policyfetcher on the endpoints so that the policy gets deployed faster.
    - Verify the policy that is deployed on the endpoint and the ACL is executed by navigating to `selang` and running `f user`. In this example, you should see the user PostMigrationUser.

## Extract PIM Shared Account Management (SAM) Data

When migrating from PIM to PAM, use the SAM Data Extraction utility to extract Shared Account Management (SAM) data from the Enterprise Manager (ENTM) database. The utility extracts the SAM data (such as Passwords, Endpoints, Accounts, Policies, etc.) into JSON files that you can import into PAM.

The utility supports releases PIM versions 12.8.x, 12.9.x, and 14.x.

### Download the SAM Data Extraction Utility

Download the SAM Data Extraction Utility from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

## **Install the SAM Data Extraction Utility**

### **NOTE**

Install the utility on the ENTM server or any other server that can communicate with the ENTM database.

The software contains two installer files:

- **SAMDataExtraction.bin** for Linux systems
- **SAMDataExtraction.exe** for Windows

### **To install on Linux, follow these steps:**

1. Copy the Utility ISO to the Linux server.
2. Mount the ISO using the following command:  

```
mount -o loop SAMDataExtraction-4.1.0.iso MountLocation
```
3. Navigate to *MountLocation* and locate the installer file named **SAMDataExtraction.bin**.
4. Run the bin file:  

```
./SAMDataExtraction.bin -i console
```
5. Accept the license agreement that appears.
6. Choose the install folder to determine where to install the utility.
7. Choose the database type to determine the type of ENTM database.
8. Provide the database connection details, and then proceed with the installation.

The SAM Data Extraction Utility installation should complete successfully.

### **To install on Windows, follow these steps:**

1. Copy the Utility ISO to the Windows server.
2. Mount the ISO.
3. In the *MountLocation*, locate the **SAMDataExtraction.exe** application and launch it.
4. Follow the prompts and accept the license agreement.
5. Choose the install folder to determine where to install the utility.
6. Choose the database type to determine the type of ENTM database.
7. Provide the database connection details, and then proceed with the installation.

The SAM Data Extraction Utility installation should complete successfully.

## **Run the SAM Data Extraction Utility**

Use the following procedure to run the SAM Extraction utility.

### **Follow these steps:**

1. Navigate to the utility installation location.
2. Navigate to the **bin** folder.
3. Open the **application.properties** file in a text editor and update it, as follows:
  - (Optional) Disable unnecessary modules: All the modules are set to **true** by default. Set the flag to **false** for the modules that you do not want to extract. The default configuration appears as follows:

```
job.enable.account_password=true
job.enable.account_password_history=true
job.enable.endpoint=true
job.enable.fwpasswordpolicy=true
job.enable.ppmpasswordpolicy=true
job.enable.users=true
job.enable.groups=true
```

```
job.enable.admin_roles=true
job.enable.privileged_access_roles=true
job.enable.eventforwarder=true
job.enable.ui_settings=true
job.enable.scheduling_config=true
job.enable.password_consumer=true
job.enable.tasks=true
```

4. Set the token ***decrypt.password*** based on the requirement. The default value is **false**. A **false** value means that the extracted passwords will be in encrypted as they are present in the PIM database.

To see the extracted passwords in plain text, set the ***decrypt.password*** token to **true**; If set to **true**, the utility requires the `FIPSSkey.dat` file to decrypt the passwords to plain text: copy the `FIPSSkey.dat` file from the ENTM server, and then place it in the utility `bin` folder. The `FIPSSkey.dat` file is located here on the ENTM server:

```
Jboss_folder\server\default\deploy\IdentityMinder.ear\config\com\netegrity\config\keys
```

5. Depending on your operating system, go to the `bin` folder and then run either `Extraction.bat` (for Windows) or `Extraction.sh` (for Linux).
6. Once the file execution completes, you can find all the extracted SAM data in the `<utility installation location>\output` folder. The output files are in JSON format.

#### NOTE

When you run the extraction utility for the second time, it archives the existing output files to a folder with a time stamp, and then it creates JSON files in the output folder.

The follow screen capture shows an output sample for your reference.

This PC > Local Disk (C:) > sam437 > output

| Name                   | Date modified     | Type        |
|------------------------|-------------------|-------------|
| 2022-01-11050149       | 1/11/2022 5:01 AM | File folder |
| 2022-01-11050232       | 1/11/2022 5:02 AM | File folder |
| AccountPassword        | 1/11/2022 5:02 AM | JSON File   |
| AccountPasswordHistory | 1/11/2022 5:02 AM | JSON File   |
| AdminRoles             | 1/11/2022 5:02 AM | JSON File   |
| EndPoint               | 1/11/2022 5:02 AM | JSON File   |
| FWPasswordPolicy       | 1/11/2022 5:02 AM | JSON File   |
| Groups                 | 1/11/2022 5:02 AM | JSON File   |
| PasswordConsumers      | 1/11/2022 5:02 AM | JSON File   |
| PPMPasswordPolicy      | 1/11/2022 5:02 AM | JSON File   |
| PrivilegedAccessRoles  | 1/11/2022 5:03 AM | JSON File   |
| RemoteSyslog           | 1/11/2022 5:02 AM | JSON File   |
| SchedulingConfig       | 1/11/2022 5:03 AM | JSON File   |
| UiSettings             | 1/11/2022 5:03 AM | JSON File   |
| Users                  | 1/11/2022 5:18 AM | JSON File   |

### **Encryption Utility**

When first installed, the SAM data extraction utility takes the ENTM database connection information, and then encrypts and stores the credentials in the `application.properties` file. The utility uses these credentials to connect to the database every time the user runs the utility to extract data.

If the database credentials change after the initial installation, the utility fails to make a connection and cannot extract data. If this extraction failure happens, you can encrypt the new password and can update it in the `application.properties` file using this two-part process:

- [Generate the encrypted format of the new database password](#)
- [Update the new database password in the `application.properties` file](#)

### **Generate the Encrypted Format of the New Database Password**

1. Navigate to `SAM_data_extraction_utility_install_location\utility`.
2. Depending on the operating system, locate either `Encryption.bat` (Windows) or `Encryption.sh` (Linux).

3. Run the Encryption file with the new password as an argument to generate the encrypted format of the new password. For example:

```
# ./Encryption.sh Notallowed
----ENVIRONMENT-----
Runtime: AdoptOpenJDK OpenJDK 64-Bit Server VM 11.0.10+9
----ARGUMENTS-----
input: Notallowed
password: supersecretz
algorithm: PBKWithMD5AndDES
----OUTPUT-----
lztZ6F9dq4Nve561o9PZ1IVz0duETrZY
```

The encrypted format of the new database password is **lztZ6F9dq4Nve561o9PZ1IVz0duETrZY**.

### **Update the New Database Password in the application.properties File**

1. Navigate to `SAM_data_extraction_utility_install_location\bin` and locate the `application.properties` file.
2. Update the key **spring.datasource.password** with the new database password (encrypted format generated previously). The password key value should be in the format **ENC(<new password>)**. For example

```
#####
Database Properties
#####
spring.datasource.url=jdbc:sqlserver://10.131.59.203:1433;DatabaseName=pim14latest
spring.datasource.username=pim14latest spring.datasource.password=ENC(lztZ6F9dq4Nve561o9PZ1IVz0duETrZY)
spring.datasource.driverClassName=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

## **Upgrade and Migrate PIM and PAM SC Endpoints**

This section describes how to upgrade and migrate the PIM and PAM SC endpoints.

Use the [table of contents](#) to access the topics in this section.

### **Upgrade a Windows Endpoint**

This article provides information about how to upgrade a Windows Endpoint.

#### **Upgrade Using Graphical User Interface**

Use the Product Explorer to upgrade a Windows endpoint. The Product Explorer uses a graphical interface to upgrade an endpoint and provides interactive feedback. The Product Explorer also lets you select among different architecture installations of the product and install the Runtime SDK.

#### **Follow these steps:**

1. Log in to the Windows system as a user with Windows administrative privileges. That is, as the Windows administrator or a member of the Windows Administrators group.
2. Close any applications that are running on the Windows system.
3. Download the Privileged Access Manager Windows Endpoint from the "Endpoints for PAM 4.0" section on [this page](#) on the Broadcom Support site.
4. Mount the ISO. If autorun is enabled, then the Product Explorer automatically appears. Otherwise, navigate to the mounted drive and double-click the `PRODUCTEXPLORERX86.EXE`.

- From the Product Explorer main menu, expand the **Components** folder, select Privileged Access Manager for Windows (*my\_architecture*), then click **Install**.

**NOTE**

The installation option that matches the architecture of the computer indicates an existing installation of endpoint.

A dialog appears asking if you want to perform an upgrade of the endpoint.

- Click **Yes**.
- The InstallShield wizard starts the installation program.
- When the endpoint upgrade is complete, restart the Windows system.

**Upgrade Silently**

To upgrade an endpoint without interactive feedback, upgrade the product silently using the command line.

**Follow these steps:**

- Log in to the Windows system as a user with Windows administrative privileges. That is, as the Windows administrator or a member of the Windows Administrators group.
- Close any applications that are running on the Windows system.
- Download the Privileged Access Manager Windows Endpoint ISO from the "Endpoints for PAM 4.0" section on [this page](#) on the Broadcom Support site.
- Mount the ISO. If you have autorun enabled, the Privileged Access Manager Product Explorer appears.
- Close the Product Explorer if it appears.
- Open a command line and navigate to the following directory on the optical disc drive:

```
\architecture
```

– *architecture*

Defines the architecture abbreviation for the operating system.

**Values:** x64

- Enter the following command:

```
setup /s /v"/qn COMMAND=<keyword> /L*v <Drive>:\<Log_File>.log
```

**NOTE**

To execute a silent installation, accept the license agreement. The *keyword* that is required to accept the license agreement and silently upgrade the endpoint is found at the bottom of the license agreement available when running the installation program.

**Post-Upgrade Task**

Post-upgrade, ensure that you change the value of the **Distribution\_Server** registry entry to the URL of the ActiveMQ Message Queue server. You can find the **Distribution\_Server** registry entry at HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Common\communication.

**Upgrade an AIX Endpoint**

This article provides information about how to upgrade an AIX endpoint.

## Upgrade Using Native Packages

AIX native packaging is a set of GUI and command-line utilities that let you manage individual software packages. With native packages, manage an endpoint installation with the other software installations that are performed using the AIX `installp`.

### NOTE

Privileged Access Manager supports the AIX native package format (`installp`) only.

Follow these steps to upgrade an endpoint using native packages:

1. [Preliminary Steps](#)
2. [Customize the bff Native Package](#)
3. [Upgrade AIX Native Packages](#)

### Preliminary Steps

Before you upgrade an endpoint, perform the following preliminary steps:

1. Download the Privileged Access Manager Endpoint Components for UNIX ISO.
2. Mount the ISO.
3. Navigate to the `NativePackages` directory in the mounted drive, and copy the following installation files to a temporary directory (`pkg_location`) with read/write permission. Example: `/tmp`. Ensure that the temporary directory does not contain any spaces.
  - `_AIX5_PKG_<Version>.tar.z`
  - `customize_eac_bff`
  - `pre.tar`
  - `parameters.tar`

```
cp /<mounted_location>/NativePackages/_AIX5_PKG_<Version>.tar.Z pkg_location
cp /<mounted_location>/NativePackages/pre.tar pkg_location
cp /<mounted_location>/NativePackages/customize_eac_bff pkg_location
cp /<mounted_location>/NativePackages/parameters.tar pkg_location
```
4. Untar `_AIX5_PKG_<Version>.tar.z`. When you untar, the `CAeAC` file is added to the temporary native package directory.
 

```
cd pkg_location
zcat _AIX5_PKG_<Version>.tar.Z | tar xvf -
```

### Customize the bff Native Package

Customize `customize_eac_bff` to accept the license agreement.

You can also specify custom installation settings when you customize a package. To customize a package, extract the installation parameters file from the package, modify as required, and load it back into the package. Some commands are available in the customization script so that you do not have to modify the parameters file.

### NOTE

Do not modify the package manually. Instead, use the script as described in the following procedure to customize the package.

### Follow these steps:

1. Log in as root.
2. Ensure that you have copied the `customize_eac_bff` script file and the `pre.tar` file to a temporary location on the file system.

### WARNING

The disk space must be at least twice the size of the package to hold temporary repackaging files.

## 3. Display the license agreement:

```
customize_eac_bff -a [-d pkg_location] CAeAC
```

Note the keyword that appears at the end of the license agreement inside a square bracket. Specify this keyword in the next step.

## 4. Customize the package to accept the license agreement:

```
customize_eac_bff -w <keyword> -i <install_location> -d [pkg_location] CAeAC*.bff
```

## 5. (Optional) Set the installation parameters file language:

```
customize_eac_bff -r -l lang [-d pkg_location] CAeAC
```

## 6. (Optional) Change the installation directory:

```
customize_eac_bff -i install_location [-d pkg_location] CAeAC
```

**NOTE**

To set up the package for installation into WPARs (Workload Partitions), change the installation location to an unshared file system using the -i option. By default, /opt and /usr are shared file systems and cannot be used for the WPAR product installations.

## 7. (Optional) Change the default encryption files:

```
customize_eac_bff -s -c certfile -k keyfile [-d pkg_location] CAeAC
```

## 8. Get the installation parameters file:

```
customize_eac_bff -g -f tmp_params [-d pkg_location] CAeAC
```

## 9. (Optional) Edit the installation parameters file to suit your installation requirements.

This file lets you set the installation defaults for the package. For example, activate the POSTEXIT setting (remove the preceding # character) and point it to the post-installation script file you want to run.

## 10. (Optional) Set the installation parameters in the customized package:

```
customize_eac_bff -s -f tmp_params [-d pkg_location] CAeAC
```

You can now use the customized package (CAeAC ) to upgrade an endpoint.

**Command: customize\_eac\_bff**

The `customize_eac_bff` command runs the native package customization script for the `bff` native package files. The script works on any available native packages for AIX. To customize a package, the package must be in a read/write directory on the file system.

**NOTE**

For localized script messages, have `pre.tar` file in the same directory as the script file.

This command has the following format:

```
customize_eac_bff -h [-l lang]
customize_eac_bff -a [-d pkg_location] pkg_name
customize_eac_bff -w keyword [-d pkg_location] pkg_name
customize_eac_bff -r [-d pkg_location] [-l lang] pkg_name
customize_eac_bff -i install_loc [-d pkg_location] pkg_name
customize_eac_bff -s {-f tmp_params | -c certfile | -k keyfile} [-d pkg_location]
pkg_name
customize_eac_bff -g [-f tmp_params] [-d pkg_location] pkg_name
customize_eac_bff -t temp_dir [-d pkg_location] [pkg_name]
```

• **pkg\_name**

The name of the package (`bff` file) you want to customize.

• **-a**

Displays the license agreement.

- **-c *certfile***

Defines the full pathname of the root certificate file.

**NOTE**

This option is applicable to the CAeAC package only.

- **-d *pkg\_location***

(Optional) Specifies the directory where the package is placed on the file system. If no directory is specified, the script defaults to `/var/spool/pkg`.

- **-f *tmp\_params***

Specifies the full path and name of the installation parameters file to create or retrieve information from.

**NOTE**

If no file is specified when using the `-g` option, the installation parameters are directed to the standard output (stdout).

- **-g**

Gets the installation parameters file and places in the file that is specified in the `-f` option.

- **-h**

Displays command usage. When used with the `-l` option, displays the language code for supported languages.

- **-i *install\_loc***

Sets the installation directory for the package to `install_loc/PAMSC`

- **-k *keyfile***

Defines the full pathname of the root private key file.

**NOTE**

This option is applicable to the CAeAC package only.

- **-l *lang***

Sets the language of the installation parameters file to *lang*. You can set the language only with the `-r` option.

**NOTE**

For a list of supported language codes, run

`-l`

with the

`-h`

option. By default, the installation parameters file is in English.

- **-r**

Resets the package to use default values as in the original package.

- **-s**

Sets the specified package to use inputs from the customized installation parameters file specified in the `-f` option.

- **-t *tmp\_dir***

Sets the temporary directory for installation operations.

**NOTE**

The default temporary directory is `/tmp`.

- **-w *keyword***

Defines the keyword that specifies that you accept the license agreement. Find this keyword at the end of the license agreement (inside square brackets). To locate the license agreement file, use the `-a` option.

## Upgrade AIX Native Packages

To manage endpoint installation with other software installations, use a customized AIX native package for upgrades. The AIX native packages (`bff` files) lets an endpoint upgrade on AIX easily.

**WARNING**

Customize the package to specify that you accept the license agreement using a keyword found inside the license agreement.

**Follow these steps:**

1. Log in as root.
2. Stop Privileged Access Manager services, and the kernel module.  

```
InstallDir/bin/secons -sk
```

```
InstallDir/bin/SEOS_load -u
```
3. (Optional) Check the level (version) of the package that you want to install:  

```
installp -l -d pkg_location
```

  - **pkg\_location**  
 Defines the directory where the CAeAC.<version>.bff package is located.  
 For each package in *pkg\_location*, AIX lists the level of the package.
4. Upgrade the customized package using the following command:  

```
installp -aX -d <pkg_location> CAeAC [pkg_level]
```

  - **pkg\_level**  
 Defines the level number of the package that is recorded earlier.

**WARNING**

If an endpoint is upgraded on WPARs, upgrade the installation in the global environment.

AIX starts installing the CAeAC package from the *pkg\_location* directory. The endpoint is now fully upgraded but not started.

5. (Optional) Upgrade on a specific WPAR *wparname*. (Use -A to install on all system WPARs).
  - From global environment:  

```
syncwpar wpar_name
```
  - From WPAR:  

```
syncroot
```

**Upgrade Using Install\_Base**

Use the Install\_Base script to upgrade an endpoint on AIX interactively or silently.

**Follow these steps:**

1. Log in as *root*.
2. Download the Privileged Access Manager Endpoint Components for UNIX ISO.
3. Mount the ISO, and copy the following files to a temporary location:
  - *install\_base*
  - *\_AIX5\_<Version>.tar.Z*
  - *pre.tar*

**WARNING**

Ensure that the directory, where you mount the endpoint ISO, does not contain any empty spaces.

4. Stop Privileged Access Manager services, and the kernel module.  

```
InstallDir/bin/secons -sk
```

```
InstallDir/bin/SEOS_load -u
```
5. Read the license agreement. To run the *install\_base* script, accept the end-user License Agreement. To get the license file name and location, run *install\_base -h*. Note the keyword that appears at the end of the license agreement inside a square bracket. Specify this keyword in the next step.

6. Run the `install_base` script. The `install_base` script starts and, based on your choices, prompts for the appropriate installation questions.

```
install_base [tar_file] [packages] [options]
```

You can provide the following inputs to the `install_base` command.

- **tar\_file**  
(Optional) Defines the name of the tar file containing the Privileged Access Manager installation files for your platform. The installation script finds the appropriate compressed tar file automatically, so typing the name of the tar file is optional.
- **packages**  
(Optional) Defines the Privileged Access Manager packages to install. If no packages are specified, the installation script considers the same packages that were installed earlier.

#### NOTE

Install the client package before you install any other package. However, you can specify to install the client package together with any other package.

The packages that can be installed are:

- **-all**  
Installs all packages; client package, server package, API package, and the MFSD package. Also enables STOP (-stop option).
- **-api**  
Installs the API package that includes API libraries and sample programs.
- **-client**  
Installs the client package that has the core Privileged Access Manager functionality required for a standalone computer.
- **-mfstd**  
Installs the MFSD package that includes the mainframe synchronization daemon.

#### NOTE

Install the server package before installing the MFSD package.

- **-server**  
Installs the server package, which includes more binaries and scripts (`selogrcd`, `sepmdd`, `sepmddadm`, `secrepsw`). And these binaries and scripts complement the client package. For example, `sepmdd` sets the computer with a Policy Model.
- **options**  
(Optional) Defines extra installation options.

#### NOTE

Installation options that affect Privileged Access Manager functionality, (for example, -stop) can only be specified when you install the *client* package. Installation options that affect the installation process (for example, -verbose) can be specified with any package.

You can specify the following options:

- **-autocfg [response\_file]**  
Runs the installation in silent mode (not in interactive mode). The installation uses the preferences that are stored in the file to respond to the interactive installation process automatically. If a response file is not specified, or if the response file is missing any options, the installation uses preset defaults.  
To create a response file:
  - Use the `-savecfg` option.
  - Edit an installation parameters file, found inside `parameters.tar`

#### WARNING

If you do not specify a response file, use the `-command` option when using the `-autocfg` option.

Consider the following points in a silent installation:

- You cannot change the encryption key.
- Only the client and server packages are installed by default.  
To install any other package or feature, specify the appropriate option as you would in a normal installation.
- The `install_base` command does not print installation details on the screen during installation.  
To view installation messages on the screen during installation, use the `-verbose` option.
- For security reasons, do not specify the Shared Secret that secures SSL communication between the Report Agent and the Distribution Server in a silent installation. To specify the Shared Secret, configure the Report Agent user (`+reportagent`) after installation.

- **-command keyword**

Defines the command that specifies to accept the license agreement. Find this command at the end of the license agreement (inside square brackets). Use it with the `-autocfg` option. To locate the license agreement file, run `install_base -h`

**NOTE**

The license agreement is only available while the help is displayed. When you finish reading the help, the license agreement is deleted.

- **-d target\_dir**

Defines a custom installation directory. The default installation directory is `/opt/CA/PAMSC`

**WARNING**

You cannot put the Privileged Access Manager database in a mounted network file system (NFS).

- **-dns | -nodns**

Creates a lookaside database with or without DNS hosts. The `-nodns` option specifies that Privileged Access Manager does not perform a `nslookup` on any hosts in the DNS during installation.

- **-fips**

Specifies to activate FIPS-only public key (asymmetric) encryption.

- **-force**

Forces the installation to ignore an active new subscriber update ( `sepmc -n` and `subs <pmdb> newsubs (sub_name)` ) and continue the installation. By default, the installation stops and prompts to finish the subscriber update first.

**NOTE**

If you use this option, the new subscriber update fails.

- **-force\_encrypt**

Forces the installation to accept a non-default encryption key without any warning.

**WARNING**

After the upgrade is complete, the encryption key is set to the default.

**NOTE**

Privileged Access Manager also provides SSL, AES (128bit, 192bit, and 256bit), DES, and 3DES encryption options.

- **-force\_install**

Forces the new installation over the already installed version. Use this option to install over the same version.

- **-force\_kernel**

Forces the installation to continue without warning even if an old kernel cannot be unloaded.

**NOTE**

Reboot the computer after the installation is complete.

- **-g groupname**

Defines the name of the group owner of Privileged Access Manager files. The default value is 0.

- **-h | -help**

Displays help.

- **-ignore\_dep**  
Specifies that the installation does *not* check for dependency with other products.
- **-key *encryption\_key***  
Restores the encryption key during an upgrade.

**NOTE**

While you upgrade, use the same encryption key that was used earlier.

- **-lang *lang***  
Defines the language to install an endpoint.
- **-lic\_dir *license\_dir***  
If the license program is not already installed, this parameter defines the license program installation directory.

**NOTE**

The license program is installed to the specified directory only if \$CASHCOMP variable is not defined in the computer environment (it can be defined in /etc/profile.CA). Otherwise, the license program is installed to \$CASHCOMP. If \$CASHCOMP is not defined and -lic\_dir is specified, the license program is installed to the /opt/CA/SharedComponents directory. CAWIN is installed to the same directory as the license package.

- **-nolink**  
Specifies not to create a link to seos.ini in the /etc directory when the endpoint is installed to the default path (/opt/CA/PAMSC).  
Privileged Access Manager creates a link to seos.ini in the /etc directory when the endpoint is installed to a non-default directory. This lets the endpoint to detect the Installation location. Use this option if you are installing to the default path and you do not want to update /etc due to a security requirement.
- **-nolog**  
Specifies that a log is not kept for the installation process. By default, all transactions that are associated with the installation process are stored to *ACInstallDir*/PAMSC\_install.log (where *ACInstallDir* is the installation directory for Privileged Access Manager).
- **-noprofile**  
Specifies not to load /etc/profile.CA to the user environment.
- **-post *program\_name***  
Specifies a program to run after the installation is complete.
- **-pre *program\_name***  
Specifies a program to run before the installation starts.
- **-rcert *certificate.pem***  
Specifies the full path name to the root certificate file.

**NOTE**

With this option, the script extracts the tar file and then repackages it with the file provided while replacing the default file ( def\_root.pem ).

- **-rkey *certificate.key***  
Specifies the full path name to the root key file.

**NOTE**

With this option, the script extracts the tar file and then repackages it with the file provided while replacing the default file ( def\_root.pem ).

- **-rootprop**  
Specifies that the *sepass* changes to the root password are sent to the Policy Model. Set this parameter after the installation is complete using the AllowRootProp token of the seos.ini file.
- **-savecfg *<response\_file>***  
Stores the responses provided during the interactive installation for later use by the *-autocfg* option.
- **-stop**

Enables the use of the STOP (Stack Overflow Protection) feature.

- **-system\_resolve**

Specifies to use system functions, which define a bypass for network caching on the system.

**NOTE**

This option cannot be used on IBM AIX platforms.

- **-v**

Displays the version of the Privileged Access Manager package.

- **-verbose**

Specifies that installation messages are displayed on the screen during installation. This parameter is the default in an interactive installation. Specify this option only to see messages when you use the *-autocfg* option.

## Post-Upgrade Steps

Perform the following post-upgrade steps:

1. Restart the endpoint.

2. Start Privileged Access Manager services.

```
seload
```

3. Verify that the `/etc/seos.ini` link is present and points to the valid `seos.ini` file of the new installation.

```
> ls -l /etc/seos.ini
/etc/seos.ini -> /opt/CA/PAMSC/seos.ini
```

4. Check if the binaries are upgraded to the latest version.

```
issec
```

5. Ensure that you configure the value of the **Distribution\_Server** token to the URL of the ActiveMQ Message Queue server. You can find the **Distribution\_Server** token in the **communication** section of the **accommon.ini** configuration file.

## Upgrade a Linux Endpoint

This article provides information about how to upgrade a Linux endpoint.

### Upgrade Using RPM

Upgrade an endpoint to the latest version using Red Hat Package Manager (RPM). RPM is a command-line utility that builds, installs, queries, verifies, updates, and erases individual software packages. RPM is used on Linux platforms such as Fedora, Red Hat Enterprise Linux, and CentOS.

Instead of a regular installation (`install_base`), use RPM as it manages an installation with other RPM software installations as well.

**TIP**

Use the "`pkginfo | grep CAeAC`" command to check the endpoint versions that are currently installed.

Follow these steps to upgrade an endpoint using native packages:

1. [Preliminary Steps](#)
2. [Customize the RPM Package](#)
3. [Upgrade the RPM Package](#)

### Preliminary Steps

Before you upgrade an endpoint, perform the following preliminary steps:

1. Download the Privileged Access Manager Endpoint Components for UNIX ISO.

2. Mount the ISO.
3. Navigate to the `NativePackages`, `RPMPackages`, `LINUX_Platform` directory in the mounted drive, and copy the following installation files to a temporary directory (`pkg_location`) with read/write permission. Example: `/tmp`. Ensure that the temporary directory does not contain any spaces.
  - `CAeAC.<Version>.rpm`
  - `customize_eac_rpm`
  - `pre.tar`

```
cp /<mounted_location>/NativePackages/RPMPackages/Linux_Platform/CAeAC.<Version>.rpm
  pkg_location
cp /<mounted_location>/NativePackages/RPMPackages/Linux_Platform/pre.tar pkg_location
cp /<mounted_location>/NativePackages/RPMPackages/Linux_Platform/customize_eac_rpm
  pkg_location
```

### Customize the RPM Package

Customize `customize_eac_rpm` to accept the license agreement. The `customize_eac_rpm` command runs the Privileged Access Manager RPM package customization script. The script works on Privileged Access Manager RPM packages only. The script is not intended for use with the license program package.

**Note:** Do not modify the package manually. Instead, use the script as described in the following procedure to customize the RPM package.

#### Follow these steps:

1. Log in as root.
2. Ensure that you have copied the `customize_eac_rpm` script file and the `pre.tar` file to a temporary read/write directory on the file system.
3. Display the license agreement:
 

```
customize_eac_rpm -a [-d pkg_location] pkg_filename
```

Note the keyword that appears at the end of the license agreement inside square brackets. Specify this keyword in the next step.
4. Customize the RPM package to specify that you accept the license agreement using a keyword that appears at the end of the license agreement.
 

```
customize_eac_rpm -u /opt/CA -p pkg_location -d . pkg_filename
```
5. (Optional) Set the language of the installation parameters file.
 

```
customize_eac_rpm -r -l lang [-d pkg_location] pkg_filename
```
6. (Optional) Change the default encryption files:
 

```
customize_eac_rpm -s -c certfile -k keyfile [-d pkg_location] pkg_filename
```
7. (Optional) Get the installation parameters file:
 

```
customize_eac_rpm -g -f tmp_params [-d pkg_location] pkg_filename
```
8. (Optional) Edit the installation parameters file to suit your installation requirements.
 

This file lets you set the installation defaults for the package. For example, activate the `POSTEXIT` setting (remove the preceding `#` character) and point it to a post-installation script file you want to run.
9. (Optional) Set the installation parameters in your customized package:
 

```
customize_eac_rpm -s -f tmp_params [-d pkg_location] pkg_filename
```

Use the package to upgrade a Linux endpoint with the customized defaults.

### Command: `customize_eac_rpm`

This command has the following format:

```
customize_eac_rpm -h [-l lang]
```

```

customize_eac_rpm -a [-d pkg_location] pkg_filename
customize_eac_rpm -w keyword [-d pkg_location] pkg_filename
customize_eac_rpm -r [-d pkg_location] [-l lang] pkg_filename
customize_eac_rpm -s [-f tmp_params] | -c certfile | -k keyfile} [-d pkg_location]
  pkg_filename
customize_eac_rpm -g [-f tmp_params] [-d pkg_location] pkg_filename
customize_eac_rpm -u install_prefix [-d pkg_location] pkg_filename
customize_eac_rpm -t tmp_dir [-d pkg_location] pkg_filename

```

- ***pkg\_filename***

Defines the file name of the package you want to customize.

**NOTE**

If you do not specify the -d option, define the full path name of the package file.

- **-a**

Displays the license agreement.

- **◆◆-c certfile**

Defines the full path name of the root certificate file.

**NOTE**

This option is applicable to the CAeAC package only.

- **-d *pkg\_location***

(Optional) Specifies the directory where the package is placed on the file system. If no directory is specified, the script assumes that the full path name to the package file is *pkg\_filename*.

- **-f *tmp\_params***

Specifies the full path and name of the installation parameters file to create or retrieve information from.

**NOTE**

If no file is specified when using the -g option, the installation parameters are directed to the standard output (stdout).

- **-g**

Gets the installation parameters file and places in the file that is specified in the -f option.

- **-h**

Displays command usage. When used in conjunction with the -l option, displays the language code for supported languages.

- **-k *keyfile***

Defines the full path name of the root private key file.

**NOTE**

This option is applicable to the CAeAC package only.

- **-l *lang***

Sets the language of the installation parameters file to *lang*. You can set the language only with the -r option.

**NOTE**

For a list of supported language codes, run -l with the -h option. By default, the installation parameters file is in English.

- **-r**

Resets the package to use default values as in the original package.

- **-s**

Sets the specified package to use inputs from the customized installation parameters file specified by the -f option.

- **-t *tmp\_dir***

Sets the temporary directory for installation operations. The default temporary directory is /tmp.

- **-u**  
Defines the target directory where you install the product.
- **-p**  
Defines the Access Control package.

### **Upgrade the RPM Package**

To manage the product installation with other software installations, install the customized Privileged Access Manager RPM package.

#### **Follow these steps:**

1. Stop Privileged Access Manager services, and the kernel module.

```
InstallDir/bin/secons -sk
InstallDir/bin/SEOS_load -u
```

2. Run the rpm command to upgrade the CAeAC package.

```
rpm -U --oldpackage CAeAC*.rpm
```

The Privileged Access Manager endpoint upgrades.

### **Upgrade Using Install\_Base**

Use the Install\_Base script to upgrade an endpoint on Linux interactively or silently.

#### **Follow these steps:**

1. Log in as *root*.
2. Download the Privileged Access Manager Endpoint Components for UNIX ISO.
3. Mount the ISO, and copy the following files to a temporary location:
  - install\_base
  - \_Linux\_<Version>.tar.Z
  - pre.tar

#### **WARNING**

Ensure that the directory, where you mount the endpoint ISO, does not contain any empty spaces.

4. Stop Privileged Access Manager services, and the kernel module.

```
InstallDir/bin/secons -sk
InstallDir/bin/SEOS_load -u
```

5. Read the license agreement. To run the install\_base script, accept the end-user License Agreement. To get the license file name and location, run install\_base -h. Note the keyword that appears at the end of the license agreement inside a square bracket. Specify this keyword in the next step.
6. Run the install\_base script. The install\_base script starts and, based on your choices, prompts for the appropriate installation questions.

```
install_base [tar_file] [packages] [options]
```

You can provide the following inputs to the install\_base command.

- **tar\_file**  
(Optional) Defines the name of the tar file containing the Privileged Access Manager installation files for your platform. The installation script finds the appropriate compressed tar file automatically, so typing the name of the tar file is optional.
- **packages**  
(Optional) Defines the Privileged Access Manager packages to install. If no packages are specified, the installation script considers the same packages that were installed earlier.

**NOTE**

Install the client package before you install any other package. However, you can specify to install the client package together with any other package.

The packages that can be installed are:

- **-all**  
Installs all packages; client package, server package, API package, and the MFSD package. Also enables STOP (-stop option).
- **-api**  
Installs the API package that includes API libraries and sample programs.
- **-client**  
Installs the client package that has the core Privileged Access Manager functionality required for a standalone computer.
- **-mfstd**  
Installs the MFSD package that includes the mainframe synchronization daemon.

**NOTE**

Install the server package before installing the MFSD package.

- **-server**  
Installs the server package, which includes more binaries and scripts (`selogrcd`, `sepmdd`, `sepmddadm`, `secrepsw`). And, these binaries and scripts complement the client package. For example, `sepmdd` sets the computer with a Policy Model.
- **options**  
(Optional) Defines extra installation options.

**NOTE**

Installation options that affect Privileged Access Manager functionality, (for example, -stop) can only be specified when you install the *client* package. Installation options that affect the installation process (for example, -verbose) can be specified with any package.

You can specify the following options:

- **-autocfg [response\_file]**  
Runs the installation in silent mode (not in interactive mode). The installation uses the preferences that are stored in the file to respond to the interactive installation process automatically. If a response file is not specified, or if the response file is missing any options, the installation uses preset defaults.  
To create a response file:
  - Use the `-savecfg` option.
  - Edit an installation parameters file, found inside `parameters.tar`

**WARNING**

If you do not specify a response file, use the `-command` option when using the `-autocfg` option.

Consider the following points in a silent installation:

- You cannot change the encryption key.
- Only the client and server packages are installed by default.  
To install any other package or feature, specify the appropriate option as you would in a normal installation.
- The `install_base` command does not print installation details on the screen during installation.  
To view installation messages on the screen during installation, use the `-verbose` option.
- For security reasons, do not specify the Shared Secret that secures SSL communication between the Report Agent and the Distribution Server in a silent installation. To specify the Shared Secret, configure the Report Agent user (`+reportagent`) after installation.
- **-command keyword**

Defines the command that specifies to accept the license agreement. Find this command at the end of the license agreement (inside square brackets). Use it with the `-autocfg` option. To locate the license agreement file, run `install_base -h`

**NOTE**

The license agreement is only available while the help is displayed. When you finish reading the help, the license agreement is deleted.

- **-d *target\_dir***

Defines a custom installation directory. The default installation directory is `/opt/CA/PAMSC`

**WARNING**

You cannot put the Privileged Access Manager database in a mounted network file system (NFS).

- **-dns | -nodns**

Creates a lookaside database with or without DNS hosts. The `-nodns` option specifies that Privileged Access Manager does not perform a `nslookup` on any hosts in the DNS during installation.

- **-fips**

Specifies to activate FIPS-only public key (asymmetric) encryption.

- **-force**

Forces the installation to ignore an active new subscriber update ( `sepmc -n` and `subs <pmdb> newsubs (sub_name)` ) and continue the installation. By default, the installation stops and prompts to finish the subscriber update first.

**NOTE**

If you use this option, the new subscriber update fails.

- **-force\_encrypt**

Forces the installation to accept a non-default encryption key without any warning.

**WARNING**

After the upgrade is complete, the encryption key is set to the default.

**NOTE**

Privileged Access Manager also provides SSL, AES (128bit, 192bit, and 256bit), DES, and 3DES encryption options.

- **-force\_install**

Forces the new installation over the already installed version. Use this option to install over the same version.

- **-force\_kernel**

Forces the installation to continue without warning even if an old kernel cannot be unloaded.

**NOTE**

Reboot the computer after the installation is complete.

- **-g *groupname***

Defines the name of the group owner of Privileged Access Manager files. The default value is 0.

- **-h | -help**

Displays help.

- **-ignore\_dep**

Specifies that the installation does *not* check for dependency with other products.

- **-key *encryption\_key***

Restores the encryption key during an upgrade.

**NOTE**

While you upgrade, use the same encryption key that was used earlier.

- **-lang *lang***

Defines the language to install an endpoint.

- **-lic\_dir *license\_dir***

If the license program is not already installed, this parameter defines the license program installation directory.

**NOTE**

The license program is installed to the specified directory only if \$CASHCOMP variable is not defined in the computer environment (it can be defined in /etc/profile.CA ). Otherwise, the license program is installed to \$CASHCOMP. If \$CASHCOMP is not defined and -lic\_dir is specified, the license program is installed to the /opt/CA/SharedComponents directory. CAWIN is installed to the same directory as the license package.

- **-nolink**

Specifies not to create a link to seos.ini in the /etc directory when the endpoint is installed to the default path (/opt/CA/PAMSC).

Privileged Access Manager creates a link to seos.ini in the /etc directory when the endpoint is installed to a non-default directory. This lets the endpoint to detect the Installation location. Use this option if you are installing to the default path and you do not want to update /etc due to a security requirement.

- **-nolog**

Specifies that a log is not kept for the installation process. By default, all transactions that are associated with the installation process are stored to *ACInstallDir*/PAMSC\_install.log (where *ACInstallDir* is the installation directory for Privileged Access Manager).

- **-noprofile**

Specifies not to load /etc/profile.CA to the user environment.

- **-post program\_name**

Specifies a program to run after the installation is complete.

- **-pre program\_name**

Specifies a program to run before the installation starts.

- **-rcert certificate.pem**

Specifies the full path name to the root certificate file.

**NOTE**

With this option, the script extracts the tar file and then repackages it with the file provided while replacing the default file ( def\_root.pem ).

- **-rkey certificate.key**

Specifies the full path name to the root key file.

**NOTE**

With this option, the script extracts the tar file and then repackages it with the file provided while replacing the default file ( def\_root.key ).

- **-rootprop**

Specifies that the *sepass* changes to the root password are sent to the Policy Model. Set this parameter after the installation is complete using the *AllowRootProp* token of the seos.ini file.

- **-savecfg <response\_file>**

Stores the responses provided during the interactive installation for later use by the *-autocfg* option.

- **-stop**

Enables the use of the STOP (Stack Overflow Protection) feature.

- **-system\_resolve**

Specifies to use system functions, which define a bypass for network caching on the system.

**NOTE**

This option cannot be used on IBM Linux platforms.

- **-v**

Displays the version of the Privileged Access Manager package.

- **-verbose**

Specifies that installation messages are displayed on the screen during installation. This parameter is the default in an interactive installation. Specify this option only to see messages when you use the *-autocfg* option.

## Post-Upgrade Steps

Perform the following post-upgrade steps:

1. Restart the endpoint.
2. Start Privileged Access Manager services.  

```
seload
```
3. Verify that the `/etc/seos.ini` link is present and points to the valid `seos.ini` file of the new installation.  

```
> ls -l /etc/seos.ini
/etc/seos.ini -> /opt/CA/PAMSC/seos.ini
```
4. Check if the binaries are upgraded to the latest version.  

```
issec
```
5. Ensure that you configure the value of the **Distribution\_Server** token to the URL of the ActiveMQ Message Queue server. You can find the **Distribution\_Server** token in the **communication** section of the **accommon.ini** configuration file.

## Upgrade a Solaris Endpoint

This article provides information about how to upgrade a Solaris endpoint.

### Upgrade Using Native Packages

Upgrade a Solaris endpoint to the latest version using Native Packages. Solaris native packaging provides command-line utilities that create, install, remove, and report on individual software packages.

#### TIP

Tip: Use the `pkginfo|grep CAeAC` command to check the endpoint versions that are currently installed.

Follow these steps to upgrade an endpoint using native packages:

1. [Preliminary Steps](#)
2. [Customize the Solaris Native Package](#)
3. [Upgrade a Solaris Endpoint](#)

### Preliminary Steps

Before you upgrade an endpoint, perform the following preliminary steps:

1. Download the Privileged Access Manager Endpoint Components for UNIX ISO.
2. Mount the ISO.
3. The `NativePackages` directory in the mounted drive contains the Solaris native package for each of the supported Solaris operating systems. Navigate to the `NativePackages` directory in the mounted drive and copy the following installation files to a temporary directory (`pkg_location`) with read/write permission. Example: `/tmp` Ensure that the temporary directory does not contain any spaces.
  - `_Solaris_PKG.<version>.tar.Z`
  - `convert_eac_pkg`
  - `customize_eac_pkg`
  - `pre.tar`
  - `parameters.tar`

```
cp /<mounted_location>/NativePackages/_Solaris_PKG.<version>.tar.Z pkg_location
cp /<mounted_location>/NativePackages/convert_eac_pkg pkg_location
cp /<mounted_location>/NativePackages/customize_eac_pkg pkg_location
```

```
cp /<mounted_location>/NativePackages/parameters.tar pkg_location
cp /<mounted_location>/NativePackages/pre.tar pkg_location
```

4. Untar `_Solaris_PKG_<Version>.tar.z`. When you untar, the `CAeAC` file is added to the temporary native package directory.

```
cd pkg_location
zcat _Solaris_PKG_<Version>.tar.Z | tar xvf -
```

#### **WARNING**

Ensure that file attributes for the entire directory structure of the package are preserved during extraction. Otherwise, the Solaris native packaging tools consider the package corrupt.

5. Verify that your system supports the correct versions of the C++ library.

```
pvs -d /usr/lib/libCstd.so.1
libCstd.so.1;
SUNW_1.1.1;
SUNW_1.1;
SUNW_1.2;
SUNW_1.3;
SUNW_1.3.1;
```

6. Verify that environment variable `LD_LIBRARY_PATH` includes path `/usr/local/lib/`

### **Customize the Solaris Native Package**

Customize `customize_eac_pkg` to accept the license agreement.

You can also specify custom installation settings when you customize a package. To customize a package, extract the installation parameters file from the package, modify as required, and load it back into the package. Some commands are available in the customization script so that you do not have to modify the parameters file.

#### **NOTE**

We recommend that you do not modify the package manually. Instead, use the script as described in the following procedure to customize the Privileged Access Manager package.

#### **Follow these steps:**

1. Log in as root.
2. Ensure that you have copied the `customize_eac_pkg` script file and the `pre.tar` file to a temporary location on the file system.
3. Display the license agreement:
 

```
customize_eac_pkg -a -d <pkg_location> CAeAC
```

Note the keyword that appears at the end of the license agreement inside square brackets. Specify this keyword in the next step.
4. Provide the *keyword* to specify that you accept the license agreement:
 

```
customize_eac_pkg -i <install_location> -d . CAeAC
```
5. (Optional) Change the language of the installation parameters file to *lang*. The installation parameters file default language is English.
 

```
customize_eac_pkg -r -l lang -d <pkg_location> CAeAC
```
6. (Optional) Change the default encryption files.
 

```
customize_eac_pkg -s -c certfile -k keyfile -d <pkg_location> CAeAC
```
7. Change the target installation directory from `/tmp` to a custom path. Example: `/opt/CA/`

```
customize_eac_pkg -i /opt/CA -d <pkg_location> CAeAC
```
8. Generate a parameter file with default values.

```
customize_eac_pkg -g -f <pkg_location>/paramtemplate -d <pkg_location> CAeAC
```

9. Modify the default values in the parameter file with data specific to your environment. The parameter file lets you set the installation defaults for the package.

**Example:** You can activate the POSTEXIT setting (by removing the preceding # character) and point it to a post-installation script file you want to run.

### **Command: customize\_eac\_pkg**

The customize\_eac\_pkg command runs the Privileged Access Manager Solaris native package customization script.

- The script works on any of the available product Solaris native packages.
- Move the package to a read/write directory on your file system.
- For localized script messages, have pre.tar file in the same directory as the script file.

This command has the following format:

```
customize_eac_pkg -h [-l lang]
customize_eac_pkg -a [-d pkg_location] [pkg_name]
customize_eac_pkg -w keyword [-d pkg_location] [pkg_name]
customize_eac_pkg -r [-d pkg_location] [-l lang] [pkg_name]
customize_eac_pkg -i install_loc [-d pkg_location] [pkg_name]
customize_eac_pkg -s {-f tmp_params | -c certfile | -k keyfile} [-d pkg_location]
    [pkg_name]
customize_eac_pkg -g [-f tmp_params] [-d pkg_location] [pkg_name]
customize_eac_pkg -t tmp_dir [-d pkg_location] [pkg_name]
```

- **pkg\_name**  
(Optional) The name of the Privileged Access Manager package you want to customize. If no directory is specified, the script defaults to the main Privileged Access Manager package (CAeAC ).
- **-a**  
Displays the license agreement.
- **-c certfile**  
Defines the full path name of the root certificate file.

#### **NOTE**

This option is applicable to the CAeAC package only.

- **-d pkg\_location**  
(Optional) Specifies the directory where the package is placed on the file system. If no directory is specified, the script defaults to /var/spool/pkg.
- **-f tmp\_params**  
Specifies the full path and name of the installation parameters file to create or retrieve information from.

#### **NOTE**

If no file is specified when using the -g option, the installation parameters are directed to the standard output (stdout).

- **-g**  
Gets the installation parameters file and places it in the file specified by the -f option.
- **-h**  
Displays command usage. When used with the -l option, displays the language code for supported languages.
- **-i install\_loc**  
Sets the installation directory for the package to *install\_loc*/PAMSC.
- **-k keyfile**  
Defines the full path name of the root private key file.

**NOTE**

This option is applicable to the CAeAC package only.

- **-l *lang***

Sets the language of the installation parameters file to *lang*. Set the language only with the -r option.

**NOTE**

For a list of supported language codes, run -l with the -h option. By default, the installation parameters file is in English.

- **-r**  
Resets the package to use default values as in the original package.
- **-s**  
Sets the specified package to use inputs from the customized installation parameters file specified by the -f option.
- **-t *tmp\_dir***  
Sets the temporary directory for installation operations.

**NOTE**

The default temporary directory is /tmp.

- **-w *keyword***  
Defines the keyword that specifies that you accept the license agreement. Find this keyword at the end of the license agreement (inside square brackets). To locate the license agreement file, use the -a option. This option is required for new installations and upgrades.

**Upgrade a Solaris Endpoint**

To manage endpoint installation with other software installations, use a customized Solaris native package for upgrades. The native package lets an endpoint upgrade on Solaris easily.

**Follow these steps:**

1. Log in as root.
2. Stop Privileged Access Manager services, and the kernel module.  

```
InstallDir/bin/secons -sk
```

```
InstallDir/bin/SEOS_load -u
```
3. Generate the installation administration file in the <pkg\_location> directory to allow package upgrade.  

```
convert_eac_pkg -p
```

The file myadmin is created from a generic template.
4. Upgrade the Solaris endpoint.  

```
pkgadd -a <pkg_location>/ -d . CAeAC
```

The installer shuts down Privileged Access Manager, and upgrades the endpoint.

**Upgrade Using Install\_Base**

Use the Install\_Base script to upgrade an endpoint on Solaris interactively or silently.

**Follow these steps:**

1. Log in as *root*.
2. Download the Privileged Access Manager Endpoint Components for UNIX ISO.
3. Mount the ISO, and copy the following files to a temporary location:
  - install\_base
  - \_Solaris\_<Version>.tar.Z
  - pre.tar

**WARNING**

Ensure that the directory, where you mount the endpoint ISO, does not contain any empty spaces.

4. Stop Privileged Access Manager services, and the kernel module.

```
InstallDir/bin/secons -sk
```

```
InstallDir/bin/SEOS_load -u
```

5. Read the license agreement. To run the `install_base` script, accept the end-user License Agreement. To get the license file name and location, run `install_base -h`. Note the keyword that appears at the end of the license agreement inside a square bracket. Specify this keyword in the next step.
6. Run the `install_base` script. The `install_base` script starts and, based on your choices, prompts for the appropriate installation questions.

```
install_base [tar_file] [packages] [options]
```

You can provide the following inputs to the `install_base` command.

– **tar\_file**

(Optional) Defines the name of the tar file containing the Privileged Access Manager installation files for your platform. The installation script finds the appropriate compressed tar file automatically, so typing the name of the tar file is optional.

– **packages**

(Optional) Defines the Privileged Access Manager packages to install. If no packages are specified, the installation script considers the same packages that were installed earlier.

**NOTE**

Install the client package before you install any other package. However, you can specify to install the client package together with any other package.

The packages that can be installed are:

- **-all**  
Installs all packages; client package, server package, API package, and the MFSD package. Also enables STOP (-stop option).
- **-api**  
Installs the API package that includes API libraries and sample programs.
- **-client**  
Installs the client package that has the core Privileged Access Manager functionality required for a standalone computer.
- **-mfstd**  
Installs the MFSD package that includes the mainframe synchronization daemon.

**NOTE**

Install the server package before installing the MFSD package.

- **-server**  
Installs the server package, which includes more binaries and scripts (`selogrcd`, `sepmc`, `sepmdd`, `sepmddadm`, `secrepsw`). And, these binaries and scripts complement the client package. For example, `sepmdd` sets the computer with a Policy Model.
- **options**  
(Optional) Defines extra installation options.

**NOTE**

Installation options that affect Privileged Access Manager functionality can only be specified when you install the *client* package. (Example: -stop) Installation options that affect the installation process can be specified with any package. (Example: -verbose)

You can specify the following options:

- **-autocfg [response\_file]**

Runs the installation in silent mode (not in interactive mode). The installation uses the preferences that are stored in the file to respond to the interactive installation process automatically. If a response file is not specified, or if the response file is missing any options, the installation uses preset defaults.

To create a response file:

- Use the `-savecfg` option.
- Edit an installation parameters file, found inside `parameters.tar`

### WARNING

If you do not specify a response file, use the `-command` option when using the `-autocfg` option.

Consider the following points in a silent installation:

- You cannot change the encryption key.
- Only the client and server packages are installed by default.  
To install any other package or feature, specify the appropriate option as you would in a normal installation.
- The `install_base` command does not print installation details on the screen during installation.  
To view installation messages on the screen during installation, use the `-verbose` option.
- For security reasons, do not specify the Shared Secret that secures SSL communication between the Report Agent and the Distribution Server in a silent installation. To specify the Shared Secret, configure the Report Agent user (`+reportagent`) after installation.
- **-command keyword**  
Defines the command that specifies to accept the license agreement. Find this command at the end of the license agreement (inside square brackets). Use it with the `-autocfg` option. To locate the license agreement file, run `install_base -h`

### NOTE

The license agreement is only available while the help is displayed. When you finish reading the help, the license agreement is deleted.

- **-d target\_dir**  
Defines a custom installation directory. The default installation directory is `/opt/CA/PAMSC`

### WARNING

You cannot put the Privileged Access Manager database in a mounted network file system (NFS).

- **-dns | -nodns**  
Creates a lookaside database with or without DNS hosts. The `-nodns` option specifies that Privileged Access Manager does not perform a `nslookup` on any hosts in the DNS during installation.
- **-fips**  
Specifies to activate FIPS-only public key (asymmetric) encryption.
- **-force**  
Forces the installation to ignore an active new subscriber update ( `sepmc -n` and `subs <pmdb> newsubs (sub_name)` ) and continue the installation. By default, the installation stops and prompts to finish the subscriber update first.

### NOTE

If you use this option, the new subscriber update fails.

- **-force\_encrypt**  
Forces the installation to accept a nondefault encryption key without any warning.

### WARNING

After the upgrade is complete, the encryption key is set to the default.

### NOTE

Privileged Access Manager also provides SSL, AES (128bit, 192bit, and 256bit), DES, and 3DES encryption options.

- **-force\_install**

Forces the new installation over the already installed version. Use this option to install over the same version.

- **-force\_kernel**

Forces the installation to continue without warning even if an old kernel cannot be unloaded.

**NOTE**

Reboot the computer after the installation is complete.

- **-g *groupname***

Defines the name of the group owner of Privileged Access Manager files. The default value is 0.

- **-h | -help**

Displays help.

- **-ignore\_dep**

Specifies that the installation does *not* check for dependency with other products.

- **-key *encryption\_key***

Restores the encryption key during an upgrade.

**NOTE**

While you upgrade, use the same encryption key that was used earlier.

- **-lang *lang***

Defines the language to install an endpoint.

- **-lic\_dir *license\_dir***

If the license program is not already installed, this parameter defines the license program installation directory.

**NOTE**

The license program is installed to the specified directory only if \$CASHCOMP variable is not defined in the computer environment (it can be defined in /etc/profile.CA ). Otherwise, the license program is installed to \$CASHCOMP. If \$CASHCOMP is not defined and -lic\_dir is specified, the license program is installed to the /opt/CA/SharedComponents directory. CAWIN is installed to the same directory as the license package.

- **-nolink**

Specifies not to create a link to seos.ini in the /etc directory when the endpoint is installed to the default path (/opt/CA/PAMSC).

Privileged Access Manager creates a link to seos.ini in the /etc directory when the endpoint is installed to a non-default directory. This lets the endpoint to detect the Installation location. Use this option if you are installing to the default path and you do not want to update /etc due to a security requirement.

- **-nolog**

Specifies that a log is not kept for the installation process. By default, all transactions that are associated with the installation process are stored to *ACInstallDir*/PAMSC\_install.log (where *ACInstallDir* is the installation directory for Privileged Access Manager).

- **-noprofile**

Specifies not to load /etc/profile.CA to the user environment.

- **-post *program\_name***

Specifies a program to run after the installation is complete.

- **-pre *program\_name***

Specifies a program to run before the installation starts.

- **-rcert *certificate.pem***

Specifies the full path name to the root certificate file.

**NOTE**

With this option, the script extracts the tar file and then repackages it with the file provided while replacing the default file ( *def\_root.pem* ).

- **-rkey *certificate.key***

Specifies the full path name to the root key file.

**NOTE**

With this option, the script extracts the tar file and then repackages it with the file provided while replacing the default file ( `def_root.key` ).

- **-rootprop**  
Specifies that the `sepass` changes to the root password are sent to the Policy Model. Set this parameter after the installation is complete using the `AllowRootProp` token of the `seos.ini` file.
- **-savecfg <response\_file>**  
Stores the responses provided during the interactive installation for later use by the `-autocfg` option.
- **-stop**  
Enables the use of the STOP (Stack Overflow Protection) feature.
- **-system\_resolve**  
Specifies to use system functions, which define a bypass for network caching on the system.

**NOTE**

This option cannot be used on IBM Solaris platforms.

- **-v**  
Displays the version of the Privileged Access Manager package.
- **-verbose**  
Specifies that installation messages are displayed on the screen during installation. This parameter is the default in an interactive installation. Specify this option only to see messages when you use the `-autocfg` option.

**Post-Upgrade Steps**

Perform the following post-upgrade steps:

1. Restart the endpoint.
2. Start Privileged Access Manager services.  
`seload`
3. Verify that the `/etc/seos.ini` link is present and points to the valid `seos.ini` file of the new installation.  
`> ls -l /etc/seos.ini`  
`/etc/seos.ini -> /opt/CA/PAMSC/seos.ini`
4. Check if the binaries are upgraded to the latest version.  
`issec`
5. Ensure that you configure the value of the **Distribution\_Server** token to the URL of the ActiveMQ Message Queue server. You can find the **Distribution\_Server** token in the **communication** section of the **accommon.ini** configuration file.

**Upgrade a Solaris Zones Endpoint**

This article provides information about how to upgrade a Solaris Zones endpoint.

**Upgrade Using Native Packages**

Upgrade on Solaris 10 zones is no different from a regular upgrade. We recommend using Solaris native packaging (`pkgadd` and `pkgrm`) commands to upgrade an endpoint on Solaris 10. When you upgrade the installation in the global zone, the upgrade is propagated into non-global zones automatically.

**WARNING**

For Privileged Access Manager to work in non-global zones, upgrade in the global zone first.

**TIP**

Use the "`pkginfo | grep CAeAC`" command to check the endpoint versions that are currently installed.

Follow these steps to upgrade an endpoint using native packages:

1. [Preliminary Steps](#)
2. [Customize the Solaris Native Packages](#)
3. [Upgrade Solaris Native Package on Solaris Zones](#)
4. [Upgrade on a Solaris Branded Zone](#)
5. [New Zone Setup](#)
6. [Start and Stop CA Privileged Access Manager Server Control in a Zone](#)
7. [Start CA Privileged Access Manager Server Control in a Non-global Zone](#)
8. [Troubleshooting](#)

**Note:** Due to a Solaris 11 limitation, the Privileged Access Manager package is not propagated into non-global zones during installation. We recommend you to install the product in each zone individually using the Solaris native packaging tool (`pkgadd`).

### **Preliminary Steps**

Before you upgrade an endpoint, perform the following preliminary steps:

1. Download the Privileged Access Manager Endpoint Components for UNIX ISO.
2. Mount the ISO.
3. The `NativePackages` directory in the mounted drive contains the Solaris native package for each of the supported Solaris operating systems. Navigate to the `NativePackages` directory in the mounted drive and copy the following installation files to a temporary directory (`pkg_location`) with read/write permission. Example: `/tmp`. Ensure that the temporary directory does not contain any spaces.

- `_Solaris_PKG.<version>.tar.Z`
- `convert_eac_pkg`
- `customize_eac_pkg`
- `pre.tar`
- `parameters.tar`

```
cp /<mounted_location>/NativePackages/_Solaris_PKG.<version>.tar.Z pkg_location
cp /<mounted_location>/NativePackages/convert_eac_pkg pkg_location
cp /<mounted_location>/NativePackages/customize_eac_pkg pkg_location
cp /<mounted_location>/NativePackages/parameters.tar pkg_location
cp /<mounted_location>/NativePackages/pre.tar pkg_location
```

4. Untar `_Solaris_PKG_<Version>.tar.z`. When you untar, the `CAeAC` file is added to the temporary native package directory.

```
cd pkg_location
zcat _Solaris_PKG_<Version>.tar.Z | tar xvf -
```

#### **WARNING**

Ensure that file attributes for the entire directory structure of the package are preserved during extraction, else the Solaris native packaging tools consider the package corrupt.

5. Verify that your system supports the correct versions of the C++ library.

```
pvs -d /usr/lib/libCstd.so.1
libCstd.so.1;
SUNW_1.1.1;
SUNW_1.1;
SUNW_1.2;
SUNW_1.3;
SUNW_1.3.1;
```

6. Verify that environment variable LD\_LIBRARY\_PATH includes path /usr/local/lib/

### **Customize the Solaris Native Packages**

Customize `customize_eac_pkg` to accept the license agreement.

You can also specify custom installation settings when you customize a package. To customize a package, extract the installation parameters file from the package, modify as required, and load it back into the package. Some commands are available in the customization script so that you do not have to modify the parameters file.

#### **NOTE**

We recommend that you do not modify the package manually. Instead, use the script as described in the following procedure to customize the Privileged Access Manager package.

#### **Follow these steps:**

1. Log in as root.
2. Display the license agreement:  

```
customize_eac_pkg -a -d <pkg_location> CAeAC
```
3. Note the keyword that appears at the end of the license agreement inside square brackets. Specify this keyword in the next step.
4. Provide the *keyword* to specify that you accept the license agreement:  

```
customize_eac_pkg -w keyword -d <pkg_location> CAeAC
```
5. (Optional) Change the language of the installation parameters file to *lang*. By default, the installation parameters file is in English.  

```
customize_eac_pkg -r -l lang -d <pkg_location> CAeAC
```
6. (Optional) Change the default encryption files.  

```
customize_eac_pkg -s -c certfile -k keyfile -d <pkg_location> CAeAC
```
7. Change the target installation directory from /tmp to a custom path. Example: /opt/CA/:  

```
customize_eac_pkg -i /opt/CA -d <pkg_location> CAeAC
```
8. Generate a response file `paramtemplate` with default values:  

```
customize_eac_pkg -g -f <pkg_location>/paramtemplate -d <pkg_location> CAeAC
```
9. Modify the default values in the `paramtemplate` file with data specific to your environment.  
 The `paramtemplate` file lets you set the installation defaults for the package. For example, activate the POSTEXIT setting (remove the preceding # character) and point it to a post-installation script file you want to run.

#### **NOTE**

Ensure that the parameters for cryptographic options of the DH are the same as those in the environment where `install_base` is installed.

### **Command: customize\_eac\_pkg**

The `customize_eac_pkg` command runs the Privileged Access Manager Solaris native package customization script.

Consider the following points when using this command:

- The script works on any of the available Privileged Access Manager Solaris native packages.
- To customize a package, the package must be in a read/write directory on your file system.
- For localized script messages, have `pre.tar` file in the same directory as the script file.

This command has the following format:

```
customize_eac_pkg -h [-l lang]
customize_eac_pkg -a [-d pkg_location] [pkg_name]
customize_eac_pkg -w keyword [-d pkg_location] [pkg_name]
```

```

customize_eac_pkg -r [-d pkg_location] [-l lang] [pkg_name]
customize_eac_pkg -i install_loc [-d pkg_location] [pkg_name]
customize_eac_pkg -s {-f tmp_params | -c certfile | -k keyfile} [-d pkg_location]
    [pkg_name]
customize_eac_pkg -g [-f tmp_params] [-d pkg_location] [pkg_name]
customize_eac_pkg -t tmp_dir [-d pkg_location] [pkg_name]

```

- **pkg\_name**  
(Optional) The name of the Privileged Access Manager package you want to customize. If no directory is specified, the script defaults to the main Privileged Access Manager package (CAeAC ).
- **-a**  
Displays the license agreement.
- **-c certfile**  
Defines the full path name of the root certificate file.

**NOTE**

This option is applicable to the CAeAC package only.

- **-d pkg\_location**  
(Optional) Specifies the directory where the package is placed on the file system. If no directory is specified, the script defaults to /var/spool/pkg.
- **-f tmp\_params**  
Specifies the full path and name of the installation parameters file to create or retrieve information from.

**NOTE**

If no file is specified when using the -g option, the installation parameters are directed to the standard output (stdout).

- **-g**  
Gets the installation parameters file and places it in the file specified by the -f option.
- **-h**  
Displays command usage. When used in conjunction with the -l option, displays the language code for supported languages.
- **-i install\_loc**  
Sets the installation directory for the package to *install\_loc*/PAMSC.
- **-k keyfile**  
Defines the full path name of the root private key file.

**NOTE**

This option is applicable to the CAeAC package only.

- **-l lang**  
Sets the language of the installation parameters file to *lang*. Set the language only in conjunction with the -r option.

**NOTE**

For a list of supported language codes run -l with the -h option. By default, the installation parameters file is in English.

- **-r**  
Resets the package to use default values as in the original package.
- **-s**  
Sets the specified package to use inputs from the customized installation parameters file specified by the -f option.
- **-t tmp\_dir**  
Sets the temporary directory for installation operations.

**NOTE**

The default temporary directory is /tmp.

- **-w keyword**

Defines the keyword that specifies that you accept the license agreement. Find this keyword at the end of the license agreement (inside square brackets). To locate the license agreement file, use the -a option. This option is required for new installations and upgrades.

**Upgrade Solaris Native Package on Solaris Zones**

To manage endpoint installation with other software installations, use a customized Solaris native package for upgrades. Use the same Privileged Access Manager endpoint version in all zones.

Solaris native packaging may require user interaction by default, and we recommend that configuring the installation as follows to run silently.

**Follow these steps:**

1. Stop Privileged Access Manager services, and the kernel module.

```
InstallDir/bin/secons -sk
InstallDir/bin/SEOS_load -u
```

2. Generate the installation administration file in the <pkg\_location> directory to activate silent installation.

```
convert_eac_pkg -p
```

The file *myadmin* is created from a generic template.

3. Edit the following settings in the *myadmin* file.

```
setuid = nocheck
action = nocheck
```

You have configured the installation administration file to run silently.

4. Install your customized package silently using the -n option.

Do *one* of the following actions:

- To install on all zones, run the following command from the global zone:

```
pkgadd -n -a <pkg_location>\myadmin -d <pkg_location> CAeAC
```

- Install on selected zones:

Run the following command from the global zone:

```
pkgadd -G -n -a <pkg_location>\myadmin -d <pkg_location> CAeAC
```

Run the following command on each of the selected non-global zones:

```
pkgadd -n -a <pkg_location>\myadmin -d <pkg_location> CAeAC
```

Endpoint upgrade is complete.

**Upgrade on a Solaris Branded Zone**

Solaris `pkgadd` does not support propagation of applications that are installed in the Solaris 10 global zone into branded zones. Privileged Access Manager must use `ioctl` instead of a `syscall` to communicate with the kernel module.

**NOTE**

The installation parameter file also lets you install on branded zones automatically when you install on the global zone.

**Follow these steps:**

1. Edit the <pkg\_location>/paramtemplate file, and change the following setting:

```
UseBrandZone = "yes"
```

2. Edit the following line in the *seos.ini* file:

```
SEOS_use_ioctl = 1
```

Privileged Access Manager is configured to use `ioctl`.

3. Install the product in the Solaris 10 branded zone using `pkgadd`.

```
customize_eac_pkg -s -f <pkg_location>/paramtemplate -d <pkg_location> CAeAC
pkgadd -G -a <pkg_location>/myadmin -d <pkg_location> CAeAC
```

4. Install the product in the Solaris 8 and 9 branded zones using `pkgadd`.

```
customize_eac_pkg -s -f <pkg_location>/paramtemplate -d <pkg_location> CAeAC
pkgadd -n -a <pkg_location>/myadmin -d <pkg_location> CAeAC
```

Ignore the warnings and confirm with 'y' when prompted.

The installation is complete. You can now start Privileged Access Manager in the branded zone.

#### **WARNING**

If `SEOS_use_ioctl` is set to 0, modify Privileged Access Manager to use `ioctl` for communication in all zones. Once you make this change and reboot all zones, the installation is complete.

### ***New Zone Setup***

If you install Privileged Access Manager using Solaris native packaging on all zones, Privileged Access Manager automatically installs on any zones you create after the original installation. However, while the post-installation Privileged Access Manager scripts run from within the non-global zone, for new zones, these scripts can only run once the new zone configuration is complete. Specifically, run the "`zlogin -C zonename`" command (which, completes the configuration of the name service, the root password, and so on).

#### **WARNING**

If you do not run the "`zlogin -C zonename`" command, or if you boot and log in to the new zone, Privileged Access Manager installation is incomplete as the post-installation scripts did not run.

### ***Start and Stop CA Privileged Access Manager Server Control in a Zone***

Starting and stopping Privileged Access Manager in Solaris 10 zones is done in the same way you would normally start and stop it on any Solaris computer.

The following exceptions apply to start the product in zones:

- Load the Privileged Access Manager kernel module (`SEOS_load`) from the global zone only.
- Load the Privileged Access Manager kernel module in the global zone before you start Privileged Access Manager in any non-global zone.  
Once the Privileged Access Manager kernel module is loaded in the global zone, you can then start and stop Privileged Access Manager in any non-global zone and in any order.

The following exceptions apply to stopping the product in zones:

- You cannot unload the Privileged Access Manager kernel module when one or more zones has maintenance mode enabled.
- Stop Privileged Access Manager in all zones in any order by issuing the `secons -s` command in each zone.
- Stop Privileged Access Manager in all zones at the same time by adding all zones to a GHOST record and then issuing the `secons -s ghost_name` command from the global zone.  
This is useful, for example, when you want to upgrade Privileged Access Manager across all zones.
- Stop the last zone with the `secons -sk` to disable event interception and prepare the Privileged Access Manager kernel module for unloading.
- You can unload the Privileged Access Manager kernel module (`SEOS_load -u`) from the global zone only.

#### **NOTE**

The `SEOS_load -u` command ensures that Privileged Access Manager is not running on any non-global zone before unloading it.

### ***Start CA Privileged Access Manager Server Control in a Non-global Zone***

You can start the product from any non-global zone just as you would normally, but first load the Privileged Access Manager kernel module in the global zone.

**Follow these steps:**

1. In the global zone, enter the `SEOS_load` command to load the Privileged Access Manager kernel module. The kernel loads and you can now start Privileged Access Manager in any zone.

**NOTE**

The Privileged Access Manager kernel loads but the product does not intercept events in the global zone.

2. In the non-global zone, enter the `seload` command to start the product in that zone. The non-global zone is protected by Privileged Access Manager.

**NOTE**

You can also start Privileged Access Manager in the non-global zone remotely.

**Post-Install Configuration Is Not Complete**

(Solaris only)

**Symptom:**

If Privileged Access Manager is running in the global zone, the installer must unload the kernel before an upgrade. It is possible that the installer fails to unload the kernel, and the switch cannot proceed automatically. You see the following error message:

```
The installer could not unload CA Privileged Access Manager Server Control and switch to the new version.
```

```
The post-install configuration is not complete.
```

```
In order to complete the installation process, choose one of the following options:
```

- Shut down and unload CA Privileged Access Manager Server Control, then run `/opt/CA/PAMSC/sbin/switch_ver.sh`
- Reboot the machine. The installation process continues automatically.

**Solution:**

Follow the instructions in the message to switch manually.

Do *one* of the following:

- Switch manually to the upgraded version without rebooting.
  - a. Shut down Privileged Access Manager.
  - b. Unload Privileged Access Manager.
  - c. Run `/opt/CA/PAMSC/sbin/switch_ver.sh` in the global zone.
  - d. Run `/opt/CA/PAMSC/sbin/switch_ver.sh` in the internal zones.  
The upgraded version of Privileged Access Manager starts running.
- Switch to the upgraded version after rebooting.
  - a. Reboot the machine running the global zone.
  - b. Wait approximately 10 minutes before logging on again.  
The upgraded version of Privileged Access Manager starts running.

**Upgrade Using Install\_Base**

Use the `Install_Base` script to upgrade an endpoint on Solaris interactively or silently.

**Follow these steps:**

1. Log in as *root*.

2. Download the Privileged Access Manager Endpoint Components for UNIX ISO.
3. Mount the ISO, and copy the following files to a temporary location:
  - install\_base
  - \_Solaris\_<Version>.tar.Z
  - pre.tar

**WARNING**

Ensure that the directory, where you mount the endpoint ISO, does not contain any empty spaces.

4. Stop Privileged Access Manager services, and the kernel services.

```
InstallDir/bin/secons -sk
```

```
InstallDir/bin/SEOS_load -u
```

5. Read the license agreement. To run the install\_base script, accept the end-user License Agreement. To get the license file name and location, run install\_base -h. Note the keyword that appears at the end of the license agreement inside a square bracket. Specify this keyword in the next step.
6. Run the install\_base script. The install\_base script starts and, based on your choices, prompts for the appropriate installation questions.

```
install_base [tar_file] [packages] [options]
```

You can provide the following inputs to the install\_base command.

- **tar\_file**  
(Optional) Defines the name of the tar file containing the Privileged Access Manager installation files for your platform. The installation script finds the appropriate compressed tar file automatically, so typing the name of the tar file is optional.
- **packages**  
(Optional) Defines the Privileged Access Manager packages to install. If no packages are specified, the installation script considers the same packages that were installed earlier.

**NOTE**

Install the client package before you install any other package. However, you can specify to install the client package together with any other package.

The packages that can be installed are:

- **-all**  
Installs all packages; client package, server package, API package, and the MFSD package. Also enables STOP (-stop option).
- **-api**  
Installs the API package that includes API libraries and sample programs.
- **-client**  
Installs the client package that has the core Privileged Access Manager functionality required for a standalone computer.
- **-mfscd**  
Installs the MFSD package that includes the mainframe synchronization daemon.

**NOTE**

Install the server package before installing the MFSD package.

- **-server**  
Installs the server package, which includes more binaries and scripts (selogrcd, sepmd, sepmdm, sepmdadm, secrepsw). And, these binaries and scripts complement the client package. For example, sepmdm sets the computer with a Policy Model.
- **options**  
(Optional) Defines extra installation options.

**NOTE**

Installation options that affect Privileged Access Manager functionality, (for example, `-stop`) can only be specified when you install the *client* package. Installation options that affect the installation process (for example, `-verbose`) can be specified with any package.

You can specify the following options:

- **-autocfg [response\_file]**

Runs the installation in silent mode (not in interactive mode). The installation uses the preferences that are stored in the file to respond to the interactive installation process automatically. If a response file is not specified, or if the response file is missing any options, the installation uses preset defaults.

To create a response file:

- Use the `-savecfg` option.
- Edit an installation parameters file, found inside `parameters.tar`

**WARNING**

If you do not specify a response file, use the `-command` option when using the `-autocfg` option.

Consider the following points in a silent installation:

- You cannot change the encryption key.
- Only the client and server packages are installed by default.  
To install any other package or feature, specify the appropriate option as you would in a normal installation.
- The `install_base` command does not print installation details on the screen during installation.  
To view installation messages on the screen during installation, use the `-verbose` option.
- For security reasons, do not specify the Shared Secret that secures SSL communication between the Report Agent and the Distribution Server in a silent installation. To specify the Shared Secret, configure the Report Agent user (`+reportagent`) after installation.
- **-command keyword**  
Defines the command that specifies to accept the license agreement. Find this command at the end of the license agreement (inside square brackets). Use it with the `-autocfg` option. To locate the license agreement file, run `install_base -h`

**NOTE**

The license agreement is only available while the help is displayed. When you finish reading the help, the license agreement is deleted.

- **-d target\_dir**

Defines a custom installation directory. The default installation directory is `/opt/CA/PAMSC`.

**WARNING**

You cannot put the Privileged Access Manager database in a mounted network file system (NFS).

- **-dns | -nodns**

Creates a lookaside database with or without DNS hosts. The `-nodns` option specifies that Privileged Access Manager does not perform a `nslookup` on any hosts in the DNS during installation.

- **-fips**

Specifies to activate FIPS-only public key (asymmetric) encryption.

- **-force**

Forces the installation to ignore an active new subscriber update ( `sepmc -n` and `subs <pmdb> newsubs (sub_name)` ) and continue the installation. By default, the installation stops and prompts to finish the subscriber update first.

**NOTE**

If you use this option, the new subscriber update fails.

- **-force\_encrypt**

Forces the installation to accept a non-default encryption key without any warning.

**WARNING**

After the upgrade is complete, the encryption key is set to the default.

**NOTE**

Privileged Access Manager also provides SSL, AES (128 bit, 192 bit, and 256 bit), DES, and 3DES encryption options.

- **-force\_install**  
Forces the new installation over the already installed version. Use this option to install over the same version.
- **-force\_kernel**  
Forces the installation to continue without warning even if an old kernel cannot be unloaded.

**NOTE**

Reboot the computer after the installation is complete.

- **-g *groupname***  
Defines the name of the group owner of Privileged Access Manager files. The default value is 0.
- **-h | -help**  
Displays help.
- **-ignore\_dep**  
Specifies that the installation does *not* check for dependency with other products.
- **-key *encryption\_key***  
Restores the encryption key during an upgrade.

**NOTE**

While you upgrade, use the same encryption key that was used earlier.

- **-lang *lang***  
Defines the language to install an endpoint.
- **-lic\_dir *license\_dir***  
If the license program is not already installed, this parameter defines the license program installation directory.

**NOTE**

The license program is installed to the specified directory only if \$CASHCOMP variable is not defined in the computer environment (it can be defined in /etc/profile.CA ). Otherwise, the license program is installed to \$CASHCOMP. If \$CASHCOMP is not defined and -lic\_dir is specified, the license program is installed to the /opt/CA/SharedComponents directory. CAWIN is installed to the same directory as the license package.

- **-nolink**  
Specifies not to create a link to seos.ini in the /etc directory when the endpoint is installed to the default path (/opt/CA/PAMSC).  
Privileged Access Manager creates a link to seos.ini in the /etc directory when the endpoint is installed to a non-default directory. This lets the endpoint to detect the Installation location. Use this option if you are installing to the default path and you do not want to update /etc due to a security requirement.
- **-nolog**  
Specifies that a log is not kept for the installation process. By default, all transactions that are associated with the installation process are stored to *ACInstallDir*/PAMSC\_install.log (where *ACInstallDir* is the installation directory for Privileged Access Manager).
- **-noprofile**  
Specifies not to load /etc/profile.CA to the user environment.
- **-post *program\_name***  
Specifies a program to run after the installation is complete.
- **-pre *program\_name***  
Specifies a program to run before the installation starts.
- **-rcert *certificate.pem***  
Specifies the full path name to the root certificate file.

**NOTE**

With this option, the script extracts the tar file and then repackages it with the file provided while replacing the default file ( `def_root.pem` ).

- **-rkey *certificate.key***

Specifies the full path name to the root key file.

**NOTE**

With this option, the script extracts the tar file and then repackages it with the file provided while replacing the default file ( `def_root.key` ).

- **-rootprop**

Specifies that the `sepass` changes to the root password are sent to the Policy Model. Set this parameter after the installation is complete using the `AllowRootProp` token of the `seos.ini` file.

- **-savecfg *<response\_file>***

Stores the responses provided during the interactive installation for later use by the `-autocfg` option.

- **-stop**

Enables the use of the STOP (Stack Overflow Protection) feature.

- **-system\_resolve**

Specifies to use system functions, which define a bypass for network caching on the system.

**NOTE**

This option cannot be used on IBM Solaris platforms.

- **-v**

Displays the version of the Privileged Access Manager package.

- **-verbose**

Specifies that installation messages are displayed on the screen during installation. This parameter is the default in an interactive installation. Specify this option only to see messages when you use the `-autocfg` option.

## Post-Upgrade Steps

Perform the following post-upgrade steps:

1. Restart the endpoint.
2. Start Privileged Access Manager services.  
`seload`
3. Verify that the `/etc/seos.ini` link is present and points to the valid `seos.ini` file of the new installation.  
`> ls -l /etc/seos.ini`  
`/etc/seos.ini -> /opt/CA/PAMSC/seos.ini`
4. Check if the binaries are upgraded to the latest version.  
`issec`
5. Ensure that you configure the value of the **Distribution\_Server** token to the URL of the ActiveMQ Message Queue server. You can find the **Distribution\_Server** token in the **communication** section of the **accommon.ini** configuration file.

## Migrate an Endpoint

Follow the procedure that is described in this article to migrate CA Privileged Identity Manager Endpoint release 12.8 through 14.0, or Privileged Access Manager Endpoint release 14.0 to Privileged Access Manager Endpoint release 14.1.

**Note:** User defined classes and properties are migrated during an endpoint upgrade but not during an endpoint migration.

**Follow these steps:**

**[Source Endpoint]** ♦♦

1. Log in to the source endpoint as a root user (UNIX) or as an administrator (Windows).
2. Stop endpoint services.

[Windows]

```
secons -s
```

[Unix]

```
/opt/CA/PAMSC/bin/secons -sk
```

3. Navigate to the following directory:

[Windows]

```
C:\Program Files\CA\PAMSC\Data\seosdb
```

(UNIX)

```
/opt/CA/PAMSC/seosdb
```

4. Back up the seosdb database:

```
dbmgr -backup backup_directory
```

5. Export the existing rules and the user-related data from the database:

```
dbmgr -export -l -f exported_filename
dbmgr -migrate -r migrated_filename
```

6. Start endpoint services.

[Windows]

```
seosd -start
```

[UNIX]

```
seload
```

**[Destination Endpoint]**

1. Log in to the destination endpoint as a root user (UNIX) or as an administrator (Windows).
2. Stop endpoint services.

[Windows]

```
secons -s
```

[Unix]

```
/opt/CA/PAMSC/bin/secons -sk
```

3. Copy the *exported\_filename* and *migrated\_filename* files from the source endpoint to the destination endpoint to a temporary directory.
4. Modify the *exported\_filename* and *migrated\_filename* files and update the rules that include the PAMSC installation path according to the new installation directory. Example: If the old installation path was C:\Program Files\CA\AccessControl, then the new installation path is C:\Program Files\CA\PAMSC. Please replace all database rules included old path according to the new path.

5. Import into the destination database the existing rules and user-related data that you exported from the source database:

```
selang -l -f exported_filename
dbmgr -migrate -w migrated_filename
```

6. Start endpoint services.

[Windows]

```
seosd -start
```

[UNIX]

```
seload
```

## Associating PAM SC Devices with PAM Devices

If you have duplicate PAM Server Control (SC) devices, you can associate them with a PAM device to reduce device duplication and to make management easier. For example, you might see duplicate PAM SC devices if you are migrating older PIM devices to PAM and PAM was unable to correctly match the PIM device to a PAM SC device.

- You can manually associate a PAM SC device from the Server Control tab. See [Manually Associating a PAM SC Device with a PAM Device](#).
- You can automatically associate multiple PAM SC devices to PAM devices from the Server Control Device Matching tab. See [Automatically Match PAM SC Devices with PAM Devices](#).

Once associated:

- The Agent Status tab and UNAB tab (if the PAM SC device is configured for UNAB) are added to the Manage Devices page. You can edit the device name and address of the PAM SC device on the Manage Devices page.
- All of the groups from the PAM SC device are added to the PAM device, and all of the PAM device group policies (if any) are deployed to the PAM SC device.
- The Server Control tab updates to show the Policies Assigned and Policies Deployed sections.

## Manually Associating a PAM SC Device with a PAM Device

To manually associate a PAM SC device with a PAM device:

1. Log in to the UI.
2. Select **Devices, Manage Devices**.
3. Select the PAM device to associate from the list and then select **Update**.
4. On the Server Control tab, select the search icon and then enter the search criteria for the PAM SC device. The PAM device info appears along with the Server Control Device Name section listing any resulting PAM SC devices.
5. Select the PAM SC device to associate and then select **OK**.

## Changing or Deleting the PAM SC Device Association

To change the PAM SC device that is associated with a PAM device or to remove the association altogether:

1. Log in to the UI.
2. Select **Devices, Manage Devices**.
3. Select the PAM device whose association should be modified from the list and then select **Update**.
4. From the Server Control tab, modify the association:

- To delete the association, select the delete icon next to the Server Control Device Name field. Optionally, delete the PAM SC device name from the Server Control Device Name field and select **OK**.
- To change the association to a different PAM SC device, enter the name of the new device in the Server Control Device Name field and then select **OK**.

If you delete the association between a PAM device and a PAM SC device, PAM performs the following operations:

1. Creates a new PAM device that has a Server Control host but no Device Type set.
2. Associates the PAM SC device with the newly created PAM device.
3. Adds all of the device groups from the existing PAM device to the newly created PAM device. The device groups are not removed from the existing PAM device.

## Automatically Match PAM SC Devices with PAM Devices

You can set PAM to automatically match multiple PAM SC devices with PAM devices. Once configured, PAM searches for matches when you import new SC devices, when SC agents are registered, or when you manually run the duplicate device matching option from the Unmatched Server Control Devices tab. Once matched, you associate them from the Unmatched Server Control Devices tab.

To enable PAM to automatically match multiple PAM SC devices with PAM devices:

1. Log in to the UI.
2. Select **Configuration, Server Control, Device Matching**.
3. On the Duplicate Device Matching Configuration tab, select **Enable Server Control Duplicate Resolution Matching** to configure PAM to search for unassociated PAM SC devices to match with PAM devices.
4. Set how PAM matches PAM SC devices with PAM devices:
  - Set which attribute PAM uses to identify a match. PAM can match the PAM device and PAM SC device by the device names, or by the fully qualified domain name or IP address of the devices. For each attribute you select, also set how strictly PAM compares those attributes.
    - Select **Exact Match** to let PAM match the PAM devices with PAM SC devices that have identical names or IP addresses.
    - Select **Partial Match** to let PAM match PAM devices with PAM SC devices that have similar host names or IP addresses. If you set this option, PAM may match multiple PAM SC devices. You should review the matches and then delete any incorrect matches. See [Deleting Multiple PAM SC Device Associations](#).
    - Select **Disabled** to have PAM ignore this attribute when matching. If you select Disabled, PAM creates a PAM device for each PAM SC device.
  - Select **Enable Automatic Duplicate Device Matching** to have PAM automatically match an SC device if one, and only one, PAM device match is found.
5. When a match is found, it appears in a table on the Unmatched Server Control Devices tab. You can associate a PAM SC device with a PAM device from this tab. See [Associating Device Matches and Running the Device Match Operation](#).

Once associated, the PAM SC device is removed from all customer-visible tables and is managed through the matched PAM device.

To view the status of your PAM SC device matches:

- View which PAM SC devices are matched from the **Matched Server Control Devices** tab of the **Configuration, Server Control Device Matching** page.
- View which PAM SC devices are not matched from the **Unmatched Server Control Devices** tab of the **Configuration, Server Control Device Matching** page. You can also view the status of duplicate device matching operations, and manually run duplicate device matches, from this page.

## Associating Device Matches and Running the Device Match Operation

Matched PAM SC devices appear on the Unmatched Server Control Devices tab of the **Configuration, Server Control** page. From this page you can:

- Review the device matching operation status. This page shows when the device matching operation was last run and what matching criteria was used. This page also shows when the matching criteria were last modified.
- Review the suggested device matches in the Device Match Suggestions table. You can filter the results of this table by column.

Each match includes a patch score. The match score identifies how many times the device matched the attributes that you set when you enabled automatic duplicate device matching. The higher the score, the closer the match.

- Associate the PAM SC devices to the PAM devices by selecting the device matches in the Device Match Suggestions table and then selecting **Match Devices**. Associated PAM SC devices are removed from all customer-visible tables. You manage these devices through the matched PAM device.
- Manually run the device matching operation by selecting **Run Duplicate Device Matching**. You must have enabled PAM to automatically associate multiple PAM SC devices with PAM devices. See [Automatically Match PAM SC Devices with PAM Devices](#).

## Deleting Multiple PAM SC Device Associations

To delete the association between multiple PAM SC devices and their associated PAM devices in one operation:

1. Log in to the UI.
2. Select the **Configuration, Server Control, Matched Server Control Devices** tab.
3. Select the PAM SC devices to disassociate, and click **Unmatch Devices**.

Once the PAM SC devices are disassociated, PAM performs the following operations for each PAM SC device:

1. Creates a new PAM device that has a Server Control host but no Device Type set.
2. Associates the PAM SC device with the newly created PAM device.
3. Adds all of the device groups from the existing PAM device to the newly created PAM device. The device groups are not removed from the existing PAM device.

## Install PAM SC Endpoints

This section describes how to install PAM SC endpoints.

Use the table of contents to access the topics in this section.

### Download the PAM SC Endpoint Installation Software

This procedure describes how to download the 14.1 Endpoint installation software.

Follow these steps:

#### NOTE

Check the 14.1 [Endpoint OS Support Matrix](#) to see if your version of Windows or Linux/Unix is compatible.

1. Open the [Broadcom Support Portal](#) in a new browser session. If you are prompted to log in, use your Broadcom Support credentials.
2. Select **Cyber Security Software** from the product selector (  ) drop-down list that is displayed to the left of your account name in the header.
3. Select **My Downloads** in the left pane.  
The **My Downloads - Cyber Security Software** page opens, listing your licensed products.

4. Select **PRIVILEGED ACCESS MANAGEMENT** from the list.
5. Search for **PAM Server Control MULTI-PLATFORM**.
6. Select **14.1** from the **Release** column, and then select **PAM Server Control MULTI-PLATFORM**.
7. Select the appropriate download:
  - For Windows, select **CA Privileged Access Manager Server Control 14.1 Endpoint Components for Windows DVD500000000001974.iso**.
  - For Linux / Unix, select **CA Privileged Access Manager Server Control 14.1 Endpoint Components for Unix DVD500000000001973.iso**.
8. Use the available controls to download your required component file or files.

**NOTE**

For more information about how to use the controls and generic information about this procedure, select the **Product Download Help** button in the top-right of the screen.

9. If necessary, copy the downloaded file or files to the systems where they are required.

## Install and Uninstall UNIX PAM SC Endpoints Using YUM

This content describes why and how to use YUM to install or uninstall UNIX PAM SC Endpoints. It also shows an example of how to install a PAM SC Endpoint on a UNIX host.

| Problem Statement                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Solution                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>You want to upgrade from existing PIM/ PAM SC Endpoints to PAM. Your primary requirement is to simplify PAM SC Endpoint installations, upgrades, and patches with <i>no</i> downtime and rollback mechanism in case of failures.</p> <p>Challenges:</p> <ol style="list-style-type: none"> <li>1. Have to copy the builds to thousands of machines.</li> <li>2. Upgrade is time-consuming in case of Large deployments.</li> <li>3. If the upgrade fails, we cannot roll back.</li> </ol> | <p>Simplify PAM SC Endpoint Installation or upgrade using YUM, which creates a central repository (repo) so that the PAM SC Endpoint can pull the software from the repo and install with the following benefits:</p> <ol style="list-style-type: none"> <li>1. Software-Dependency Resolution</li> <li>2. Increased efficiency through automation</li> <li>3. Improved user experience</li> <li>4. Reduce risk if the upgrade fails. You can Roll back to the previous good installation.</li> </ol> |

### Prepare the Repo

Use the following steps to configure a private YUM repo, add the package that contains the rpm to copy to the repo, and then configure.

#### Follow these steps:

1. Configure a private YUM repo on the machine. For example, the repo @ `radra02-I10333` hosts the following rpm packages for testing:
  - CAeAC-1410-0.1141.x86\_64.rpm
  - CAeAC-1401-1.0.616.x86\_64.rpm
  - ca-lic-01.90.04-00.x86\_64.rpm
2. Add the package that contains the rpm to copy to the repo. The following commands add a sample of the package and updates the repo with the new changes:
 

```
radra02-I10333:/var/ftp/pub/PAMRepo/ run
#createrepo --update /var/ftp/pub/PAMRepo/
```
3. Set `pupm_flags` for the account used for auto-login to establish an auto-login session. Otherwise, the session is not established and the session times out. Run the `selang` command shell, and then enter the following `selang` command:

```
editusr <Account that is used for Autologin> pupm_flags(use_original_identity)
```

For example:

```
editusr administrator pupm_flags(use_original_identity)
```

4. Configure the private repo to the Endpoint host by creating the `/etc/yum.repos.d/pam-package.repo` file. The `pam-package.repo` file should include content similar to the following snippet:

```
[pam-package]
name=PAM_PAM SC Endpoint_Repo
baseurl=ftp://radra02-I10333/pub/PAMRepo/
gpgcheck=0
enabled=1
```

5. Run the following command to list `pam-package repo` with packages.

```
#yum repolist
```

The output looks similar to the following snippet:

```
RHEL6_Update_u8
RHEL 6 $releasever Update 8 0
RHEL6_u8 RHEL 6 $releasever Update 8 3,997
pam-package PAM_PAM SC Endpoint_Repo
```

## **Install or Uninstall the Endpoint Using YUM**

Once the private YUM repo is ready, you can install or uninstall the Endpoint using YUM:

- To install the Endpoint, run:  

```
#yum install CAeAC-1410-0.1141.x86_64
```
- To uninstall the Endpoint, run:  

```
#yum erase CAeAC-1410-0.1141.x86_64
```

## **Install a PAM SC Endpoint on a UNIX Host**

This topic describes how to install a PAM SC Endpoint on a UNIX host. Before you proceed with this procedure, you must configure a private YUM repo.

### **Follow these steps:**

1. Run the following command to install the Linux PAM SC Endpoint using YUM:

```
yum install CAeAC-<Version>.<Architecture>.rpm
```

2. Enable the PUPM Agent to enable integration with Privileged Access Manager:

- a. Enter the following command to stop the `seosd` service:

```
/opt/CA/PAMSC/bin/secons -sk
```

- b. Using a standard text editor, open the file `etc/accommon.ini`. Make the following changes:

- Set the tokens in the `accommon.ini` file to the following values:

```
accommon.ini File PupmAgent OperationMode = 1 (default is 0) Communication Distribution Server =
ssl://<hostname>: 61616
```

Where `<hostname>` is the ActiveMQ Broker, such as `pamsc14-integration`

- Enable the PUPM agent as a plugin:

```
Plugins = PupmAgent
```

- Provide the IP of the Distribution Server (Utility Appliance) by replacing the existing `Distribution_Server` IP Address configuration with the actual Utility Appliance IP. For example:

```
Distribution_Server = ssl://10.131.60.166:61616
```

3. Provide the communication password that was specified during the installation of Utility Appliance (the default is "N0tall0wed"):

```
/opt/CA/PAMSC/bin/sechkey -t -pwd "N0tall0wed"
```

4. Load the Access Control daemons:

```
/opt/CA/PAMSC/bin/seload
```

5. Specify the Distribution Server (Utility Appliance) that the PAM SC Endpoint uses for Message Queue communication:

```
/opt/CA/PAMSC/bin/selang
```

```
PAMSC>so dh-
```

```
PAMSC>so dh+ (DH__@Utility Appliance IP)
```

6. Unload the kernel:

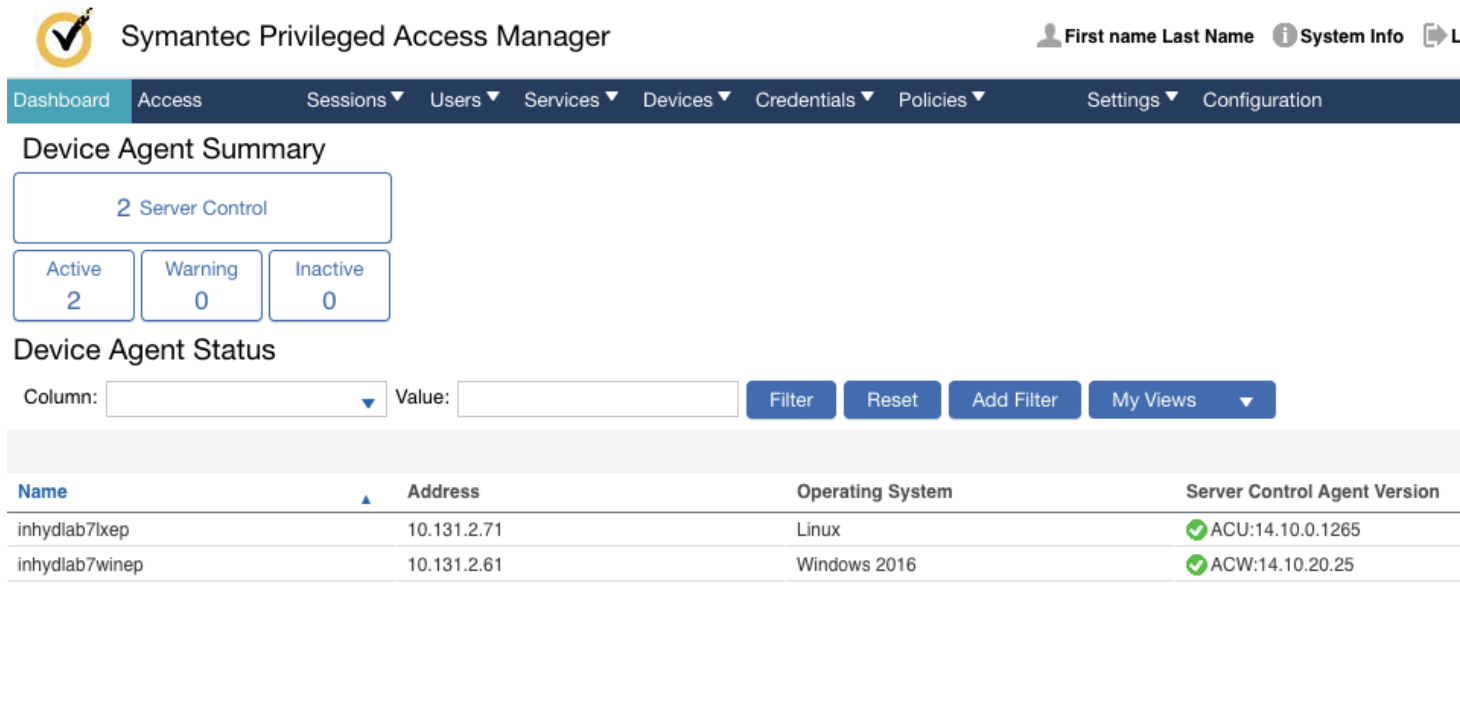

```
/opt/CA/PAMSC/bin/secons -sk
```

7. Reload the Access Control daemons:

```
/opt/CA/PAMSC/bin/seload
```

8. Validate the Server Control Agent is communicating with PAM.

- a. Log into PAM and navigate to Devices/Device Agent Status screen.
- b. Confirm that agent is communicating with PAM.

The screenshot shows the Symantec Privileged Access Manager web interface. The top navigation bar includes links for Dashboard, Access, Sessions, Users, Services, Devices, Credentials, Policies, Settings, and Configuration. The main content area is titled "Device Agent Summary" and shows "2 Server Control" agents. Below this, there are three boxes for "Active" (2), "Warning" (0), and "Inactive" (0). The "Device Agent Status" section includes a filter bar with "Column:" and "Value:" dropdowns, and buttons for "Filter", "Reset", "Add Filter", and "My Views". Below the filter bar is a table with the following data:

| Name           | Address     | Operating System | Server Control Agent Version |
|----------------|-------------|------------------|------------------------------|
| inhydlab7lxep  | 10.131.2.71 | Linux            | ✓ ACU:14.10.0.1265           |
| inhydlab7winep | 10.131.2.61 | Windows 2016     | ✓ ACW:14.10.20.25            |

## Native Package Installation Procedures

If repo is not configured, see the appropriate native package installation information.

### Linux Native Package Installation

- Package filename: CAeAC-<version>.<architecture>.rpm
- Package installation command: rpm -i CAeAC-<version>.<architecture>.rpm

**NOTE**

The installation process uses the source file for the package.

- Package removal command: `rpm -e CAeAC`

**NOTE**

The removal process uses the package name. The source file for the package is not used as the package name.

- Considerations:
  - `rpmbuild` utility must be present to update the package parameters and sign the package.
  - On Linux, you must install the CALic and CAWin packages first.

**Solaris Native Package Installation**

- Package filename: `_SOLARIS_PKG_128.tar.Z`
- Package name: `CAeAC`

**NOTE**

To prevent zone installation problems, install the package from a public directory such as `/var/spool/pkg`.

- Package installation command: `pkgadd [-G] -d <pkg_dir> CAeAC`  
The package is contained in the `CAeAC` directory. Use the `-G` switch to install in a Solaris 10 global zone.
- Package removal command: `pkgrm CAeAC`

**HP-UX Native Package Installation**

- Package filename: `_HPUX11_PKG_128.tar.Z`
- Package name: `CAeAC`
- Package installation command: `swinstall -s <pkg_dir> CAeAC`
- Package removal command: `swremove CAeAC`

**AIX Native Package Installation**

- Package filename: `_AIX_PKG_128.tar.Z`
- Package name: `CAeAC.<version>.bff`
- Package installation command: `installp -ac -d <pkg_dir> CAeAC`
- Package removal command: `removep -u CAeAC`

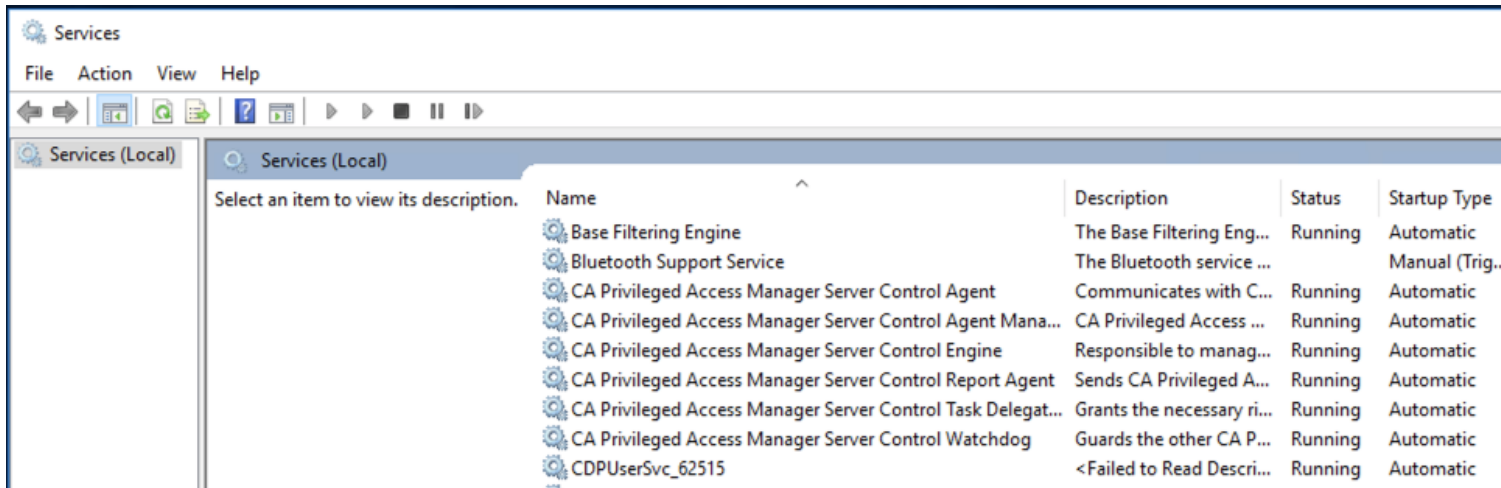

**Install a PAM SC Endpoint on Windows**

You must be a member of the local Administrators group to perform the installation.

The following example describes how to install the endpoint software on Windows using the graphical user interface (GUI):

1. Mount the ISO.
2. Locate the `PRODUCTEXPLORERX86.EXE` executable. Right-click the executable and choose **Run as administrator** to start the installation.
3. From the Components folder of the Product Explorer, select **CA PAMSC for Windows (64-Bit x64)**.
4. Select **Install**.
5. Select the language for the installation and select **OK**.
6. If you are prompted to install the Microsoft Visual C++ Redistributable libraries, select **Install** and wait for the installation to finish.
7. Review the License Agreement, select **I accept the terms of the License Agreement**, and select **Next**.
8. Provide your customer information (user name and organization) and select **Next**. For beta testing, just select **Next**.
9. Select the components to install. Consider the following options:

- If you plan to use PAMSC reporting functionality and audit event collection, select **Report Agent**. Otherwise, leave this item unchecked (the default).
  - Select PUPM Integration to enable integration with Privileged Access Manager, such as login integration.
  - Select the installation directory and select **Next**.
10. Configure the CA PAM SC Administrators and user store:
- Provide DNS domain names to add to the hostname when identifying the endpoint.
  - Provide the names of your PAM SC administrators. You must also identify the servers from which the PAM SC administrators are allowed to manage the endpoint. Typically, this server is the endpoint itself.
- The user installing PAM SC is added as an administrator by default. Do not remove this user or the installation fails. You can remove this user after the installation has completed.
- Select **Next**.
11. Select **Yes** for **Support users and groups from primary stores** (the default) unless there is a specific need to do otherwise. Keeping this setting allows PAM SC to recognize users from the native environment.
- Select **Next**.
12. Configure CA PAM SC communication. Keep the default encryption settings unless the encryption of the server was customized after the installation. The server installation uses AES 256 with the default key and no SSL by default. The client configuration must match the server settings.
- If you want to use SSL:
- Select **Yes** to use Secure Socket Layer (SSL) communication.
  - Leave the **Use Symmetric key encryption** checkbox checked.
- Select **Next**.
13. Select the encryption method to be used for symmetric encryption. 256bit AES is the default and preferred method. Other methods are available for backward capability.
- Typically, the organization specifies a unique encryption key. When symmetric encryption is used, the same key must be used between all endpoints and servers.
14. Enter `DH_@<IP Address Of Utility Appliance (Distribution Server)>` as the Policy Management Server Host. All communication between the endpoint and the PAM Server flows through the Distribution Server (Utility Appliance).
- Select **Next**.
15. Configure audit data collection by specifying when the Report Agent sends audit data to the Event Forwarder. The audit data is used for reporting purposes for SIEM integration.
- Select **Next**.
16. Specify the Distribution Server (Utility Appliance) that the endpoint uses for Message Queue communication. Use the same hostname as specified for Advanced Policy Management screen.
- Also provide the communication key (password) that was specified during the installation of the Utility Appliance (the default is `N0tall0wed`).
- NOTE**  
This setting can also be configured later.
- Select **Next**.
17. Review the installation parameters and select **Next**.
18. Select **Install** and wait for the installation to finish.
19. Select **Finish** to complete the installation.
20. You must reboot the server to load the PAM SC kernel drivers. Select **Yes** to reboot now, or select **No** to manually reboot later.
21. After the server has been rebooted, CA PAM SC components will be automatically started. Validate that all the CA PIM / PAM SC services are running.

22. You need to set `pupm_flags` for the account used for auto login to establish an auto-login session. Otherwise, the session is not established and the session times out. Run the `selang` command shell, and then enter the following `selang` command:

```
editusr <Account that is used for Autologin> pupm_flags(use_original_identity)
```

For example:

```
editusr administrator pupm_flags(use_original_identity)
```

23. Log into the PAM UI and navigate to **Devices, Device Agent Status** screen and confirm that agent is communicating with PAM.

## Uninstall a PAM SC Endpoint from a Windows System

Use one the following methods to uninstall a PAM SC Endpoint from a Windows computer:

### Regular Uninstall

The regular uninstall method uses a graphical interface to uninstall Privileged Access Manager Endpoint and provides interactive feedback.

#### Follow these steps:

1. Log in to the Windows system as a user with Windows administrative privileges. That is, as the Windows administrator or a member of the Windows Administrators group.
  2. (Optional) Stop PAM SC Endpoint services. For more information see, [Start and Stop PAM Server Control Endpoint Services](#)
- Note:** If you do not shut Privileged Access Manager services manually, the installation program shuts.
3. Select **Start, Settings, Control Panel**.  
The Windows Control Panel appears.
  4. Double-click **Add/Remove Programs**.  
The **Add/Remove** dialog appears.
  5. Select Privileged Access Manager Endpoint from the installed programs list and click **Add/Remove**.
  6. Click **Yes** to remove Privileged Access Manager Endpoint.
  7. Click **OK** when the Endpoint uninstallation completes.
  8. Reboot the computer to remove all Privileged Access Manager Endpoint components.

### Silent Uninstall

Use the command line to uninstall Privileged Access Manager Endpoint without interactive feedback.

**Follow these steps:**

1. Log in to the Windows system as a user with Windows administrative privileges. That is, as the Windows administrator or a member of the Windows Administrators group.
2. Enter the following command:

```
Msixexec.exe /x{822BFADC-E040-4F5C-A00A-B8E558A2D616} /qn insert_params_here
```

The *<insert\_params\_here>* variable specifies the installation settings that you want to pass to the installation program. For example, this command uninstalls Privileged Access Manager and creates an uninstall login c:\ac\_uninst.log:

```
Msixexec.exe /x{822BFADC-E040-4F5C-A00A-B8E558A2D616} /qn /l*v c:\ac_uninst.log
```

## Install a PAM SC Endpoint on a UNIX Host

This topic describes how to install a PAM SC Endpoint on a UNIX host. Before you proceed with this procedure, you must configure a private YUM repo. For instructions, see [Installing and Uninstalling an Endpoint Using YUM](#).

**Follow these steps:**

1. Run the following command to install the Linux PAM SC Endpoint using yum:

```
yum install CAeAC-<Version>.<Architecture>.rpm
```

2. Enable the PUPM Agent to enable integration with Privileged Access Manager:

- a. Enter the following command to stop the seosd service:

```
/opt/CA/PAMSC/bin/secons -sk
```

- b. Using a standard text editor, open the file etc/accommon.ini. Make the following changes:

- Set the tokens in the acccommon.ini file to the following values:

```
accommon.ini File PupmAgent OperationMode = 1 (default is 0) Communication Distribution Server =  
ssl://<hostname>: 61616
```

Where <hostname> is the ActiveMQ Broker, such as pamscl4-integration

- Enable the PUPM agent as a plugin:

```
Plugins = PupmAgent
```

- Provide the IP of the Distribution Server (Utility Appliance) by replacing the existing Distribution\_Server IP Address configuration with the actual Utility Appliance IP. For example:

```
Distribution_Server = ssl://10.131.60.166:61616
```

3. Provide your PAM SC communication password (default "N0tall0wed"):

```
/opt/CA/PAMSC/bin/sechkey -t -pwd "PAMSC_communication_password"
```

**NOTE**

You can change the default communication password from the **Configuration, Server Control** screen by deselecting the **Use Default** option and specifying a different value.

4. You can change the Load the Access Control daemons:

```
/opt/CA/PAMSC/bin/seload
```

5. Specify the Distribution Server (Utility Appliance) that the PAM SC Endpoint uses for Message Queue communication:

```
/opt/CA/PAMSC/bin/selang
```

```
PAMSC>so dh-
```

```
PAMSC>so dh+ (DH__@Utility Appliance IP)
```

6. Unload the kernel:

```
/opt/CA/PAMSC/bin/secons -sk
```

7. Reload the Access Control daemons:

```
/opt/CA/PAMSC/bin/seload
```

8. Validate that the Server Control Agent is communicating with PAM.
  - a. Log into PAM and navigate to Devices/Device Agent Status screen.
  - b. Confirm that agent is communicating with PAM.

## Native Package Installation Procedures

If repo is not configured, see the appropriate native package installation information.

### Linux Native Package Installation

- Package filename: CAeAC-<version>.<architecture>.rpm
- Package installation command: `rpm -i CAeAC-<version>.<architecture>.rpm`

#### NOTE

The installation process uses the source file for the package.

- Package removal command: `rpm -e CAeAC`

#### NOTE

The removal process uses the package name. The source file for the package is not used as the package name.

- Considerations:
  - The rpmbuild utility must be present to update the package parameters and sign the package.
  - On Linux, you must install the CALic and CAWin packages first.

### Solaris Native Package Installation

- Package filename: `_SOLARIS_PKG_128.tar.Z`
- Package name: CAeAC

#### NOTE

To prevent zone installation problems, install the package from a public directory such as `/var/spool/pkg`.

- Package installation command: `pkgadd [-G] -d <pkg_dir> CAeAC`

The package is contained in the CAeAC directory. Use the -G switch to install in a Solaris 10 global zone.

- Package removal command: `pkgrm CAeAC`

### HP-UX Native Package Installation

- Package filename: `_HPUX11_PKG_128.tar.Z`
- Package name: `CAeAC`
- Package installation command: `swinstall -s <pkg_dir> CAeAC`
- Package removal command: `swremove CAeAC`

### AIX Native Package Installation

- Package filename: `_AIX_PKG_128.tar.Z`
- Package name: `CAeAC.<version>.bff`
- Package installation command: `installp -ac -d <pkg_dir> CAeAC`
- Package removal command: `removep -u CAeAC`

## Use a Warning Period

In addition to deciding what to protect, the implementation team decides how to phase in the new security controls. To minimize disruption to current work patterns, consider an initial period in which you only monitor access to resources, rather than enforcing access restrictions.

You can monitor access by putting the resources into Warning Mode. When Warning Mode is enabled for a resource or a class, and user access violates access restrictions, Privileged Access Manager records a Warning message in the audit log. The product gives the user access to the resource.

**Note:** If you use Warning Mode, consider increasing the maximum size of the audit logs. For more information about Warning Mode, see the *Endpoint Administration* section.

### Privileged Access Manager Backdoor

When you first install Privileged Access Manager, you might incorrectly define rules in the database. Incorrectly defined rules can prevent users from logging in or executing commands. For example, you mistakenly define a rule that denies access to the system directory or to vital parts of the Windows registry.

Because it is difficult to stop the product and fix these mistakes, the product comes with a backdoor that lets you fix these types of problems. Because backdoors can be maliciously exploited, you can disable this backdoor once your system is set up and stable.

To access this backdoor when you start the computer, select the Windows Safe Mode or Safe Mode with Networking from the boot menu. When you select one of these options, the system starts without automatically starting the Privileged Access Manager services.

To disable this backdoor, define the registry value 'LockEE' of the data type `reg_dword` under the registry key `HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\AccessControl\` and set it to 1.

**Note:** This registry value does not exist by default.

Now when you start the system with LockEE set to 1 in:

- Safe Mode, only Privileged Access Manager Engine and Privileged Access Manager Watchdog load. The Privileged Access Manager Agent (and any Policy Models), which rely on network services, do not load.
- Safe Mode with Networking, Privileged Access Manager starts normally.

On UNIX, you can work with Privileged Access Manager in single user mode. When you work in single user mode, the following limitations apply:

- selang is supported in local mode (selang -l) only
- Network classes are not supported
- PMDB functionality (including using selang env pmd) does not work

## Security Implementation Tips

This section provides some implementation information to consider once you have installed Privileged Access Manager.

### **Types of Security**

You can handle security at your site by using one of the following approaches:

- Whatever is not explicitly allowed is forbidden. This is the ideal approach, but it is impossible to use during implementation. Because no rules exist that allow anything to be done on the system, the system blocks all attempts to define access rules. It is like locking yourself out of your car with the keys still in the ignition.
- Whatever is not forbidden is allowed. This approach may be less secure, but it is a practical way to implement a security system.

Privileged Access Manager lets you start with the second approach and, once access rules have been defined, switch to the first approach. Default access (defaccess) and universal access (\_default) rules let you define approach and switch protection policy at any time.

#### **WARNING**

You may need to add all users to the \_restricted group when switching a protection policy. Performance may be significantly affected when switching between protection policies.

### **Accessors**

An *accessor* is an entity that can access resources. The most common type of accessor is a user or group, for whom access authorities should be assigned and checked. When programs access resources, the owner (a user or group) of the program is the accessor. Accessors fall into three categories:

- A person who is associated with a specific user ID
- A person who is a member of a group that has access authority
- A production process that is associated with a certain user ID

The most common type of accessor is a user, a person who can perform a login and for whom access authorities should be assigned and checked. One of the most important features of Privileged Access Manager is accountability. Each action or access attempt is performed on behalf of a user who is held responsible for the request.

Privileged Access Manager lets you define groups of users. Users are usually grouped together by projects, departments, or divisions. By grouping users together, you can significantly reduce the amount of work needed to administer and manage security.

You can define new users and groups and modify existing users and groups through Privileged Access Manager Endpoint Management or through selang commands.

### **Resources**

An essential part of any security policy is deciding which system resources to protect and defining the type of protection these resources receive.

#### ***Resource Classes and Access Rules***

When installed, Privileged Access Manager immediately begins to intercept system events and checks for user authority to access resources. Until you tell the product how to restrict access to your system's resources and which resources to restrict, the result of all authorization checks is to permit access.

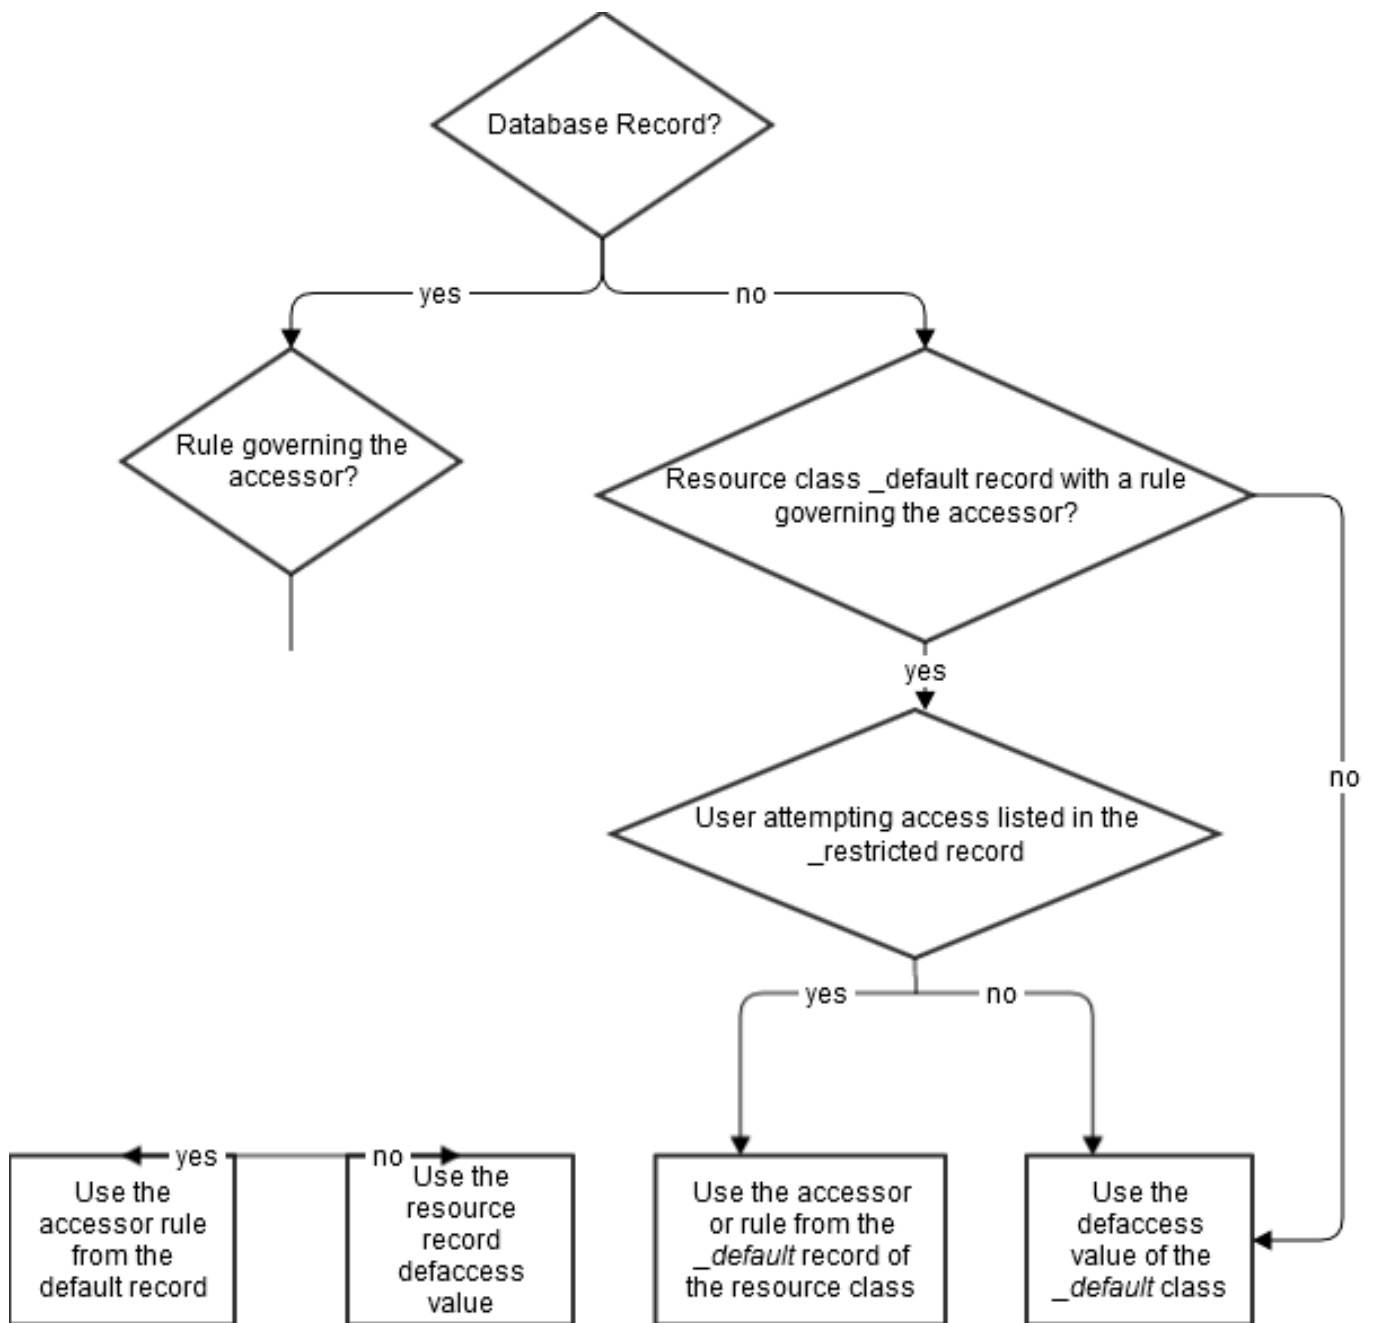

The properties of a protected resource are stored in a resource record. Resource records are grouped into classes. The most important information that is contained in a resource record is the access rules. An *access rule* governs the permission of one or more accessors to work with one or more resources. The following methods are ways to define access rules:

- **Access control list (ACL)**  
A specific list of the accessors authorized to access the resource and the exact access they can have.
- **Negative access control list (NACL)**  
A specific list of the accessors for which access should be denied.
- **Default access for the resource**  
Specifies access rules for accessors that are not listed in an ACL.
- **Universal access** (the `_default` record for a class)  
Specifies access for resources that do not have specific resource records in that class.
- **Program ACL**  
Defines access for a specific accessor through a specific program.
- **Conditional ACL**  
Requires that access depends on some condition. For example, in a TCP record, you can define access to a specific remote host through a specific accessor.
- **Inet ACL**  
Defines access for inbound network activity through specific ports.

### ***Using defaccess and \_default***

When access to a resource is requested, the database is searched in the following order to determine how the request is treated. Privileged Access Manager uses the first access rule that is found. Notice the distinction between *default access* (defaccess) and `_default`.

1. If the resource has a record in the database, and the record has a rule governing the accessor, then Privileged Access Manager uses that rule.
2. If the record exists but does not have a rule governing the accessor, that *record's* default access rule's *defaccess value* is applied to the accessor.
3. If the record does not exist, but in the resource class the `_default` record has a rule governing the accessor, then Privileged Access Manager uses that rule.
4. If the record does not exist, and in the resource class the `_default` record does not have a rule governing the accessor, then the `_default` record's default access rule (the record's defaccess value) is applied to the accessor. For files and registry keys, this applies only to `_restricted` users.

**Figure 38: Resource Class and Access Rules1**

The diagram above shows how the database record is searched to determine which access rules are applied.

**Note:** For more information about resource classes and access rules, see the *selang Reference* section.

## UNAB Endpoint Post Installation Configuration

This content describes how to perform the following two important post-installation configurations procedures:

## Register UNAB Endpoints in Active Directory

To let users defined in the Active Directory log in to UNIX computers, register a UNIX host in the Active Directory server for each UNIX computer on which you installed UNAB.

### Follow these steps on each UNAB Endpoint:

1. Log in to the UNIX/Linux host and become the root user.
2. Register the system with Active Directory by running the following command:

```
/opt/CA/uxauth/bin/uxconsole -register -a <domain user name>
```

For example:

```
root@usliac01aixlab:/opt/CA/uxauth/bin # ./uxconsole -register -a sonvi02 -w 1Qaz2wsx -d gisaclab.local
```

The output is similar to the following:

```
CA Access Control UNAB uxconsole v12.55.0.921 - console utility
Copyright (c) 2010 CA. All rights reserved.

Successfully registered the client.
Starting uxauthd.sh after a 20-second delay to allow for computer object replication in AD ...
UNAB Agent daemon started.
```

Note that registering the system with Active Directory starts the `uxauthd` process.

3. After you have registered the UNIX host in Active Directory, activate UNAB. Activation is the final step in the implementation process of UNAB. Once UNAB is activated, UNAB authenticates users, based on their Active Directory password.

Activate domain authentication by running the following command:

```
root@usliac01aixlab:/ # /opt/CA/uxauth/bin/uxconsole -activate
```

The output is similar to the following:

```
CA Access Control UNAB uxconsole v12.55.0.921 - console utility
Copyright (c) 2010 CA. All rights reserved.

Activation completed successfully.
root@usliac01aixlab:/
```

4. To enable centralized management of UNAB endpoints from the PAM server, configure UNAB for the distribution server (PAM Utility Appliance). This configuration lets users deploy policies to all the UNAB endpoints from a single PAM UI.

- Switch to the `/opt/CA/AccessControlShared/` directory.
- In a standard text editor, modify `accommon.ini` file. Set `Distribution_Server` token to `ssl://<distribution_server:7243>`.

For example, `Distribution_Server = ssl://usilss28-qa.gisaclab.local:7243`

For 12.x (TIBCO), the default TIBCO port is 7243. For PAMSC 14.1 (ACMQ), the default ActiveMQ port is 61616.

- Change directory to `/opt/CA/uxauth/bin`.
- Configure the password for communicating with the Utility Appliance by running the following command:

```
acuxchkey -t -pwd <distribution_server_password>
```

For example:

```
root@usliac01aixlab:/opt/CA/uxauth/bin # ./acuxchkey -t -pwd N0tall0wed
```

The output is similar to the following:

```
CA Access Control UNAB acuxchkey v12.55.0.921
Copyright (c) 2010 CA. All rights reserved.
```

Message queue password updated.

### **Configure UNAB Endpoints to Communicate With a Utility Appliance**

To enable centralized management of UNAB endpoints from the PAM server, UNAB must be configured to communicate with a Utility Appliance. Centralized management of UNAB endpoints allows users to deploy policies to all the UNAB endpoints from the PAM UI.

#### **Follow these steps on each UNAB Endpoint:**

1. Log in to the UNIX or Linux host and become the root user.
2. Change directory to `/opt/CA/AccessControlShared/`.
3. Open the `accommon.ini` file for editing in vi or other preferred text editor.
4. Locate the `Distribution_Server` token and modify its value to reference the IP address and port number of the Utility Appliance: `ssl://<utility_appliance:port>`

For example:

```
Distribution_Server = ssl://usilss28-qa.gisaclab.local:7243
```

5. Configure the password for communicating with the Utility Appliance by running the following command:

```
acuxchkey -t -pwd <utility_appliance_password>
```

For example:

```
/opt/CA/uxauth/bin # ./acuxchkey -t -pwd N0tall0wed
```

## **Server Control Configuration Settings**

Access the **Configuration, Server Control** settings to set endpoint agent status interval, configure a non-default ActiveMQ password, or enable and configure legacy Server Control login integration.

### **Agent Status Interval**

Use the **Agent Status Interval** controls to specify the warning and failure status intervals for Agents (PAM SC Endpoints).

- **Warning Status Interval:** The amount of time expired since the last heartbeat was received by PAM before a warning state is set for the PAM SC Endpoint on a device.
- **Failure Status Interval:** The amount of time expired since the last heartbeat was received by PAM before a failure state is set for the PAM SC Endpoint on a device.

#### **Follow these steps to also see the Agent Status:**

1. To view the status of the device agents, navigate to **Devices, Device Agent Status** to view all agents for Server Control, UNAB, and PUPM devices.
2. Use the Agent Status Interval settings to show agent status, and filter the devices on the Agent Status panel.

See [Agent Status Interval](#) for more information.

### **ActiveMQ Password**

Use the **ActiveMQ Password** option to manage the ActiveMQ password on PAM. By default, when PAM is deployed the password is "N0tall0wed." ActiveMQ sends messages between the PAM server and agents running on endpoints. The ActiveMQ section allows the PAM server to either use the default ActiveMQ password, or enter a new password that is used by all endpoints. This password must match the one used by your endpoints. This password does not override or replace the existing password of an endpoint.

#### **NOTE**

The Server Control Administrator and Configuration manager roles can see (view) the ActiveMQ section; however, these roles cannot change any fields.

To update the ActiveMQ password, the user should be Server Control Administrator, Configuration Manager, and Password Manager. For the Password Manager role, the user must be associated with the ActiveMQ Credential Manager Group. (The Credential Manager Group is installed by default, and comes out-of-the-box.) The superuser, as always, can also change these options.

**To change the ActiveMQ password, follow either one these steps:**

1. Log in to the PAM UI.
2. Select **Configuration, Server Control**.
  - Selecting **Use Default** means that the PAM server uses the default ActiveMQ password, which is N0tall0wed
  - To use a uniform, universal password for all your devices, clear the **Use Default** option, and enter a new password or accept the default in the text fields. The default is "N0tall0wed."

#### NOTE

If you enter a password, the Use Default option becomes unavailable.

### Enable Legacy Server Control Configuration

Set the **Enable Legacy Server Control Configuration** option to configure (or maintain) *legacy* Distribution Servers that were configured in previous PAM versions. PAM continues to support using the legacy integration but without the access control policy management features. This configuration setting is not applicable to new Utility Appliances (which replace Distribution Servers in this release).

#### NOTE

For more information, see [Privileged Access Manager Server Control Login Integration](#).

## Enabling Server Control TLS Settings

Transport Layer Security (**TLS**) is an encryption protocol that protects Internet communications. TLS is an improved version of SSL. The Distribution Host (implemented in the **pam-dh** service) in the Utility Appliance ships with TLS enabled by providing a default root certificate and default public and private keys that were derived from the default root certificate. As a best practice, it is recommended that an administrator replace the default root certificate with your own root certificate (a third-party certificate or a self-signed certificate). As a result of replacing the default root certificate, you need to create new public and private keys derived from the new root certificate.

You, as an administrator, can use the **TLS Settings** screen to specify your own root certificate, a corresponding public key certificate, a corresponding private key, and an optional passphrase for the private key. The contents of the root certificate, public key certificate, and private key with an optional passphrase are represented as Secrets within PAM. The Secrets are referred to in the **TLS Settings** screen by their aliases. The aliases for TLS Settings are collectively referred to as **Distribution Host TLS Aliases**.

After configuring the **TLS Settings**, you can assign them to Utility Groups. OnePAM then distributes the configured root certificate and the public and private keys to individual Utility Groups whenever a Utility Appliance's pam-dh service restarts.

As a last step, modify your UNIX and Windows Endpoints to trust the configured root certificate and enable exclusive TLS communication. For more information, see the [crypto topic](#) that describes the **communication\_mode** parameter for the **[crypto]** section of the **seos.ini** file. Specifically, make sure to set the **communication\_mode** parameter to **ssl\_only** to ensure that data is encrypted. Otherwise, your data may not be using SSL at all.

For more information, see [Enable SSL Encryption](#).

You use this feature by following these general steps:

1. Create Utility Groups containing Utility Appliances, for which you want to apply the TLS settings. See Step 1. Create Utility Groups.
2. Update the Utility Appliances with the proper patches. See Step 2. Updating Utility Appliances.
3. Obtain or create a root certificate. See Step 3. Create or Obtain a Root Certificate.

4. Use your root certificate to produce your server's public and private keys. See Step 4. Generate the Server, Public, and Private Keys.
5. Create a vault, and within the vault, create secrets from the TLS certificates with aliases. Create an authorization for the secrets, mapping the alias for each secret's alias within the vault to a utility group that contains the Utility Appliances to which you want the secrets to apply. See Step 5. Create a Vault and Add Your Secrets.
6. Apply the secrets to the Utility Groups in the **TLS Settings** screen. See Step 6. Enable the TLS Settings.
7. If needed, perform troubleshooting. See Troubleshooting.

### **Step 1. Create Utility Groups**

Before you can apply your TLS settings to your Utility Appliances, you must first create one or more Utility Groups containing one or more Utility Appliances. For more information on creating Utility Groups, see [Add Utility Appliance Devices to Utility Groups](#).

### **Step 2. Updating Utility Appliances**

The TLS settings use two services to help monitor their endpoints and communicate with PAM. Specifically, they appear on the **View Utility Group** window: the **pam-dh** service on the **View Utility Devices** tab, and the **dh-config** service on the **Config Maps** tab.

You need to go to **Configuration**, **Utility**, and then **Patches** to apply any needed patches to every Utility Appliance that uses the TLS settings to make these two services available.

For more information, see [Deploy and Manage Utility Appliance Update Patches](#).

### **Step 3. Create or Obtain a Root Certificate**

You may obtain a third-party X.509 certificate from a certificate authority, or you may create self-signed certificate. One method for creating a self-signed certificate is to use the open-source OpenSSL command-line utility.

### **Step 4. Generate the Server, Public, and Private Keys**

For more information about how to generate the server public and private keys, see [Enable SSL Encryption](#).

Specifically, in the [Use a Server Certificate You Generate from a Third-Party Root Certificate](#) section, see the example in step 5 named **Use seckey to Create a Server Certificate**.

### **Step 5. Create a Vault and Add Your Secrets**

Create a vault or use an existing vault. Within the vault, create secrets with aliases for the root certificate, server public key, and server private key. Optionally, if your public or private key uses a passphrase, you should add that as a secret as well.

Create an authorization for the all of the secrets, mapping the alias for each secret's alias within the vault to a Utility Group that contains the Utility Appliances to which you want the secrets to apply. This action provides authorization so the **pam-dh** service in the Utility Appliance can access the secrets that correspond to each of the aliases when it is restarted.

Note the following items when creating secrets:

- The private key is a binary file; to save the private key as a secret, convert the private key to base64-encoding using a base64 tool.
- You should not schedule any type of future use with TLS secrets. Ensure that when you create a secret, **NONE** of the **Future Use** options are enabled: Specifically, do not enable the **Expire Secret** or **Delete Secret** options.
- Enter only **one** name for the secret's alias in the Aliases field. If you accidentally enter more than one name, PAM only uses the first alias name with TLS settings.
- You cannot update or delete secrets that are currently assigned and are in use as TLS settings.

**Follow these steps:**

1. Make sure that you know the certificates and, optionally, the passphrase you want to add to the vault as secrets.
2. Create a vault or use an existing vault. For more information, see the [Adding or Updating a Vault](#) section in the [Managing Vaults](#) topic.
3. Make the certificates and keys into secrets, and then add your certificates as secrets to that vault. Optionally, if your public or private key uses a passphrase, you must add that as a secret as well. These secrets allow you to distribute your own crypto-certificates using the TLS settings. For more information, see [Adding or Updating a Secret](#).
4. After creating these secrets and their vault, you have to authorize them so they can be accessed. For more information, see [Managing Secret Authorizations \(Mappings\)](#).

**Step 6. Enable the TLS Settings**

As an administrator, you can use the **TLS Settings** screen to enable OnePAM to distribute your own root certificate, as well as the private and private keys to individual Utility Groups. You do this by associating Aliases (collectively known as the **Distribution Host TLS Aliases**) for the root certificate, server public key, and server private key to individual utility groups or to all Utility Groups. Optionally, if your public or private key uses a passphrase, you use that secret's alias as well.

**NOTE**

If you upgrade from 4.0 (or 4.1), all Utility Groups appearing will use the Default TLS alias values.

You cannot use the aliases used with an A2A account. Specifically, when you select **Credentials**, **Manage Targets**, **Accounts**, **Add Account**, and then select A2A as the **Target Account** type with an Alias.

The **TLS Settings** screen has two tabs:

- The **Initial TLS Settings** tab
- The **TLS Settings** tab

**Using the Initial TLS Settings Tab**

The DH component of the Utility Appliance comes with *Default* encryption already configured (expiration in year 2037). This default appears automatically within the **Initial TLS Settings** tab of the **TLS Settings** screen. The default encryption relies on a self-signed certificate, which may not be allowed within some users' production environments.

Use this tab to set the **Distribution Host TLS Aliases**: the root certificate, server public key, server private key, and the private key passphrase alias values to apply to every Utility Group that you create subsequently from saving the values entered here. Specifically, whenever you create a new Utility Group, its alias values populate with the values selected in this tab. You can also choose to immediately and universally apply the values entered in the **Initial TLS Settings** tab to all existing Utility Groups.

**Follow these steps:**

1. Select **Configuration**, **Sever Control**, **TLS Settings**. The **TLS Settings** screen appears, displaying the **Initial TLS Settings** tab. The Utility Appliance's default TLS encryption automatically populates the aliases' fields.
2. Use the **TLS Communication Allowed** option to select the TLS communication version to use with the Utility Group:
  - **All Versions**: This option, the default, enables TLS communication using your current TLS settings setup.
  - **TLS V1.2 Only**: This option enables TLS communications using only TLS V1.2.
3. Use the search icon to filter and select an alias value for the root certificate, server public key, server private key, and the private key passphrase.

**NOTE**

If you select a public key and private key, you must also provide a root certificate alias value. Otherwise, you can leave all fields blank. If you provide a value for either the root certificate, the public key, OR the private key, then you must provide values for all three fields.

4. Select **Save** to apply these values to every Utility Group that you subsequently create from saving the values entered here.

5. Select **Save All and Apply to All Utility Groups** to immediately and universally apply the values entered here to all existing utility groups.

### Using the TLS Settings Tab

Use this tab to set the alias values for the TLS communication version, the root certificate, server public key, server private key, and the private key passphrase for Utility Groups. You can simultaneously select any number of Utility Groups.

You can also display the **View Utility Status** window for a Utility Group by selecting a Utility Group and then selecting the **Status** button. For more information on this window, see [View Utility Group Status](#). This window is also useful for [Troubleshooting](#).

### **Follow these steps:**

1. Select **Configuration, Sever Control, TLS Settings**.
2. Select the **TLS Settings** tab. A list of existing Utility Groups appears. The **Distribution Host TLS Aliases** section lists the current alias values for the TLS communication version, root certificate, server public key, server private key, and the private key passphrase.
3. Select a Utility Group whose **Distribution Host TLS Aliases** you want to edit, and then select **Update**. The **Update <selected utility group name>** window appears, listing the **Distribution Host TLS Aliases**.

#### **NOTE**

You can simultaneously update multiple Utility Groups if you select multiple groups, and then select **Update**. All edits apply to all selected Utility Groups.

4. Choose the TLS communication allowed, or use the search icon to filter and select an alias value for the root certificate, server public key, server private key, and the private key passphrase.

#### **NOTE**

If you select a public key and private key, you must also provide a root certificate alias value. You can otherwise leave any field blank, and PAM uses the default value. If you provide a value for either the root certificate, the public key, OR the private key, then you must provide values for all three fields.

5. Select **OK** to confirm and exit this window. The values entered in this window apply and update the values of the **Distribution Host TLS Aliases** section of the **TLS Settings** tab.

### Troubleshooting

#### Check the Log Files

Select the **View Utility Devices** tab, and then select Log file for pam-dh. If the log displays values for `DH_ROOT`, `DH_PRIVATE`, and `DH_PUBLIC`, a line appears that says:

```
Custom Crypto required = true
```

If there is a value in the log for `DH_PRIVATE_PASSPHRASE`, then a line appears that says:

```
Passphrase required = true
```

The log file also displays any possible errors.

#### Using the Status Button

1. On **TLS Setting** tab, select a Utility Group, and then the **Status** button to display the **View Utility Group** window.
2. Select the **Config Maps** tab. The **Config Map** tab displays the values of Config Map objects (key-value pairs) that determine the behavior of the Utility Appliances in the Utility Group. The **dh-config** section displays the root certificate alias, as well as the public key alias, private key alias, and optional passphrase alias for every Utility Group.

For more information, see [View Utility Group Status](#).

#### Confirming Communication Between OnePAM and an Endpoint

Use these methods to help determine if there is a communication between OnePAM and an endpoint.

- Use the **Deployment Audit** tab on the **Policies, Manage Server Control** screen to view whether your policies have been properly deployed. For more information, see [View Server Control Policy Deployment Audit Data](#). If policies are not deploying properly, there may be an issue with the TLS settings.
- Select **Devices, Device Agent Status** to access the **Device Agent Status** screen, which shows the status, version, and other information about PAM SC Endpoint Agents of all types. For more information, see [View Server Control Endpoint Agent Status on the Device Agent Status Screen](#).
- Examine the **[policyfetcher]** section of the seos.ini file on the endpoint. This file contains various setup and initialization tokens that are used by Privileged Access Manager. For more information, see [policyfetcher](#).

## High Availability

The Enterprise Management Server uses mirrored sites to provide high-availability deployments. *Mirrored* sites are fully redundant facilities with full, real-time information mirroring and are identical to the primary site in all technical aspects. Data is processed and stored at the primary and mirrored sites simultaneously.

Mirrored sites employ an active-passive deployment for failover. An *active-passive* deployment includes two or more data centers, with one actively processing requests and the other ready to service requests if the active one fails. The clustering solution software that you select is responsible for controlling the active and passive servers and switching between them in case of failure.

In an active-passive deployment, the active server is referred to as the primary server, and the passive server is referred to as the secondary server.

## Configure Endpoints for High Availability

After you installed and configured the primary and secondary Enterprise Management Servers, you set up the Privileged Access Manager endpoints to work in a High Availability environment.

### Follow these steps:

1. Install Privileged Access Manager with the Advanced Policy Management Client feature that is enabled on the endpoint.
2. Open a Command Prompt window on the endpoint and enter the following command:

```
dmsmgr -config -dhname names
```

This command configures the endpoint to work with the comma-separated list of Distribution Hosts.

**Note:** For more information about the dmsmgr utility, see the *Reference section*.

3. Set the *Distribution\_Server* configuration setting to list the Distribution Servers, which are separated by a comma:

```
ssl://ds1.sample.com:7243, ssl://ds2.sample.com:7243
```

4. Save the settings.  
You have configured a list of Distribution Hosts and Distribution Servers with which the endpoint can communicate. The endpoint can now work in a High Availability environment.

### Example: Configure a List of Distribution Servers

The following example shows you how to configure a list of Distribution Servers for High Availability.

During the installation of the endpoint, you are asked to enter the parameters of the Distribution Server that the endpoint communicates with. By default, this is the Enterprise Management Server. For High Availability, you configure the endpoint to use the secondary Distribution Server when the primary Distribution Server fails.

1. Enter the names of the primary and secondary Distribution Servers:

```
dmsmgr -config -dhname DH__@node1.computer.com,DH__@node2.computer.com
```

A message appears confirming the action.

2. Specify the list of primary and secondary Distribution Server URLs.
  - **UNIX:** Modify the Distribution\_Server parameter in the [communication] section of accommon.ini file.
  - **Windows:** Modify the Distribution\_Server value in the Windows Registry. This parameter is found in:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\common\communication
```

## Communication Encryption

You can use the following methods to encrypt communication between Privileged Access Manager components and to encrypt client/server communication:

- Symmetric encryption
- SSL

### NOTE

When you change the encryption mode on Windows (for example, to FIPS-only mode), restart Privileged Access Manager services if you need to propagate passwords from a password PMDB.

## Uninstall HP-UX Package

To uninstall a UNAB HP-UX package installation, you need to uninstall the UNAB packages in the reverse order of their installation.

To uninstall Privileged Access Manager packages, uninstall the main UNAB package:

```
swremove unab_package_name
```

- *unab\_package\_name*  
Defines the name of the UNAB native package.

## Configure PAM SC to Protect Your Endpoints

This section describes how to protect your endpoints.

**Use the table of contents to access the topics in this section.**

### Server Control Policy Management Operations

This section describes how to do Server Control policy management operations.

**Use the table of contents to access the topics in this section.**

### Manage and Troubleshoot Server Control Policies

Use the controls on the **Policies, Manage Server Control** panel to create, update, and delete Server Control policies and audit and troubleshoot those policies on Server Control devices and device groups.

This topic describes how to use the default **Server Control Policies** tab to create, update, and delete Server Control policies.

### NOTICE

For information about the auditing and troubleshooting tasks available from the other tabs on the **Manage Server Control** panel, see the following topics:

- [Audit your Server Control policy deployments](#) (**Deployment Audit** tab).
- [Troubleshoot policies on Server Control devices](#) (**Device Troubleshooting** tab).
- [Troubleshoot policies on Server Control device groups](#) (**Device Group Troubleshooting** tab).

## Create a Server Control Policy

Do this procedure to create a Server Control Policy.

### Follow these steps:

1. Navigate to **Policies, Manage Server Control**.
2. On the **Server Control Policies** tab, select **Add**. The **Add Policy** dialog appears.
3. On the **General** tab, enter the name and description of the policy.
4. On the **Policy Script** tab, load a deploy policy script and an undeploy script by either importing the policy script or typing the `selang` commands directly in the dialog box. For example:

**Policy Script - Use Case:** Limit the scope of superuser "root."

Define a new FILE resource record with a default access of `none` and owner `nobody`. No user should be able to access this file. If you specify an owner as `nobody`, Access Control denies permission even if the logged in user is "root."

### NOTE

The FILE `/tmp/test1` must be present in the file system.

### Selang Script:

```
newres FILE /tmp/test1 owner(nobody) defaccess(none) audit(all)
```

5. In the **Description** field, enter an appropriate description to provide deployment script-specific information.
6. If you have further edits to make on the policy script, unset the **Finalize** option. When your edits are complete, set the **Finalize** option. You cannot deploy a policy script unless the **Finalize** option is selected. The default is checked.
7. On the **Policy Dependency** tab, move the appropriate dependent policies from the **Available Policies** list to the **Selected Policies** list. Assigning the dependent policies is a prerequisite to assign this newly created policy.
8. Select **OK**. The policy that you have now created is listed on the **Server Control Policies** page.

## Copy a Server Control Policy

Do this procedure to copy a Server Control Policy.

### Follow these steps:

1. Navigate to **Policies, Manage Server Control**.
2. On the **Server Control Policies** tab, select the policy to be copied and select **Copy**.
3. On the **General** tab, enter a new name and appropriate description of the policy.
4. Make the appropriate changes in the **Policy Script** tab and the **Policy Dependency** tab.
5. Select **OK**.

The new policy is created and listed on the **Server Control Policies** page.

## Update a Server Control Policy

Do this procedure to update a Server Control Policy.

**Follow these steps:**

1. Navigate to **Policies, Manage Server Control**.
2. On the **Server Control Policies** tab, select a policy that you want to update.
3. Select **Update**. You can also double-click any policy to update the policy.
4. On the **General** tab, enter a description of the policy in the **Description** field.
5. If the Policy was not finalized, update the policy scripts on the **Policy Script** tab as needed. If the Policy was finalized, select **Create New Version** on the **Policy Script**, and update the policy scripts to create a new version of the policy.
6. Enter appropriate description to provide deployment scripts-specific information in the **Description** field, if needed.
7. Clear the **Finalize** check box to allow further updates to the policy scripts. Select the option to finalize the policy. The default is checked.
8. On the **Version history** tab, all the previous versions of the policy are listed.  
You can select on each version to see the policy script details of that version in the Deploy Script and Undeploy Script sections. You can also select **Download** to download the commands of deploy script and undeploy script of the listed versions, as needed.
9. On the **Policy Dependency** tab, the dependent policies appear under the Members List. Select **OK**. Verify that **Confirmation: PAM-UI-0010: Policy Deleted** appears on the top of the screen.

**NOTE**

You cannot add or remove policies in the existing dependent policies.

**Delete a Server Control Policy**

Do this procedure to delete a Server Control Policy.

**Follow these steps:****NOTE**

Once deleted, you cannot restore a deleted policy. Verify that the following conditions are met before deleting the policies:

- The policy is not dependent on another policy. Remove any dependencies on a policy before you delete the policy.
- All the versions of the policies that are deployed are deleted before you delete a policy.
- The policy is not assigned or deployed on a Server Control Device or Server Control Device Groups.  
Unassign or undeploy the policy from the Server Control Device or Group before you delete the policy.

1. Navigate to **Policies, Manage Server Control**.
2. On the **Server Control Policies** tab, select a policy that you wish to delete.
3. Select **Delete**. Verify that **Confirmation: PAM-UI-0009: Policy Saved** appears on the top of the screen.

**Advanced Server Control Policy Management**

Use advanced policy management functions to manage policies across Server Control devices and device groups by assigning, unassigning, upgrading, and downgrading policies.

To access the advanced policy management functions, navigate to the **Policies, Manage Server Control** screen in the PAM UI. From here you can assign, unassign, deploy, and undeploy policies.

**Assign a Policy**

When you assign a policy, Privileged Access Manager deploys the latest finalized policy version of the stored policy. You can assign a policy on a Server Control device, Server Control device group, or both.

**Follow these steps:**

1. Navigate to **Policies, Manage Server Control** in the PAM UI.  
The **Server Control Policies** page appears.
2. Select a policy that you want to assign and select **Assign/Unassign**.
3. In the **Assign/Unassign Change DS** dialog that opens, move the appropriate device or devices from the **Available Server Control Devices** list to the **Selected Server Control Devices** list.
4. Select **OK**.
5. Select **Yes** to confirm the policy assignment.  
The following message appears at the top of the page: "Policy assign request successfully completed. Check the deployment audit for status"

**Unassign a Policy**

You can unassign a selected policy only on the devices or device groups to which it is assigned. When you unassign a policy, the undeploy policy script is executed. If there is no undeploy policy script, then the deploy policy script is reverted.

**Follow these steps:**

1. Navigate to **Policies, Manage Server Control** in the PAM UI.  
The **Server Control Policies** page appears.
2. Select a policy that you want to unassign and select **Assign/Unassign**.
3. In the **Assign/Unassign Change DS** dialog that opens, move the appropriate device or devices from the **Selected Server Control Devices** list to the **Available Server Control Devices** list.
4. Select **OK**.
5. Select **Yes** to confirm the policy unassignment.  
The following message appears at the top of the page: "Policy UnAssign request successfully completed. Check the Deployment Audit for status."

**Upgrade a Policy**

Upgrade a policy to set it to its latest finalized version on defined hosts. You can only upgrade a policy on a device if a higher version of the policy exists. When you perform the upgrade function on a device, the lower version of the policy is undeployed and the higher version of the policy is deployed.

**TIP****Example:**

Consider you have two versions of a finalized policy Policy\_1 - Policy\_1#1, Policy\_1#2, and the latest finalized policy version, that is Policy\_1#2, is deployed on a Server Control device.

You have updated the policy Policy\_1 which results in a new finalized policy version, that is Policy\_1#3.

To deploy Policy\_1#3 on the mentioned Server Control device, you must perform an upgrade function. When you upgrade the policy on the Server Control device, Policy\_1#2 is undeployed and Policy\_1#3 is deployed.

**Follow these steps:**

1. Navigate to **Policies, Manage Server Control** in the PAM UI.  
The **Server Control Policies** page appears.
2. Select a policy that you want to upgrade and select **Upgrade**.  
The **Upgrade Policy Change** dialog appears.
3. Optionally, filter the available Server Control devices using the **Device Group** field or the search (magnifying glass) icon below it.
4. Select the devices or groups that you want to upgrade from the **Available Server Control Devices** list and move them to **Selected Server Control Devices** list.

5. Select **OK**.
6. Select **Yes** to confirm the policy upgrade.  
The following message appears at the top of the page: "Policy Upgrade request successfully completed. Check the Deployment Audit for status."

### **Downgrade a Policy**

Downgrade a policy to set a specified policy version on defined hosts. You can only downgrade a policy on a device if a lower version of the policy exists. When you downgrade a policy, the higher version of the policy is undeployed and the lower version of the policy is deployed.

#### **TIP**

#### **Example:**

Consider you have two versions of a finalized policy Policy\_1-Policy\_1#1, Policy\_1#2, and the latest finalized policy version, that is Policy\_1#2, is deployed on a Server Control device.

To re-deploy Policy\_1#1 on the mentioned Server Control device, you must perform a downgrade function. When you perform the downgrade function on the Server Control device, Policy\_1#2 is undeployed and Policy\_1#1 is deployed.

#### **Follow these steps:**

1. Navigate to **Policies, Manage Server Control** in the PAM UI.  
The **Server Control Policies** page appears.
2. Select a policy that you want to downgrade and select **Downgrade**.
3. Select the version to which you want to downgrade from the **Policy Versions** drop-down.  
The Server Control Devices on which you can downgrade this policy are listed under **Available Server Control Devices**.
4. Select the devices from the **Available Server Control Devices** list and move them to **Selected Server Control Devices** list.
5. Select **OK**.
6. Select **Yes** to confirm the policy downgrade.  
The policy is downgraded.

## **Server Control Policy Management APIs**

This topic describes the Server Control policy management APIs.

1. Enable and configure the API Docs. See [Use the External REST API \(Programmers\)](#) for details.
2. Select **Settings, API Doc** to access the API Docs.
3. Navigate to **serverControlAccessPolicies** to see a list of available Server Control APIs, implementation notes, parameters, response message, and test API requests.

## **Configure Login Integration for a Server Control Endpoint**

PAM Integrated Server Control supports login integration (auto login) for endpoints connected to Utility Appliances (UAs) and those still connected to legacy Distribution Servers (DSs).

Utility appliances allow PAM to support login integration and access control policy management. To use the PAM access control policy management features, migrate your PIM or PAM SC environment to PAM release 4.0 or later.

As a security administrator, you want to audit the actual user of your server, not the shared local privileged user name. Using PAM Integrated Server Control, login integration integrates the login process and user information. When activated, it allows the use of the actual user name for auditing in PAM Integrated Server Control.

The topics in this section describe how to configure login integration in detail.

**Use the table of contents to access the topics in this section.**

## Agent Status Interval

This content describes how to check the status interval for Agents (endpoint devices) using PAM Integrated Server Control.

**Follow these steps:**

1. To view the status of the device agents, navigate to **Devices, Device Agent Status** to view all agents for Server Control, UNAB, and PUPM devices.
  2. Use the agent status interval settings to show agent status, and filter the devices on the Agent Status panel.
- **Warning Status Interval:** The amount of time expired since the last heartbeat was received by PAM before a warning state is set for the agent on a device.
  - **Failure Status Interval:** The amount of time expired since the last heartbeat was received by PAM before a failure state is set for the agent on a device.
  - **Enable Legacy Login Integration:** Use this option when configuring (or maintaining) *existing* legacy DS systems configured in previous PAM versions. PAM continues to support using the legacy integration but without the access control policy management features. This configuration setting is not applicable to new Distribution Server systems.

## Configure Server Control Login Settings

Complete the following procedures to configure Server Control Login settings:

In general, integrating Server Control Login requires configuring specific Server Control settings and creating the following endpoint definitions:

- Device
- Account
- Application
- Policy

Complete the procedures in this section to configure Server Control Login settings. **Use the table of contents to access the procedures.**

### NOTE

To use server names instead of IP addresses, verify that DNS Servers are configured in the Network Configuration section. In the PAM UI, select **Configuration, Network, Network Settings**. Verify that a DNS IP address is listed in the **DNS Servers** field. If no DNS IP address appears, add your DNS Servers. Select **Update** to save the changes.

## Configure ActiveMQ for Server Control

If you migrated from a legacy PIM or PAM SC environment, you must configure ActiveMQ using the procedure outlined in this content.

### NOTE

This procedure requires information from the Server Control setup.

**Follow these steps:**

1. Log in to the PAM UI.
2. Select **Configuration, Server Control**.

3. Set the **Enable Login Integration** option.
4. In the **ENTM Host Name or IP** field, enter the target server hostname or IP address.
5. Enter the **Port** number, or accept the default 61616.
6. Optionally, unset the **Use SSL** option, which is set by default.
7. Enter the **ActiveMQ Broker Account**. The default is "reportserver."
8. Enter the **Password**.
9. Optionally, specify a different **Message time-to-live** value. The default is 60 minutes.
10. Optionally, specify a different **Reply Timeout**. The default is 10 seconds.
11. Select **Ping AMQ Console** when complete.
12. Verify that your information is correct, and then select **Save**.

## Create PAM Devices for Server Control Endpoints

Create PAM devices to represent endpoint devices on which the user runs the login integration.

Create PAM devices to represent endpoint devices on which the user runs the login integration.

The user needs the device, application, and account so the end user can create an access policy for the login integration to go through. Use the following procedure to create a device for a Server Control endpoint.

### Follow these steps:

1. Select **Devices, Manage Devices**.
2. Select **Add** to create a device.
3. Enter the host name in the **Name** field.
4. Enter the IP address in the **Address** field. To verify the IP address, select **Scan**.
5. Specify the target **Operating System**.
6. Set the **Password Management** option.
7. Select the **Access Methods** tab and select the plus sign (+) Button to add an Access Method.
8. Select the access type (such as SSH or RDP) from the **Name** drop-down list. Specific access method details appear. Add or alter the information as necessary.
9. All other fields on all tabs are optional.
10. Select **OK** to save your changes.

## Create an Application for Server Control Endpoints

The user needs the device, application, and account so the end user can create an access policy for the login integration to go through. Use the following procedure to create an Application for the Privileged Access Manager Server Control endpoint.

The user needs the device, application, and account so the end user can create an access policy for the login integration to go through. Use the following procedure to create an application for the Privileged Access Manager Server Control endpoint.

### Follow these steps:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add** to create an application.
3. In the **Host Name** field, either enter the host name, or use the magnifying glass icon to the right of the field to select an existing Device.
4. Enter the **Device Name**. You can also select an existing device using the magnifying glass icon to the right of the **Host Name** field.

5. Enter the target **Application Name**.
6. Select the **Application Type**. If nothing else applies, select **Generic**. Certain Application Types display more options when selected. For example, Windows Proxy allows selection of Local or Domain Account. Most fields are optional or show a default value.
7. Select **OK** to save your changes.

#### NOTE

Windows or Windows-proxy applications using a local account require that you do one of the following steps:

- Use the target device's machine name (netbois name) in the **Address** field of the target device.
- If you use an IP address in the **Address** field, create a selang user for the target account manually: IP\_Address\target\_account.

## Create an Account for Server Control Endpoints

Create an Account for the Privileged Access Manager Server Control endpoint.

#### Follow these steps:

1. Select **Credentials, Manage Targets, Accounts**.
2. Select **Add** to create an account.
3. In the **Host Name** field, either enter the host name in the Host Name field, or use the magnifying glass icon to the right of the field to select an existing Device.
4. Enter the **Device Name**. You can select an existing device using the Select magnifying glass icon to the right of the **Host Name** field.
5. Use the magnifying glass icon to the right of the **Application Name** field to select Applications that have already been created for the Device. Alternatively, use the Add Target Application plus sign (+) icon to add an application directly from this screen.
6. Enter the **Account Name** to use for connecting to the Server Control endpoint.
7. Enter the **Password** for the Account Name that you selected.
8. Other fields are optional. At this point, you may want to enable password management options. For more information, see [Implementing Credential Manager](#).
9. Select **OK** to save your changes.

## Create an Access Policy for Server Control Endpoints

Create an Access Policy for the Server Control host.

#### Follow these steps:

1. Select **Policies, Manage Policies**.
2. Select the **Add** button to create a policy.
3. Select the **User** to use for connecting to the Server Control device.
4. Select the Server Control **Device**.
5. On the **Access** tab, select one or more entries from the **Available Access** list, and then move them to the **Selected Access** list.
6. On the **Symantec PAM Server Control** tab, set the **Login Integration** option.
7. Other fields are optional.
8. Select **OK** to save your changes.

## Test the Login Integration for Server Control Endpoints

To test the Privileged Access Manager Server Control Login Integration, you connect through the Access link on the Access Management page and verify the user name substitution.

### Follow these steps:

1. In the PAM UI, select **Access**. A list of Device Names appears with corresponding Access Methods and Target Applications.
2. Select the **Access Method** link (such as RDP or SSH) for the Server Control Device you are integrating. An RDP or SSH session opens to the Device.
3. For Windows RDP, open PowerShell or the Command prompt. For Linux, use the SSH prompt. The prompt includes the local Server Control privileged user login, not the Privileged Access Manager user.
4. For Windows, enter `secons -whoami`. For Linux, enter `/opt/CA/AccessControl/bin/sewhoami -a`. The Server Control `secons` utility writes several lines of text.
5. Find the "PUPM User" from the output of the previous command. This output should be the Privileged Access Manager user, not the local Server Control privileged user.

### IMPORTANT

Login Integration between PIM 12.x and PAM 4.0 is not supported.

## Change the ActiveMQ Password

The ActiveMQ password is meant for managing the ActiveMQ password on PAM. By default, when PAM is deployed the password is N0tall0wed.

ActiveMQ sends messages between the PAM server and agents running on endpoints. The ActiveMQ section allows the PAM server to either use the default ActiveMQ password, or enter a new password used by all endpoints. This password must match the one used by your endpoints: it does not override or replace an endpoint's existing password.

### NOTE

The Server Control Administrator and Configuration manager roles can see (view) the ActiveMQ section; However, these roles cannot change any fields.

To update the ActiveMQ password, the user should be Server Control Administrator, Configuration Manager, and Password Manager. For the Password Manager role, the user needs to be associated with the ActiveMQ Credential Manager Group; the Credential Manager Group is installed by default, and comes out-of-the-box. The superuser, as always, can also change these options.

### To change the ActiveMQ password, follow either one these steps:

1. Log in to the PAM UI.
2. Select **Configuration, Server Control**.
  - Selecting **Use Default** means the PAM server uses the default ActiveMQ password, which is N0tall0wed
  - To use a uniform, universal password for all your devices, make sure to clear the **Use Default** option, and either enter a new password, or accept the default in the text fields. The default is N0tall0wed.

### NOTE

If you enter a password, the Use Default option becomes unavailable.

## Import PIM and PAM SC Active Directory Users into PAM

Do the following procedure to import PIM and PAM SC Active Directory users into PAM.

**Follow these steps:**

1. In the PAM UI, select **Devices, Manage Devices**. A list of configured devices is displayed.
2. Select **Add**. The **Add Device** page is displayed.
3. Enter the details of the Active Directory server:
  - **Name**: The Active Directory server name
  - **Address**: The Active Directory IP address
  - **Description**: Optionally, provide a description for the device.
  - **Device Type**: Set the **Password Management** option.
4. Select **Save and Add Target Applications**. The **Add Target Application** page is displayed.
5. On the **Add Target Application** page that opens, complete the following details:
  - **Application Name**: The application name
  - **Application Type**: Active Directory
6. Select the **Active Directory** tab and complete the following details:
  - **Domain Name**: *AD\_Domain\_name*
  - **Domain Controller Port (SSL)**: 389
  - **Groups**: Domain Users
7. Navigate to **Credentials, Manage Targets, Accounts**. The **Target Accounts** page is displayed with the list of already existing accounts.
8. Select **Add**. The **Add Target Account** page is displayed.
9. On the **Add Target Account** page that opens, enter the following details:
  - **Host Name**: The IP address of the Active Directory server
  - **Device Name**: The Name of the Device Created Earlier
  - **Application Name**: The Name of the Application Created Earlier
  - **Account Name**: The Name of an AD User who is a member of the Domain Admins Group
  - **Password**: An Active Directory User Password
10. Select the **Active Directory** tab and enter the Distinguished Name.
11. Navigate to **Configuration, 3rdParty, LDAP**. Verify that the AD domain that you added previously is listed.
12. Double-click the domain and verify that all the details are correct.
13. Log in to the PAM UI through the PAM client.
14. Select **Users, Manage User Groups**, and then select **Import LDAP Groups**.
15. In the **Select LDAP domain** dialog that opens, select the AD domain that you added previously and click **OK**.
16. Select the required groups and select **Register selected groups with the PAM appliance**.
17. Select **Register groups**. The selected groups are registered.
18. Go to **Users, Manage Users** and verify that all the imported AD users are displayed.

## Configure UNAB to Provide Access to UNIX Computers Using Active Directory

The content in this section describes how to configure UNAB to provide access to UNIX systems using an Active Directory data store.

**NOTE**

In contrast to PIM and PAM SC, PAM 4.0 does not support manually creating either UNAB users or UNAB user groups. PAM 4.0 also does not support creating a Login Authorization Policy for UNAB users or UNAB user groups. You can only use LDAP to import Users or User Groups. For more information, [Import LDAP User Groups](#) and [Import LDAP Device Groups](#).

Use the table of contents to access the topics in this section.

## UNIX Authentication Broker (UNAB) Overview

This content provides an overview of the UNIX Authentication Broker (UNAB).

### UNAB Components

The UNIX Authentication Broker (UNAB) consists of several components that manage and control access to the UNIX host by Active Directory users.

- **UNAB authentication agent:** The UNAB authentication agent (uxauthd) daemon services the connection with Active Directory. The agent has the following responsibilities, among others:
  - Maintaining a secure connection with Active Directory for user authentication and login authorization purposes
  - Host registration with Active Directory
  - User and group migrations
  - Administering the local access files
- **uxconsole:** The uxconsole is the UNAB management console. Use the console to register the UNIX host with Active Directory, migrate users and groups, and to register and activate UNAB.
- **Privileged Access Manager Server Control Enterprise Management:** This component lets you manage your UNAB hosts from a central location. Using Privileged Access Manager Server Control Enterprise Management, you can:
  - Control Active Directory users access to every UNAB host in the enterprise.
  - Manage hosts login authorizations.
  - Resolve hosts migration conflicts.
  - Generate reports

### How To Set up UNAB

Understanding how the UNIX Authentication Broker (UNAB) controls access to the UNIX host provides you with information that helps you during the implementation and configuration process. After you install UNAB on the UNIX host, register UNAB with Active Directory. Activate UNAB to enable enterprise users to authenticate to UNIX endpoints. You then begin the migration process to migrate local users and groups in to Active Directory.

1. Register the UNIX host with Active Directory.  
At this stage UNAB does not intercept any login requests.
2. Define which enterprise users and groups are permitted or denied access to the UNIX host. You do so by creating login authorization policies from **Privileged Access Manager Server Control Enterprise Management**.
3. Activate UNAB to enable enterprise users authentication to the UNIX host.
4. Add more enterprise users and groups to the UNAB login authorization policies to enable new users to log in.  
At this stage, users who are defined in the local user store (for example, etc/passwd) and enterprise users who are permitted by UNAB login authorization policies can log in.
5. Migrate users and groups into Active Directory.

### How UNAB Authenticates Users

After you install and configure UNAB on the UNIX host, users can log in with their Active Directory user account or their local user account, according to the integration mode you implemented. When a user attempts to log in to a UNIX host where UNAB is running, the following events occur:

1. The user is prompted for an Active Directory or local account user name and password.
2. UNAB authenticates the user credentials with Active Directory, using the login authorization policy or the local host access files. UNAB also checks for additional information that is taken from the user account.
3. If the user is authenticated, UNAB grants the user access to the UNIX host. If not, UNAB blocks the user access to the host.

## Information Stored on the UNAB Endpoint

After UNAB authenticates a user, UNAB stores the following information about the endpoint:

- User name
- Hashed password (using SHA-2)
- User class attributes
- User account control
- Time of the last good login
- Time of the last bad login
- Number of bad logins since last good login

UNAB saves the user details in the `logon.db` file. The NSS database saves the user and groups attributes in the `nss.db` file. Both files reside in the directory `/opt/CA/uxauth/etc`.

## Manage UNAB Login Authorization for Devices and Device Groups

The content in this section describes how to manage UNAB login authorization for devices and device groups, most of which occurs on the **UNAB Login Authorization Policies** panel.

### NOTE

Unlike PIM and PAM SC, Integrated PAM SC does not support manually creating UNAB users or UNAB user groups. Integrated PAM SC also does not support creating a Login Authorization Policy for UNAB users or UNAB user groups. You can only use LDAP to import Users or User Groups. For more information, [Import LDAP User Groups](#) and [Import LDAP Device Groups](#).

- [Add a UNAB User Login Authorization to Devices](#)
- [Add a UNAB Config Token to a Device Group](#)
- [Add UNAB User Group Login Authorization to a Device](#)
- [Add a UNAB User Group Login Authorization to a Device Group](#)
- [Update the UNAB User Login Authorization Policy for a Device or Device Group](#)
- [Update the UNAB User Group Login Authorization Policy for a Device or Device Group](#)

### TIP

For information about troubleshooting tasks available from the other tabs on the **UNAB Login Authorization Policies** panel, see the following topics:

- [Troubleshoot Policies Deployed on UNAB Devices](#) (**Device Troubleshooting** tab).
- [Troubleshoot Policies Deployed on UNAB Device Groups](#) (**Device Group Troubleshooting** tab).

## Add a UNAB User Login Authorization to Devices

Do the following procedures to add a UNAB user login authorization to devices.

### NOTE

In contrast to PAMSC, PAM 4.0 does not support either manually creating either UNAB users or UNAB user groups, nor creating a Login Authorization Policy for these UNAB users or UNAB user groups. You can only use LDAP to import Users or User Groups. For more information, [Import LDAP User Groups](#) and [Import LDAP Device Groups](#).

## Add Users and User Groups

Do this procedure to add users and user groups.

**Follow these steps:**

1. In the PAM UI, select **Policies, Manage UNAB Policies**. The **UNAB Login Authorization Policies** screen appears.
2. Select **Add**. The **Add UNAB Login Authorization Policy** dialog appears.
3. Add a description for the policy in the **Description** field.
4. Use the **Device Name** tab to select the device to add to the policy.  
The Available Groups list identifies all UNAB Users that exist on this Privileged Access Manager appliance.
5. Use the **Users** tab to select the users or user groups to associate with a policy. The Available Users and Groups lists identify all Active Directory users and user groups that exist and that are linked to a UNAB host machine. These users and user groups are imported from AD/LDAP using the PAM LDAP importer. These users and user groups must have a CA ControlMinder attribute to appear in the **Login Authorization** policy page.
6. Select the desired user or user group, and then select **OK**.

**Add Users to Policies**

Do this procedure to add users to policies.

**Follow these steps:**

1. In the PAM UI, select **Policies, Manage UNAB Policies**. The **UNAB Login Authorization Policies** screen appears.
2. From the **UNAB Login Authorization Policies** tab, select the policy to update, and then select **Update**.  
The **Update UNAB Login Authorization Policy** dialog appears.
3. Select the **Users** tab and use the shuttle to select users for your policy.
4. Select **OK** to confirm the change and exit this dialog.

**Add User Groups to Policies**

Do this procedure to add user groups to policies.

**Follow these steps:**

1. In the PAM UI, select **Policies, Manage UNAB Policies**. The **UNAB Login Authorization Policies** screen appears.
2. From the **UNAB Login Authorization Policies** screen, select the policy to update, and then select **Update**.  
The **Update UNAB Login Authorization Policy** dialog appears.
3. Select the **User Groups** tab and use the shuttle to select user groups for your policy.
4. Select **OK** to confirm the change and exit this dialog.

**Audit UNAB Policy Deployments**

You can audit your UNAB policy deployments. This audit gives you a view of your UNAB policy deployments and a descriptive list of deployment tasks. The list details what triggered each deployment task, when it was created, and what type of deployment was involved. For each deployment task, you can further explore the following details:

- For which host and policy pair the deployment task created
- The version of the policy that was deployed
- The status of the deployment task (queued, succeeded, or failed)
- The `selang` output (result of deploying the command)

**To audit UNAB policy deployments, follow these steps:**

1. In the PAM UI, select **Policies, Manage UNAB Policies**. The **UNAB Login Authorization Policies** screen appears.
2. In the **UNAB Login Authorization Policies** screen, select **Deployment Audit**. The **Deployment Audit** dialog appears.

3. Define a scope for the deployment audit using the Column and Value filters, and then select **View**. To view the policy, the user selects a particular policy and then selects **View**. The Privileged Identity Manager Enterprise Console retrieves information about deployments that are in the scope you defined and displays the results after a short delay.

## Add a UNAB Config Token to a Device Group

Do this procedure to add a UNAB Configuration Token to a device group.

### Follow these steps:

1. In the PAM UI, select **Devices, Manage Devices, Groups**.  
A list of all devices groups is displayed.
2. Select the UNAB device group and double-click or click on **Update**.  
The **Update Device** page is displayed.
3. Click on the **UNAB** tab. The current **UNAB Configuration Token Update** page is displayed.
4. Click on the **+** icon.  
A new blank row is displayed.
5. Select the appropriate section, token, and value from the drop-down menu and click **OK**.

## Add UNAB User Group Login Authorization to a Device

Use the following procedure to add a UNAB User Group Login Authorization to a device.

1. In the PAM UI, select **Policies, Manage UNAB Policies**.  
The **UNAB Login Authorization Policies** tab appears.
2. From the **UNAB Login Authorization Policies** tab, select **Add**.  
The **Add UNAB Login Authorization Policy** window appears.
3. Add a description for the policy in the **Description** field.
4. Use the **Device Name** tab to select the device to add to the policy.
5. Use the **User** tabs to select the User Group to associate with a policy.  
The Available Users and Groups lists identify all Active Directory users and Groups that exist and are linked to a UNAB host machine. These users and user groups are imported from AD/LDAP using the PAM LDAP importer. These users and user groups must have a CA ControlMinder attribute to appear in the Login Authorization policy page.
6. Select the desired user, and then select **OK**.

## Add a UNAB User Group Login Authorization to a Device Group

This procedure describes how to add a UNAB User Group Login Authorization to a Device Group:

### Follow these steps:

1. In the PAM UI, select **Policies, Manage UNAB Policies**.  
The UNAB Login Authorization Policies tab appears.
2. From the **UNAB Login Authorization Policies** tab, select **Add**.  
The **Add UNAB Login Authorization Policy** window appears.
3. Add a description for the policy in the **Description** field.
4. Use the **Device Name** tab to select the device group to add to the policy.  
The Available Groups list identifies the UNAB users that exist on this Privileged Access Manager appliance.
5. Use the **User** tab to select the user group to associate with a policy.

The Available Users and Groups lists identify the Active Directory users and groups that exist and that are linked to a UNAB host machine. These users and user groups are imported from AD/LDAP using the PAM LDAP importer. These users and user groups must have a CA ControlMinder attribute to appear in the Login Authorization policy page.

6. Select the desired user, and then select **OK**.

## Update the UNAB User Login Authorization Policy for a Device or Device Group

This procedure describes how to update the UNAB User login authorization policy for a device or device group.

### Follow these steps:

1. In the PAM UI, select **Policies, Manage UNAB Policies**.  
The **UNAB Login Authorization Policies** tab appears.
2. From the **UNAB Login Authorization Policies** tab, select the policy and then select **Update**.  
The **Update UNAB Login Authorization Policy** window appears.
3. Select the **Users** tab.
  - Use the shuttle to select users for your policy.
  - Select **OK** to confirm the changes and exit this window.

## Update the UNAB User Group Login Authorization Policy for a Device or Device Group

This procedure describes how to update the UNAB User Group Login Authorization Policy for a device or device group.

### Follow these steps:

1. In the PAM UI, select **Policies, Manage UNAB Policies**.  
The **UNAB Login Authorization Policies** tab appears.
2. From the **UNAB Login Authorization Policies** tab, select the policy and then select **Update**.  
The **Update UNAB Login Authorization Policy** window appears.
3. Select the **Users Groups** tab.
  - Use the shuttle to select groups for your policy.
  - Select **OK** to confirm the changes and exit this window.

## Configure a UNAB Host or Host Group

Use these procedures to configure a UNAB host or host group.

This page contains the following topics:

### Add a UNAB Configuration Token to a Device

Do this procedure to add a UNAB Configuration Token to a device.

### Follow these steps:

1. In the PAM UI, select **Devices, Manage Devices**.  
A list of all devices appears.
2. Select the UNAB device, and then select **Update**.  
The **Update Device** page appears.
3. Select the **UNAB** tab. The current **UNAB Configuration Token Update** page appears.
4. Select the **+** icon. A new blank row appears.
5. Select the appropriate section, token, and value from the drop-down menu.
6. Select **OK**.

## **Add a UNAB Configuration Token to a Device Group**

Do this procedure to add a UNAB Configuration Token to a device group.

### **Follow these steps:**

1. In the PAM UI, select **Devices, Manage Device Groups**.  
A list of all devices groups appears.
2. Select the UNAB device group and then select **Update**.  
The **Update Device** page appears.
3. Select the **UNAB** tab. The current **UNAB Configuration Token Update** page appears.
4. Select the **+** icon.  
A new blank row appears.
5. Select the appropriate section, token, and value from the drop-down menu, and select **OK**.

## **Verify Policy Deployment from a UNAB Endpoint**

Do this procedure to verify policy deployment from a UNAB endpoint.

### **Follow these steps:**

1. In the PAM UI, go to **Policies, Manage UNAB Policies, Deployment Audit**.  
All deployed policies are listed.
2. Double-click on any of the policies to view its status. The details of the deployed policy appear in the box.
3. Verify that a successfully deployed login authorization policy has taken effect in the UNAB endpoint:
  - a. Log in to the UNAB endpoint.
  - b. Run the following UNAB command to verify the deployed login authorization policy. Replace <user name> with the name of an AD user.  
`uxconsole -manage -show -user <user name>`
  - c. If the login authorization policy is successfully deployed, the AD user is allowed to log in. The login reason displays as **"According to login policy."**
  - d. Log in to the UNAB endpoint as this AD user. The user is allowed to log in.
4. Verify that a successfully deployed config policy has taken effect in the UNAB endpoint:
  - a. Log in to the UNAB endpoint.
  - b. Access the `/opt/CA/uxauth/uxauth.ini` and `/opt/CA/AccessControlShared/ acccommon.ini` files and verify if the configuration changes appear.
  - c. Cross-check the values of the token, based on the config policy deployed from the PAM UI.

## **Manage Server Control UNAB Policies Using the PAM External API**

This content describes how to use the External API documentation to learn how to manage Server Control policies using the PAM external API.

This page contains the following topics:

### **Find Policy Information**

1. In the PAM UI, navigate to **Settings, API Doc**.
2. Go to **servercontrolUNABPolicies**.
3. Select **GET/PUT/POST** and select **Try it out**. The appropriate policy information appears (GET) or the policy updates (PUT or POST).

### **Finding Device Config Policy**

1. In the PAM UI, navigate to **Settings, API Doc**.
2. Select **Devices**.
3. Select GET /api.php/v1/devices.json/{id}/unabConfig
4. Enter a valid device ID and select **Try it out**. The config policies deployed on the device appear.

### **Finding Device Group Config Policy**

1. In the PAM UI, navigate to **Settings, API Doc**.
2. Select **deviceGroups**.
3. Select GET /api.php/v1/deviceGroups.json/{id}/unabConfig.
4. Enter a valid device group ID and select **Try it out**. The deployed config policies in the device group appear.

## **TIBCO Configuration in PAM**

Complete these procedures to set up a TIBCO configuration in PAM to support older PIM Agents. You must have configured a Utility Server for your PAM implementation before you begin. See [Download and Deploy a Utility Appliance](#) for procedures.

1. In PAM, navigate to **Configuration, Utility Appliance Patches, Available Patches**.
2. Click **Upload**. In the Upload utility appliance dialog box, choose the TIBCO patch file and click **Upload**  
The TIBCO patch appears under **Available Patches**.
3. Click the TIBCO patch and select **Stage**. A confirmation message appears, stating that the Utility Appliance Patch stage process has initiated.
4. Navigate to the Patch level tab. The TIBCO patch appears without a version number.
5. Select the TIBCO patch and click **Update**.
6. In the Change Utility Appliance Version dialog box, select the version to which the patch should be updated and click **OK**.  
A confirmation message appears stating that the item was saved, and the TIBCO patch appears with the updated version number.

## **Administrate PAM SC**

This section describes how to do PAM Server Control administration functions.

**Use the table of contents to access the topics in this section.**

### **Endpoint Administration for UNIX**

This section describes UNIX endpoint management tasks and concepts.

- Migrate User Trace Filters
- Improve Performance
- UNIX Exits
- Interact with LDAP
- NIS Configuration

## Manage Endpoints

Privileged Access Manager is a software product that is an active, comprehensive security software solution for Open Systems, tied dynamically to the operating system. Each time a user requests a security-sensitive operation, such as opening a file, substituting a user ID, or obtaining a network service, the product can intercept the event in real time. The product can evaluate the validity of the operation before passing control to the standard operating system (OS) functions.

Privileged Access Manager provides two ways to manage the resources in your enterprise and control who has access to them:

- **selang:** the Privileged Access Manager command language.  
The selang command language lets you make definitions in the Privileged Access Manager database. The selang command language is the command definition language.  
**Note:** For more information about using selang, see the *selang Reference* section.
- **Privileged Access Manager Endpoint Management:** the endpoint administration interface.  
The web-based interface lets you administer remote endpoints through a central administration server.  
**Note:** For more information about installing Privileged Access Manager Endpoint Management, see the *Implementation* section.

This article contains the following sections:

### About Privileged Access Manager

Privileged Access Manager provides you with a powerful tool for managing security for your native platforms. The product makes it possible to implement a security policy that you customize to the security requirements of the enterprise. Privileged Access Manager lets you provide security for users, groups, and resources beyond what is available in native operating systems. It lets you centrally manage security across the organization and integrate your Windows and UNIX security policies in a heterogeneous environment.

### **Why Does UNIX Need Protecting?**

Many operating systems have built-in access control, using one technique or another. IBM z/OS, a well-established and mature mainframe operating system, includes the System Authorization Facility (SAF). SAF is a set of calls that the operating system issues to verify the authorization of a user.

Access control software in a z/OS environment sets a return code for the SAF call and z/OS grants or denies access according to the code. The decision of what return code to set is based on the access rules and policies defined in the security database by the security administrator.

Other operating systems, such as OS/2, provide similar techniques for access control. The OS/2 access control module, named Security Enabling Services (SES), is based on the same concept as z/OS SAF.

Unfortunately, UNIX-based operating systems were not designed this way. Authorization decisions are made mainly for file accesses. The operating system performs these decisions using the 9 bits (rwx-rwx-rwx) in the *inode* entry of the file. Unlike SAF, no exit point for event interception is provided. Therefore, further security is necessary to perform functions that are more complex than those functions of mainframe-type security packages.

### **What is Protected?**

#### **Valid on UNIX**

In addition to supplying the regular security functions such as an access rule database, an audit log, and administration tools, Privileged Access Manager intercepts the operating system events that are to be protected. Because Privileged Access Manager works with many different operating systems, it intercepts events in memory. No changes are made to system files, and the operating system is not modified.

Privileged Access Manager protects the following entities:

- **Files**

Is a user authorized to access a particular file?

Privileged Access Manager restricts the ability of a user to access a file. You can give a user one or more types of access, such as READ, WRITE, EXECUTE, DELETE, and RENAME. You can specify the access to an individual file or to a set of similarly named files.

- **Terminals**

Is a user authorized to use a particular terminal?

This check is done during the login process. Individual terminals and groups of terminals can be defined in the Privileged Access Manager database, with access rules. These rules determine which users, or groups of users, are allowed to use the terminal or terminal group. Terminal protection ensures that no unauthorized terminal or station is used to log in to the accounts of powerfully authorized users.

- **Sign-on time**

Is a user authorized to log in at a particular time on a particular day?

Most users use their stations only on weekdays and only during work hours. The time-of-day and day-of-week login restrictions, and holiday restrictions, provide protection from hackers and from other unauthorized accessors.

- **TCP/IP**

Is another station authorized to receive TCP/IP services from the local computer? Is another station authorized to supply TCP/IP services to the local computer? Is another station permitted to receive services from every user of the local station?

An open system is a system in which both the computers and the networks are open. The advantage of an open system is also a disadvantage. Once a computer is connected to the outside world, one can never be sure who enters the system and what damage an alien user may do, intentionally or by mistake. Privileged Access Manager includes firewalls that prevent local stations and servers from providing services to unknown stations.

- **Multiple login privileges**

Is the user permitted to log in from a second terminal?

The term *concurrent logins* refers to the ability of a user to log in to the system from more than one terminal. Privileged Access Manager can prevent a user from logging in more than once. This protection prevents intruders from logging in to the accounts of users who are already logged in.

- **User-defined entities**

You can define and protect both regular entities (such as TCP/IP services and terminals) and functional entities. Functional entities are known as *abstract* objects, such as performing a transaction and accessing a record in a database.

- **Aspects of administrator authority**

Privileged Access Manager provides the means to both delegate superuser authorities to operators and restrict the permissions of the superuser account.

- **Substitute-user**

Are users authorized to substitute their user IDs?

The UNIX *setuid* system call is one of the most sensitive services that are provided by the operating system. Privileged Access Manager intercepts this system to determine whether the user is authorized to perform the substitution. The substitute-user authority check includes program pathing—users are permitted to substitute their user IDs only through specific programs. This check is especially important in controlling who can substitute to root and therefor gain root access.

- **Substitute-group**

Is a user authorized to issue the *newgrp* (substitute-group) command?

Substitute-group protection is similar to substitute-user protection.

- **Setuid and setgid programs**

Can a particular *setuid* or *setgid* program be trusted? Is the user authorized to invoke it?

The security administrator can test programs that are marked as *setuid* or *setgid* executables to ensure that they do not contain any security loopholes that can be used to gain unauthorized access. Programs that pass the test and are considered safe are defined as trusted programs. The Privileged Access Manager Self-Protection Module (also referred to as the Privileged Access Manager *watchdog*) knows which program is in control at a particular time. The module checks whether the program has been modified or moved because it was classified as trusted. If a trusted program is modified or moved, the program is no longer considered trusted and Privileged Access Manager does not allow it to run.

In addition, Privileged Access Manager protects against various deliberate and accidental threats, including:

- **Kill attempts**

Protects critical servers and services or daemons against kill attempts.

- **Password Attack**

Protects against various types of password attacks, enforces the password-definition policies of your site, and detects break-in attempts.

- **Password Delinquency**

Delineates rules that force users to create and use passwords of sufficient quality. To ensure that users create and use acceptable passwords, Privileged Access Manager can set maximum and minimum lifetimes for passwords, restrict certain words, prohibit repetitive characters, and enforce other restrictions. Passwords are not permitted to last too long.

- **Account Management**

Ensures that dormant accounts are dealt with appropriately.

- **Domain Management**

Implements password protection and enforce security across NIS and non-NIS domains.

## About Symantec Privileged Access Manager Server Control

Privileged Access Manager provides a powerful tool for managing security for your native platforms, enabling you to:

- Implement a security policy customized for the requirements of your enterprise.
- Provide security for users, groups, and resources beyond what is available in native operating systems.
- Centrally manage security across the organization and integrate your Windows and UNIX security policies in a heterogeneous environment.

**To access the topics in this section, use the table of contents.**

## Why Does UNIX Need Protecting?

Many operating systems have built-in access control, using one technique or another. IBM z/OS, a well-established and mature mainframe operating system, includes the System Authorization Facility (SAF). SAF is a set of calls that the operating system issues to verify the authorization of a user.

Access control software in a z/OS environment sets a return code for the SAF call and z/OS grants or denies access according to the code. The decision of what return code to set is based on the access rules and policies defined in the security database by the security administrator.

Other operating systems, such as OS/2, provide similar techniques for access control. The OS/2 access control module, named Security Enabling Services (SES), is based on the same concept as z/OS SAF.

Unfortunately, UNIX-based operating systems were not designed this way. Authorization decisions are made mainly for file accesses. The operating system performs these decisions using the 9 bits (rwx-rwx-rwx) in the *inode* entry of the file. Unlike SAF, no exit point for event interception is provided. Therefore, further security is necessary to perform functions that are more complex than those functions of mainframe-type security packages.

## What Is Protected

### Valid on UNIX

In addition to supplying the regular security functions such as an access rule database, an audit log, and administration tools, Privileged Access Manager intercepts the operating system events that are to be protected. Because Privileged Access Manager works with many different operating systems, it intercepts events in memory. No changes are made to system files, and the operating system is not modified.

Privileged Access Manager protects the following entities:

- **Files**

Is a user authorized to access a particular file?

Privileged Access Manager restricts the ability of a user to access a file. You can give a user one or more types of access, such as READ, WRITE, EXECUTE, DELETE, and RENAME. You can specify the access to an individual file or to a set of similarly named files.

- **Terminals**

Is a user authorized to use a particular terminal?

This check is done during the login process. Individual terminals and groups of terminals can be defined in the Privileged Access Manager database, with access rules. These rules determine which users, or groups of users, are allowed to use the terminal or terminal group. Terminal protection ensures that no unauthorized terminal or station is used to log in to the accounts of powerfully authorized users.

- **Sign-on time**

Is a user authorized to log in at a particular time on a particular day?

Most users use their stations only on weekdays and only during work hours. The time-of-day and day-of-week login restrictions, and holiday restrictions, provide protection from hackers and from other unauthorized accessors.

- **TCP/IP**

Is another station authorized to receive TCP/IP services from the local computer? Is another station authorized to supply TCP/IP services to the local computer? Is another station permitted to receive services from every user of the local station?

An open system is a system in which both the computers and the networks are open. The advantage of an open system is also a disadvantage. Once a computer is connected to the outside world, one can never be sure who enters the system and what damage an alien user may do, intentionally or by mistake. Privileged Access Manager includes firewalls that prevent local stations and servers from providing services to unknown stations.

- **Multiple login privileges**

Is the user permitted to log in from a second terminal?

The term *concurrent logins* refers to the ability of a user to log in to the system from more than one terminal. Privileged Access Manager can prevent a user from logging in more than once. This protection prevents intruders from logging in to the accounts of users who are already logged in.

- **User-defined entities**

You can define and protect both regular entities (such as TCP/IP services and terminals) and functional entities. Functional entities are known as *abstract* objects, such as performing a transaction and accessing a record in a database.

- **Aspects of administrator authority**

Privileged Access Manager provides the means to both delegate superuser authorities to operators and restrict the permissions of the superuser account.

- **Substitute-user**

Are users authorized to substitute their user IDs?

The UNIX *setuid* system call is one of the most sensitive services that are provided by the operating system. Privileged Access Manager intercepts this system call to determine whether the user is authorized to perform the substitution. The substitute-user authority check includes program pathing—users are permitted to substitute their user IDs only through specific programs. This check is especially important in controlling who can substitute to root and therefore gain root access.

- **Substitute-group**

Is a user authorized to issue the *newgrp* (substitute-group) command?

Substitute-group protection is similar to substitute-user protection.

- **Setuid and setgid programs**

Can a particular *setuid* or *setgid* program be trusted? Is the user authorized to invoke it?

The security administrator can test programs that are marked as *setuid* or *setgid* executables to ensure that they do not contain any security loopholes that can be used to gain unauthorized access. Programs that pass the test and are considered safe are defined as trusted programs. The Privileged Access Manager Self-Protection Module (also referred to as the Privileged Access Manager *watchdog*) knows which program is in control at a particular time. The module checks whether the program has been modified or moved because it was classified as trusted. If a trusted program is modified or moved, the program is no longer considered trusted and Privileged Access Manager does not allow it to run.

In addition, Privileged Access Manager protects against various deliberate and accidental threats, including:

- **Kill attempts**

Protects critical servers and services or daemons against kill attempts.

- **Password Attack**

Protects against various types of password attacks, enforces the password-definition policies of your site, and detects break-in attempts.

- **Password Delinquency**

Delineates rules that force users to create and use passwords of sufficient quality. To ensure that users create and use acceptable passwords, Privileged Access Manager can set maximum and minimum lifetimes for passwords, restrict certain words, prohibit repetitive characters, and enforce other restrictions. Passwords are not permitted to last too long.

- **Account Management**

Ensures that dormant accounts are dealt with appropriately.

- **Domain Management**

Implements password protection and enforces security across NIS and non-NIS domains.

## How Privileged Access Manager Server Control Protects UNIX

Privileged Access Manager starts immediately after the operating system finishes its initialization. Privileged Access Manager places hooks in system services that must be protected. In this way, control is passed to Privileged Access Manager before the service is performed. The product decides whether to grant the service to the user.

For example, a user attempts to access a resource protected by Privileged Access Manager. This access request generates a system call to the kernel to open the resource. Privileged Access Manager intercepts that system call and decides whether to grant access. If permission is granted, Privileged Access Manager passes control to the regular system service. If the product denies permission, it returns the standard permission-denied error code to the program that activated the system call. The system call ends.

The decision is based on access rules and policies that are defined in the database. The database describes two types of objects: accessors and resources. *Accessors* are users and groups. *Resources* are objects to be protected, such as files and services. Each record in the database describes an accessor or a resource.

Each object belongs to a class—a collection of objects of the same type. For example, `TERMINAL` is a class containing objects that are terminals (workstations) protected by Privileged Access Manager.

### **Class Activation**

Privileged Access Manager stores information about whether a `CLASS` is active or inactive in the database. When Privileged Access Manager starts, it passes a list of active classes to `SEOS_syscall`, so Privileged Access Manager does not have to constantly intercept these classes. The only time Privileged Access Manager intercepts a class is when a user changes the activity status of a class. If a class is inactive, access to the resource is not intercepted.

You can use the inactive class bypass with the following classes: `FILE`, `HOST`, `TCP`, `CONNECT`, and `PROCESS`.

### **Accessor Elements**

An *accessor element* (ACEE) represents each user. The accessor element is an in-memory reflection of the record of the user in the database. Privileged Access Manager builds the accessor element during the login process. The accessor element is associated with the process of the user. Whenever the process requests a system service that is protected by Privileged Access Manager, or issues an implicit request to access a resource, the product accesses the record of the resource. The product then determines whether the information in the previously created accessor element, such as the security level of the user, mode, and group—lets the user access the resource.

### **Class Activation**

Privileged Access Manager stores information about whether a `CLASS` is active or inactive in the database. When Privileged Access Manager starts, it passes a list of active classes to `SEOS_syscall`, so Privileged Access Manager does not have to constantly intercept these classes. The only time Privileged Access Manager intercepts a class is when a user changes the activity status of a class. If a class is inactive, access to the resource is not intercepted.

You can use the inactive class bypass with the following classes: `FILE`, `HOST`, `TCP`, `CONNECT`, and `PROCESS`.

### **Accessor Elements**

An *accessor element* (ACEE) represents each user. The accessor element is an in-memory reflection of the record of the user in the database. Privileged Access Manager builds the accessor element during the login process. The accessor element is associated with the process of the user. Whenever the process requests a system service that is protected by Privileged Access Manager, or issues an implicit request to access a resource, the product accesses the record of the resource. The product then determines whether the information in the previously created accessor element, such as the security level of the user, mode, and group—lets the user access the resource.

## **Expanding UNIX Native Security**

The following Privileged Access Manager features expand native security.

## **Superuser Account Limitations**

Users who administer and manage operating systems are typically members of predefined accounts. These accounts are automatically created during the system setup, such as the root account on UNIX systems and the Administrator account on Windows systems. Each of the predefined accounts exists to perform a certain set of system functions.

For example, users acting as root or Administrator can create, delete, and modify users and lock, reconfigure, and shut down servers.

One of the major security risks is that an unauthorized user gains control of these accounts. If this happens, the user can seriously damage the system.

Privileged Access Manager can limit the rights that are granted to these accounts. The product can limit the rights of members of user groups that have these accounts as members. This reduces the vulnerability of your operating system.

## **Privileged Access Manager Administrator**

When you install Privileged Access Manager, you are asked to name one or more Privileged Access Manager administrators. Administrators have the authority to modify all or part of the rules database. You should have at least one full-authority administrator. This administrator can modify or create access rules freely and can designate other levels of administrators.

Once you have defined users for your system, you can assign administrative authority to other users by assigning the ADMIN attribute to them.

**Note:** A user with the ADMIN attribute possesses powerful authority. Consequently, the number of ADMIN users should be strictly limited. It is also a good policy to separate the roles of the native superuser and ADMIN, removing the ADMIN attribute from the superuser after you have set up one or more Privileged Access Manager security administrators.

Because you always need at least one user with authority to manage the database, Privileged Access Manager does not let you delete the last user that has the ADMIN attribute.

If you expect any of the Privileged Access Manager administrators to administer other hosts from this workstation, be sure that a rule in the database on that host gives them READ and WRITE access from this workstation.

## **Sub Administration**

Privileged Access Manager contains a *sub administration* feature. This lets administrators grant specific privileges that enable regular users to manage specific classes. These users are then called sub administrators.

For example, you can allow a specific user to manage users and groups only.

You can also specify a higher level of sub administration by granting access not only for specific classes, but for specified records in these classes.

## **Administration Rights for Regular Users**

Privileged Access Manager lets you grant ordinary users (non-administrators) the rights and privileges to perform administrative tasks without being members of the Administrators group. The ability to delegate tasks by granting administrative privileges in this granular way is a significant advantage of Privileged Access Manager.

- A record in the SUDO class stores a command script to allow users to run the script with borrowed permissions.
- The data property value is the command script. This value can be modified by adding to it optional script parameter values.
- Each record in the SUDO class identifies a command for which a user can borrow permissions from another user.
- The key of the SUDO class record is the name of the SUDO record. This name is used instead of the command name when a user executes the commands in the SUDO record.

## Program Pathing

*Program pathing* is an access rule associated with a file that requires that the file is accessed only through a specific program. Program pathing greatly increases the security of sensitive files. Privileged Access Manager lets you use program pathing to provide additional protection for the files in your system.

## B1 Security Level Certification

Privileged Access Manager includes the following B1 Orange Book features: security levels, security categories, and security labels.

- Accessors and resources in the database can be assigned a *security level*. The security level is an integer from 1 through 255. An accessor can gain access to a resource only if the accessor has a security level equal to or greater than the security level assigned to the resource.
- Accessors and resources in the database can belong to one or more *security categories*. An accessor can access a resource only if the accessor belongs to all of the security categories assigned to the resource.
- A *security label* is a name that associates a particular security level with a set of zero or more security categories. Assigning a user to a security label gives the user both the security level and any security categories that are associated with the security label.

**Note:** For more information about B1 Orange Book features, see the *Implementation* section.

## Superuser Account Limitations (UNIX)

Users who administer and manage operating systems are typically members of predefined accounts. These accounts are automatically created during the system setup, such as the root account on UNIX systems and the Administrator account on Windows systems. Each of the predefined accounts exists to perform a certain set of system functions.

For example, users acting as root or Administrator can create, delete, and modify users and lock, reconfigure, and shut down servers.

One of the major security risks is that an unauthorized user gains control of these accounts. If this happens, the user can seriously damage the system.

Privileged Access Manager can limit the rights that are granted to these accounts. The product can limit the rights of members of user groups that have these accounts as members. This reduces the vulnerability of your operating system.

## UNIX Account Administrative Authority in PAM SC

When you install Privileged Access Manager, you are asked to name one or more Privileged Access Manager administrators. Administrators have the authority to modify all or part of the rules database. You should have at least one full-authority administrator. This administrator can modify or create access rules freely and can designate other levels of administrators.

Once you have defined users for your system, you can assign administrative authority to other users by assigning the ADMIN attribute to them.

### NOTE

A user with the ADMIN attribute possesses powerful authority. Consequently, the number of ADMIN users should be strictly limited. It is also a good policy to separate the roles of the native superuser and ADMIN, removing the ADMIN attribute from the superuser after you have set up one or more Privileged Access Manager security administrators.

Because you always need at least one user with authority to manage the database, Privileged Access Manager does not let you delete the last user that has the ADMIN attribute.

If you expect any of the Privileged Access Manager administrators to administer other hosts from this workstation, be sure that a rule in the database on that host gives them READ and WRITE access from this workstation.

## PAM SC Sub Administration for UNIX

Privileged Access Manager contains a *sub administration* feature. This lets administrators grant specific privileges that enable regular users to manage specific classes. These users are then called sub administrators.

For example, you can allow a specific user to manage users and groups only.

You can also specify a higher level of sub administration by granting access not only for specific classes, but for specified records in these classes.

## PAM SC Administration Rights for Regular Users (UNIX)

Privileged Access Manager lets you grant ordinary users (non-administrators) the rights and privileges to perform administrative tasks without being members of the Administrators group. The ability to delegate tasks by granting administrative privileges in this granular way is a significant advantage of Privileged Access Manager.

- A record in the SUDO class stores a command script to allow users to run the script with borrowed permissions.
- The data property value is the command script. This value can be modified by adding to it optional script parameter values.
- Each record in the SUDO class identifies a command for which a user can borrow permissions from another user.
- The key of the SUDO class record is the name of the SUDO record. This name is used instead of the command name when a user executes the commands in the SUDO record.

## PAM SC Program Pathing (UNIX)

*Program pathing* is an access rule associated with a file that requires that the file is accessed only through a specific program. Program pathing greatly increases the security of sensitive files. Privileged Access Manager lets you use program pathing to provide additional protection for the files in your system.

## PAM SC B1 Security Level Certification (UNIX)

Privileged Access Manager includes the following B1 Orange Book features: security levels, security categories, and security labels.

- Accessors and resources in the database can be assigned a *security level*. The security level is an integer from 1 through 255. An accessor can gain access to a resource only if the accessor has a security level equal to or greater than the security level assigned to the resource.
- Accessors and resources in the database can belong to one or more *security categories*. An accessor can access a resource only if the accessor belongs to all of the security categories assigned to the resource.
- A *security label* is a name that associates a particular security level with a set of zero or more security categories. Assigning a user to a security label gives the user both the security level and any security categories that are associated with the security label.

### NOTE

For more information about B1 Orange Book features, see the *Implementation Guide*.

## PAM SC Endpoint Management (UNIX)

Privileged Access Manager provides two ways to manage the resources in your enterprise and control who has access to them:

- **selang** - the Privileged Access Manager command language.  
The selang command language lets you make definitions in the Privileged Access Manager database. The selang command language is the command definition language.

**NOTE**

For more information about using *selang*, see the *selang Reference Guide*.

- **Privileged Access Manager Endpoint Management** - the endpoint administration interface.  
The web-based interface lets you administer remote endpoints through a central administration server.

**NOTE**

For more information about installing Privileged Access Manager Endpoint Management, see the *Implementation Guide*.

## PAM SC Safe User Substitution

The UNIX `su` command lets a user switch to another user using the password of the target user. A user who wants to switch a user ID must memorize the password of the target user, write it down, or ask the target user to use a trivial password. These actions violate several password policies. Also, the `su` command does not record who invoked the command. A user pretending to be the owner of an account is indistinguishable from the actual owner.

Privileged Access Manager includes the `sesu` utility, which is an enhanced version of the UNIX `su` command. You can configure `sesu` to prompt the user for their password as a means of authentication, rather than prompting for the password of the target user. The authorization process is based on the access rules that are defined in the SURROGATE class and, optionally, on the password of the user executing the command.

Unlike permission to `su`, permission to `sesu` does not depend on knowing the password of the target user. Instead, it depends on permissions that are specified in the database. Users remain accountable for their actions because their login identities are remembered.

If a user is a surrogate to one of the users in the `_surrogate` group, Privileged Access Manager sends a full trace of the actions of the user as the new user to the audit trail.

To protect against inadvertent use, `sesu` is marked in the file system so that no one can run it. The security administrator must mark the program as executable and `setuid` to root before you can use it.

**WARNING**

Before you use the `sesu` utility, define all users to the Privileged Access Manager database and set `sesu` prerequisites. This prevents you from opening up the entire system to users who are not defined to the product.

This page contains the following sections:

### **Set User ID Substitution Rules**

To prevent or allow users to substitute other users, set user ID substitution rules. These rules are governed through SURROGATE class resources. To define any user substitution rules, create SURROGATE records.

#### **Follow these steps:**

1. In Privileged Access Manager Endpoint Management click the Users tab, then click the Authorization and Delegation subtab.  
The Authorization and Delegation menu options appear on the left.
2. Click Users ID Substitution.
3. Click Create User ID Substitution.
4. Complete the fields in the tabbed pages, then click Save.

**Note:** For more information on SURROGATE class properties, see the *selang Reference* section.

## Set Up `sesu` for User Substitution

By default, the `sesu` utility is marked in the file system so that no one can run it. Before you make `sesu` available to your users, set database rules to ensure that it is used safely. You then lock the `su` utility so that users are forced to use the Privileged Access Manager `sesu` utility instead.

**Note:** After you complete this setup and Privileged Access Manager is running, the `su` utility does not execute. Users are forced to use the secured `sesu` utility. When Privileged Access Manager is not running, the `su` utility works.

### Set Basic User Substitution Rules

Before you start using the `sesu` utility, set up some common user substitution rules in the database. These rules prevent unknown users substituting privileged user accounts. However, these rules do permit specific users and processes to perform necessary user substitution activities.

#### Follow these steps:

1. Create a surrogate resource for the root user (USER.root) with the following attributes:

- `nobody` as owner
- Default access `none`
- All administrators have full control

This surrogate resource prevents all users from substituting root, unless explicitly authorized. All administrators are explicitly authorized to substitute root.

**Note:** You can authorize individual administrators separately or can authorize all administrators using the administrator's group.

2. Create a surrogate resource for the group of root (GROUP.other) with the following attributes:

- `nobody` as owner
- default access of `none`
- All administrators have full control

This surrogate resource prevents all users from substituting the group of root, unless explicitly authorized. All administrators are explicitly authorized to substitute the group of root.

**Note:** On most UNIX systems root's group is either `other` or `sys`.

3. Change the user substitution rules for USER.\_default as follows:

- `nobody` as owner
- Default access `none`
- Authorize root to substitute to any undefined user
- Authorize the administrators' group to substitute to any undefined user

Changing the rules prevents all users from substituting any group, unless explicitly authorized, and authorizes root and root's group to substitute any user, unless explicitly denied.

**Note:** You specifically authorize root to permit programs such as `dtlogin` to switch session ownership from root, the default X window owner (`uid=0`), to anyone else. If you do not do this, login attempts fail because Privileged Access Manager is blocking any user substitution activity that has not been explicitly authorized.

4. Change the group substitution rules for GROUP.\_default as follows:

- `nobody` as owner
- Default access `none`
- Authorize root to substitute any undefined groups
- Authorize the administrators' group to substitute to any undefined group

Changing the rules prevents all users from substituting any group, unless explicitly authorized, and authorizes root and root's group to substitute any group, unless explicitly denied.

### Example: Set Basic User Substitution Rules in `selang`

Use the following `selang` commands to set basic user substitution rules in your environment:

```
nr surrogate USER.root defacc(n) own(nobody)

auth surrogate USER.root gid(sys_admin_GID) acc(a)

nr surrogate GROUP.other defacc(n) own(nobody)

auth surrogate GROUP.other gid(sys_admin_GID) acc(a)

cr surrogate USER._default defacc(n) own(nobody)

cr surrogate GROUP._default defacc(n) own(nobody)

auth surrogate USER._default uid(root) acc(a)

auth surrogate GROUP._default uid(root) acc(a)

auth surrogate USER._default gid(sys_admin_GID) acc(a)

auth surrogate GROUP._default gid(sys_admin_GID) acc(a)
```

### ***Replace the System su Utility with the sesu Utility***

By default, the sesu utility is marked in the file system so that no one can run it. To let users substitute other users by using the sesu utility, you must enable sesu and replace the system su with this utility.

**Follow these steps: Note:** You need to be root or another authorized user to perform the following steps.

1. Permit users to run the sesu utility using the following command:

```
chmod +s /opt/CA/PAMSC/bin/sesu
```

2. Find out the location of the system's su utility using the following command:

```
which su
```

3. Rename the system's su utility using the following command:

```
mv su_dir/su su_dir/su.ORIG
```

where *su\_dir* is the directory where su resides.

4. Link the sesu utility to the su command:

```
ln -s /opt/CA/PAMSC/bin/sesu su_dir/su
```

This lets users continue to use the su command, although it now runs the sesu utility.

5. Stop Privileged Access Manager using the following command:

```
secsns -s
```

6. Modify Privileged Access Manager configuration settings using the following commands:

```
seini -s sesu.SystemSu su_dir/su.ORIG

seini -s sesu.UseInvokerPassword yes
```

The token SystemSu is set so that sesu can call the original system su utility if Privileged Access Manager is not running.

The token UseInvokerPassword is set to tell Privileged Access Manager to prompt the user for their original password instead of root's password or another user's password. The user needs to re-authenticate before the user substitution is permitted.

7. Reload Privileged Access Manager using the following command:

```
seload
```

### ***Prevent Users from Running the su Utility of the System***

Although the sesu utility is configured, anyone can run su.ORIG (the renamed system su utility) as before, with the password of root or a user. To prevent unauthorized use, use the PROGRAM class to prevent su.ORIG execution when Privileged Access Manager is running.

**Note:** If you used seuidpgm during Privileged Access Manager installation and configuration, you do not need to follow this procedure. su does not run as it has been modified (renamed to su.ORIG).

**Follow these steps:**

1. In selang, set Privileged Access Manager to monitor the renamed su utility, using the following command:

```
nr program su_dir/su.ORIG defacc(x) own(nobody)
```

2. Log in as root to change file access and modification time. Use the following command:

```
touch su_dir/su.ORIG
```

Privileged Access Manager is watching su.ORIG and, because the file has been *touched*, prevents it from being executed.

## **Define PAM SC SUDO Records**

A record in the SUDO class stores a command script so that users can run the script with borrowed permissions. The SUDO record and the sesudo command that executes the scripts control the ability to borrow permissions.

In a SUDO record, the comment property is used for a special purpose. The comment property is often known by its alternate name: the data property.

The value of the data property is the command script, with the optional addition of one or more script parameter values that are to be prohibited or permitted. The entire data property value must be enclosed in single quotes. Reference executables by their complete path names to prevent Trojan horses from taking their place.

The format for the data property is this:

```
data('cmd[;[prohibited-values][;permitted-values]] ')
```

Because the lists of prohibited and permitted values are optional, a simple data property value could be the following:

```
newres SUDO MountCd data('mount /dev/cdrom /cdr')
```

The simple value in the command means that the command sesudo MountCd executes the script mount /dev/cdrom /cdr. No particular script parameter values are prohibited; all are permitted.

Wildcards and powerful variables give you flexibility in specifying prohibited and permitted parameters. The wildcards that you can use are the standard UNIX wildcards. The following table lists the variables:

| Variable | Description                                        |
|----------|----------------------------------------------------|
| \$A      | Alphabetic value                                   |
| \$G      | ExistingPrivileged Access Manager group name       |
| \$H      | Home path pattern of the user                      |
| \$N      | Numeric value                                      |
| \$O      | User name of the Executor                          |
| \$U      | ExistingPrivileged Access Manager user name        |
| \$e      | SUDO commands with no parameters                   |
| \$f      | Existing file name                                 |
| \$g      | Existing UNIX group name                           |
| \$h      | Existing host name                                 |
| \$r      | Existing UNIX file name with UNIX read permission  |
| \$u      | Existing UNIX user name                            |
| \$w      | Existing UNIX file name with UNIX write permission |
| \$x      | Existing UNIX file name with UNIX exec permission  |

If you append a list of *prohibited* parameter values to the script:

- Separate the script from the prohibited parameter values with a semicolon, but keep them all inside the single quotes. Example: you want to prevent the user from using -9 but permit the user to use all other parameters, enter the following command:

```
newres SUDO scriptname data('cmd;-9')
```

where *cmd* represents your script.

Alternatively, define the SUDO record as follows if you do not allow any parameter values, but you want all parameters defaulted:

```
newres SUDO scriptname data('cmd;*')
```

- If a script parameter has more than one prohibited value, use the space character as a separator. Example: you want to prevent the user from using -9 and -HUP but permit the user to use all other parameters, enter the following command:

```
newres SUDO scriptname data('cmd;-9 -HUP')
```

- If more than one script parameter has prohibited values, use the pipe character (|) as a separator between sets of prohibited values. Example: you want to prevent the user from using -9 and -HUP for the first parameter of the script, and from using any existing UNIX user name for the second parameter (see the previous list of variables), enter the following command:

```
newres SUDO scriptname data('cmd;-9 -HUP | $u')
```

If the script has more parameters than you list, then your last set of prohibited parameters applies to all the remaining parameters.

If you append a list of *permitted* parameter values to the script:

- The *sesudo* utility enforces two checks: Not only must the parameter values not match any of the corresponding prohibited values; they must also match at least one of the corresponding permitted values. Separate the list of *permitted* values from the list of *prohibited* values with a semicolon, but keep them all inside the single quotes. Even if you have no list of prohibited values, you still need the semicolon; otherwise what you intend to permit is prohibited. Example: if you want to allow only the value NAME as a parameter value for the script, enter the following command:

```
newres SUDO scriptname data('cmd;;NAME')
```

As in the other list:

- If a script parameter has more than one permitted value, use the space character as a separator.
- If more than one script parameter has permitted values, use the pipe character (|) as a separator between sets of permitted values.

Example: if you have two parameters, and the first must be numeric but must not be a UNIX user name, and the second must be alphabetic but must not be a UNIX group name, enter the following command:

```
newres SUDO scriptname data('cmd; $u | $g ; $N | $A')
```

If the script has more parameters than you list, then your last set of permitted parameters applies to all the remaining parameters.

Thus, the overall format for the data property is this: first the script; then the prohibited values, parameter by parameter; then the permitted values, parameter by parameter:

```
data('cmd;
param1_prohib1 param1_prohib2 ... param1_prohibN | \
param2_prohib1 param2_prohib2 ... param2_prohibN | \
...
paramN_prohib1 paramN_prohib2 ... paramN_prohibN ; \
param1_permit1 param1_permit2 ... param1_permitN | \
param2_permit1 param2_permit2 ... param2_permitN |
...
paramN_permit1 paramN_permit2 ... paramN_permitN')
```

## PAM SC Tools for Preventing Password Attacks

The most common type of unauthorized access is that of hackers who guess passwords. Privileged Access Manager provides two tools that detect and protect against password attacks:

- serevu
- pam\_seos

Another method of protecting against password attacks is controlling passwords that are used in your environment by setting password policy rules.

### **serevu**

The serevu daemon locks the accounts of users who performed more than a specified number of login attempts. This prevents potential password attacks by rejecting further attempts to enter the account; it also prevents “dictionary attacks”.

Typically, the danger in using the user lockout utility is that it opens the system to denial of service attacks. One common type of denial of service attack is an attempt to break into the system administrator account. After a few attempts, the system administrator account is revoked and the system administrator can no longer log in. If similar attacks are performed on all critical user accounts, the system may be rendered unusable, with no way of recovering. To prevent this, the serevu daemon provides the following two modes of operation:

- The account is revoked for a specified time frame, after which it is automatically restored.
- The account is permanently revoked.

serevu does not revoke root, so the system is never locked out.

**Note:** Take special care regarding the root user password to prevent successful dictionary attacks on root.

## **pam\_seos**

pam\_seos is a Pluggable Authentication Module (PAM) that Privileged Access Manager uses for advanced account management functions. Privileged Access Manager calls pam\_seos during the login procedure of any login program. The module is a shared object that can be dynamically loaded to provide the necessary functionality upon demand.

You can configure pam\_seos to perform three actions:

- **Detect login failures**

The Account Management Component detects any failed login attempt and logs it to both the audit file and a special failed logins file. This module detects UNIX failures, not cases in which Privileged Access Manager denies access. Privileged Access Manager writes the failed login attempts to a special file. The serevu utility reads this file and uses the information to determine if and when user access should be revoked.

- **Provides debug mode**

When Privileged Access Manager denies a login, it usually does not show the reason for denial during the login session. If the pam\_seos module debug mode is set, Privileged Access Manager gives a short description of the reason for login denial. For example, "grace logins" means that the user has no remaining logins.

- **Checks for expired passwords and grace logins**

The Password Management Component invokes the segrace utility, which checks for a user password expiration and the number of grace logins. If a user password expires, and the user has no grace logins left, segrace invokes the sepass utility to allow the user to change the password.

**Note:**

- Privileged Access Manager invokes segrace only when a password change is needed.
- To obtain failed login events from SSH, the SSH version you are using must be compiled and configured to support PAM. If your version of SSH does not use PAM, Privileged Access Manager cannot detect whether a user has violated the failed login rules.

The installation program adds the relevant lines to the pam.conf configuration file, and stores the old configuration file as /etc/pam.conf.bak.

Configuration of the pam\_seos modules is performed through the seos.ini file. Set the following tokens, which are located in the [pam\_seos] section, according to the required functionality:

To use the Password Expiration and Grace Logins check, set the following token in the seos.ini file:

```
call_segrace = Yes
```

To use Login Debug Mode, set the following token in the seos.ini file:

```
debug_mode_for_user = Yes
```

To make serevu use pam\_seos login failure detection, set the following token in the seos.ini file:

```
serevu_use_pam_seos = Yes
```

## **Restrictions and Limitations**

The protection techniques that are described in this section have the following restrictions and limitations:

- On Sun Solaris, after five failed login attempts, serevu is notified.
- The pam\_seos module is only implemented in the versions of Sun Solaris, HP-UX, and Linux that support PAM.
- Enable PAM on AIX (5.3 and above) before you install Privileged Access Manager.

## **PAM SC Restrictions and Limitations**

The protection techniques that are described in this section have the following restrictions and limitations:

- On Sun Solaris, after five failed login attempts, serevu is notified.
- The pam\_seos module is only implemented in the versions of Sun Solaris, HP-UX, and Linux that support PAM.
- Enable PAM on AIX (5.3 and above) before you install Privileged Access Manager.

## PAM SC Enhanced Access Restrictions for UNIX Files and Directories

Privileged Access Manager leaves the UNIX system of permissions intact but adds a layer of enhanced access control to it.

Privileged Access Manager intercepts each of the following file access operations. The product verifies that the user has authorization for the specific operation before returning control to UNIX. The access type is in parentheses.

- File create (create)
- File open for read (read)
  - Note:** Read privileges can control whether users can perform operations that obtain information about the file (such as ls -l). Set the STAT\_intercept configuration setting to 1 to do this. For more information, see the *Reference* section.
- File open for write (write)
- File execute (execute)
- File delete (delete)
- File rename (delete, rename)
- Change permission bits (chmod)
- Change owner (chown)
- Change timestamp for example, as a result of executing the touch command (utime)
- Edit native ACL using the acledit command for systems that support ACLs (sec)
- Change directory (chdir)

Privileged Access Manager access checking differs from the native UNIX authorization in the following ways:

- Privileged Access Manager bases its authorization checks on the original user ID of the user who logged in, not on the effective user ID (euid). Example: if *user* invokes the su command to surrogate to another user, *userA* still only has access to those files to which *userA* is permitted. Surrogating to another user does *not* automatically give the original user access to the files of the target user as it does in UNIX.
- Privileged Access Manager does not give the superuser (root) automatic access to every file on the system. The superuser is subject to authorization checking like all other users of the system.
- Authorization checking is based on the following conditions: Privileged Access Manager normal and conditional access lists, day and time restrictions, security levels, security categories, and security labels.
- If you do not specifically authorize a user to access a file, Privileged Access Manager checks whether that user belongs to any group authorized to access the file.
- Each file access is audited through the normal Privileged Access Manager audit procedures.
- When deleting a file, Privileged Access Manager requires the user to have DELETE access authority to the specified file. UNIX requires the user to have WRITE authority for the parent directory.
- To rename a file, the user must have DELETE access authority to the source file and RENAME access authority to the target file. UNIX also requires that they user have WRITE access authority for the parent directory.
- All users are given permanent READ access (as a minimum) to the files /etc/passwd and /etc/group, regardless of the default setting of these files. This access prevents the system from hanging.
- The owner of a FILE object in the Privileged Access Manager database always has full access to the file protected by the object.
- The chdir access type controls the chdir command specifically, and does not execute, as UNIX does.

The following conditions are the limits of the File Protection System:

- Concerning users who are not members of the special \_restricted group, Privileged Access Manager protects only those files and directories that:

- Are defined by their individual names in the database
- Match a name pattern (for example, /etc/\*) that is defined in the database

For users that belong to the group `_restricted`, all system files are protected by Privileged Access Manager. For files that are not defined in the database, authorization is based on the `_default` record of the FILE class.

- Privileged Access Manager maintains a table of all file names and directory names (including patterns using wildcards) that indicate resources that need protection. The amount of memory available for this table is limited. Typically, the maximum number of files and directories you can define by individual names in the database is 4096. The maximum number of name patterns is 512.
- Some files receive protection even if no explicit access rules exist for them. These files include the Privileged Access Manager database files, audit logs, and configuration files.

**Note:** For more information, see the FILE class in the *Reference* section.

Privileged Access Manager supports the following access types for files.

- ALL
- CHDIR
- CHMOD
- CHOWN
- CONTROL
- CREATE
- DELETE
- EXECUTE
- NONE
- READ
- RENAME
- SEC
- UPDATE
- UTIME
- WRITE

The File Protection System is useful for protecting selected sets of files that contain sensitive data. For example, you can use Privileged Access Manager to protect the following files:

- /etc/passwd
- /etc/group
- /etc/hosts
- /etc/shadow

Use Privileged Access Manager to protect databases and all other sensitive files at your site. Grant access only to the server daemon.

Rules govern some files that always need access control even without you specifying them.

This page contains the following sections:

### **How File Protection Works**

When the `seosd` daemon starts, it performs the UNIX `stat` command for each discrete file object that is defined in the database. The daemon then builds a table in memory that contains an entry for each file object. In addition, the table contains the inode and device of the file for each discrete file. With this information, Privileged Access Manager can also protect the hard links to the files because the protection is according to device and inode. The database does not keep information about the inode and device of a file.

When you create a file rule through Privileged Access Manager:

- If the file exists in UNIX, Privileged Access Manager first performs a stat command for the file. Then it adds an entry to the file table with the inode and device information of the file.
- If the file does not exist in UNIX, Privileged Access Manager adds an entry of the name of the file to the file table (without inode and device information). This entry is the same as the entry for a generic file object. Simultaneously, the kernel keeps an indication in its internal tables that this file must be checked during creation for inode and device information. When the file is created, the kernel intercepts its creation. The kernel informs seosd of the inode of the file and device information. The seosd daemon can then update the entry of the file in the file table.

When you delete a file, Privileged Access Manager deletes its entry in the seosd file table. The entry remains in the Privileged Access Manager database in case you create it again.

## Protect Files

To define a protected file in selang, enter the following command:

```
newres FILE filename
```

For example, to register a file named /tmp/binary.bkup, enter the following command:

```
newres FILE /tmp/binary.bkup
```

**Note:** When you define a file rule without specifying its access type, the default access of NONE is assigned. In this case, the owner of the file is the only one who can access the file.

Most protected files should be protected from access by the superuser. Otherwise, any user who knows the password of the superuser gains automatic access to the files. At the same time, you can prevent all other users except the owner of the file from accessing the file.

To protect several similarly named files, use a file name pattern that includes a wildcard. The wildcards are \* (which indicates zero or more characters) and ? (which indicates any one character, other than /).

The pattern that you specify is matched against the full path name of the file so that the pattern /tmp/x\* matches files that are named /tmp/x1, /tmp/xxx, and even /tmp/xdir/a.

Patterns that Privileged Access Manager does *not* let you specify are: /\*, /tmp/\*, and /etc/\*.

### WARNING

Because file name patterns are such a powerful tool, do not experiment freely with them.

Example: The following command defines as protected every file in the /tmp directory that has a name starting with a, and ending with b. This would include a file like /tmp/xyz/xyzab :

```
newres FILE /tmp/a*b
```

## Wildcards in FILE Resource Names

By using wildcards in a file resource name, you can create a file record that corresponds to multiple files: any file with a name that matches the wildcard pattern is protected by the access authorities associated with the record.

The wildcards that you can use are:

- \* for any number of any characters
- ? for any one character

If a physical resource name matches more than one resource record name, the longest nonwildcard match is used for that resource.

Privileged Access Manager does *not* accept the following patterns in names of FILE resources:

- \*
- /\*
- /tmp/\*
- /etc/\*

### Example: Use of Wildcards in a FILE Resource

The FILE resource `/usr/lpp/bin/*` protects all files and subdirectories under `/usr/lpp/bin` (however deeply nested).

## How PAM SC File Protection Works

When the `seosd` daemon starts, it performs the UNIX `stat` command for each discrete file object that is defined in the database. The daemon then builds a table in memory that contains an entry for each file object. In addition, the table contains the inode and device of the file for each discrete file. With this information, Privileged Access Manager can also protect the hard links to the files because the protection is according to device and inode. The database does not keep information about the inode and device of a file.

When you create a file rule through Privileged Access Manager:

- If the file exists in UNIX, Privileged Access Manager first performs a `stat` command for the file. Then it adds an entry to the file table with the inode and device information of the file.
- If the file does not exist in UNIX, Privileged Access Manager adds an entry of the name of the file to the file table (without inode and device information). This entry is the same as the entry for a generic file object. Simultaneously, the kernel keeps an indication in its internal tables that this file must be checked during creation for inode and device information. When the file is created, the kernel intercepts its creation. The kernel informs `seosd` of the inode of the file and device information. The `seosd` daemon can then update the entry of the file in the file table.

When you delete a file, Privileged Access Manager deletes its entry in the `seosd` file table. The entry remains in the Privileged Access Manager database in case you create it again.

## Protect Files Using the PAM SC `selang` Command Shell

To define a protected file in `selang`, enter the following command:

```
newres FILE filename
```

For example, to register a file named `/tmp/binary.bkup`, enter the following command:

```
newres FILE /tmp/binary.bkup
```

### NOTE

When you define a file rule without specifying its access type, the default access of `NONE` is assigned. In this case, the owner of the file is the only one who can access the file.

Most protected files should be protected from access by the superuser. Otherwise, any user who knows the password of the superuser gains automatic access to the files. At the same time, you can prevent all other users except the owner of the file from accessing the file.

To protect several similarly named files, use a file name pattern that includes a wildcard. The wildcards are `*` (which indicates zero or more characters) and `?` (which indicates any one character, other than `/`).

The pattern that you specify is matched against the full path name of the file so that the pattern `/tmp/x*` matches files that are named `/tmp/x1`, `/tmp/xxx`, and even `/tmp/xdir/a`.

Patterns that Privileged Access Manager does *not* let you specify are: `/*`, `/tmp/*`, and `/etc/*`.

### WARNING

Because file name patterns are such a powerful tool, do not experiment freely with them.

Example: The following command defines as protected every file in the /tmp directory that has a name starting with a, and ending with b. This would include a file like /tmp/xyz/xyzab :

```
newres FILE /tmp/a*b
```

## Wildcards in FILE Resource Names

By using wildcards in a file resource name, you can create a file record that corresponds to multiple files: any file with a name that matches the wildcard pattern is protected by the access authorities associated with the record.

The wildcards that you can use are:

- \* for any number of any characters
- ? for any one character

If a physical resource name matches more than one resource record name, the longest nonwildcard match is used for that resource.

Privileged Access Manager does *not* accept the following patterns in names of FILE resources:

- \*
- /\*
- /tmp/\*
- /etc/\*

### Example: Use of Wildcards in a FILE Resource

The FILE resource /usr/lpp/bin/\* protects all files and subdirectories under /usr/lpp/bin (however deeply nested).

## Restrict File Access

To restrict a file from access by the superuser in selang, use a longer version of the newres command. Example: To prevent the super user from accessing the file /tmp/binary.bkup, and any other user except the user myuser, use the following selang command:

```
newres FILE /tmp/binary.bkup owner(myuser) defaccess(N)
```

This command does the following:

1. Defines /tmp/binary.bkup as a protected file.
2. Sets the user myuser as the owner of the file, granting myuser access to the file.
3. Sets the default access of the file to NONE, preventing any other user from accessing the file. To permit other users access to the file, you must explicitly define access rules for that file.

### WARNING

If you invoke the selang command under root authority and then define FILE records without explicitly specifying another user as their owner, root becomes the owner of those files. As the owner, root (or any user who logs in as root) has complete and free access to the files.

### NOTE

You can set the token use\_unix\_file\_owner in the seos.ini file to yes. This permits regular UNIX users to define access rules for the files they own.

## Prevent File Access

Sometimes it is convenient to define a FILE record that has no owner. To define a FILE record that does not have an owner in selang, use the special owner nobody.

Example: To define the file `/tmp/binary.bkup` as a protected file and prevent all users from accessing the file, enter the following selang command:

```
newres FILE /tmp/binary.bkup owner(nobody) defaccess(N)
```

This newres command ensures that even the user who defined the command, whether root or otherwise, cannot access the file. After preventing all users from accessing a file, grant one or more users access to that file explicitly.

To permit a user to access to a protected file explicitly, use the authorize command. Example: To grant the user `userJo` update access to all files in the `/tmp` directory beginning with `Jo`, enter the selang command:

```
authorize FILE /tmp/Jo* uid(userJo) acc(Update)
```

#### NOTE

Privileged Access Manager protects only those files defined in its database.

### Restrict Users from Getting File Information

If you do not provide users with *read* access permissions to a file or directory, they can still use the `stat` function to get information about the file by default. For example, a user without *read* access permissions to file `/tmp/abc` can perform the following operation:

```
ls -l /tmp/abc
```

To prevent users who do not have *read* access permissions from getting file information, set the [STAT\\_intercept](#) configuration setting to 1.

### View Default Access Authority

To view the default access of users in the `_restricted` group (when no matching records are found), use the selang `showres` command with the `_default` record of the class.

For example, to view the default access that users in the `_restricted` group have for files that are not in the Privileged Access Manager database, use the `showres` selang command to display the `_default` resource of `FILE` class:

```
showres FILE _default
```

#### NOTE

All other users have the access defined by specific Privileged Access Manager database rules.

### Use Conditional Access Control Lists

You can make access to a file conditional on the program that is used to access the file. Making file access conditional in this way is named program pathing.

#### NOTE

If the program specified to access the file is a shell script, the shell script must have `#!/bin/sh` as its first line. Because the shell script treats `#!/bin/sh` line as a comment and does not process it, do not execute the shell script following `# /home/test/test.sh` or `# sh /home/test/test.sh`.

Example: This code allows any process to update the file `/etc/passwd` under the control of the password change program `/bin/passwd`. All access attempts to the `/etc/passwd` file that do not originate from `/bin/passwd` are blocked.

```
newres FILE /etc/passwd owner(nobody) defaccess(R)
authorize FILE /etc/passwd gid(users) access(U) via(pgm(/bin/passwd))
```

The newres command defines the file `/etc/passwd` to Privileged Access Manager. This command allows any user, including the owner of the file, to read the file. The authorize command allows all users to access the file when the access is made under the program `/bin/passwd`. Once the password file is protected in this manner, any Trojan horse that inserts

entries into the `/etc/passwd` file or any update to the password file by a user of the group `users` is blocked if the user is not using the `/bin/passwd` program.

Conditional access lists are also useful for controlling access to the files of a database management system (DBMS). Usually, you permit users to access such files only through the programs and utilities supplied by the database vendor. Consider the following commands:

```
authorize FILE /usr/dbms/xyz uid(*) via (pgm(/usr/dbms/bin/pgm1)) access (U)
authorize FILE /usr/dbms/xyz uid(*) via (pgm(/usr/dbms/bin/pgm2)) access (U)
```

This set of `authorize` commands allows all Privileged Access Manager users to access the file `xyz` of the DBMS system provided the access is made by either program `pgm1` or program `pgm2`, which belong to the DBMS binaries directory. Note the use of the asterisk in the user operand. The asterisk specifies all users who are defined to Privileged Access Manager. The use of the asterisk is similar in concept to the default access. However, default access also applies to users who are not defined to Privileged Access Manager. You can use the `_undefined` group for users who are not defined in the Privileged Access Manager database.

### Use Negative Access Control Lists

You can deny a user or group specific access types using a Negative Access Control List (NACL).

With the Privileged Access Manager language (selang), use the following command to deny access:

```
auth className resourceName [gid(group-name...)] \
[uid({user-name...|*})] [deniedaccess(accessvalue)]
```

### Block Trojan Horses with the `_abspath` Group

Any relative path names in the `$PATH` variable, particularly the dot (`.`) path name meaning current directory, are a security weakness. Consider the following scenario:

- At the top of the `PATH` variable for root is the current (`.`) directory.
- A malicious user creates a destructive program—a Trojan horse—and stores it as `/tmp/lis`.
- In time, as the malicious user expects, root issues the `lis` command in the `/tmp` directory. Instead of running the usual `lis` command, root actually runs—with full administrative privileges—the Trojan horse that had been stored in the `/tmp` directory.

To eliminate this security weakness, Privileged Access Manager provides a user group named `_abspath`. All members of the `_abspath` group are forbidden to use relative path names in invoking programs.

You can add a user to the `_abspath` group as you add one to any other group. Effective at the next login, the user is forbidden to use relative path names when accessing programs.

### PAM SC Synchronization with Native UNIX Security

Although Privileged Access Manager permissions are more complex than native UNIX permissions, you can synchronize your native UNIX permissions to the product permissions. That is, you can make the permissions coincide. However, the synchronization is subject to some limitations:

- Synchronization is not retroactive. Once it is in effect, it governs all newly issued Privileged Access Manager authorization commands, but it does not govern pre-existing access rules.
- Permissions that you grant in Privileged Access Manager can be passed to UNIX. However, permissions that you grant in UNIX are not passed to Privileged Access Manager.
- Because of limitations in its own system of permissions, UNIX can be unable to adopt more than a simplified form of the Privileged Access Manager permissions. Even UNIX versions that feature access control lists (ACLs) can be unable to reflect all the complexity of the Privileged Access Manager ACLs.

UNIX platforms with ACLs that can be synchronized to Privileged Access Manager are Sun Solaris and Tru64.

Without such ACLs, you can still synchronize the traditional UNIX rwx permissions to the Privileged Access Manager permissions, to the extent possible.

The combination of the UNIX option of the authorize command and the SyncUnixFilePerms token of the seos.ini file control synchronization:

- By including the UNIX option, the authorize command calls for implementation in UNIX and in Privileged Access Manager. The command can even grant UNIX permission where permission did not exist before. When the UNIX option is *not* used, selang commands do not effect on UNIX security. Moreover, where UNIX retains a prohibition, a Privileged Access Manager permission is not effective. So the only way that selang can overcome a UNIX prohibition is with the UNIX option of the authorize command.
- In the authorize command, the UNIX option works only when the SyncUnixFilePerms token is appropriately set in the [seos] section of the seos.ini file. The token has several permitted values:
  - **no** - specifies not to synchronize ACL permissions. This value is the default.
  - **warn** - specifies not to synchronize ACL permissions, but to issue a warning if the product permissions and native UNIX permissions conflict.
  - **traditional** - specifies to adjust the rwx permissions for the group according to the Privileged Access Manager ACL (and permissions for individual users are not copied to UNIX).
  - **acl** - specifies to adjust the UNIX ACL according to the Privileged Access Manager ACL.
  - **force** - specifies to adjust the UNIX world access attribute according to the Privileged Access Manager defaccess permissions.

Any change in the SyncUnixFilePerms token value takes effect only after you restart the seosd daemon.

**Use the table of contents to access the topics in this section.**

## Example Synchronization

The following example involves a file that is named /var/temp/newdata and a user who is named fowler. The example assumes that a record in the FILE class already represents the file.

1. Shut down the seosd daemon, so you can edit the seos.ini file:

```
# secons -s
```

2. Logged in as a user with permission to edit the seos.ini file, edit the seos.ini file to make the SyncUnixFilePerms line, in the [seos] section, look like this:

```
SyncUnixFilePerms = acl
```

Remember, acl means that the UNIX option adjusts the UNIX ACL according to the Privileged Access Manager ACL. The UNIX option has this function as long as the token remains set to acl.

3. Restart the seosd daemon:

```
# seosd
```

4. Invoke selang, then issue the following selang command:

```
authorize FILE /var/tmp/newdata uid(fowler) access(r w) unix
```

The command gives fowler Read and Write access to the new data file. By specifying the UNIX option, it grants the corresponding native UNIX permissions.

## Sun Solaris Limitations

Under Sun Solaris, native UNIX ACLs are not implemented in the /tmp directory.

## Monitor Sensitive Files

The Watchdog protects the binaries of your setuid/setgid programs, and any other files you specify. The [seoswd utility](#) (the Watchdog daemon) continually checks two issues:

- Whether the [seosd daemon](#) is alive and responding. If necessary, the watchdog daemon restarts the seosd daemon.
- Whether a user has modified any trusted programs or files. If so, seoswd prevents these files from executing.

When the seosd daemon forks, it automatically executes the seoswd program to start the Watchdog.

The [seos.ini](#) file contains several tokens that control the scanning and time-out values of the watchdog. The file also contains the most up-to-date documentation on these values.

You can use the Watchdog to perform the same background checks as those checks made for the setuid and setgid programs on ordinary files. These checks include generating audit records when these files are altered.

For example, consider a configuration where only the security administrator is allowed to modify the file `/etc/inittab`. To make Privileged Access Manager monitor the file and generate an alert in any case of modification, use the following command in `selang`:

```
newres SECFILE /etc/inittab
```

The file `/etc/inittab` is now constantly monitored for modifications.

## Protect the Internal Files (UNIX)

During installation, Privileged Access Manager writes rules to protect two types of internal files:

- **Internal File Rules:** Protect configuration files, log files, and database files.  
You cannot delete internal rules.
- **Default File Rules:** Protect sensitive files such as root and server certificates that you use to encrypt and authenticate communication.  
You can delete default rules after installation.

### Internal File Rules

Internal file rules protect configuration files, log files, and database files. Internal file rules are not visible in `selang` and cannot be deleted.

Files that Privileged Access Manager protects with internal file rules have the following access rights:

- Full access for Privileged Access Manager internal processes
- Read and execute (where relevant) access for all other accessors

You can write FILE rules to replace the internal file rules. If you delete these FILE rules, Privileged Access Manager reverts to the internal file rules.

Privileged Access Manager protects the following files with internal file rules. The second column of the table lists the configuration setting that specifies the file location, where applicable.

**Note:** Some file locations are defined internally and do not have a corresponding configuration setting. You cannot configure the location of these files.

| File                  | Configuration Setting and Section in <code>seos.ini</code> | Default File Location      |
|-----------------------|------------------------------------------------------------|----------------------------|
| All database files    | [seosd] dbdir                                              | <i>ACInstallDir/seosdb</i> |
| <code>seos.ini</code> | -                                                          | <i>ACInstallDir</i>        |

|                                     |                       |                                                         |
|-------------------------------------|-----------------------|---------------------------------------------------------|
| privpgms.ini                        | -                     | <i>ACInstallDir/etc</i>                                 |
| loginpgms.ini                       | -                     | <i>ACInstallDir/etc</i>                                 |
| xdmpgms.init                        | -                     | <i>ACInstallDir/etc</i>                                 |
| nfsdevs.init                        | [seosd] nfs_devices   | <i>ACInstallDir/etc</i>                                 |
| osver                               | -                     | <i>ACInstallDir/etc</i>                                 |
| accommon.ini                        | -                     | <i>ACSharedDir</i>                                      |
| seos.audit                          | [logmgr] audit_log    | <i>ACInstallDir/log</i>                                 |
| seos.audit.bak*                     | [logmgr] audit_back   | <i>ACInstallDir/log</i>                                 |
| seos.error                          | [logmgr] error_log    | <i>ACInstallDir/log</i>                                 |
| kbl.audit                           | [kblaudit] audit_log  | <i>ACInstallDir/log</i>                                 |
| kbl.audit.bak                       | [kblaudit] audit_back | <i>ACInstallDir/log</i>                                 |
| kbl.error                           | [kblaudit] error_log  | <i>ACInstallDir/log</i>                                 |
| All files<br>(If protect_bin is ON) | -                     | <i>ACInstallDir/bin</i>                                 |
| AC                                  | [kblaudit] cmd_log    | /etc<br>Symbolic link to <i>ACInstallDir/bin/cmdlog</i> |

## Default File Rules

Privileged Access Manager creates default file rules during installation to protect sensitive files. Default file rules are visible in selang and can be deleted.

The following table lists the sensitive files that Privileged Access Manager protects with default file rules, and the access rights and permitted accessors for the files.

In the table, *PMDBDir* is the directory in which the policy model databases (PMDBs) reside, and *pmd\_name* is the name of each policy model. By default, *PMDBDir* is located at *ACInstallDir/policies*. The location of *PMDBDir* is defined in the *\_pmd\_directory\_* token in the pmd section of the seos.ini file.

| File                                          | Default Access                                 | Permitted Accessors |
|-----------------------------------------------|------------------------------------------------|---------------------|
| <i>ACInstallDir/data/crypto/crypto.dat</i>    | None                                           | sechkey             |
| <i>ACInstallDir/data/crypto/def_root.pem*</i> | None                                           | sechkey             |
| <i>ACInstallDir/data/crypto/sub.key</i>       | None                                           | sechkey             |
| <i>ACInstallDir/data/crypto/sub.pem</i>       | None                                           | sechkey             |
| <i>ACInstallDir/log/policyfetcher.log</i>     | Read                                           | +policyfetcher      |
| <i>ACInstallDir/ladb/*db.la*</i>              | Read                                           | sebuildla           |
| /etc/passwd                                   | All                                            | All                 |
| /etc/shadow                                   | All                                            | All                 |
| <i>PMDBDir/pmd_name/hsock</i>                 | Read, Write, Execute, Cre, Chown, Chmod, Utime | seagent, sepmdd     |
| <i>PMDBDir/pmd_name/pmd.ini</i>               | Read                                           | seagent, sepmdd     |
| <i>PMDBDir/pmd_name/seos_*</i>                | Read, Write, Execute, Cre, Chown, Chmod, Utime | seagent, sepmdd     |

|                                |                                                |                 |
|--------------------------------|------------------------------------------------|-----------------|
| <i>PMDBDir/pmd_name/socket</i> | Read, Write, Execute, Cre, Chown, Chmod, Utime | seagent, sepmdd |
|--------------------------------|------------------------------------------------|-----------------|

## Protect setuid and setgid Programs

Set user ID (setuid) programs are among the most frequently used programs at a UNIX site. A process that invokes a setuid program automatically acquires the identity of the owner of the setuid program. If the owner of a setuid program is root, then any user automatically becomes a superuser by invoking the setuid program. When the setuid program starts, the process performs any task which a superuser has permission for. Ensure that the setuid programs perform only the required task. Back doors or shells within a setuid program grant the user access to everything on the system.

Privileged Access Manager uses the PROGRAM class to protect setuid and setgid programs. Upon installation, Privileged Access Manager permits any program execution by default. After you define trusted programs in the database, you can change the behavior of Privileged Access Manager so that execution of a setuid or setgid program is prohibited unless the program is defined as a trusted program. Example: to allow /bin/ps (the process status program) to run as a setgid program (as it is supposed to), use the following selang command:

```
newres PROGRAM /bin/ps defaccess(EXEC)
```

Privileged Access Manager registers the program /bin/ps as a trusted program. The product then calculates and stores the following information about the program: the CRC, inode number, size, device number, owner, group, permission bits, last modification time, and, optionally, other digital signatures in a record in the PROGRAM class of the database.

The Watchdog periodically checks the CRC, size, inode, and the rest of the characteristics of the program. If any of these values have changed, the Watchdog automatically asks seosd to remove the program from the trusted programs list and deny access to it. This ensures that no one can misuse the program by modifying or moving setuid programs. The permission in the example newres command allows all users, including those not defined in the database, to run the /bin/ps command.

Untrusted setuid programs are possibly the most dangerous security loophole of UNIX-based operating systems. By using the trusted access rules of the program, the security administrator can restrict the use of setuid to certain trusted programs that were tested and checked to ensure their integrity. However, any user cannot automatically start a trusted executable. The access rule must specify explicit users and groups that are granted access to that setuid program. Example: the following set of selang commands grants the execution of /bin/su only to the System Department users (group sysdept):

```
newres PROGRAM /bin/su defaccess(NONE)
authorize PROGRAM /bin/su gid(sysdept) access (EXEC)
```

Use an asterisk (\*) to specify all users who are defined in the database. For example, to permit all users who are defined to Privileged Access Manager to perform the su command, enter the following command:

```
authorize PROGRAM /bin/su uid(*) access (EXEC)
```

This description is also true for setgid executables.

You can use the nr and er commands to register the setuid and setgid programs in the PROGRAM class. Important non setuid and setgid programs can be registered in the PROGRAM class similarly. Define a FILE rule for these programs to prevent unauthorized users from upgrading them. If you want to allow the program execution when it is untrusted (after upgrade, the program is executed without being retrusted), set the blockrun property to no.

- If the blockrun property is set to yes, the program is not executed until it is retrusted and is not allowed to access any file that the relevant PACL would allow. The PACL is effectively disabled until the program is retrusted.
- If the blockrun property is set to no, the program is executed. However, the program cannot access any resources the relevant PACL would allow.

To set the value of the blockrun property to yes, use the following editres/newres command:

```
er program /bin/p blockrun
```

To set the value of the blockrun property to no, use the following editres/newres command:

```
er program /bin/p blockrun-
```

By default, for all the programs that are registered in the PROGRAM class, the blockrun property is set to yes. You can change this using the SetBlockRun token in the seos.ini file. Refer to the seos.ini file description for details.

#### NOTE

Privileged Access Manager uses the PROGRAM class and not the FILE class to protect setuid and setgid programs.

## Kernel Modules Load and Unload Protection

A *kernel module* is a component of the UNIX operating system that you can load to extend the running kernel. You can unload it when it is no longer required. The kernel module adds flexibility, letting you load functionality as required. You avoid wasting memory resources that would otherwise be required to cover all possible expected functionality in the base kernel.

You can disable and enable kernel module protection in Privileged Access Manager. If you enable kernel module protection, Privileged Access Manager intercepts the system calls that load and unload a kernel module. The product then checks the requested access against the associated record in the database, which is a record of class KMODULE. When access is requested for a kernel module record, the requested access is either "load" or "unload".

On all non-Linux systems, the name of the KMODULE record must match the name of the kernel module file, not the full path. This is because the name of the module is the same as the name of the file. On Linux, the name of KMODULE record must match only the name of the kernel module, which can differ from the actual file name. Changing the file name on Linux does not change the module name which Linux uses and the KMODULE record remains valid.

If you enable file path checking on kernel module loads and the requested access is load, Privileged Access Manager performs the following extra checks:

- The filepath property in the KMODULE record holds only valid absolute file paths.
- The files in the path name filepath have modules that match the KMODULE record name.
- The kernel module matches the KMODULE properties (filepath for non-Linux systems, signature for Linux systems).

#### NOTE

Privileged Access Manager produces a unique signature for the kernel module file on Linux systems, and inserts this as the value of the signature property in the kernel module record. Privileged Access Manager checks the signature on each access. You do not need to enter the signature yourself, because Privileged Access Manager calculates and inserts it automatically. However you can do so using the seretrust utility.

**Use the table of contents to access the topics in this section.**

## Protect a Kernel Module

You can protect the loading and unloading of kernel modules, and so help protect the operating system.

### To protect a kernel module:

Ensure that you have enabled kernel module protection. Create a KMODULE record in Privileged Access Manager.

1. 1. To create a kernel module, define:
  2. • The name of the kernel module

On all non-Linux systems, the name of the KMODULE record must match the name of the kernel module file (not the full path). This is because the name of the module is the same as the name of the file. On Linux, the

name of KMODULE record needs to match only the name of the kernel module, which, might be different from the actual file name.

- The owner of the record (defaults to the user creating the module)
- (Optional) The absolute file path to the kernel module file, or a list of file paths if there is more than one version of the module.

#### NOTE

On HP and Solaris systems, you can define the special kernel module `_ALL_MODULES` to protect the unloading of all kernel modules.

1. Define the users or groups that are authorized to load and unload the module.

#### Example: Protect a Kernel Module Using `selang` Commands

The following `selang` commands define and authorize a kernel module `serial.o` to Privileged Access Manager, and authorizes the enterprise user `kadmin` to load and unload it:

```
newres kmodule serial.o owner(kadmin) defaccess(none) \
filepath(/lib/modules/2.2.19/serial.o:/lib/modules/2.2.20/serial.o)
authorize kmodule serial.o access(load, unload) xuid(kadmin)
```

### Enable and Disable Kernel Module Protection

When kernel module protection is enabled, Privileged Access Manager checks the loading and unloading of the kernel modules that are defined in the database.

By default, Privileged Access Manager enables protection of kernel modules.

To enable or disable kernel mode protection, enable or disable the KMODULE class. For example, use the `setoptions` command.

#### Example: Enable Kernel Mode Protection Using `selang`

The following `selang` command enables kernel mode protection:

```
setoptions class+(kmodule)
```

#### Example: Disable Kernel Mode Protection Using `selang`

The following `selang` command disables kernel mode protection:

```
setoptions class-(KMODULE)
```

### Enable and Disable File Path Checking on Kernel Module Loads

If kernel module protection is enabled, you can also enable file path checking on kernel module loading. When this is enabled, Privileged Access Manager checks that the kernel module to be loaded matches the `filepath` property of the KMODULE record (for non-Linux systems), or matches the signature of the KMODULE record (for Linux systems).

To enable file path checking, set the `special_check` token to `yes` in the `seosd` section of the configuration file `seos.ini`. The default is `no`.

Privileged Access Manager does file path checking only if file path checking and kernel mode protection are both enabled.

#### Example: Enable File Path Checking for Kernel Module Loads Using the `seini` Utility

To enable file path checking for kernel module loads, you can use the `seini` and `secons` utilities as follows:

```
seini -s seosd.special_check yes
```

```
secons -rl
```

## Protect Binary Files from the kill Command

Protect mission-critical processes, such as database servers or application daemons, against denial of service attacks. The native UNIX security system bases its process protection on the process user ID. This implies that under native UNIX, root can do anything to any process. Privileged Access Manager adds to UNIX process protection by defining rules that are based on the executable file running in the process. Privileged Access Manager process protection is *independent* of the user ID of the process. A record in the PROCESS class must define every process that Privileged Access Manager protects.

For example, to protect the ASCII viewer /bin/more from being killed, follow this procedure:

1. Start selang.

2. Enter the following selang command:

```
newres PROCESS /bin/more defaccess(N) owner(nobody)
```

This command defines /bin/more as a process to be protected from kill attempts; therefore the default access is *none* (N). The **owner(nobody)** setting ensures that even the user who defined this rule cannot kill the /bin/more process.

3. Exit selang.

4. Test the rules that Step 2 defined:

a. Enter the command:

```
/bin/more /tmp/seosd.trace
```

b. Assuming the file /tmp/seosd.trace is large enough to keep /bin/more from exiting immediately, press Ctrl+Z to suspend the /bin/more process.

c. Try to kill the suspended job by entering the command:

```
kill %1
```

Your attempt fails, with Privileged Access Manager displaying the Permission denied message.

To make an exception that permits a specific user to kill the /bin/more processes, enter the selang command:

```
authorize PROCESS /bin/more uid(username)
```

### NOTE

Use the same procedure to protect other binary executables on your system from being killed.

Privileged Access Manager protects regular kill signals (SIGTERM) and the kill signals that an application cannot mask (SIGKILL and SIGSTOP). It passes other signals, such as SIGHUP or SIGUSR1, to the process to determine whether to ignore or react to the kill signal.

## Control Login Commands

This section provides information about control login commands.

**Use the table of contents to access the topics in this section.**

### Control the Login Process

Privileged Access Manager provides two types of login protection: by terminal, and by application. Using the TERMINAL class, you can establish which users can log in from which terminals or hosts.

### NOTE

For more information about the TERMINAL class, see the *Reference Guide*.

You can also control which user or group can log in using a certain login application such as Telnet, ftp, and rlogin with the LOGINAPPL class. By establishing the access rules of the class, you define specific rules for each login application. For instance, you can define rules that enforce the following conditions:

- Permit all users to ftp to your host
- Permit a limited number of users to Telnet to your system
- Permit no one to rlogin to the system

Each record in the LOGINAPPL class defines access rules for a specific login application.

## Examples LOGINAPPL

Example: The following procedure permits only an anonymous user to use the ftp application:

1. Change the ftp default access to none with the following selang command:

```
cr LOGINAPPL FTP defaccess(NONE) owner(nobody)
```

2. Permit the user anonymous to use ftp with the following selang command:

```
auth LOGINAPPL FTP uid(anonymous) access(X)
```

To restrict users from the group that is named account to use only telnet:

1. Block the use of rlogin and rsh with the following selang command:

```
auth LOGINAPPL(RLOGIN RSH) gid(account) access(N)
```

2. Permit the group that is named account to use telnet with the following selang command:

```
auth LOGINAPPL TELNET gid(account) acc(X)
```

### NOTE

The previous example shows RLOGIN and RSH restrictions, but other login programs should be included as well.

### NOTE

Whenever you add or use a new login program, you must add a LOGINAPPL record.

The login interception sequence always starts with setgid or setgroup events, which are called *triggers*. The sequence ends with a setuid event that changes the identity of the user to the real user who logged in.

Login applications issue various system calls, which Privileged Access Manager uses to monitor login activity. These login sequences are preset for standard login applications. You can see them by studying the Privileged Access Manager trace file.

### NOTE

For more information about the LOGINAPPL class and setting a sequence, see the *selang Reference Guide*.

## Enable SFTP Login Interception

When a user logs in to an endpoint using SFTP, the SFTP application uses SSH to authenticate the user. When Privileged Access Manager intercepts the login attempt from the SFTP application, it treats the login as an SSH login by default. The product uses the rules for the SSH LOGINAPPL record to permit or deny the login attempt.

To configure Privileged Access Manager to distinguish SFTP and SSH login attempts and to write separate rules for SFTP and SSH logins, enable SFTP login interception.

### To enable SFTP login interception

1. Open a command prompt window on the endpoint.
2. Enter the following selang command:

```
er LOGINAPPL SSH loginflags(EXECLOGIN)
```

This command specifies that the trigger for SSH logins is the first EXEC action that a process performs.

### 3. Enter the following selang command:

```
er LOGINAPPL SFTP loginpath(path) defaccess(a)
loginpath(path) Specifies the full path to the SFTP login application.
```

```
er LOGINAPPL SFTP loginpath(path) defaccess(a)
```

– loginpath(*path*)

Specifies the full path to the SFTP login application.

This command creates a LOGINAPPL record that is named SFTP. The command defines the path to the SFTP login application, and specifies that all users can use SFTP to log in to the endpoint if no additional restrictions exist.

### Example: Enable SFTP Login Interception

This example enables SFTP login interception for the SFTP login application located at /usr/libexec/openssh/sftp-server. The first selang command also specifies that Privileged Access Manager uses PAM login interception for SSH logins:

```
er LOGINAPPL SSH loginflags(EXECLOGIN, PAMLOGIN)
er LOGINAPPL SFTP loginpath(/usr/libexec/openssh/sftp-server) defaccess(a)
```

#### NOTE

For more information about the LOGINAPPL class, see the *selang Reference Guide*.

## Control Generic Login Applications

Privileged Access Manager can also control and protect generic login applications. This feature enables you to protect groups of login applications that match a certain rule with a generic pattern. To define a generic login application, use the LOGINAPPL class.

### Define a Generic Login Application

To define a generic login application with selang, use the same commands as setting regular login restrictions. The exception is the LOGINPATH parameter. This parameter must include a generic path composed of a regular expression using one or more of the following characters: [, ], \*, ?. For example, to define a generic Telnet application, issue the following command:

```
er LOGINAPPL GENERIC_TELNET loginpath(/usr/sbin/in.tel*)
```

### Generic Login Program Interception

With regular login restrictions, these rules are the activated rules:

- If a LOGINAPPL object that has the intercepted login program that is specified for the loginpath property exists in the database, the rules for that object apply.
- For generic LOGINAPPL objects, Privileged Access Manager follows these steps:
  - a. seosd searches for an exact match for the intercepted login application (a matching login path for the LOGINAPPL object). If found, the rules for that object apply.
  - b. If not found, the search continues for a LOGINAPPL object with a generic login path that matches.
  - c. If there is more than one match, the rules for the object with the more specific match apply.

## Define User Authority to Use Terminals

One of the most effective ways to block intruders from accessing the system is by terminal protection, which is the source of the login. The source can be the host or the terminal (such as an X terminal or a console) from which the user logs in.

In modern architecture, a terminal is no longer the teletype device UNIX was developed for. On most sites, a pseudo terminal is allocated through the pseudo terminal server (PTS) or by the X window manager. The name of the terminal is a meaningless symbol for the security system. Privileged Access Manager protects what we understand as a terminal. The product implements terminal protection during the login stage, when the product defines a terminal in one of three ways:

- When the user logs in from an X terminal using the XDM login window, Privileged Access Manager takes the IP address of the X terminal that is translated to host name (from /etc/hosts, NIS, or DNS) to be the terminal that is used for the login request. The product can also protect using the IP addresses if the translation to the host name fails or if you prefer to use IP addresses.
- When the user logs in from a dumb terminal, the TTY name identifies the terminal.
- When the user logs in from the network (through Telnet, rlogin, rsh, and so on), the requesting IP address that is translated to the host name (through /etc/hosts, NIS, or DNS) is taken to be the terminal name.

You can define login rules for a specific host by defining this host in the **TERMINAL** class. Add the appropriate users and groups to the access list of the object. For each login source, you can also limit the days and hours in which log in from this host or terminal is allowed. To do this, set the day and time restrictions for the **TERMINAL** object. Use wildcards in the **TERMINAL** class to define hosts that match a pattern (host name or IP address).

Usually, highly authorized users such as the superuser or system administrators are restricted to terminals that are located in secure places. Intruders and hackers who want to enter the system as superuser are not able to do it from their own remote stations. They have to work from one of the authorized terminals, which should be in a secured location.

When logging in from the network, you cannot be certain that the user is indeed sitting in front of the host console. The user could be sitting in front of any terminal that is attached to that host or communicating from any other node in the network authorized to receive services from the requesting host. Permitting a user to log in from another host implies that we permit login to that user not only from that specific station but also from any other terminal authorized by that station. To ensure isolation between departments, define terminal groups. Allow users of each department to work only from the terminal group of their department.

Unlike other resources, in terminal authorizations the more the user is authorized to access information, the lower the terminal authorization of the user should be. The superuser must be the most restricted user in terminal access. This restriction ensures that nobody can log in as root from remote unsafe terminals.

When defining terminals, Privileged Access Manager requires you to specify the owner of the terminal definition explicitly. The reason is that if the root user, as the security administrator, becomes the owner of the terminal by default, it makes the terminal eligible for superuser login. In most cases, this is not wanted. To prevent such mistakes that might unintentionally cause loopholes, Privileged Access Manager makes you define an owner when defining the terminal.

To define the terminal `tty34`, use the following command:

```
newres TERMINAL tty34 defaccess(none) owner(userA)
```

This command creates a record for the terminal `tty34`, sets its default access to `NONE`, and defines `userA` as its owner. `userA`, as the owner of the terminal, is automatically allowed to enter the system through terminal `tty34`.

To prevent all users from logging in from the terminal `tty34`, specify `nobody` as the owner:

```
newres TERMINAL tty34 defaccess(none) owner(nobody)
```

To permit a user to log in from a particular terminal, enter the following command:

```
authorize TERMINAL tty34 uid(USR1)
```

This command permits `USR1` to log in from terminal `tty34`.

Permission to use a terminal can also be granted to a group. For example, the following command permits members of the group `DEPT1` to use the terminal `tty34`:

```
authorize TERMINAL tty34 gid(DEPT1)
```

To define a group of terminals (known as a terminal group), enter the following command:

```
newres GTERMINAL TERM.DEPT1 owner(ADM1)
```

To add member terminals to the terminal group TERM.DEPT1, enter the following command:

```
chres GTERMINAL TERM.DEPT1 mem(tty34, tty35)
```

To authorize USR1 to use this terminal group, enter the following command:

```
authorize GTERMINAL TERM.DEPT1 uid(USR1)
```

This grants USR1 the authority to use both tty34 and tty35.

## Restrict Terminals for Root Users

Another issue to consider is the default rule of the TERMINAL class. At the initial implementation stages, the default is set to permit anything that is not defined. If this thing is a TERMINAL, this default could be a shortcoming.

Consider the following situation: A site has a few hundred terminals, and you want most users to be able to log in from any terminal. However, you want the root user to be able to log in only from two predefined terminals.

First, consider that setting the default of the TERMINAL class to READ enables anyone, including root, to log in from any terminal that does not have a specific TERMINAL record in the database. You do not want the superuser to be able to log in from any terminal. Also consider that setting the default of the TERMINAL class to NONE forces you to define each terminal in the database. This situation can be impractical.

To solve this problem, Privileged Access Manager supports the definition of an access control list within the \_default record of the TERMINAL class. The following commands show you how to restrict root to two terminals with minimum effort:

```
newres TERMINAL term1 defaccess(N) owner(root)
newres TERMINAL term2 defaccess(N) owner(root)
newres TERMINAL _default defaccess(R)
authorize TERMINAL _default uid(root) access(N)
```

The first two commands define term1 and term2 as terminals owned by root, so they are eligible for superuser login. The newres TERMINAL \_default and chres commands set the default access to READ, so that any terminal that is not defined in the database is accessible to anyone. The authorize command explicitly denies access of the superuser to undefined terminals.

### NOTE

The UACC class still exists; you can use it to specify the default access of a resource. However, using \_default records to specify the default access of a resource is much easier.

## Recommended Restrictions

Restrict the use of the loopback terminals, local host terminals, and station host names if the default access for the TERMINAL class is READ. Allowing users to use these terminals permits all other users to substitute their own user IDs if they know the password of the target user. For example, consider the following scenario:

- User U is allowed to work from terminal T.
- Terminal T is not allowed for superuser login.
- User U is not authorized to substitute user ID to root.
- User U managed to get the superuser password.
- All users are permitted to log in from terminal loopback.

User U can bypass this set of access rules by simply performing the command `telnet loopback`, specifying the user ID `root`, and supplying the password. Now a superuser session has started from terminal T, which is not supposed to allow superuser login. A user can similarly bypass access rules by exploiting the local host or the host name of the station.

To restrict these three vulnerabilities, use the following definitions:

```
newres TERMINAL loopback defaccess(N) owner(nobody)
newres TERMINAL localhost defaccess(N) owner(nobody)
chres TERMINAL hostname defacc(N) owner(nobody)
```

An alternative approach to preventing this security breach is to limit the TCP requests for `telnet`, `ftp`, and so forth, from local host.

Yet another option is to set default access for the `TERMINAL` group to `NONE`, then specify `TERMINAL` and `GTERMINAL` rules.

## Password Checking and Login Restrictions

Privileged Access Manager does not replace the `/bin/login` executable. Even when Privileged Access Manager is running, passwords continue to be checked against `/etc/passwd`, the shadow password file, or the NIS `passwd` map. But Privileged Access Manager also performs more checks, described in the following section.

## Defining Time and Day Login Rules

Information security is most vulnerable in times of low activity. Late hours of the night and weekends are ideal times for breaking in, because fewer people are available to monitor the audit records. Setting up appropriate terminal authority rules forces an intruder to use a terminal that is in a protected location. Setting up days-of-week (DOW) and time-of-day (TOD) access rules forces the intruder to attempt break-ins during work hours when offices are open and active. This combination severely restricts break-ins.

Limiting the days and hours in which a user can log in is done on a user-by-user basis. To define the DOW and TOD login restrictions for a user, use the following command:

```
chusr USR1 restrictions(days (Mon,Tue,Wed)time (800:1700))
```

This command permits user `USR1` to log in only between 8:00 and 17:00 on Mondays, Tuesdays, and Wednesdays. `USR1` cannot log in outside the specified time on the specified days, or on days other than those specified.

The `days` parameter also accepts the values `ANYDAY` (allow logins on all seven days of the week) and `WEEKDAYS` (allow logins Monday through Friday). The `time` parameter also accepts the value `ANYTIME` (allow logins at any time of the day).

### NOTE

You can apply the DOW and TOD restrictions to *many* resources defined in the database. This feature is useful for giving terminals and terminal groups limited periods of usability.

## Disabling Concurrent Logins

Most UNIX-based operating systems allow concurrent logins. But if a user is permitted to log in from more than one terminal, other users can log in from elsewhere and can masquerade as that user while that user is logged in.

After you log in, Privileged Access Manager allows you to disable your own concurrent login permission. Doing so ensures that no one else can log in as you from another terminal. However, you can still log in repeatedly from the particular terminal that you are using. Use the `secons` command with the following switches:

```
# secons -d- (disables concurrent login)
```

```
# secons -d+ (enables concurrent login)
```

Any user can issue the -d option. (All other options are only allowed for users with the ADMIN or OPERATOR attribute). Users who want to disable concurrent logins can use this command in their initial scripts. Although they are then able to open as many windows as they want, they cannot log in from a second terminal.

#### NOTE

If you use the secons -d- command to prevent concurrent logins, you must remember to use secons -d+ before logging out, to avoid being locked out of the system. If you forget to reinstate concurrent logins and try to log in again, Privileged Access Manager allows you to log in provided no process with the same user ID is running.

## Limit Concurrent Logins for a User

Privileged Access Manager can control the number of concurrent logins in two ways:

- **Administrator Level**

Set a systemwide definition in the database of the number of concurrent sessions a user can have. You can set this value globally, for a profile group, or for individual users.

- **User Level**

Users individually control the number of concurrent logins allowed for them. This way, when logging in, users can block the option of more login sessions with their names, thus protecting themselves.

#### NOTE

The number of concurrent logins is independent of the number of sessions the user is running on a particular terminal. Multiple sessions on one terminal are considered as a single login. The concurrent-logins limit restricts the number of *terminals* a user can concurrently log in from, not the number of logins from each terminal.

## Limit Concurrent Logins Globally

In `selang`, enter the following command:

```
setoptions maxlogins(NumLogins)
```

## Limit Concurrent Logins Individually

In `selang`, enter the following command:

```
chusr username maxlogins(NumLogins)
```

The concurrent logins limit set for a user overrides the systemwide limit. To prevent Privileged Access Manager from enforcing the concurrent logins limit for a specific user, set the concurrent logins limit to zero for the user. You cannot use `selang` if you set the maximum number of concurrent logins to one.

## Recognize a Login Event

Privileged Access Manager does not treat all attempts to change the user ID of a process as login events. Usually a program attempts to change its user ID with a `setuid` system call. The SURROGATE class controls these events, which are not necessarily considered login events. These events do not necessarily change the user identity from the point of view of Privileged Access Manager.

Privileged Access Manager always preserves the original user identity--the identity with which the user logged in initially. Ordinary `setuid` system calls do not cause Privileged Access Manager to register a change in user identity.

For Privileged Access Manager to recognize the identity change, it must recognize this event as a login event. The product recognizes login events using the following rules:

- The program that attempts to change the identity is defined as a *login program*. All programs in the LOGINAPPL class are login programs.
- The program executes a series of system calls corresponding to its definition in the LOGINAPPL class.

When you begin an administration session (in *selang* or Privileged Access Manager Endpoint Management), Privileged Access Manager performs a dummy login event. This event is not a true login; rather, Privileged Access Manager performs certain internal checks, which are similar to log in checks.

#### NOTE

For more information, see the SEQUENCE property for the LOGINAPPL class in the *selang Reference Guide*.

At the start of an administration session, the user name is checked in the machine to be administered. You get access to this machine for administration only if you have WRITE access for the terminal from which you perform the session.

For example, if you are logged in to host Minerva and would like to administer Privileged Access Manager on host Artemis, two conditions are necessary:

- A TERMINAL object called Minerva (or the relevant fully qualified name) is in the database record for Artemis.
- You are listed in the ACL of this object with WRITE permission.

These conditions are checked before any other user authority check. You also need administrative authority in the database.

## Protect TCP/IP Services

Protecting TCP/IP services is most important for file servers that contain sensitive data. These servers must provide certain services only to trusted stations, and not to intruders or computers that are unknown to the host.

## Restrict TCP IP Services

In an open network, any station can request services from other computers on the network. The TCP/IP protocol can be used to supply many services. Some of these services, such as *rlogin*, *rcp*, *rsh*, *ftp*, *telnet*, and *rexec*, are common to all UNIX-based operating systems. Others are provided by in-house and third-party software.

Privileged Access Manager intercepts the accept processes of TCP/IP at the host computer and determines whether the accept program should continue normally or be overridden. Privileged Access Manager bases its decision on access rules governing hosts and services that you define. You can create TCP/IP access rules in the database to specify the computers and networks that are allowed to receive services such as file transfers, remote login, and remote shell from a specific computer.

The following examples show how TCP/IP access rules can be defined and set to efficiently block unwanted outsiders. If you have not yet had time to develop a complete database, you may want to let any station that is not defined in the database receive any service. If so, set the HOST record in the UACC class as follows:

```
chres UACC HOST defaccess(READ)
```

A station that is to have access rules for TCP/IP services from the local host is defined in a record in the database under the HOST class. For each of these stations, the services allowed are listed in the record. For example, the following command sequence defines a record for station *ws5* and denies it from receiving any TCP/IP service from the local host:

```
newres HOST ws5
```

```
authorize HOST ws5 service(*) access(NONE)
```

The following command allows *ws5* to perform *telnet* to the local computer:

```
authorize HOST ws5 service(telnet)
```

These settings allow users to telnet to the local computer, which means that the remote user must specify a user name and password before using the local system. To allow a station to receive all TCP/IP services from the local computer, you can use an asterisk in the service keyword. For example, the following command allows ws5 to invoke any TCP/IP service from the local computer:

```
authorize HOST ws5 service(*)
```

The service can be specified in several ways, some of which involve the *port number*. The port number is an identification number for a service. All services have port numbers, and the port numbers are mapped to the services in the file `/etc/services`. You can specify a service in the following ways:

- By its name as defined in the file `/etc/services`
- By its port number
- As a range of port numbers
- As an RPC port that is listed in the `/etc/rpc` system file

For example, the following command permits ws5 to receive any TCP/IP service whose port number falls between 7045 and 7050:

```
authorize HOST ws5 service(7045-7050)
```

In many cases, it is more economical to define a group of hosts and set its permissions once, instead of making permissions for each individual computer. Privileged Access Manager provides the GHOST class, where each GHOST record defines a group of hosts. To define a GHOST record and add hosts to its member list, enter the following commands:

```
newres GHOST gh1 mem(ws2, ws3, ws5)
```

```
authorize GHOST gh1 service(ftp)
```

The `newres` command defines a group of hosts called `gh1` that contain the members `ws2`, `ws3`, and `ws5`. The `authorize` command allows all three stations to receive `ftp` (file transfer) services.

Managing host groups is easier than managing individual stations, but to supply more flexibility, Privileged Access Manager also supports the definition of network access rules. Networks are defined in the HOSTNET class. For example, consider the following set of commands:

```
newres HOSTNET hn1 mask(255.555.0.0) match(192.168.0.0)
```

```
authorize HOSTNET hn1 service(*) access(NONE)
```

```
authorize HOSTNET hn1 service(ftp)
```

- In the first line, the `newres` command, defines a network called `hn1`. With its `mask` and `match` values, it specifies that any computer with an IP address whose first two qualifiers are `192.168` is considered as coming from the `hn1` network.
- The combination of the second and third lines permits any station from the `hn1` network to perform `ftp`, but not any other service, in the host computer.

Another method that this product provides for defining TCP/IP access rules is name-pattern access rules. The product supports the definition of generic records in the HOSTNP class (host name pattern) with wildcards.

**Note:** For information on how Privileged Access Manager performs string matching, see the *Selang Reference* section.

For example, the following command sequence permits all hosts whose names start with the characters `lin` and end with the characters `.org.com` to receive all TCP/IP services on the local host:

```
newres HOSTNP lin*.org.com
authorize HOSTNP lin*.org.com service(*).
```

**Note:** Hosts that are managed by NIS must be identified by their official names that appear in a NIS map and not by their aliases. The chart in the following section summarizes the TCP/IP check flow.

## Use the TCP Class

You can specify protection by service instead of by host, by using the TCP class.

### NOTE

For more information about the TCP class, see the *Reference Guide*.

Use the TCP class to control incoming *and* outgoing services.

For example, the following commands create a record for the `ftp` service, with `READ`, meaning the service can be used, as default access type. This example also prevents hosts that match the name pattern `PUBLIC*` from receiving the service.

```
newres TCP ftp defaccess(READ)
authorize- TCP ftp hostnp(PUBLIC*) access(N)
```

You can also specify that a particular user or group be only permitted to receive a particular service. For example, to allow all users to `ftp` to a host called `hermes`, but to specify that only members of the group that is called `acctng` can access `hermes` with `Telnet`, enter the following commands:

```
newres HOST hermes
newres TCP ftp owner(nobody) defaccess(read)
newres TCP telnet owner(nobody) defaccess(read)
authorize TCP ftp uid(*) host(hermes) access(write)
authorize TCP telnet gid(acctng) host(hermes) access(write)
```

### NOTE

`defaccess(read)` disables outgoing services. `defaccess(write)` disables incoming services.

### NOTE

If the `HOST` class is active (that is, if it is used as a criterion for access), then the `TCP` class cannot effectively be active. You can use the command `setoptions class- HOST` to deactivate the `HOST` class; then use the command `setoptions class+ TCP` (if necessary) to activate the `TCP` class. Deactivating the `HOST` class automatically deactivates `GHOST`, `HOSTNET`, and `HOSTNP` as well.

Also, if the `TCP` class is active, use the `setoptions` command `class- CONNECT` to deactivate the `CONNECT` class.

## Streams Module for Network Interception

By default, the `TCP` class is not active. Before you activate the `TCP` class, the `CONNECT` class, or the `HOST` class, be sure that the streams module is enabled.

To load the Privileged Access Manager streams module on Solaris, complete the following steps:

1. Stop Privileged Access Manager. Enter the following command:

```
secons -s
```

2. Enter the following command:

```
SEOS_load -s
```

3. Start Privileged Access Manager. Enter the following command:

```
seload
```

**NOTE**

If you attempt to activate the TCP class when the streams module is not loaded, an error appears:

```
ERROR: className class cannot be activated when streams are not loaded.
```

```
Please use SEOS_load -s to load the streams.
```

The algorithm for incoming authorizations is:

Figure 39: File\_Incoming\_Authorization\_Algorithm

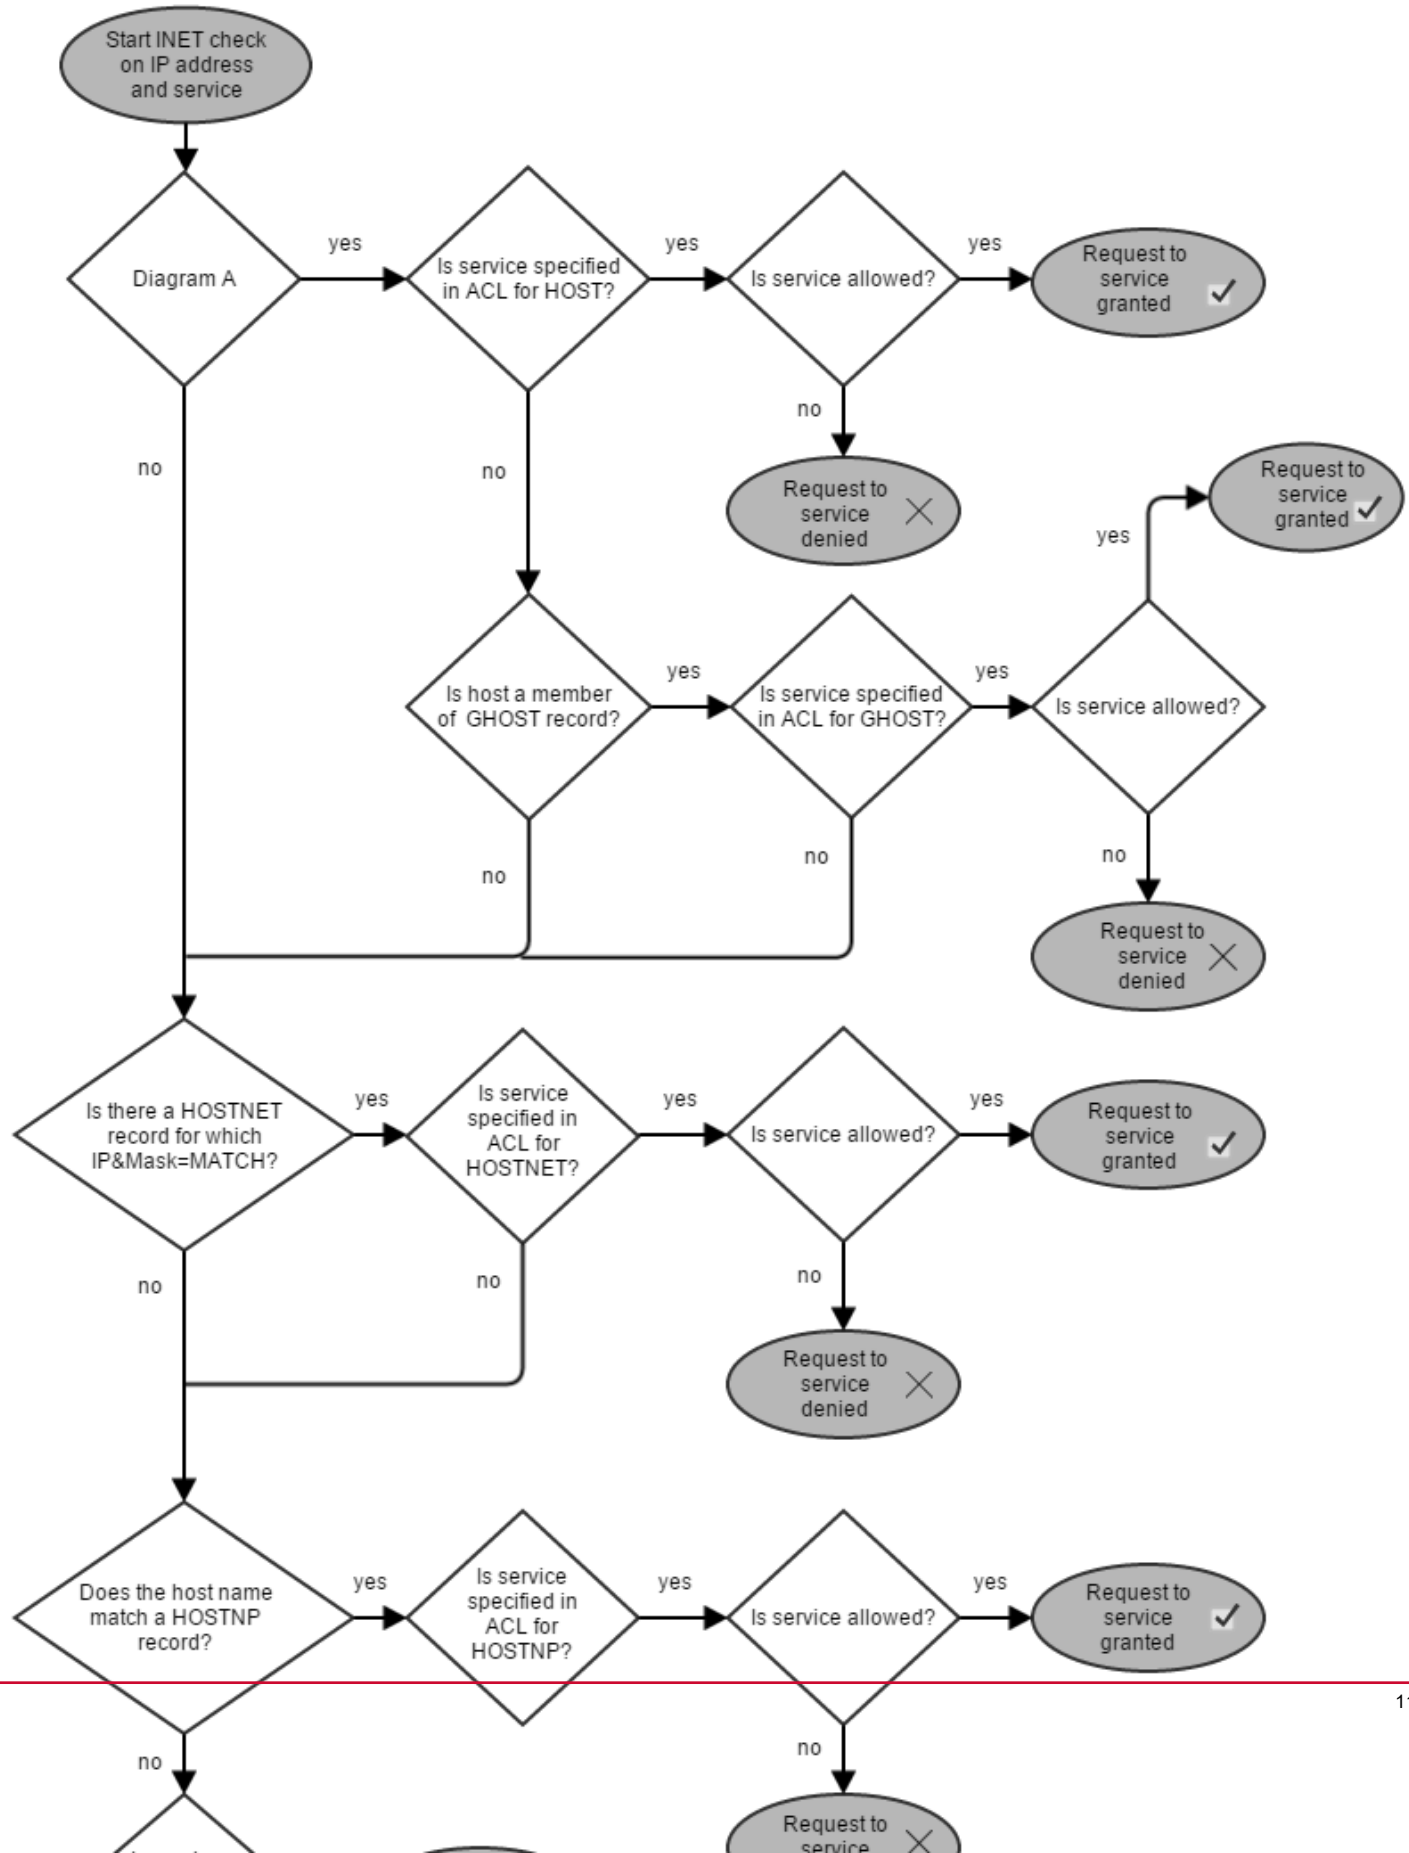

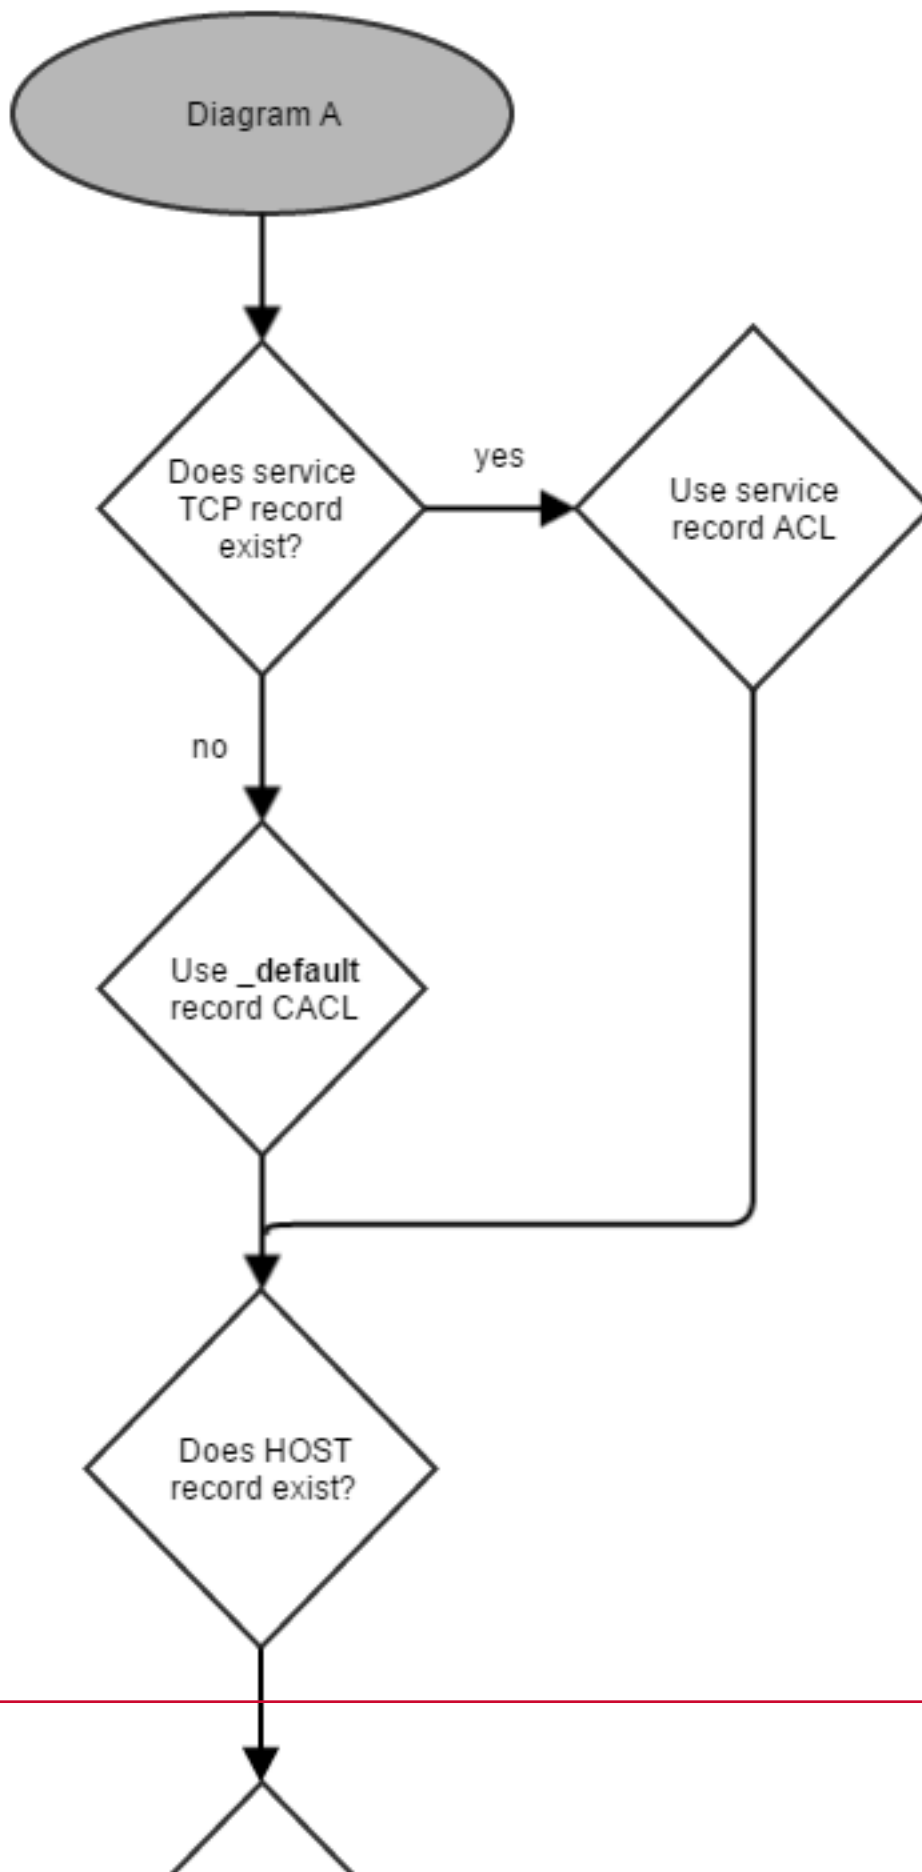

Figure 40: Incoming Authorization 2

The algorithm for outgoing authorizations is:

Figure 41: Outgoing Authorization

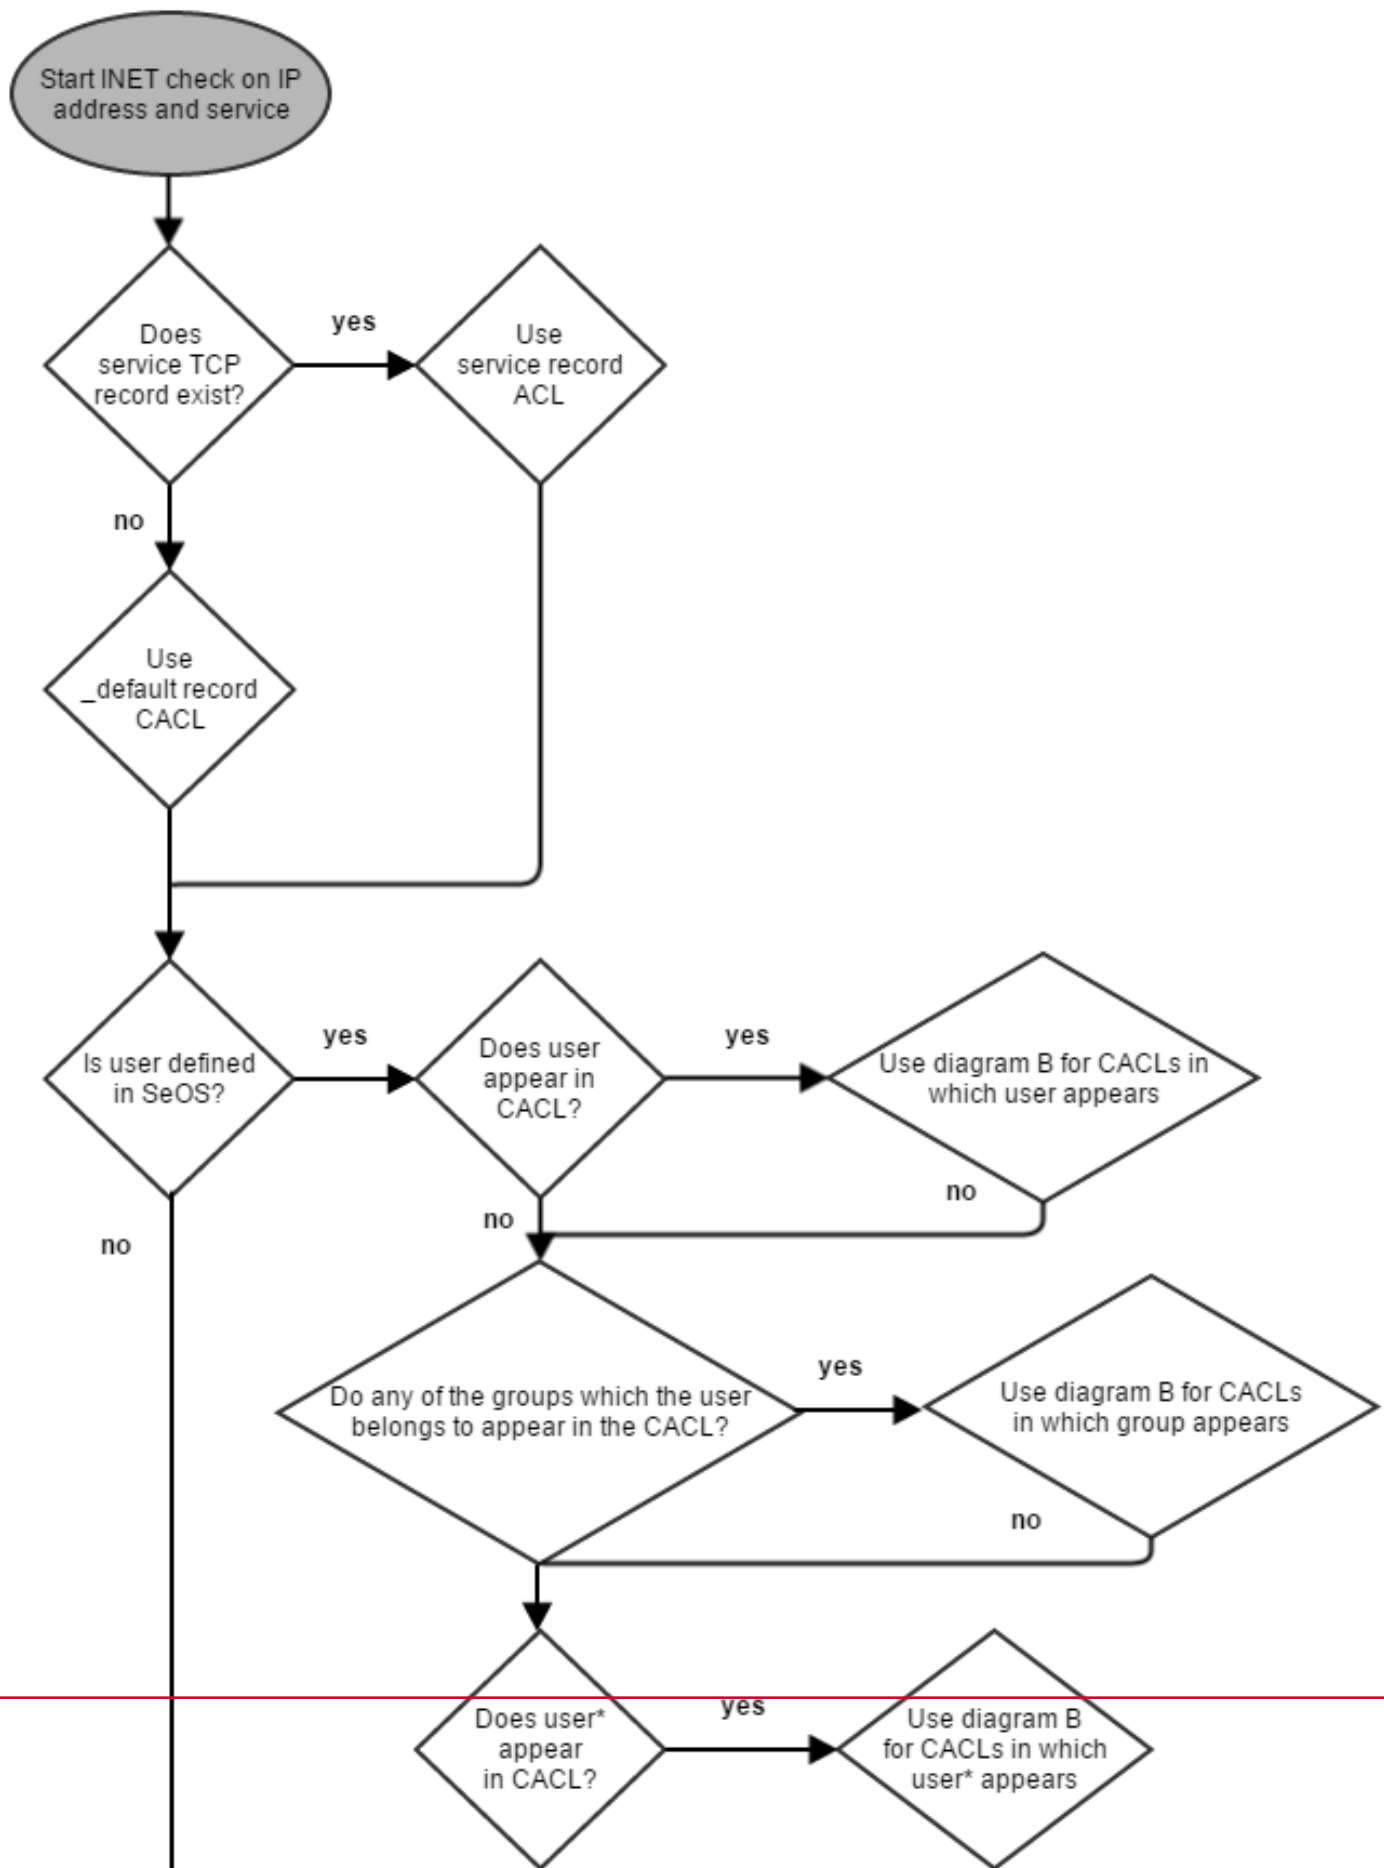

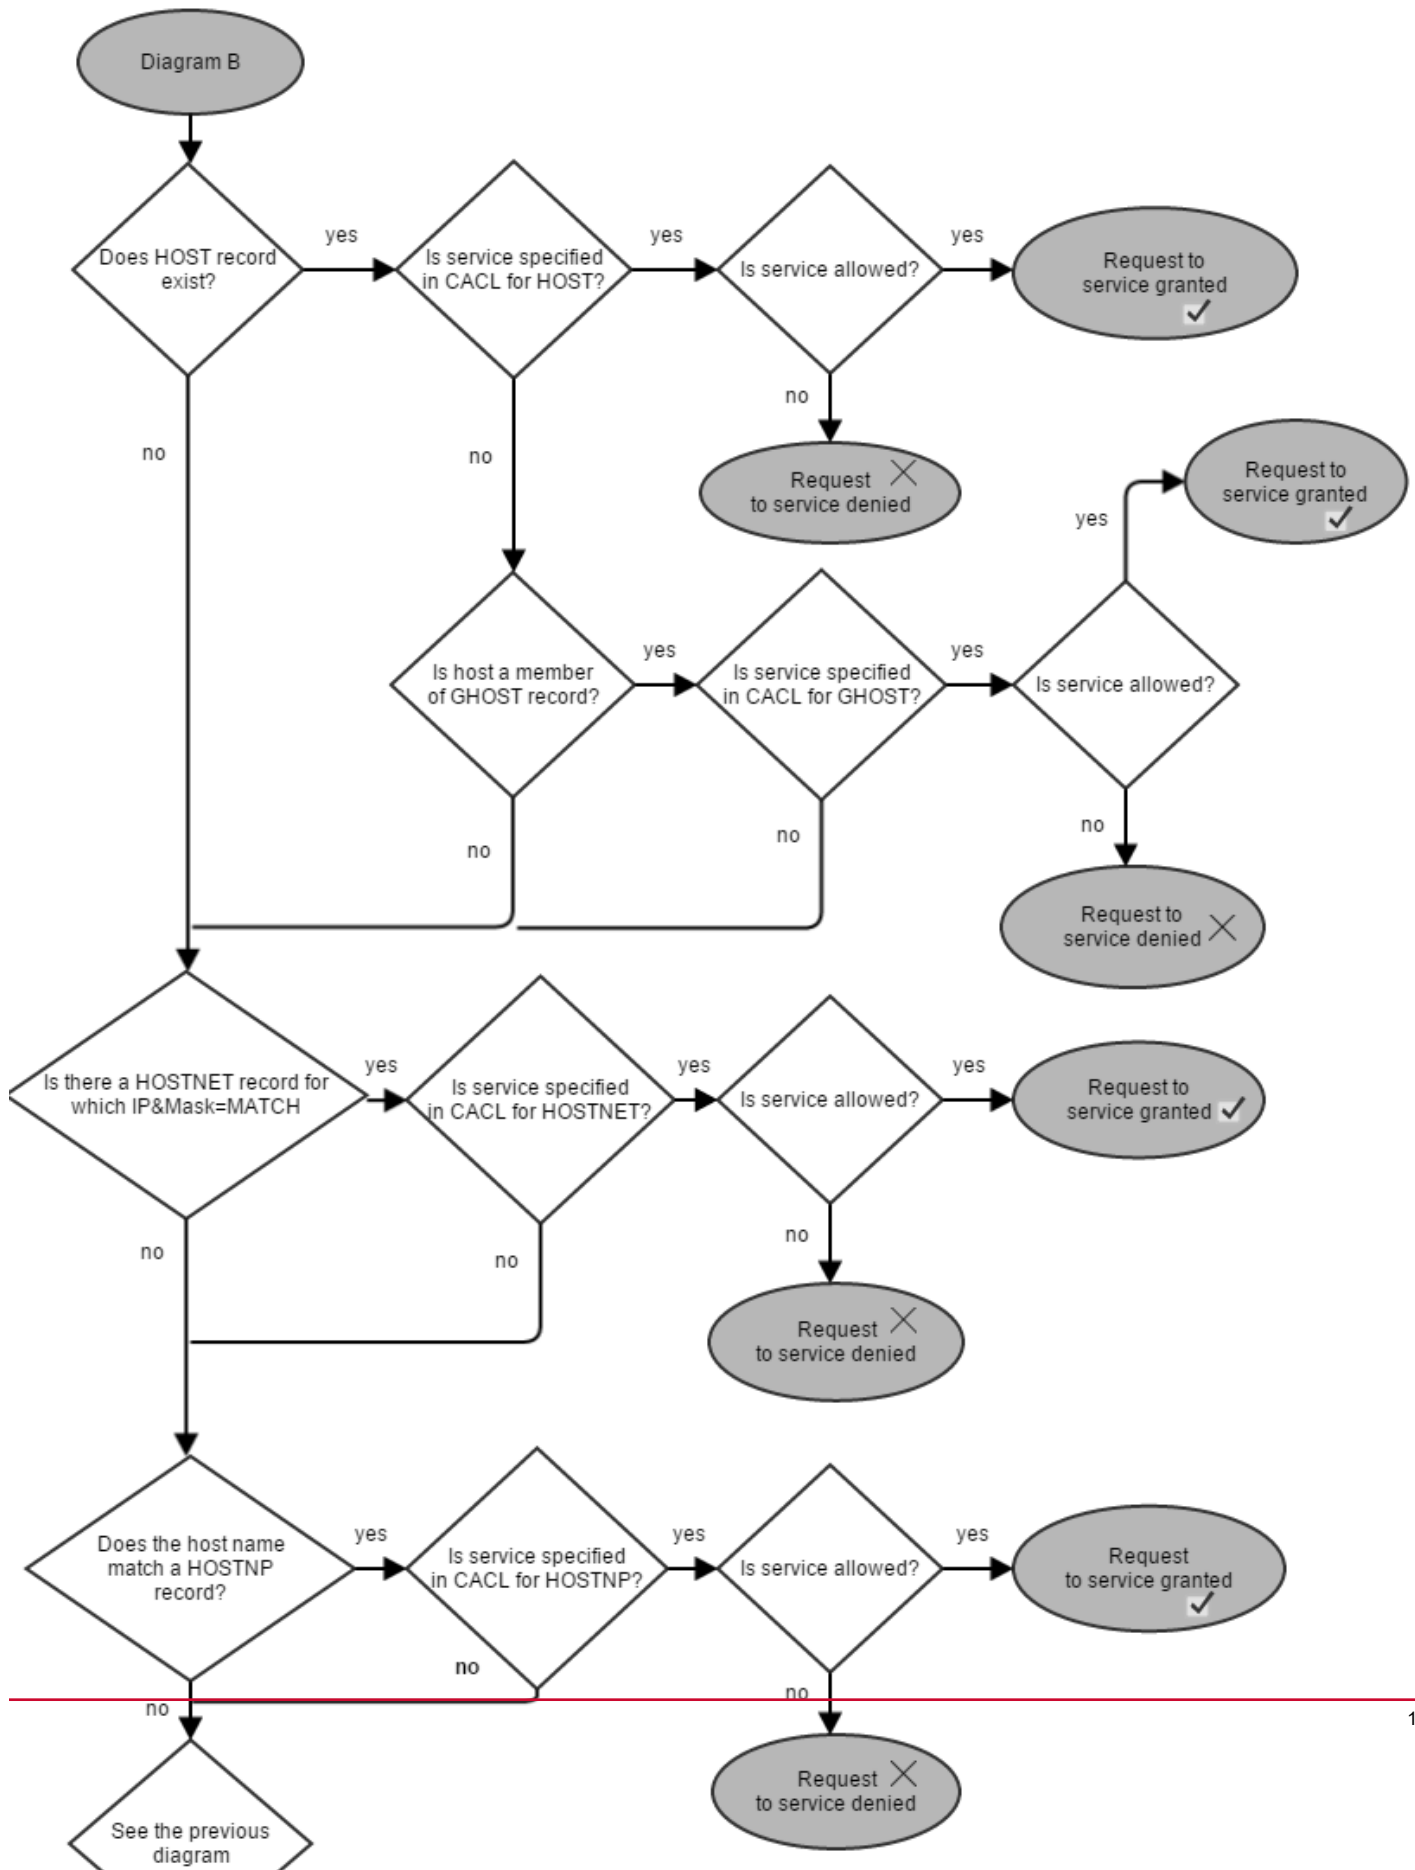

Figure 42: Outgoing Authorization 2

## Policy Model Database (UNIX)

Managing tens or hundreds of databases individually is not practical. Privileged Access Manager supplies the Policy Model service, a component that lets you manage many databases from one central database. Using the Policy Model service is optional, but it greatly simplifies administration at large sites.

The Policy Model (PMD) service uses a Policy Model database (PMDB). Like other Privileged Access Manager databases, the PMDB contains users, groups, protected resources, and rules governing access to the resources. In addition, the PMDB contains a list of *subscriber* databases. Each subscriber is a Privileged Access Manager database that resides on a separate computer, or another PMDB that resides on the same or another computer. A PMDB that updates a subscriber is the *parent* of the subscriber.

The PMDB is a useful tool for managing many databases that have similar authority restrictions and access rules.

### NOTE

For information about administrating a PMDB (sepmd utility), see the *Reference Guide*. For information about managing PMDBs remotely using selang, see the *selang Reference Guide*.

## Configure Automatic Rule-based Policy Updates

Single-rule policy updates (regular selang rules) you make in a central database are automatically propagated to the subscriber databases. By subscribing several computers to the same database, and by subscribing one database to another, you can create a hierarchy. You configure your environment for automatic rule-based policy updates after installation.

### NOTE

This method of managing policies is limited to letting you make single-rule policy updates across your hierarchy. Other functionality is only available through implementing advanced policy management and reporting.

## How Automatic Rule-based Policy Updates Work

When you configure your environment for automatic rule-based policy updates, each rule you define in the central database is automatically propagated to all its subscribers in the following way:

1. A rule is defined for any PMDB with at least one subscriber.
2. The PMDB sends the command to all subscriber databases.
3. The subscriber database applies the propagated command.
4. If the subscriber database does not respond, the PMDB sends the command at a regular interval (by default, every 30 minutes) until the subscriber database has been updated.

Alternatively, you can update subscriber databases when they become available, by setting the pull\_option token to yes in the [pmd] section of the seos.ini file on the subscriber computer.

1. If a subscriber database is responding, but refuses to apply the command, the PMDB places the command in the [Policy Model error log](#) (see page).
2. If the subscriber database is a parent to other subscribers, it then sends the command to its subscribers.

### Example: Removing a user from all computers in a hierarchy

If a user is deleted from a PMDB using the rmusr command, the same rmusr command is sent to all the subscriber databases. In this way, a single rmusr command can remove a user from many databases on various computers.

## How You Can Set Up a Hierarchy

Privileged Access Manager uses the Policy Model service to propagate rule-based policy updates across the configured hierarchy. By subscribing several Privileged Access Manager computers to the same PMDB, and by subscribing one PMDB to another, you create a hierarchy.

To enable automatic rule-based policy updates, do the following:

1. Create and configure the master PMDB.
2. (Optional) Create and configure subscriber PMDBs.
3. [Define parent PMDBs for the subscribing computers](#) (see link), called *endpoints*.

### NOTE

The following sections show how you set up a PMDB hierarchy. There are other ways of creating PMDBs and then setting their hierarchy. For a comprehensive discussion of the Policy Model utilities, see the *Reference Guide*.

## Create and Configure the Master PMDB

To let you manage policies from a central location, you first create and configure a master PMDB. On a local host, you can use the `sepmdbadm` command.

### NOTE

The following procedure shows the interactive form of the `sepmdbadm` command. For information about using the command-line parameters for all input, see the *Reference Guide*.

### Follow these steps:

1. In a command line, enter the following command:

```
sepmdbadm i
```

Privileged Access Manager starts the Policy Model database administration script (`sepmdbadm`) and displays a menu with options for you to choose from.

2. Enter 1, to select the first option (create a master PMDB and define its subscribers).

The script is configured to ask you the relevant questions.

3. Press Enter to continue.

The script continues to ask you the first question.

### NOTE

If Privileged Access Manager is not running, the script issues a warning and lets you start Privileged Access Manager before the script is rerun.

4. Enter a name for the Policy Model you want to create.

The script registers the Policy Model name and continues.

### NOTE

The first character for a PMDB name should consist of the alphanumeric characters "-" and "\_".

5. Enter the name of the first subscriber computer you want to specify.

The script registers the name of the first subscriber and then asks you to enter the name of the next subscriber.

6. Continue to enter subscriber names as necessary, then press Enter without entering a subscriber name.

The script registers all subscriber names and continues.

**NOTE**

You still must point each subscriber computer to its parent PMDB.

7. If you are running NIS, NIS+, or DNS, choose whether you want to update the NIS/DNS tables with PMDB changes.

Updates are made to users and groups in the PMDB. The tables provide information on users and their characteristics. If you choose yes, a UNIX user or UNIX group that is updated through the Policy Model is also updated in the NIS passwd and group files.

8. Enter **y** if you want to update the NIS/DNS tables.

The script now asks you for the location of the NIS passwd and group files.

9. Enter the full path of the NIS password file.

The script registers the full path and continues.

10. Enter the full path of the NIS group file.

The script registers the full path and continues.

11. Enter **n** or press Enter if you want to update the NIS/DNS tables.

The script registers your answer and continues.

12. Enter the users that you want to give special attributes for the PMDB:

13. Enter Privileged Access Manager administrator names as necessary, then press Enter without entering an administrator name.

Administrators are authorized to change the properties of the PMDB.

**NOTE**

At least one administrator must be defined in a PMDB (*root* is the default).

14. Enter enterprise user administrator names as necessary, then press Enter without entering an administrator name.

15. Enter Privileged Access Manager auditor names as necessary, then press Enter without entering an auditor name.

Auditors are authorized to view the PMDB audit log files

16. Enter enterprise user auditor names as necessary, then press Enter without entering an auditor name.

17. Enter Privileged Access Manager password manager names as necessary, then press Enter without entering a password manager name.

18. Enter enterprise user password manager names as necessary, then press Enter without entering a password manager name.

Password managers are authorized to change passwords in the PMDB.

The script registers your answer and continues.

19. Enter administration terminals as necessary, then press Enter without entering an administration terminal.

The script registers all administration terminals and then reports the selections that you have made and asks you to confirm them.

20. Press Enter to confirm the selections you have made, or enter **n** to rerun the script with new inputs.

If you confirm your selections, a new PMDB is created using the answers that you supplied.

**More information:**

[Define Parent PMDBs for Subscribing Computers](#)

## Create and Configure Subscriber PMDBs

Once you have a master PMDB configured, if you want to extend your hierarchy, create and configure subscriber PMDBs. On a local host, you can use the `sepmdadm` command.

### NOTE

The following procedure shows the interactive form of the `sepmdadm` command. For information about using the commandline parameters for all input, see the *Reference Guide*.

### Follow these steps:

1. In a command line, enter the following command:

```
sepmdadm i
```

Privileged Access Manager starts the Policy Model database administration script (`sepmdadm`) and displays a menu with options for you to choose from.

2. Enter 2, to select the second option (create a subsidiary PMDB and define its subscribers and parent.).

The script is configured to ask you the relevant questions.

3. Press Enter to continue.

The script continues to ask you the first question.

4. Enter a name for the Policy Model you want to create.

The script registers the Policy Model name and continues.

5. Enter the name of the first subscriber computer you want to specify.

The script registers the name of the first subscriber and then asks you to enter the name of the next subscriber.

6. Continue to enter subscriber names as necessary, then press Enter without entering a subscriber name.

The script registers all subscriber names and continues.

**Note:** You still must [point each subscriber computer to its parent PMDB](#).

7. Enter the name of the parent PMDB.

The script registers the parent PMDB name and continues.

### NOTE

`sepmdadm` only lets you enter one parent for each subscribing database. You can, however, define multiple parents for each database. To do this, modify the `parent_pmd` token of the `pmd.ini` configuration file. For more information about using this token, see the *Reference Guide*.

8. If you are running NIS, NIS+, or DNS, choose whether you want to update the NIS/DNS tables with PMDB changes.

Updates are made to users and groups in the PMDB. The tables provide information on users and their characteristics. If you choose yes, a UNIX user or UNIX group that is updated through the Policy Model is also updated in the NIS `passwd` and group files.

9. Enter **y** if you want to update the NIS/DNS tables.

The script now asks you for the location of the NIS `passwd` and group files.

10. Enter the full path of the NIS password file.

The script registers the full path and continues.

11. Enter the full path of the NIS group file.

The script registers the full path and continues.

12. Enter **n** or press Enter if you want to update the NIS/DNS tables.

The script registers your answer and continues.

13. Enter the users that you want to give special attributes for the PMDB:

14. Enter Privileged Access Manager administrator names as necessary, then press Enter without entering an administrator name.

Administrators are authorized to change the properties of the PMDB.

#### **NOTE**

At least one administrator must be defined in a PMDB (*root* is the default).

15. Enter enterprise administrator names as necessary, then press Enter without entering an administrator name.

16. Enter Privileged Access Manager auditor names as necessary, then press Enter without entering an auditor name.

Auditors are authorized to view the PMDB audit log files.

17. Enter enterprise user auditor names as necessary, then press Enter without entering an auditor name.

18. Enter Privileged Access Manager password manager names as necessary, then press Enter without entering a password manager name.

Password managers are authorized to change passwords in the PMDB.

19. Enter enterprise user password manager names as necessary, then press Enter without entering a password manager name.

The script registers your answer and continues.

20. Enter administration terminals as necessary, then press Enter without entering an administration terminal.

The script registers all administration terminals and then reports the selections that you have made and asks you to confirm them.

21. Press Enter to confirm the selections you have made, or enter **n** to rerun the script with new inputs.

If you confirm your selections, a new PMDB is created using the answers that you supplied.

### **Define Parent PMDBs for Subscribing Computers**

To establish an endpoint computer as a subscriber to a PMDB, you must do more than register the subscriber's name in the PMDB. You also need to complete a procedure at the subscriber computer.

#### **To define parent PMDBs for subscribing computers**

1. In a command line on the subscriber computer, start `sepmdadm` in interactive mode:

```
sepmdadm i
```

Privileged Access Manager starts the Policy Model database administration script (`sepmdadm`) and displays a menu with options for you to choose from.

2. Enter 3, to select the third option (define the parent and password PMDBs of the local host).

The script is configured to ask you the relevant questions.

3. Press Enter to continue.

The interactive script continues to ask you the first question.

**NOTE**

If Privileged Access Manager is running, the script issues a warning and lets you stop Privileged Access Manager before the script is rerun.

4. Enter the name of the parent PMDB.

The script registers the name of the parent PMDB name and continues.

5. Enter the name of the parent password PMDB.

The script registers the name of the parent password PMDB name and then reports the selections you have made and asks you to confirm them.

6. Press Enter to confirm the selections you have made, or enter **n** to rerun the script with new inputs.

If you confirm your selections, the subscriber computer is set up with these inputs.

**NOTE**

sepmdadm only lets you enter one parent for each subscribing database. You can, however, define multiple parents for each database. To do this, modify the parent\_pmd token of the seos.ini configuration file. For more information about using this token, see the *Reference Guide*.

**How You Use a PMDB to Propagate Configuration Settings**

When you edit a Policy Model's configuration, the new configuration values are propagated to the Policy Model's subscribers.

The following process describes how configuration updates are propagated to a Policy Model's subscribers:

1. You edit one or more of the Policy Model's configuration values.
2. The Policy Model writes the new configuration values to the virtual configuration file.

**Note:** The virtual configuration file does not contain values for the audit.cfg file. The Policy Model does not write any changes that you make to this file to the virtual configuration file.

1. The Policy Model sends the new configuration values to its subscribers.
2. selang commands update each subscriber with the new configuration values.

**Virtual Configuration File**

Each Policy Model has a virtual configuration file that contains the configuration values for its subscribers. The virtual configuration file is located in the PMD directory, and is named `cfg_configname`, where *configname* is the name of the Policy Model configuration.

The virtual configuration file does not contain the configuration values held in the audit.cfg file.

**How New Subscribers Are Configured**

The Policy Model configures each new subscriber with the existing configuration values. The existing configuration values are stored in the virtual configuration file.

**Note:** The virtual configuration file does not store configuration values from the audit.cfg file. Any changes that you make to the audit.cfg file before creating a subscriber are not propagated to the new subscriber.

The following process describes how a Policy Model configures new subscribers:

1. You create a subscriber to the Policy Model.
2. The Policy Model reads the values in its virtual configuration file.
3. The Policy Model adds the configuration values from its virtual configuration file to the updates.dat file. The updates.dat file also contains the access rules for the Policy.
4. The Policy Model sends the updates.dat file to the new subscriber.

5. `selang` commands configure the new subscriber with the values in the `updates.dat` file.

## UID/GID Synchronization

As an administrator, you receive messages that refer to users by UID and to groups by GID. Verify that the UIDs and GIDs have the same meaning everywhere.

By default, the PMDB attempts to use the same UIDs and GIDs for new users and groups everywhere. You can help by providing the necessary conditions from the start as follows:

- Start with identical `passwd` files and identical group files.
- Make sure that the `synch_uid` token in the `pmd.ini` file is set to yes.

You can depend on compatibility between the UIDs and between the GIDs of your local database, your PMDB, and your PMDB subscribers if the following conditions exist:

- Your local database is a subscriber to your PMDB
- The PMDB is the only source of new users and new groups for your subscriber databases

If you create a user with a UID that is already in use in the PMDB or in some other subscriber computer, the individual update of the subscriber fails. In all other subscriber computers where no such conflict exists, the update succeeds.

An alternative to synchronizing your `passwd` and group files is to specify the UID of each new user and the GID of each new group explicitly.

## Synchronize Users and Groups

To ensure the lists of users and groups in your various databases correspond correctly at all times, you need an initial set of identical lists. Because the password and group files are so important, synchronize them before they begin accumulating local user and group information.

### To synchronize users and groups

1. Copy your `/etc/passwd` file and `/etc/group` file to your Policy Model directory.

This is a onetime procedure that destroys any previous `passwd` and group files in your [Policy Model directory](#).

#### NOTE

If you are using a shadow file and want to synchronize passwords, we recommend using the `secrepsw` utility. For more information, see the *Reference Guide*

2. Copy the `/etc/passwd` file and `/etc/group` file to each subscriber computer so that they are identical to the ones on your own computer.

3. On the computer where the PMDB resides, ensure that the `synch_uid` token in your `pmd.ini` file is set to yes.

By default, the value of the token `synch_uid` is yes. If you ever want a subscriber database to have independent default UIDs and default GIDs (that is, not necessarily attempting to match those of the PMDB), you can set `synch_uid` to no.

## Specify UIDs Explicitly

Another way to send an identical UID or GID to the PMDB and to all its subscribers is to explicitly set it when you create a new user.

To specify UIDs explicitly, use the `userid` or `groupid` parameter with each `newusr` command.

### Example: Create a new user with a specified UID

If you want to establish 1234 explicitly as the UID of new user `terry_jones` (and assuming that no one else in the database has that UID yet), enter the command:

```
newusr terry_jones unix (userid(1234))
```

If the specified UID is already being used in the PMDB, then the PMDB will not itself be updated, but the command will still propagate to the other subscriber databases. Among the other databases, wherever the particular UID is already in use, the subscriber's individual update will fail; but where no such conflict exists, the update succeeds.

## How the Policy Model Updates Subscribers

When updating subscribers, the Policy Model performs the following actions:

1. The Policy Model tries to qualify subscriber names fully as they are added to or deleted from the Policy Model.
2. The PMDB daemon, `sepmdd`, attempts to update a subscriber database for the amount of time defined by the token `QD_timeout`.
3. If the maximum time elapses and the daemon does not succeed in updating a subscriber, it skips that particular subscriber. The daemon then tries to update the remainder of the subscribers on its list.
4. After it completes its first scan of the subscriber list, `sepmdd` performs a second scan. In the second scan, `sepmdd` tries to update the subscribers that it did not succeed in updating during its first scan. During the second scan, it tries to update a subscriber until the connect system call times out (approximately 90 seconds).

### NOTE

The token `QD_timeout` may be found in both the `seos.ini` and `pmd.ini` files. If the token exists in both files, `sepmdd` uses the value in the `pmd.ini` file.

Whenever a PMDB encounters an error while propagating updates to subscribers, the `sepmdd` daemon creates an entry in the [Policy Model error log file](#) (see link). This file, `ERROR_LOG` by default, is located in the [PMDB directory](#).

## Clean Up the Update File

The `sepmdd` utility automatically writes each update it receives in the `updates.dat` file. To prevent the file from growing too large, we recommend that you delete processed updates from the file periodically.

To clean up the update file, use the following command:

```
sepmdd t pmdbName auto
```

`sepmdd` calculates the offset of the first update entry that has not been propagated and deletes all the update entries before it.

### NOTE

For more information about `sepmdd` utility, see the *Reference Guide*.

## Encrypt the Update File

After you create a PMDB, but *before* you start `sepmdd`, you can specify that information saved to the `updates.dat` file be encrypted.

To encrypt the update file, set the `UseEncryption` token to `yes` in the `[pmd]` section of the `pmd.ini` file.

To decrypt the `updates.dat` file, use the `sepmdd` utility with the `de` switch.

### NOTE

For more information about `sepmdd`, see the *Reference Guide*.

## Exclude Subscribers

You can skip subscribers so that they do not receive updates from parent PMDBs.

To exclude the local host, set the token `exclude_localhost` to `yes` in the `pmd.ini` file.

To add additional subscribers to the excluded list, set the token `exclude_file` (*name of file*).

To make a subscriber receive updates, remove the subscriber from the excluded list.

## Filter Updates

If you want your PMDB to update different subsets of data at different subscriber databases, you need to define which records are sent to subscriber databases.

### To filter updates

1. [Configure PMDBs to serve as parents to subsets of subscribers.](#)
2. Modify the *filter* token in the `pmd.ini` file of the parent PMDB to point to a filter file you set up on the same computer.

Updates to the subscriber databases are then limited to the records that pass the filter.

### NOTE

When you execute a `join` or `join- selang` command in the native UNIX environment, Privileged Access Manager changes the command to `change group (cg)`. To filter `join` or `join-` commands in the native UNIX environment, use the following line in the filter file:

```
MODIFY UNIX GROUP GroupName USERS NOPASS
```

You cannot filter `join` or `join-` commands by user name in the native UNIX environment. This rule does not apply to `join` or `join-` commands in any other environment.

## Policy Model Error Log File

The Policy Model error log, which is organized chronologically, looks similar to this:

| Error Text                                                                                                                                                                                                                              | Error Category         |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| 20 Nov 03 11:56:07 (pmdb1): fargo nu u5 0 Retry<br>ERROR: Login procedure failed (10068)<br>ERROR: Cannot accept update from a nonparent PMDB<br>(pmdb1@name.company.com) (10104)                                                       | Configuration Errors   |
| 20 Nov 03 19:53:17 (pmdb1): fargo nu u5 0 Retry<br>ERROR: Connection failed (10071)<br>Host is unreachable (12296)                                                                                                                      | Connection Errors      |
| 20 Nov 03 11:57:06 (pmdb1): fargo nu u5 560 Cont<br>ERROR: Failed to create USER u5 (10028)<br>Already exists (9)<br>20 Nov 03 11:57:06 (pmdb1): fargo nu u5 1120 Cont<br>ERROR: Failed to create USER u5 (10028)<br>Already exists (9) | Database Update Errors |

The Policy Model error log is in binary format; you can view it only by entering the following command:

```
ACInstallDir/bin sepmd e pmdname
```

### NOTE

Do not manually delete an error log (for example, with the UNIX `rm` command). To delete the log, only use the following command:

```
ACInstallDir/bin sepmd c pmdname
```

**WARNING**

The error log in Privileged Access Manager r5.1 and later versions has a format that is not compatible with the format of earlier versions. sepmdd cannot handle error logs from these earlier versions. When you upgrade to a version that has this format, the old error log is copied to ERROR\_LOG.bak; a new log file is created when you start sepmdd.

**Example: PMDB Update Error Message**

The following example shows a typical error message:

```

date      time      pmdb name      subscriber      command      offset      flag
  ↓          ↓          ↓          ↓          ↓          ↓          ↓
20 Nov 03 19:53:17 (pmdb1): fargo nu u5 0 Retry
ERROR: Connection failed (10071) ← major level (type of error)
Host is unreachable (12296) ← minor level (cause of error)
                        ↑
                    return code

```

- The top line always consists of the date, time, and subscriber. The command that generated the error appears next, followed by the offset (in decimal format), which indicates the location of the failed update inside the updates file. Lastly, the flag indicates whether the PMDB retries the update automatically or continues without it.
- The second line shows an example of a major level message (what type of error occurred) and its return code.
- The third line displays an example of a minor level message (why the error occurred), and its return code.

**Example: Error Message**

A command may generate and display more than one error. Also, an error may consist of a major level message, a minor level message, or both.

The following error has only one message level:

```
Fri Dec 29 10:30:43 2003 CIMV_PROD:Release failed. Return code = 9241
```

This message occurs when sepmdd pull attempts to release a subscriber that is already available.

**Policy Model Filter File**

A filter file consists of lines, each with six fields. The fields contain information about:

- The form of access that is permitted or denied.  
For example, READ or MODIFY
- The environment that is affected:  
For example, AC or native
- The class of the record.  
For example, USER or TERMINAL
- The objects, within the class, that the rule covers.  
For example, User1, AuditGroup, or TTY1
- The properties that the record grants or cancels.

For example, OWNER and FULL\_NAME in the filter line means that any command having those properties is filtered. You must enter each property exactly as it appears in the *Reference Guide*.

- Whether such records should be forwarded to the subscriber database or not:

PASS or NOPASS

The following rules apply to each line in the filter file:

- You can use an asterisk \* to denote all possible values in any field.
- If more than one line covers the same records, the *first* applicable line is used.
- Spaces separate the fields.
- In fields with more than one value, semicolons separate the values.
- Lines beginning with # are considered comment lines.
- Empty lines are not allowed.

#### Example: Filter file

The following example describes a line from a filter file:

|                |             |       |                      |                    |           |
|----------------|-------------|-------|----------------------|--------------------|-----------|
| CREATE         | AC          | USER  | *                    | FULL_NAME;OBJ_TYPE | NOPASS    |
| form of access | environment | class | record name( * =all) | properties         | treatment |

In this example, if we name the file with this line TTY1\_FILTER and edit the pmd.ini file for PMDB TTY1 so that filter=/opt/CA/PAMSC/TTY1\_FILTER, then PMDB TTY1 does not propagate to its subscribers any records that create new users with the FULL\_NAME and OBJ\_TYPE property.

### Propagate Passwords

When a user changes a password using the sepass utility, the new password is normally sent to the computer's parent PMDB. The parent PMDB is defined in the parent\_pmd or the passwd\_pmd token in the [seos] section of the seos.ini file or in both. However, if the user changes the password with the utility sepass, you can also specify that the user's new password should be sent to and propagated by a separate PMDB.

To send a new user's password to a separate PMDB, use the pmd parameter with the newusr, chusr, or editusr command.

#### Example: Specifying a separate PMDB for password propagation

To specify that the new passwords created with sepass for the user Tony should be sent to and propagated by a separate PMDB pw\_pmd@name1.yourorg.com, enter the following command:

```
editusr tony pmd(pw_pmd@name1.yourorg.com)
```

### Remove a Subscriber

If you no longer want to propagate updates to a particular subscriber, remove it. Alternatively, you can [exclude a subscriber from receiving updates](#).

#### To remove a subscriber

1. Remove the computer from the subscription list:

```
sepm u PMDB_name computer_name
```

The computer is removed from the Policy Model subscription list.

2. Shut down seosd on the computer that you removed from the subscription list:

```
secons -s
```

The daemon seosd is shut down.

3. Delete the value of the parent\_pmd token in the [seos] section of the seos.ini file on the computer you removed from the subscription list.

The computer will stop accepting updates from the parent PMDB.

4. Restart seosd.

The active database on the computer that you removed from the subscription list is no longer a subscriber of the specified PMDB.

#### NOTE

Once the database is unsubscribed from the PMDB, the PMDB no longer sends commands.

### Update a Policy Model Database

Working at the computer where the PMDB resides does not automatically update the PMDB itself. To update a PMDB, specify it as your target database.

To specify a target database, use the hosts command in the selang command shell:

```
hosts pmd_name@pmd_host
```

All selang commands now update the policy model database specified. The commands then automatically propagate to the active databases on this computer and of all subscriber computers.

#### Example: Specify a target PMDB

To set the target database to policy1 on myPMD\_host, use the following command:

```
hosts policy1@myPMD_host
```

If you now enter the newusr command, the new user is added to the policy1 database. The new user is also added to the active databases on this computer and all subscriber computers.

### Policy Model Backup

When you back up a PMDB, you copy the data in the Policy Model database to another directory. This includes:

- Policy information
- The list of the Policy Model's subscribers
- Configuration settings
- Registry entries
- The updates.dat file

You cannot restore a PMDB from backup files that use another platform, operating system, or version of Privileged Access Manager. Ensure you back up the Policy Model to a host running the same platform, operating system, and version of Privileged Access Manager.

### Back Up a PMDB Using sepmd

When you back up the PMDB, you copy the data from the Policy Model database to a specified directory. You should store the backed up PMDB files in a secure location, preferably protected by Privileged Access Manager access rules.

You can use the sepmd utility to back up a PMDB on a local host. You can also use selang commands to back up a PMDB on a remote host.

**Note:** You can back up a PMDB recursively. A recursive backup backs up all the PMDBs in a hierarchy to the host you specify, and modifies the PMDB subscribers so that the subscription still works when the backup is moved to the host. You can only use a recursive backup if the master and child PMDBs are deployed on the same host.

#### To back up a PMDB using sepmd:

1. Lock the PMDB using the following command:

```
sepmd -bl pmdb_name
```

The PMDB is locked and cannot send commands to its subscribers.

2. Do one of the following:

- Back up the PMDB using the following command:

```
sepmdb -bh pmdb_name [destination_directory]
```

- Back up the PMDB recursively using the following command:

```
sepmdb -bh pmdb_name [destination_directory] [backup_host_name]
```

### NOTE

If you do not specify a destination directory, the backup is saved to the following directory:  
*ACInstallDir\data/policies\_backup/pmdb\_name*

3. Unlock the PMDB using the following command:

```
sepmdb -ul pmdb_name
```

The PMDB is unlocked and can send commands to its subscribers.

## Back Up a PMDB Using selang

When you back up the PMDB, you copy the data from the Policy Model database to a specified directory. You should store the backed up PMDB files in a secure location, preferably protected by Privileged Access Manager access rules. You can use selang commands to back up a PMDB on a local or remote host. You can also use the sepmdb utility to back up a PMDB on a local host.

### NOTE

You can back up a PMDB recursively. A recursive backup backs up all the PMDBs in a hierarchy to the host you specify, and modifies the PMDB subscribers so that the subscription still works when the backup is moved to the host. You can only use a recursive backup if the master and child PMDBs are deployed on the same host.

### Follow these steps:

1. (Optional) If you are using selang to connect to the PMDB from a remote host, connect to the PMDB host using the following command:

```
host pmdb_host_name
```

2. Move to the PMD environment using the following command:

```
env pmd
```

3. Lock the DMS using the following command:

```
pmd pmdb_name lock
```

The PMDB is locked and cannot send commands to its subscribers.

4. Back up the DMS database using the following command:

```
backuppmd pmdb_name [destination(destination_directory)] [hir_host(host_name)]
```

### NOTE

If you do not specify a destination directory, the backup is saved to the following directory:  
*ACInstallDir\data/policies\_backup/pmdbName*

5. Unlock the PMDB using the following command:

```
pmd pmdb_name unlock
```

The PMDB is unlocked and can send commands to its subscribers.

## Policy Model Restoration

When a Policy Model is restored, Privileged Access Manager copies the backup PMDB files into the specified directory. Everything that is in the original PMDB files is copied to the new PMDB directory, including:

- Policy information
- The list of the Policy Model's subscribers
- Configuration settings
- registry entries
- The updates.dat file

If there is an existing PMDB in the destination directory, Privileged Access Manager deletes the existing files before copying the restoration files into that directory.

You cannot restore a PMDB from backup files that use another platform, operating system, or version of Privileged Access Manager. Ensure you back up the Policy Model to a host running the same platform, operating system, and version of Privileged Access Manager.

## Restore a PMDB

When you restore a PMDB, Privileged Access Manager copies the data from the PMDB backup files into the directory you specify. Privileged Access Manager must be running on the terminal you do the restoration on.

**Note:** If you back up and restore the PMDB on different terminals, the PMDB does not automatically update the terminal resource in the restored PMDB database. You must add the new terminal resource to the restored PMDB. To add the new terminal resource, stop the restored PMDB, run the *selang -p pmdb* command, then start the restored PMDB.

To restore a PMDB, run *one* of the following on the terminal that you want to restore the PMDB on:

- *sepmc -restore* utility
- *selang restore pmd* command

### NOTE

For more information about the *sepmc* utility, see the *Reference Guide*. For more information about *selang* commands, see the *selang Reference Guide*.

## Architecture Dependency

When deploying Privileged Access Manager, consider the hierarchy of your environment. At many sites, the network includes various architectures. Some policy rules, such as the list of trusted programs, are architecture-dependent. On the other hand, most rules are independent of the system architecture.

You can cover both kinds of rules by using a hierarchy. Define a global database for architecture-independent rules, and give it subscriber PMDBs that define architecture-dependent rules.

### NOTE

The root PMDB and all its subscribers can reside on the same computer or on separate computers, depending on the physical needs of your environment.

## Example: A Two-tiered Deployment Hierarchy

The following UNIX example also applies to a Windows architecture with small modifications.

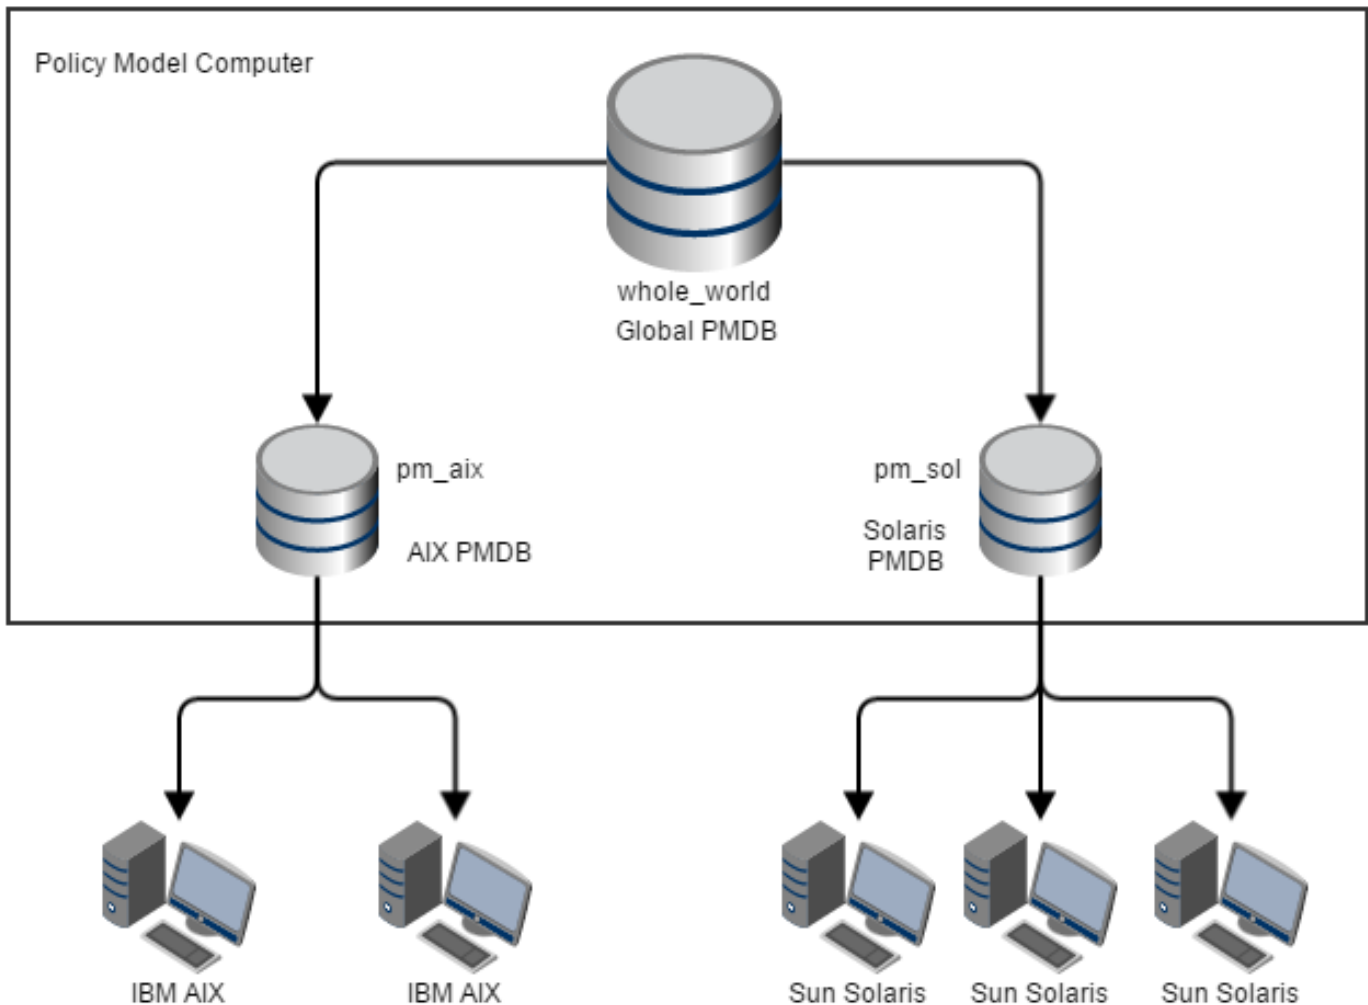

In the example, the site consists of IBM AIX and Sun Solaris systems. Since the list of trusted programs on IBM AIX differs from the one on Sun Solaris, the PMDBs need to consider architecture dependency.

To set up a multiple-architecture PMDB, set up your PMDBs as follows:

1. Define a PMDB named `whole_world`, to contain the users, groups, and all other architecture independent policies.
2. Define a PMDB named `pm_aix`, to contain all the IBM AIX specific rules.
3. Define the PMDB `pm_sol`, to contain all the Sun Solaris specific rules.

The PMDBs `pm_aix` and `pm_solaris` are subscribers of the PMDB `whole_world`. All IBM AIX computers at the site are subscribers of `pm_aix`. All Sun Solaris computers at the site are subscribers of `pm_sol`. The concept is illustrated in the following chart:

**Figure 43: Architecture dependency**

4. When you enter platform-independent commands in `whole_world`, such as adding a user or setting a SURROGATE rule, all databases at the site are automatically updated.

5. When you add a trusted program to `pm_aix`, only IBM AIX computers are updated, without affecting the Sun Solaris systems.

## Manage Local PMDBs

Privileged Access Manager offers several utilities for administering local PMDBs:

### **sepmdb**

A PMDB administration utility that lets you:

- Administer subscribers
- Truncate the update file
- Administer Dual Control
- Manage the Policy Model log file
- Perform other administrative tasks

### **sepmdbadm**

Creates PMDBs and configures them with the necessary settings for setting up your hierarchy.

#### **NOTE**

The root PMDB and all of its subscribers can reside on the same computer or on separate computers, depending on the physical needs of your environment.

## Manage Remote PMDBs

Privileged Access Manager offers a range of selang commands that you can use in the pmd environment. These commands let you manage PMDBs remotely:

### **backuppmd**

Backs up a PMDB.

### **createpmd**

Creates a PMDB.

### **deletepmd**

Deletes a PMDB.

### **findpmd**

Displays the names of all PMDBs on the computer.

### **listpmd**

Lists the following information about a PMDB:

- Subscribers and their status
- PMDB description and its status
- Commands in the update file and their offsets
- Contents of the error log

### **pmd**

A PMDB administration command that lets you:

- Remove a subscriber from the list of unavailable subscribers
- Clear the Policy Model error log
- Lock and unlock the Policy Model
- Start and stop the Policy Model daemon
- Truncate the update file
- Reload the initialization files

### **restorepmd**

Restores a PMDB from its backup files.

**subs**

A PMDB subscription command that lets you:

- Add an existing subscriber to a parent PMDB
- Add a new subscriber to a parent PMDB
- Assign a parent PMDB to a database (Privileged Access Manager or another PMDB)

**subspmd**

Assigns a parent PMDB to the local database.

**unsubs**

Removes a subscriber from the PMDB.

**NOTE**

For a comprehensive description of *selang* commands you can use in the *pmd* environment, see the *selang Reference Guide*.

**Methods for Centrally Managing Policies**

Privileged Access Manager lets you manage several databases from a single computer in the following ways:

- **Automatic rule-based policy updates:** Regular rules you define in a central database (PMDB) are automatically propagated to databases in a configured hierarchy.

**NOTE**

Dual control is only available with this method and on UNIX only. Information about dual control for automatic rule-based policy updates is found in the *Endpoint Administration Guide for UNIX*. Information about automatic rule-based policy updates can also be found in the *Endpoint Administration Guide for Windows*.

- **Advanced policy management:** Policies (groups of rules) you deploy are propagated to all databases based on host or host group assignment. You can also undeploy (remove) policies and view deployment status and deployment deviation. You need to install and configure additional components to use this functionality.

**NOTE**

Information about advanced policy management is found in the *Enterprise Administration Guide*.

**PMDB Location on Disk**

All PMDBs reside in a common directory (one per computer). The name of the directory is specified by the *pmd\_directory* token in the [pmd] section of the *seos.ini* file. The default value of *pmd\_directory* is *ACInstallDir/policies*, where *ACInstallDir* is the installation directory for Privileged Access Manager (by default */opt/CA/PAMSC*).

Each PMDB occupies a subdirectory in the common directory. The name of the subdirectory is the name of the Policy Model. The files in the subdirectory contain all the data required to define the Policy Model, including the *pmd.ini* file.

**Dual Control**

Dual Control is a way of operation that divides the process of updating the PMDB into two stages:

- Creating a transaction which consists of one or more commands.  
The *maker*--any user with the ADMIN attribute--enters one or more commands that update the PMDB. The transaction is given a unique ID number and placed in a file, where it waits to be processed before execution.
- Authorizing the transaction for execution.

The *checker*--not the same user, but any *other* user with the ADMIN attribute--locks the commands in the transaction, checks the commands, and authorizes or rejects them. If the transaction is authorized, then the commands are executed in the PMDB. If the transaction is rejected, then the transaction is deleted and the PMDB is not updated. The checker cannot authorize some of the commands in a transaction and reject others. The checker must process the transaction as a whole.

#### NOTE

Only the find and show commands do not need the authorization of a checker.

Using the parameters in the `sepmdd` utility, makers can list, retrieve and edit, or delete unprocessed transactions. Checkers can lock transactions to authorize or reject them. Checkers can also unlock transactions for processing later or by a different checker.

When the `sepmdd` daemon receives the `start_transaction` command, it sends the child process a unique number. The child process tags any further commands with this identifying number. The number is added to the new transaction and kept in the memory of the `sepmdd` daemon. When `sepmdd` receives the `end_transaction` command, the authorization algorithm is invoked. The authorization algorithm checks that none of the commands in the transaction pertain to the maker of the transaction. The algorithm also checks that none of the objects in the commands are already locked by another transaction that is waiting to be processed before execution.

You cannot use the same objects in different transactions before they are processed. If the check passes, then the relevant objects are locked, the transaction is assigned a unique sequential number, and the data is saved in a file. Each transaction is saved in a different file.

#### NOTE

For more information about the `sepmdd` utility or the `sepmdd` daemon, see the *Reference Guide*.

## Activate Dual Control

Dual Control lets you divide the duty of updating PMDBs between two people: a maker and a checker.

To activate Dual Control, set the `is_maker_checker` token, in the `pmd.ini` file *and* in the `[pmd]` section of the `seos.ini` file, to `yes`:

```
is_maker_checker=yes
```

#### NOTE

Create the Policy Model maker *before* setting these token values.

## Create or Edit Transactions

When Dual Control is activated, the maker needs to create transactions before these are processed by a checker.

### To create a transaction:

1. Ensure that the following is true:
  - You (as a maker) have the ADMIN authority.
  - None of the commands pertain to you. (You cannot enter commands that change yourself.)
  - None of the objects in the commands are already part of another transaction that has not been processed by a checker yet.
  - All the objects in the commands exist.
  - You are not editing an existing transaction that another maker invoked. (You can only edit your own transactions.)
2. Connect to the maker PMDB:

```
hosts maker@
```

The hosts command connects you to the PMDB (maker). When Dual Control is activated, the name of the PMDB is always maker. After you enter the hosts command, a message reports whether the connection to the host is successful or not.

3. Start the transaction:

```
start_transaction transactionName
```

Use the start\_transaction command as the first step when entering or updating a transaction. You can describe the transaction or can give it any name that you want, up to 256 alphanumeric characters.

4. Enter your transaction.

This is a list of commands. For example:

```
newusr mary owner(bob) audit(failure,loginfailure)
```

```
chres TERMINAL tty30 defaccess(read) \ restrictions(days(weekdays)time(0800:1800))
```

5. End the transaction:

```
end_transaction
```

The transaction is complete; you are presented with the unique ID number assigned to your transaction. The commands are placed in a file, where you can still access and change them until a checker, in preparation for processing, locks them.

**NOTE**

Make sure you record the transaction ID number if you want to be able to edit the transaction later.

**To edit a transaction:**

- When you enter the end\_transaction command, an ID number displays. This is a unique number that identifies the transaction. If you want to overwrite your transaction later, then the process is the same as creating a transaction, except that you add to the file the transaction's ID number after the name. You can enter to the file any changes you want to make. For example:

```
hosts maker@
```

```
start_transaction transactionName transactionId
```

You can then enter the appropriate commands to update the transaction:

```
chusr mary category (FINANCIAL)
```

```
end_transaction
```

- View specific unprocessed transactions with the following parameters.

Make sure you are in the *ACInstallDir/bin* path (where *ACInstallDir* is the installation directory for Privileged Access Manager, by default */opt/CA/PAMSC*).

| Command with Parameter   | Description                                                                                                                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sepmc -m l</code>  | Lists the unprocessed transactions of the user who invoked the parameter.                                                                                                                                                                                     |
| <code>sepmc -m la</code> | Lists all the transactions of all the makers that are waiting to be processed.                                                                                                                                                                                |
| <code>sepmc -m lo</code> | Lists the transactions of all the makers except those of the user who invoked the parameter<br>Each transaction in the list includes the name of the maker, the ID number of the transaction, and a description of the transaction, if the maker entered one. |

- Retrieve a specific transaction to the standard output with the following command:

```
sepmc -m r transactionId
```

- Delete a specific transaction with this command:

```
sepmc -m d transactionId
```

## Check and Process Transactions

When Dual Control is activated, the checker needs process transactions created by a maker.

### To check a transaction:

1. Make sure that the following conditions are true:
  - You (as the checker) have ADMIN authority.
  - Another Checker does not lock the transaction.
  - None of the commands pertain to you. (You cannot process commands that involve yourself.)
2. Navigate to the *ACInstallDir/bin* path  
where *ACInstallDir* is the installation directory for Privileged Access Manager, by default */opt/CA/PAMSC*.
3. View the transactions that are waiting to be processed before execution:

```
sepmc -m la
```

Or, view all the transactions except the transactions that you yourself created:

```
sepmc -m lo
```

Each transaction includes the name of the maker, the ID number of the transaction, and the name or description of the transaction.

4. Lock the transactions before processing them:

```
sepmc -m r transactionId
```

**NOTE**

A locked transaction cannot be changed.

## 5. Process the transaction:

```
sepmdd -m p transactionIdcode
```

codeCan be one of the following:

- 0—The transaction is rejected. In this case, all the commands in the transaction are deleted and no changes are implemented in the PMDB.
- 1—The transaction is authorized. The commands in the transaction are immediately implemented in the PMDB.
- 2—The transaction is unlocked. The transaction returns to the queue of waiting transactions and can be processed later, perhaps by a different checker.

```
sepmdd -m p transactionId code
```

— *code*

Can be *one* of the following:

- **0** The transaction is rejected.  
In this case, all the commands in the transaction are deleted and no changes are implemented in the PMDB.
- **1** The transaction is authorized.  
The commands in the transaction are immediately implemented in the PMDB.
- **2** The transaction is unlocked.  
The transaction returns to the queue of waiting transactions and can be processed later, perhaps by a different checker.

A message appears stating which commands were successful and which failed.

**NOTE**

For more information on makers and checkers, see the `sepmdd` utility in the *Reference Guide* and the `start_transaction` command in the *selang Reference section*.

## Use the seagent and sepmdd Daemons

The seagent daemon is responsible for accepting requests from remote computers and applying them to PMDBs; the seagent daemon also sends requests to seosd. The sepmdd daemon is the PMDB daemon. This section describes how these daemons work together in the PMDB environment.

**Use the table of contents to access the topics in this section.**

### The seagent Daemon

The seagent daemon waits for connections on the seoslang2 TCP service (whose default value is 8891). When a connection request arrives, seagent forks a child process to handle the communication on the connection and then continues waiting for new connections.

When a user enters the `hosts` command in `selang`, seagent forks a child process on the machine that the user is connected to. The child process then receives commands from the command language interface and passes them on to the sepmdd daemon.

### The sepmdd Daemon

The sepmdd daemon performs the following functions:

- Administers the PMDB
- Administers the subscriber databases
- Propagates changes from the PMDB to the subscriber databases

The sepmdd daemon is automatically started by seagent when seagent has to access the PMDB. Normally you do not need to run sepmdd explicitly.

**NOTE**

sepmdd runs under the logical user `_seagent` (*not* under root) in the AC environment. To permit or restrict access to resources by sepmdd (for example, to restrict access to the PMDB directory), create the relevant rules for `_seagent`.

## Use a Shadow File

Usually, sepmdd does not use a shadow file when updating a native environment. You can, however, set up a shadow file. To do this, set the UseShadow token in the [pmd] section of the pmd.ini file to yes.

If the UseShadow token is set to yes, sepmdd uses a default shadow file in the same directory as the PMDB. If you want to change the location of the shadow file, specify the new location with the YpServerSecure token in the [pmd] section of the pmd.ini.

If you change the location of the shadow file (with the YpServerSecure), to the local host's shadow file (for example, /etc/shadow), sepmdd sets a token, UseSystemFiles, to yes.

**WARNING**

Do not change the UseSystemFiles token yourself. The sepmdd or seagent daemons change it automatically.

**NOTE**

For more information about the seagent or sepmdd daemons, see the seagent and sepmdd utilities in the *Reference Guide*.

## Protect Idle Stations

Information is extremely vulnerable when terminals are left open and active. An intruder who happens upon such a terminal (for example, during a lunch break) need not try to break passwords or have complicated equipment to sniff the network lines, since all terminals at the site are already logged in and ready for work. Although screen savers that prompt for the password before restoring the desktop are useful, the security administrator cannot make sure that all users are using secured screen savers.

Privileged Access Manager provides selock, a screen-locking utility that guards all terminals and stations by locking them whenever they are idle for more than a specified period of time. When returning to work, the user is prompted to specify the password. If the correct password is not specified within one minute, the terminal remains locked. The selock utility can find the password of users who can unlock a screen even if those users change their passwords while selock is active.

**NOTE**

For more information about the screen lock utility selock, see the *Reference Guide*.

You should choose to use selock options that suit your requirements:

- Less security, more convenience  
Use the -timeout option to set the timeout to a large value, such as 10 minutes, and the -lock-timeout option to set the lock timeout to an even larger value, such as 60 minutes. This prevents selock from excessively interrupting your work by switching to the *saver* mode. Also, this setting locks your screen only in cases when your terminal is left inactive for extended periods.
- More security, less convenience

Use the `-timeout` option to set the timeout to a small value, such as 1 minute, and `-lock-timeout` option to set the lock timeout to a small value, between 0 and 2 minutes. This always hides your work soon after you stop accessing your terminal, and requires a password for restoring access. To ensure that `selock` always requires password-entry to reactivate your terminal after the saver mode starts, use the `-lock-timeout` option to set the lock timeout to zero.

- The `selock` command can be part of the X startup shell, so that it starts automatically every time the user logs in to the system. The script must be run under the user ID, not under the root ID. The way you integrate the `selock` command into the startup script depends on the specific environment of the site.

#### NOTE

For more information on startup scripts, see the documentation for your UNIX system.

## Choose a Protection Mode

`selock` offers three modes of operation:

- **Monitor Mode**

The monitor mode is the initial mode of `selock`. In this mode, `selock` monitors keyboard and mouse activity. If `selock` detects no keyboard or mouse activity during the time-out period--and the transparent parameter is off--`selock` automatically switches to the saver mode. No password entry is required for the transition from the monitor mode to the saver mode.

- **Saver Mode**

In the saver mode `selock` blanks the entire screen and displays a system icon that shifts position. The blank screen and shifting icon provide two operational advantages:

- Reduced risk of screen viewing by unauthorized people
- Reduced screen burn-in

You can manipulate the appearance and repositioning of the icon using `selock` options. When `selock` detects any keyboard or mouse activity, it immediately returns from the saver mode to the monitor mode, restoring the screen display to what it was before it switched to saver mode. No password entry is required for the transition from the monitor mode to the saver mode.

If `selock` remains in the saver mode for the period specified by the `lock-timeout` parameter, it automatically switches to the lock mode. `selock` does not give any visual indication of the transition from the saver mode to the lock mode.

- **Lock Mode**

In lock mode with the default settings, `selock` continues to display a moving icon on a black background. When `selock` detects any keyboard or mouse activity, a dialog containing a prompt for the user's password appears.

When the user enters the correct password, `selock` switches back to monitor mode. If the user enters an incorrect password, the password-entry dialog closes and `selock` remains in the lock mode.

If you set the `-transparent` option to `on`, `selock` locks the screen but displays the contents and updates the on-going processes. The background of the screen changes to indicate that the screen is locked. When you use the lock mode, saver mode is never invoked.

## Set Stations to Lock When Idle

The `selock` utility lets you lock idle stations to prevent unauthorized access to these stations when they are left idle.

### To set stations to lock when idle

1. (Optional) Set the `DISPLAY` environment variable.

#### NOTE

For the `selock` command to work, you must set the `DISPLAY` environment variable. However, you can specify the target display directly in the `selock` command instead.

2. Place the `selock` command in the user's login script (the `.login` file).  
Alternatively, you can place the `selock` command in the `/etc/login` or `/etc/cshrc` file.

**NOTE**

Two users can always unlock a locked screen. By default, these users are the current user and root. However, you can replace root with any other user if you specify the other user's name in the `unlocking_user` token, located in the `[selock]` section of the `seos.ini` file. You can replace the current user with any other user by using the `-user` option when executing `selock`.

**Example: Idle station lockup command in a startup file**

The following is a typical startup command, suitable to be placed in X startup files:

```
selock -display $DISPLAY -timeout 5
```

This command activates `selock` after five minutes of terminal inactivity.

We recommend that you place the following line in the global `xstartup` script. The `xstartup` script usually resides in the directory `/usr/lib/X11/xdm/Xstartup`.

```
selock -display $DISPLAY -user $USER -timeout 3 &
```

This statement enforces use of the terminal locking program for all users who are using X terminals.

**Change the Screen Lock Icon**

The default system icon that `selock` uses is the Privileged Access Manager logo and is located in the file `ACInstallDir/data/admin/Selogo.xpm`

To select an icon of your own choice, replace this file.

**NOTE**

The icon file must be in XPM version 3.3 format.

**Protect Resources Using APIs**

If you have defined resources that are not part of Privileged Access Manager (that is, in-house resources), you can protect them by using Privileged Access Manager APIs. Each API has two layers:

- **The function library**  
Enables programmers to use the Privileged Access Manager authorization engine.
- **The user exits**  
Enable the system administrator to tailor Privileged Access Manager behavior to the requirements of the site.

**NOTE**

For more information about Privileged Access Manager APIs, see the *SDK Guide*.

**Protect Against Stack Overflow STOP**

Stack overflow enables hackers to execute arbitrary commands on remote or local systems, many times as the root user (the superuser). They do this by exploiting bugs in the operating system or other programs. These bugs allow users to overwrite the program stack, changing the next command to be executed.

Stack overflow is not simply a bug; it is possible to create a block that overwrites the return address with a meaningful address, resulting in transferred control to unauthorized code (usually in the same block).

Stack Overflow Protection (STOP) is a feature that prevents hackers from creating and exploiting stack overflow to break into systems.

## Stack Overflow Protection on UNIX Linux Platforms

When using Stack Overflow Protection on a UNIX or Linux platform, consider the following:

- (Solaris 11 AMD) STOP is disabled for Solaris 11 and later because Solaris 11 natively provides stack protection: Solaris 11 changes process stack location and has built-in support for Address Space Layout Randomization (ASLR). By default, this protection is turned on for tagged files, which includes zones.
- (Red Hat Linux, SuSE Linux) When Linux native stack randomization (exec-shield-randomize) is enforced, the STOP feature is not activated.

To deactivate native stack randomization, enter the following command:

```
echo 0 > /proc/sys/kernel/exec-shield-randomize
```

## Start and Stop STOP

When STOP is first installed, stack overflow protection is activated by default. To deactivate it, you must change a token in the [seos\_syscall] section of the seos.ini file and restart Privileged Access Manager. To do this, use the seini command as follows:

```
seini -s SEOS_syscall.STOP_enabled 0
```

You could manually change the seos.ini file instead.

To re-enable STOP, change the value of the token to 1 and restart Privileged Access Manager.

### NOTE

When STOP is active on Sun Solaris 7 systems, the dbx program cannot work properly. If you need to use dbx on a system that is protected by STOP, you must first disable STOP.

## Define Day and Time Access Rules for Resources

You can use Privileged Access Manager to specify day-of-week and time-of-day restrictions for resource access. This feature can be exploited for TERMINAL access, SURROGATE requests, and user-defined resources. For example, the following rule completely disables the terminal ws3 on weekends and outside the 08:00-19:00 time period every day:

```
chres TERMINAL ws3 restrictions(days(weekdays) time(0800:1900))
```

No login request from that station is accepted outside these periods.

You can use Privileged Access Manager to protect against substitution requests to highly authorized users outside work hours. Suppose user AcctMgr is the Accounting Manager, who is allowed to perform financial transactions, and you have restricted AcctMgr login to work hours and weekdays only. Intruders or unauthorized personnel may try to access the account of AcctMgr by invoking the command **su** AcctMgr. Use the following command to make it impossible to substitute the user name to AcctMgr outside the specified period:

```
chres SURROGATE USER.AcctMgr restrictions(days(weekdays) time(0800:1900))
```

The same technique can be implemented for any protected resource, including user-defined abstract classes that are used for implementing in-house applications.

## Protect System Devices

You can use Privileged Access Manager to protect system devices against unauthorized copy. By creating a copy of an existing system node, unauthorized accessors can export the content of the protected device and read the content as raw data.

When a user attempts to create a block-oriented or character special file based on an existing one using the `mknod` command, Privileged Access Manager checks the device. If the user attempts to create a copy of a protected device, Privileged Access Manager blocks the attempt and prevents the operation.

By default, Privileged Access Manager does not block the device copy operation.

You can enable the system devices protection from the `seos.ini` file under the `SEOS_syscall` section in the `file_rdevice_max` token.

#### NOTE

For more information about the `file_rdevice_max` token, refer to the *Reference Guide*.

## Security Levels (UNIX)

When security level checking is enabled, Privileged Access Manager performs security level checking in addition to its other authorization checking. A security level is a positive integer from 1 through 255 that can be assigned to users and resources. When a user requests access to a resource that has a security level that is assigned to it, Privileged Access Manager compares the security level of the resource with the security level of the user. If the security level of the user is equal to or greater than the security level of the resource, Privileged Access Manager continues with other authorization checking. Otherwise, the user is denied access to the resource.

If the `SECLABEL` class is active, Privileged Access Manager uses the security level associated with the security labels of the resource and user; the security level that is explicitly set in the resource and user records is ignored.

- To protect a resource with security level checking, assign a security level to the record of the resource. The `level` parameter of the `newres` or `chres` command assigns a security level to a resource.
- To allow a user access to resources protected by security level checking, assign a security level to the record of the user. The `level` parameter of the `newusr` or `chusr` command assigns a security level to a user.

## Enable Security Level Checking

The following `setoptions` command enables security level checking:

```
setoptions class+ (SECLEVEL)
```

## Disable Security Level Checking

The following `setoptions` command disables security level checking:

```
setoptions class- (SECLEVEL)
```

## Security Categories (UNIX)

When security category checking is enabled, Privileged Access Manager performs security category checking in addition to its other authorization checking. When a user requests access to a resource that has one or more security categories assigned to it, Privileged Access Manager compares the list of security categories in the resource record with the category list in the user record. If every category assigned to the resource appears in the category list of the user, Privileged Access Manager continues with other authorization checking; otherwise, the user is denied access to the resource.

If the `SECLABEL` class is active, Privileged Access Manager uses the list of security categories that are associated with the security labels of the resource and user; the lists of categories in the user and resource records are ignored.

To protect a resource by security category checking, assign one or more security categories to the record of the user. The `category` parameter of the `newres` or `chres` command assigns security categories to a resource.

To allow a user access to resources protected by security category checking, assign one or more security categories to the record of the user. The category parameter of the `newusr` or `chusr` command assigns security categories to a user.

## Enabling Security Category Checking

The following `setoptions` command enables security category checking:

```
setoptions class+ (CATEGORY)
```

## Disable Security Category Checking

The following `setoptions` command disables security category checking:

```
setoptions class-(CATEGORY)
```

## Define a Security Category

Define a security category by defining a resource in the `CATEGORY` class. The following `newres` command defines a security category:

```
newres CATEGORY name
```

where *name* is the name of the security category.

To define the security category *Sales*, enter the following command:

```
newres CATEGORY Sales
```

To define the security categories *Sales* and *Accounts*, enter the following command:

```
newres CATEGORY (Sales,Accounts)
```

## List Security Categories

To display a list of all the security categories that are defined in the database, use the `show` command as follows:

```
find CATEGORY
```

The list of security categories displays on the screen.

## Delete a Security Category

Delete a security category by removing its record from the `CATEGORY` class. The following `rmres` command removes a security category:

```
rmres CATEGORY name
```

where *name* is the name of the security category.

To remove the security category *Sales*, enter the following command:

```
rmres CATEGORY Sales
```

## Security Labels (UNIX)

A security label represents an association between a particular security level and zero or more security categories.

When security label checking is enabled, Privileged Access Manager performs security label checking in addition to other authorization checks. When a user requests access to a resource that has a security label that is assigned to it, Privileged Access Manager makes the following comparison: the product compares the list of security categories specified in the resource record's security label with the list of security categories specified in the user record's security label. If every category assigned to the resource's security label appears in the user's security label, Privileged Access Manager continues with the security level check. Otherwise, the user is denied access to the resource. Privileged Access Manager compares the security level specified in the resource record's security label with the security level specified in the user record's security label. If the security level assigned in the user's security label is equal to or greater than the security level assigned in the resource's security label, Privileged Access Manager continues with other authorization checking; otherwise, the user is denied access to the resource.

When security label checking is enabled, the security categories and security level specified in the user and resource records are ignored; only the security level and categories that are specified in the security label definitions are used.

To protect a resource by security label checking, assign a security label to the resource's record. The label parameter of the newres or chres command assigns a security label to a resource.

To allow a user access to resources protected by security label checking, assign a security label to the record of the user. The label parameter of the newusr or chusr command assigns security labels to a user.

## Enable Security Label Checking

The following setoptions command enables security label checking:

```
setoptions class+(SECLABEL)
```

## Disable Security Label Checking

The following setoptions command disables security label checking:

```
setoptions class-(SECLABEL)
```

## Define a Security Label

Define a security label by defining a resource in the SECLABEL class. The following newres command defines a security label:

```
newres SECLABEL name category(securityCategories) level(securityLevel)
```

where:

- **name**  
Specifies the name of the security label.
- **securityCategories**  
Specifies the list of security categories. To specify more than one, separate the security category names with a space or a comma.
- **securityLevel**  
Specifies the security level. Use an integer between 1 and 255.

To define the security label Managers to contain the security categories Sales and Accounts and a security level of 95, enter the following command:

```
newres SECLABEL Manager category(Sales,Accounts) level(95)
```

## List the Security Labels

To display a list of all the security labels that are defined in the database, use the show command as follows:

```
find SECLABEL
```

The list of security labels appears on the screen.

## Delete a Security Label

A security label is deleted by removing its record from the SECLABEL class. The following rmres command removes a security label:

```
rmres SECLABEL name
```

where *name* is the name of the security label.

To remove the security category, *Manager* enter the following command:

```
rmres SECLABEL Manager
```

## Audit Logs (UNIX)

The audit records are stored in a file that is named the audit log. The location for the audit log is specified in the seos.ini file. Use the seaudit utility or Privileged Access Manager Endpoint Management to list recorded events in the audit log. Filter events by time restrictions or event type, and so on.

### NOTE

For more information about seaudit, see the *Reference Guide*.

The audit logs are stored locally. However, you can use Privileged Access Manager to distribute the auditing information by using the log routing facility. Consider archiving old audit logs to tape, to allow you to scan the events later.

By default, the authorization daemon seosd creates the audit logs with root ownership, because the user root executes the seosd program. For the same reason, the audit logs are created with read/write permissions granted only to root.

To enable other users to read the audit logs without having to su (substitute user) to root, Privileged Access Manager includes two entries in the seos.ini file. These entries specify which group ownership is assigned to the log files.

- One entry is for the audit log.  
Suppose that the auditors at your site are all members of a group named auditforce. You want these users to be able to browse through the local audit log files. Edit the seos.ini file so that the audit\_group token in the [logmgr] section is set to auditforce. Privileged Access Manager then gives the auditforce group read permission to your local audit logs. From this point, any local audit logs created at your station have the auditforce group as their owner.  
The log routing daemons consult the same token to see who can have access rights to the audit logs that the daemons produce and collect. The audit logs are subject to access control like any other files, and Privileged Access Manager rules can keep users from accessing them.
- The other entry is for the error log. This entry is used in the same way to specify group ownership for that file.

## Configure an Endpoint to Send seaudit Logs to syslog

This article explains the procedure to configure Privileged Access Manager endpoint to send *seos* audit logs to *syslog*. This procedure is helpful when a syslog collector is installed on an endpoint and you must collect endpoint *seos* audit logs along with syslogs.

**Follow these steps:**

1. Stop the Privileged Access Manager endpoint agent.  
`<INSTALL_DIRECTORY>/PAMSC/bin/secons -sk`  
`<INSTALL_DIRECTORY>` is the directory where the Privileged Access Manager endpoint agent is installed.
2. Open `<INSTALL_DIRECTORY>/PAMSC/log/selogrd.cfg` for editing (if it does not exist, create the file). Add the following rule to the file:

```
Rule#1
syslog LOG_INFO
.
```

**Note:** '.' at the end of the rule is mandatory.

3. Save the file.
4. Restart the Privileged Access Manager endpoint agent.  
`<INSTALL_DIRECTORY>/PAMSC/bin/seload`
5. Restart the `selogrd` daemon.  
`<INSTALL_DIRECTORY>/PAMSC/bin/selogrd`
6. Restart `syslogd` on the server.

Now you can view the `seos` audit logs in the messages file (`/var/log/messages`).

**Detect and Handle Failed Logins through SSH**

To prevent brute force-based break-in attacks into UNIX systems, Privileged Access Manager for UNIX provides detection of the failed user logons on a host and revocation of the user ID.

The `serevu` module facilitates revocation and optional subsequent re-enablement of a revoked user ID.

This topic describes how to configure Privileged Access Manager to detect and handle failed logins that occurred on SSH. This topic also helps you understand the data flow between failed logins through SSH, PAM (Pluggable Authentication Modules), `seosd`, and `serevu`.

**Follow these steps:**

1. Configure the `serevu` module to detect failed logins occurred through applications that use PAM. PAM is the default authentication subsystem on UNIX-flavors.  
 To allow `serevu` to work with PAM, set the following token in the `seos.ini` configuration file:

```
[pam_seos]
serevu_use_pam_seos = yes
```

2. To configure `sshd` to use PAM for authentication, set the following token in `/etc/opt/ssh/sshd_config`:  
`UsePAM yes`

This configuration allows the daemon `sshd` to signal the PAM system that a failed login occurred.

3. Add the following line to `/etc/pam.conf` to ensure Privileged Access Manager is set up to intercept PAM signals coming from `sshd`:

```
sshd auth optional /usr/lib/security/pam_seos.sl
```

4. Ensure that the local `seosdb` holds a `loginappl` record for the `sshd`. Add the following lines in `Selang`:

```
PAMSC> nr loginappl SSHD loginpath(/usr/sbin/sshd) loginseq(SGRP SUID) defaccess(x)
```

You can now find any failed logins done on an SSH client in the file: `/opt/CA/PAMSC/log/pam_seos_failed_logins.log`

With this configuration done, the data flows as follows:

- a. `sshd` signals PAM that a failed login occurred.
  - b. Privileged Access Manager intercepts this PAM signal and writes information into the `pam_seos_failed_logins.log`.
  - c. `serevu` periodically scans that log and acts accordingly.
5. The number of failed logins each user is entitled to before being revoked can be set in `seos.ini`.

```
[serevu]
def_fail_count = 3
```

6. To startup `serevu` automatically upon `seload`, add the following code to `seos.ini`:

```
[daemons]<>
serevu = yes
```

## The System Auditor

A system auditor is a user to whom the AUDITOR attribute is assigned. Users defined as system auditors are permitted to perform auditing tasks such as changing the auditing attribute that is assigned to users and resources.

Auditing tasks can be carried out from central locations. To collect auditing information from the various stations on the network in a single host, the auditor can use the log routing facility.

## Set Up the Log Routing Facility

### To set up the log routing:

1. Create a log routing configuration file.  
Unless you specify otherwise with the `RouteFile` token in the `seos.ini` file, Privileged Access Manager expects your log routing configuration file to be named `ACInstallDir/log/selogrd.cfg` where `ACInstallDir` is the installation directory for Privileged Access Manager, by default `/opt/CA/PAMSC`. You can find sample log routing configuration files in the directory `ACInstallDir/samples/selogrd.init`. Alternatively, as a very simple log routing configuration file, you can create a file consisting of the following three lines:

```
Rule
host destination
.
```

For *destination*, enter the name of the host that should receive the audit records. All classes, resources, accessors, and results are logged.

#### NOTE

For more information about the syntax of the configuration file, see the `selogrd` utility in the *Utilities section*.

2. Start the emitter daemon (`selogrd`) on all hosts that are to route auditing information, and execute the collector daemon (`selogrcd`) on all hosts that are to collect auditing information.

#### NOTE

For more information about using these daemons, see the *Reference section*.

## File Notifications

In addition to compiling the log, the log routing facility can send notifications to the display screen of the host, to an email address, or to other destinations. You can base notifications on information from your station's own audit log or from logs that the collector daemon has brought to your station.

To set up such notifications, use the log routing configuration file *and* a selang command. Example: Notify the user John whenever a setuid request to the user root is successfully made.

1. Issue the following selang command:

```
chres SURROGATE USER.root notify(John)
```

This chres command specifies that each time someone surrogates user to root, a special audit log record is created, and the seosd daemon is to notify the user named John. The daemon also creates a special audit record that is named a *notification record*.

2. Once you have specified notification for one or more resources, you can add the following three lines to the log routing configuration file.

```
Rule2
notify default
.
```

This line causes the log routing emitter to create a mail message for the notification audit record.

### NOTE

For more information about the configuration file format and setting up the log routing daemons, see the *Reference Guide*.

## Log Routing

Privileged Access Manager uses the log routing daemon, selogrd, for the following tasks:

- To distribute selected local audit log records to specific hosts
- To reformat audit log records in to email messages, ASCII files, or user windows
- To transmit notification messages based on audited events

To determine audit record routing, selogrd uses a configuration file, selogrd.cfg. This file is a list of which audit log records to route, or not to route, and where to route them. For a complete description of this file, see the *Reference Guide*.

**Use the table of contents to access the topics in this section.**

## Log Routing Configuration

To start selogrd or selogrcd automatically when seosd starts, set the seos.ini tokens selogrd or selogrcd in the [daemons] sections to yes. Then when you run seload, seload starts the daemons for you.

For example, the appropriate tokens in the [daemons] section of the soes.ini should look as follows:

```
selogrd = yes
selogrcd = yes
```

Since the log-routing facility uses RPC to route audit records, placing a log audit collector behind a firewall does not allow simple blocking of UDP ports because there is no way to know which port the portmapper assigns to the server daemon. To solve this problem, you can use the token ServicePort to assign a predefined port to the server daemon.

If the firewall allows port 111 from outside the network (portmapper port), you should only change the seos.ini file in the server. If the firewall does not allow communication to portmapper in the protected network, both clients and server must agree on a specific port.

You can ensure this by setting the same value in the ServicePort token in the seos.ini files of both clients and the server. You can specify a number--which means that the daemons bind to the specified port--or a service name. If you specify a service name, both clients and the server must have the same service resolution. For example, if you specify the service name seoslogr, then add the following to the /etc/services file of the clients and the server:

```
seoslogr 2022/udp # Audit log-routing
```

If the clients or the server are using NIS to resolve services, you must update the NIS services map.

## Audit Log Route Encryption

You can encrypt audit log records. When you use encryption, the selogrd daemon encrypts audit log record before sending it to the collector (selogrcd or audit log router). The collector in turn decrypts the received records.

Privileged Access Manager provides two encryption styles for selogrd: Privileged Access Manager standard encryption, and audit log encryption through adcipher. For encryption, selogrd uses functions from shared library objects, as specified in the [selogrd] section of the seos.ini file.

Standard encryption uses the shared library libcrypt; Audit encryption uses functions from a file specified by the CipherName token. By default, the file name is adcipher, which is a symbolic link to the desired shared library. The product installation process places four shared libraries in the lib directory: lib1des, lib3des, libIDEA, and libblowfish.

Privileged Access Manager maintains the standard encryption key in the shared library, while the audit encryption uses a separate file as specified by the KeyFile token (default value: adcipher.bin).

Use the UseEncryption token to determine the type of encryption:

- To use Privileged Access Manager standard encryption, specify UseEncryption=native.
- To use audit log encryption through adcipher, specify UseEncryption=eTrust, and enter the appropriate values for the CipherName and KeyFile tokens.
- To disable selogrd encryption, specify UseEncryption=no.

Use the RefuseUnencrypted token to accept or deny unencrypted audit. It is used in conjunction with the UseEncryption token and is redundant if the UseEncryption is set to no:

- To refuse unencrypted audit, specify RefuseUnencrypted=yes
- To accept both encrypted and unencrypted audit, specify RefuseUnencrypted=no

**Note:** The selogrcd daemon uses the same tokens in the seos.ini file.

To change the encryption key, use the seckey utility, described in this chapter.

### WARNING

If you send records to the audit collector, be sure that both selogrd and the collector use the same shared encryption file and encryption key.

## Send Audit Log Records using Email

selogrd can send records to email targets directly. You can direct email messages through a mailer utility, or directly to the mail exchange server using SMTP.

To send audit log records directly to the mail exchange server, set the UseSmtpMail token in the [selogrd] section of the seos.ini file.

You can specify the following:

- A time-out in case the mail server does not answer, using the `SmtptimeLimit` token
- The From: mail header field, using the `SmtptimeFrom` token
- The mail server host address, using the `SmtptimeServer` token

**NOTE**

This method does not use UNIX mail utility; rather, it establishes a direct connection with mail server, and uses SMTP protocol to send mail.

**Configure SNMP Traps**

For systems that use the Internet network management protocol SNMP (Simple Network Management Protocol), you can configure `selogrd` to create SNMP traps using Privileged Access Manager audit records.

To implement the SNMP traps, first locate the SNMP shared objects provided in the Privileged Access Manager libraries, and then configure `selogrd` correctly using these shared objects.

**Note:** If you want to use the SNMP extension of `selogrd`, and Privileged Access Manager is not installed in the default location (`/opt/CA/PAMSC`), set an environment variable before running `selogrd`. The environment variables are as follows, where *ACInstallDir* is the directory where you installed Privileged Access Manager:

- In AIX, set `LIBPATH` to *ACInstallDir*/lib
- In Solaris, set `LD_LIBRARY_PATH` to *ACInstallDir*/lib
- In LINUX, set `LD_LIBRARY_PATH` to *ACInstallDir*/lib
- In HP, set `SHLIB_PATH` to *ACInstallDir*/lib

The shared objects-usually found in the directory *ACInstallDir*/lib- are called `snmp.xx` and `libsnp.xx`, where the `xx` extension varies according to the platform. The possible extensions are:

- `.o` AIX platform
- `.sl` HP platform
- `.so` All other platforms

If you want to use the SNMP extension of `selogrd`, and Privileged Access Manager is not installed in the default location, you must set the following environment variables before running `selogrd`:

- In AIX, set `LIBPATH` to *ACInstallDir*/lib
- In Solaris, set `LD_LIBRARY_PATH` to *ACInstallDir*/lib
- In Linux, set `LD_LIBRARY_PATH` to *ACInstallDir*/lib
- In HP, set `SHLIB_PATH` to *ACInstallDir*/lib

where *ACInstallDir* is the directory where you installed Privileged Access Manager.

**Follow these steps:**

1. Create a file called *ACInstallDir*/etc/`selogrd.ext`.
2. Define where the SNMP shared objects are by adding a single line to the file *ACInstallDir*/etc/`selogrd.ext` with the appropriate path for the `snmp.so`. (It is enough to specify this shared object for the other to automatically be linked.) For example:

```
snmp /opt/CA/PAMSC/lib/snp.so
```

3. Finally, you must configure the `selogrd.cfg` file to specify what type of action should trigger SNMP traps, and which location should be notified when SNMP traps are triggered. Configuration is very similar to that for other auditing notification, with the delivery system specified as `snmp`.

For example, suppose you want to have SNMP traps activated when Privileged Access Manager starts and shuts down, and have notification of these SNMP traps sent to AuditPC. You can do this by adding the following section to the `selogrd.cfg` configuration file:

```
snmpRule

snmp AuditPC

include Class(START) .

include Class(SHUTDOWN) .

.
```

To send SNMP traps to a gateway with a community name, use the following format:

```
snmp gateway[@community name]
```

#### Example:

```
snmp AuditPC@secure
```

Similarly, you can activate the SNMP traps by other actions or types of access, or have them sent to other locations.

## Migrate User Trace Filters

If you set a user to be traceable, each time a trace record is written for that user, a matching audit record is written to the `seos.audit` file. In previous releases of Privileged Access Manager, these audit records were filtered by the `trcfilter.init` file. In Privileged Access Manager r12.0 SP1 and later, the audit records generated by user trace records are filtered by the `audit.cfg` file, which filters all other audit records.

You must manually migrate the audit record filters from `trcfilter.init` to `audit.cfg`. If you do not migrate the filters, the audit records generated by user traces will not be filtered.

#### NOTE

Trace records are still filtered by `trcfilter.init`. Do not migrate trace filters from `trcfilter.init` to `audit.cfg`.

#### Follow these steps:

1. In `trcfilter.init`, find the user trace filter that you need to migrate.  
The `trace_filter` setting in the `seosd` section of the `seos.ini` file determines the location of this file.
2. In `audit.cfg`, type the following, where *usertracefilter* is the user trace filter from `trcfilter.init`:  
`TRACE;*;*;*;usertracefilter`
3. (Optional) Repeat Steps 1-2 for each user trace filter that you need to migrate.

#### Example: Migrate User Trace Filter

In this example, the following user trace filter is in the `trcfilter.init` file:

```
*ExampleFilter
```

To migrate this user trace filter, type the following on a new line in the `audit.cfg` file:

```
TRACE;*;*;*;*ExampleFilter
```

## Improve Performance

This section describes different ways to improve performance on UNIX endpoints.

### Use Global Access Check

The Global Access Check feature (GAC) lets you access protected, frequently opened files--whose access rules are unlikely to change--much faster than otherwise possible.

GAC allows a Privileged Access Manager administrator to cache rules for read, write, chown, chmod, rename, unlink, utimes, chattr, link, chdir, create, and all, so that appropriate access to files is granted without passing control to seosd. The default is all. Execute requests, however, are not eligible for GAC because they could pose a security loophole.

Without GAC, Privileged Access Manager runs thorough security checks whenever a user or program attempts to access protected files. Frequently accessed files need repeated in-depth checks to confirm access permissions.

GAC allows an administrator for Privileged Access Manager to take for granted that certain frequently accessed protected files require shorter security checks. An administrator for Privileged Access Manager can select files suitable for a shorter check. Before Privileged Access Manager allows a shorter security check, the file must first undergo a full security check based on the set rule. The rule itself consists of a generic file name and a list of accesses. Rules are cached according to users.

Selecting certain files for a shorter check is reliable because, with the GAC feature in place, if a change is actually made to rules regarding the protected files, the shorter security check table is flushed, and an initial full security check is instituted.

#### NOTE

GAC restrictions mean that this feature works for every user except root.

### How Does Global Access Check Work

Privileged Access Manager monitors access to specified files and builds a table of permitted accesses during execution time. These are the files you specify in advance in order to set up Global Access Check (GAC) rules.

Whenever Privileged Access Manager concludes that a user should be granted a certain level of access to a certain file, it checks whether the following two additional conditions are met:

- The granted access is unconditional. It is not dependent on time, day, program from which executed, or other conditions.
- The file matches one of its preselected sets of file masks.

#### NOTE

File rules define permissions for access to files.

#### NOTE

If these conditions are met, Privileged Access Manager generates a UID-file rule-access triplet and stores it in a table composed of such triplets. This table is examined before any database access rule interpretation takes place. Whenever a user attempts to access a file, this table is consulted as a filtering mechanism.

The table is best described as a do-not-call-me table because it contains a list of file masks that, once recognized, no longer need to undergo access permission checks. It is also described as an always-grant table because access is always granted to files specified within its list of file masks.

Whenever a user attempts to access a file, the table is consulted. If the file matches one of the triplets found in the table, the appropriate access is granted without passing control to seosd. This bypasses the access rules analysis. Subsequently, all access to files that match this pattern is granted, based on the triplet stored in the table, without consulting the access rule database.

Whenever a new access rule is added to the database, the entire table is flushed, and the learning process starts from the beginning.

## Implement Global Access Check

To set up Global Access Check (GAC), choose masks for sets of files that are accessed often, set up a GAC file containing these file masks, and then start the caching process.

### Set Up Global Access Check Rules

#### NOTE

File rules in the database are created using the class FILE parameter and file masks. Rules apply to all files matching the file masks. FILE access types include: all, chdir, control, create, delete, execute, none, read, rename, sec, update, utime, write.

From the file rules defined in the database, choose the file masks that you want to cache. Enter a list of file masks into the *ACInstallDir/etc/GAC.init* file (where *ACInstallDir* is the installation directory for Privileged Access Manager, by default /opt/CA/PAMSC), in exactly the same form as they appear in the database.

Each such mask should be specified on a separate line. For example, if the database contains a file mask for */tmp/mydir/\** and you want it to be cached, add the following line to the *ACInstallDir/etc/GAC.init* file:

```
/tmp/mydir/*
```

#### NOTE

Specific file names cannot be specified in the GAC.init file. Only file masks are used.

### Start Global Access Check

To turn your current version of Privileged Access Manager into a Global Access Check (GAC)-compatible version, prepare the file *ACInstallDir/etc/GAC.init* with the file masks that are eligible for caching. Only file masks can be used.

An example is a file named GAC.init in *ACInstallDir/etc/* with only one line:

```
/IBBS/REL63/*
```

## Use the Resource Cache

Another performance improvement tool that Privileged Access Manager offers is resource caching (file cache).

The cache remembers the previous answer to an authorization request (permit or deny) for resources in the FILE class. The result is saved with the file name, user name, and authorization response (access mode, program name, and result). When an identical authorization is requested, the request is answered with the last response that was stored in the cache memory tables. This saves time because Privileged Access Manager does not have to reevaluate the request; Privileged Access Manager can return the answer immediately. When rules are changed, the cache is automatically and immediately synchronized.

The cache is a runtime table. An administrator can configure it in two ways:

- Set initialization parameters in the seos.ini file.
- Switch caching to ON or OFF and change parameters at runtime.

The security administrator can define table size, intervals between cleaning tables, and other internal table parameters with tokens in the seos.ini file.

A user with administrative privileges can switch cache tables ON or OFF, change cache parameters, and write cache tables to standard output.

**NOTE**

For more information about the secons utility or the [seosd] section of the seos.ini initialization file, see the *Reference Guide*.

## Tuning Recommendations

Use these recommendations to improve performance even more:

- If one of the three tables (pools) has the maximum number of records and another table does not, expand the size of the full table.

**NOTE**

The three tables are file, user, and authorization. If a pool has low settings, increase them to expand the pool.

- Do not set the maximum size tokens unless you must. Larger tables take more time when scanning for records.

## Use the Network Cache

The network or IP caching feature stores accepted, incoming TCP requests, so they are not sent to the database. Instead, they are automatically permitted with the syscall function. This feature improves performance for hosts, which launch many incoming TCP connections.

To activate the IP caching feature, change the following tokens in the [seosd] section of the seos.ini file and restart Privileged Access Manager:

- **network\_cache\_timeout**  
Defines how often to clean the cache table. This token is important if you want to set time limits for the accept requests.
- **UseNetworkCache**  
Set this token to yes to activate IP caching.

When caching is enabled, all accepted TCP connections are saved in the kernel table. The records consist of a peer IP address, peer port, and local port. Every new connection is searched in this cache. If a matching set of data for IP address, IP port, and local port is located, the connection is immediately permitted. The time to establish connection is reduced.

## Use the Real Path Cache

File name resolution is a long process because Privileged Access Manager uses information from the file system. The kernel of Privileged Access Manager translates node numbers to full file names when it intercepts appropriate events. Real path caching saves file names within an internal table.

To enable this feature, set the token cache\_enabled to 1 in the [SEOS\_syscall] section of the seos.ini file. File names are cached in the table with a data pair: inode number and device number.

**NOTE**

For more information about the seos.ini initialization file, see the *Reference Guide*.

## Use Fork Synchronization

The fork synchronization token (synchronize\_fork) in the [SEOS\_syscall] section of the seos.ini file manages fork event behavior when new processes are created. Lowering the value of this token improves performance because fork events are frequent.

**NOTE**

For more information about seos.ini initialization file, see the *Reference Guide*.

**Use High Priority**

Privileged Access Manager contains an option to set a real-time priority for the seosd daemon on some platforms. To activate this feature, set the `rt_priority` token in the `[seosd]` section of the `seos.ini` file to `yes`. Running in real time improves system performance.

**NOTE**

For more information about the `seos.ini` initialization file, see the *Reference Guide*.

**Bypass the Process File System**

To reduce system load, you can specify whether Privileged Access Manager should check file access when the file belongs to a process file system (`/proc`).

To activate this feature, use the `proc_bypass` token in the `[SEOS_syscall]` section of the `seos.ini` file. The token stores access information to be bypassed whenever Privileged Access Manager must access the process file system.

**NOTE**

For more information about `seos.ini` file tokens, see the *Reference Guide*.

**Bypass Real Paths**

Searching for files with absolute file paths (instead of relative paths) creates heavier system loads; bypassing this search accelerates file events.

To activate this bypass, set the `bypass_realpath` token to `1` in the `[SEOS_syscall]` section of the `seos.ini` file. If you enable this token, Privileged Access Manager does not obtain real file names, which, for example, could be a symbolic link.

**NOTE**

For more information about `seos.ini` file tokens, see the *Reference Guide*.

**WARNING**

This feature should be used with extreme care because it impacts security-generic rules that do not work when files are accessed with a relative path.

**Bypass Trusted Process Authorization**

Privileged Access Manager allows you to define programs as trusted. Privileged Access Manager stores the trusted programs and their children programs in a table. All events (inbound *and* outbound) related to trusted processes (and their corresponding ports) are permitted without authorization as part of a full network bypass.

To specify these programs, use the `SPECIALPGM` class:

- To bypass file and network events for the specified program, use the property `PGMTYPE` with values `pbf` and `pbn`.
- To bypass `setuid` and `setgid` events for a specified program, use the property `PGMTYPE` with the value `surrogate`.
- To bypass all Privileged Access Manager authorization checks for a specified program, use the property `PGMTYPE` with the value `fullbypass`.  
Privileged Access Manager ignores a process that has the `PGMTYPE(fullbypass)` property, and no record of any process events appears in Privileged Access Manager audit, trace, or debug logs.
- To propagate bypasses to all programs that are called from the specified program, use the property `PGMTYPE` with the value `propagate`.

**NOTE**

Security privilege propagation works with PBF, PBN, DCM, FULLBYPASS, and SURROGATE privileges only.

**Bypass Ports for Network Activity**

To specify that all connection events (inbound *and* outbound) related to specific TCP/IP ports can be established without Privileged Access Manager authorization, you can define a bypass for these ports. Bypassing these ports reduces system load and speeds event processing. Bypassed connection events are not logged in the audit and trace files.

**NOTE**

Privileged Access Manager lets you bypass the network connection event only, not any subsequent events that use the network connection (for example, opening a file).

Trusted inbound connections are specified separately from outbound connections:

- To bypass *incoming* connections, modify the *bypass\_TCPIP* configuration setting in the [seosd] section of the seos.ini file.
- To bypass *outgoing* connections, modify the *bypass\_outgoing\_TCPIP* configuration setting in the [seosd] section of the seos.ini file.

**NOTE**

For more information about the seos.ini initialization file, updating tokens, and affecting changes, see the *Reference Guide*.

**Example: Bypass incoming Telnet events**

If you set the *bypass\_TCPIP* configuration setting to 23 (the Telnet port), the audit and trace files no longer log the network event when you Telnet *to* that workstation. Events related to other services, such as ssh, login, and FTP, and subsequent events that use the network connection (for example, opening a file), will still be logged.

**Example: Bypass outgoing FTP events**

If you set the *bypass\_outgoing\_TCPIP* configuration setting to 21 (the FTP port), the audit and trace files no longer log the network event when you FTP *from* that workstation. Events related to other services, such as ssh, login, and Telnet, and subsequent events that use the network connection (for example, opening a file), will still be logged.

**Reduce Audit and Trace Loads**

Privileged Access Manager uses a file system to keep audit data and trace data. Most processes in the system could be blocked while Privileged Access Manager writes to this file system. To reduce access time to the file system, do the following:

- Set the audit mode only for resources and accesses you need.
- Open the trace only when you need to.
- Store audit file, trace file, and Privileged Access Manager database files on the fastest available file system.
- Store the lookaside database directory on a fast file system.

**Reduce Database Loads**

How you define rules to the database effects system performance:

- Generic rules for commonly used directories produce many verifications, resulting in a greater system load. For example, protecting `/usr/lib/*` causes every action in the system to be checked by Privileged Access Manager. To improve performance, avoid using generic rules for frequently used files.
- Deep hierarchies of users and resources require system loads to obtain and check all dependencies. To improve performance, avoid deep hierarchies in the database.

## Improve PMDB Updates

Policy Models send commands to their subscribers one by one in a loop. To control the maximum number of commands that the Policy Models send to each subscriber during each loop, use the `updates_in_chunk` token, which is described in the [pmd] section of the appendix, "The pmd.ini File."

If you increase the value of this token, the Policy Model uses fewer cycles to send commands. After each loop, the Policy Model checks for new requests. If the token is set higher, the Policy Model does not check for new requests as often.

For example, when you add a new subscriber to the Policy Model (using the `sepm -n` option), increase the token value because other subscribers have already received the commands that the Policy Model is sending. The Policy Model spends less time sending commands to the other subscribers and spends more time sending commands to the new subscriber, shortening the time it takes to add the subscriber.

### NOTE

Do not set this token value to more than 100.

## Improve Watchdog Performance

To reduce system load, set the Watchdog daemon (`seoswd`) to periodically scan secured files instead of constantly scanning. You can specify the Watchdog to scan at times when the system is less loaded.

To activate this feature, use the `IgnoreScanInterval` token in the [seoswd] section of the `seos.ini` file, and set additional tokens for intervals and start times.

### NOTE

For more information about these tokens, see the `seos.ini` initialization file in the *Reference Guide*.

## Improve Class Parameters

Use the class activation and class authorization features for Privileged Access Manager to improve performance further.

### Class Activation (UNIX)

Privileged Access Manager stores information about whether a CLASS is active or inactive in the database. When Privileged Access Manager starts, it passes a list of active classes to `SEOS_syscall`, so Privileged Access Manager does not have to constantly intercept these classes. The only time Privileged Access Manager intercepts a class is when a user changes the activity status of a class. If a class is inactive, access to the resource is not intercepted.

You can use the inactive class bypass with the following classes: FILE, HOST, TCP, CONNECT, and PROCESS.

### Class Authorization

The resource class SEOS controls the behavior of the Privileged Access Manager authorization system. The SEOS class has modifiable properties that specify whether a class is active. You can disable unused classes (using the `setoptions` command) to reduce authorization time.

## Resolve Names

Several tokens in the [seosd] section of the `seos.ini` file (including `GroupidResolution`, `HostResolution`, `ServiceResolution`, and `UseridResolution`) control how Privileged Access Manager performs name resolution. Setting these tokens appropriately improves performance.

Alternatively, you can create a lookaside database (instead of using system name resolution). To improve performance, select the lookaside database option. Tokens for this feature include the `lookaside_path` and `use_lookaside`.

**NOTE**

For more information about these tokens, see the seos.ini initialization file in the *Reference Guide*.

Whenever Privileged Access Manager must perform UID to username, GID to groupname, ipaddr to host name, and port to service translations, it may have an impact on Privileged Access Manager performance. How Privileged Access Manager performs these translations depends on the value of certain tokens in the seos.ini file--in particular, the under\_NIS\_server, use\_lookaside, GroupidResolution, HostResolution, ServiceResolution, UseridResolution, and resolve\_timeout tokens.

When native operating system mechanisms perform the resolution, the impact on system performance is relatively small. When translating ipaddr to host name, an external mechanism such as DNS must perform the translation. This may result in significant degradation of system performance. This degradation occurs because, while seosd is waiting to receive the host name, all other processes that Privileged Access Manager has intercepted must also wait until seosd completes its processing.

- If you set the value of the under\_NIS\_server token to no, seosd allows UNIX to translate UID, GID, IP addresses, and port numbers by taking data from the following sources:

| Type of Station     | Source                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Stand-alone         | seosd uses the following files for translations:<br>/etc/passwd for UID to user name<br>/etc/group for GID to group name<br>/etc/hosts for IP address to host name<br>/etc/services for service ports to service names                                                                                                                                                                                                    |
| NIS client          | The source of the information varies, depending on the operating system and its version number. The information is usually taken from /etc files and the NIS server. However, in some systems, the /etc files are not the source and the order in which translation is made is changed during system configuration. For instance, in the Solaris 2.x system the file /etc/nsswitch.conf determines the translation order. |
| DNS client          | Translation for users, groups, and services is performed using /etc files. Host names are translated by calls to the DNS server and, on some systems, the /etc/hosts file is also read.                                                                                                                                                                                                                                   |
| NIS and DNS clients | The ipaddr to host name translation is performed by DNS. For user, group, and service translations, the translations are performed in the same way as NIS client translations.                                                                                                                                                                                                                                            |

- If you set the value of the under\_NIS\_server token to yes, seosd performs its own translations. If seosd caches data for its translations, the sources of its data are as follows:

| Type of Station | Source                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NIS server      | The server machine usually behaves as both server and client, and consults the NIS server daemon for any type of translation. The files which contain the sources of the NIS resolution maps are usually located in /var/yp, but the location may vary, depending on the site configuration, and the type and version of the operating system.                                                              |
| DNS server      | The source of the information used for translation depends on the configuration of the site. DNS does not have an option to scan its resolution database; therefore, Privileged Access Manager cannot use caching, and must use a look-aside database. You must configure the look-aside database so that the utility sebuildla uses a host list file. For more information, see sebuildla in this chapter. |

|            |                     |
|------------|---------------------|
| all others | Same as DNS server. |
|------------|---------------------|

In versions 2 and higher of Privileged Access Manager, `seosd` can also use the tokens `GroupidResolution`, `HostResolution`, `ServiceResolution`, `UseridResolution`, and `resolve_timeout` to control the translation process. For more information about these tokens, see the *Reference Guide*.

## UNIX Exits

A UNIX exit is a specified program—a shell script or an executable—that runs automatically as a result of another defined Privileged Access Manager activity taking place. Privileged Access Manager supports UNIX exits when loading or unloading the Privileged Access Manager kernel module, or when issuing specific `selang` commands. For example, you can run an initialization process for each new user that you add.

A UNIX exit can run on one or more of the following occasions:

- As a pre-update exit, *before* each `selang` command that updates a *user* or *group* record
- As a post-update exit, *after* each `selang` command that updates a *user* or *group* record
- As a pre-load exit, *before* `SEOS_load` loads the kernel
- As a post-load exit, *after* `SEOS_load` loads the kernel
- As a pre-unload exit, *before* `SEOS_load -u` unloads the kernel
- As a post-unload exit, *after* `SEOS_load -u` unloads the kernel

## User or Group Record Update Exits

UNIX exits are called whenever a `selang` command that updates user or group records is executed in the UNIX environment, regardless of whether the tool is a command-line interface (`selang`) or a GUI (such as Privileged Access Manager Endpoint Management).

The term *update* refers to creating, modifying, or deleting a user or group record. Querying a user or a group does not cause any UNIX exit to run. These are the commands that can cause a UNIX exit to run:

- `newusr`
- `newgrp`
- `chusr`
- `chgrp`
- `editusr`
- `editgrp`
- `rmusr`
- `rmgrp`

From the UNIX point of view, each exit processes runs as a root process, but from the Privileged Access Manager point of view, it runs under the agent identity `_seagent`.

## How the `selang` Exit Script Works

Privileged Access Manager provides a script that you can use as a master script to call other programs according to the nature and status of the current `selang` command. The exit script that is supplied as part of Privileged Access Manager is

*ACInstallDir/exits/lang\_exit.sh* (where *ACInstallDir* is the Privileged Access Manager installation directory.) Here is how it works:

1. Privileged Access Manager automatically gives values to three parameters of the script.

| Parameter | Possible Values          |
|-----------|--------------------------|
| CLASS     | USER   GROUP             |
| ACTION    | CREATE   MODIFY   DELETE |
| STAGE     | PRE   POST               |

The parameters indicate whether Privileged Access Manager is dealing with a user or a group; whether the user or group is being created, deleted, or modified; and whether the *lang* command is about to be executed (PRE) or has just been executed (POST).

The script can pass the parameter values to programs that it calls.

| Parameter | Possible Values                                                                                                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXEC_RV   | <p>Receives the return value of a UNIX command that you use to determine whether the exit command succeeded or failed. For PRE commands, the value is always zero. For POST commands, you can use the value to decide whether to run or skip an exit.</p> <p>For an example of how to use this parameter, locate <i>ACInstallDir/samples/exits_src</i></p> |

1. Using the CLASS and STAGE parameters, Privileged Access Manager looks for programs in the appropriate directory:

```
ACInstallDir/exits/USER_PRE/
ACInstallDir/exits/USER_POST/
ACInstallDir/exits/GROUP_PRE/
ACInstallDir/exits/GROUP_POST/
```

2. In the appropriate directory, Privileged Access Manager selects all the programs that have file names that begin with a capital S, refer to the appropriate action, and have the following format:

```
Snnaction_string
```

Where *nn* is a two-digit decimal number defining the order of the program in the execution sequence, *action* is one of CREATE, MODIFY, or DELETE, and *string* is a descriptive string.

3. Privileged Access Manager runs all the appropriate programs according to the numerical order of the second and third characters of their names.

### Example: UNIX Exit Script

You are going to delete a user, and the directory *ACInstallDir/exits/USER\_PRE/* includes the following files:

- S10CREATE\_precustom.sh
- S10DELETE\_precustom.sh
- S99DELETE\_permusrdir.sh

When you issue the command to delete the user, the first program is not run because you are deleting and not creating a user. The second and then the third programs are run in that order based on the two digits after the initial S.

## Arguments You Can Pass to `selang` Exits

When writing exits you can take advantage of the three parameters mentioned previously (CLASS, ACTION, and STAGE), and all the standard Privileged Access Manager data such as names and permissions. You can also designate extra user or group data, especially for use by the exit scripts. To store such additional data for a user or group, define it within single quotes as the value of the user's or group's UNIX APPL property in a `newusr`, `chusr`, `newgrp`, or `chgrp` command. For example:

```
chusr JONESY unix APPL('HIRED=MAY93,CLEARANCE=2')
```

Your exit program must be able to handle whatever is between the single quotes.

## Specify `selang` Exit Programs to Run

To tell Privileged Access Manager which exit programs to run, modify the [lang] section of the `seos.ini` file. Privileged Access Manager provides the `lang_exit.sh` script for pre-user, post-user, pre-group, and post-group exits. You can also specify no exit or create your own exit.

To specify your own `selang` exits, set any or all of the settings in the [lang] section of `seos.ini` as required.

### NOTE

An exit is called only if its full pathname appears as the value of an exit token.

## Example: Specify `selang` Exits

In the following example, the `seos.ini` file tokens are set so that the program `groupcheck` runs before group operations, the program `flag_exceptions` runs after group operations, the program `lang_exit.sh` runs after user operations, and no exit program runs before user operations. The `seos.ini` file tokens are set as follows:

```
[lang]

pre_group_exit = /opt/CA/PAMSC/exits/groupcheck

post_group_exit = /opt/CA/PAMSC/exits/flag_exceptions

post_user_exit = /opt/CA/PAMSC/exits/lang_exit.sh
```

## Time Out and Other Failures

Exit execution times out after 15 seconds, unless the `exit_timeout` variable in the `seos.ini` file specifies otherwise. A nonzero return value indicates failure.

- If a *pre*-update exit times out or returns a return code of greater than or equal to 16, then Privileged Access Manager kills the exit process, displays an error message, and aborts execution of the Privileged Access Manager update command. Any other positive return code does not abort the execution of the command.
- If a *post*-update exit times out or returns a nonzero value, then Privileged Access Manager kills the exit process and displays an error message. Having already been executed, the Privileged Access Manager update command remains in force.

## `selang` Exit Samples

By examining the scripts in the following directories, you can familiarize yourself with recommended scriptwriting techniques.

```
ACInstallDir/samples/exits-src
```

ACInstallDir/samples/sample\_exits

## Kernel Loader Exits

UNIX exits are called whenever the Privileged Access Manager kernel is being loaded or unloaded (SEOS\_load). This lets you define how you want to handle operating system and third-party programs when loading or unloading the Privileged Access Manager kernel. For example, you can use kernel-unloading UNIX exits to stop automatically, and later restart, processes that prevent Privileged Access Manager from unloading when running *SEOS\_load -u*.

For some operating systems, Privileged Access Manager comes with some kernel load exits, kernel unload exits, or both out of the box.

**Note:** For more information about identifying processes that prevent Privileged Access Manager kernel from unloading, see the *secons* utility in the *Reference Guide*.

## How the Kernel Loading Exits Work

To let you control operating system and third-party processes, Privileged Access Manager lets you make calls to UNIX exits automatically when loading the kernel extension.

When you run **SEOS\_load**, Privileged Access Manager does the following:

1. Looks for programs in the following directory:

```
ACInstallDir/exits/LOAD
```

2. Selects all the programs that have file names of the following format:

```
SEOS_load_string.always
```

Where *string* can be any descriptive strings.

3. Executes, in lexicographical order, each file it found in the directory *ACInstallDir/exits/LOAD*:

```
SEOS_load_string.always -pre
```

Each file is executed with the *-pre* parameter so that you can write your exits to detect the parameter and perform the actions required before the kernel is loaded.

**Note:** If the exit returns a nonzero value, Privileged Access Manager kills the exit process, displays an error message, and aborts the kernel loading.

4. Loads the kernel (SEOS\_syscall).
5. Executes, in lexicographical order, each file it found in the directory *ACInstallDir/exits/LOAD*:

```
SEOS_load_string.always -post
```

Each file is executed with the *-post* parameter so that you can write your exits to detect the parameter and perform the actions required after the kernel is loaded.

**Note:** If the exit returns a nonzero value, the product kills the exit process and displays an error message. Having already been loaded, the kernel remains loaded.

## How the Kernel Unloading Exits Work

To let you control operating system and third-party processes, Privileged Access Manager lets you make calls to UNIX exits automatically when unloading the kernel extension.

When you run **SEOS\_load -u**, Privileged Access Manager performs the following actions:

1. Looks for programs in the following directory:

ACInstallDir/exits/LOAD

2. Selects all the programs that have file names of the following format:

```
SEOS_unload_string.always
```

where *string* can be any descriptive strings.

3. Executes, in lexicographical order, each file it found in the directory *ACInstallDir/exits/LOAD*:

```
SEOS_load_string.always -pre
```

Each file is executed with the *-pre* parameter so that you can write your exits to detect the parameter and perform the actions required before the kernel is unloaded.

**Note:** If the exit returns a nonzero value, Privileged Access Manager kills the exit process, displays an error message, and aborts the kernel unloading.

4. Tries to unload the kernel, if the kernel *does not* unload: Selects all the programs that have file names of the following format:

```
SEOS_unload_string.opt
```

Executes, in lexicographical order, each file it found in the directory *ACInstallDir/exits/LOAD*:

```
SEOS_unload_string.opt -pre
```

Each file is executed with the *-pre* parameter so that you can write your conditional exits to detect the parameter and perform the additional optional actions required before the kernel is unloaded.

**Note:** If the exit returns a nonzero value, then the product kills the exit process, displays an error message, and aborts the kernel unloading, unloads the kernel. Executes, in lexicographical order, each file it found in the directory *ACInstallDir/exits/LOAD*:

```
SEOS_unload_string.opt -post
```

Each file is executed with the *-post* parameter so that you can write your conditional exits to detect the parameter and perform the additional optional actions required before the kernel is unloaded.

**Note:** If the exit returns a nonzero value, then the product kills the exit process and displays an error message. Having already been unloaded, the product kernel remains unloaded.

```
SEOS_unload_string.opt
```

Executes, in lexicographical order, each file it found in the directory *ACInstallDir/exits/LOAD*:

```
SEOS_unload_string.always -post
```

Each file is executed with the *-post* parameter so that you can write your exits to detect the parameter and perform the actions required after the kernel is loaded.

**Note:** If the exit returns a nonzero value, the product kills the exit process and displays an error message. Having already been unloaded, the product kernel remains not loaded.

## Interact with LDAP

This topic describes ways that Privileged Access Manager interacts with LDAP.

### Transfer User Names

If you are using both Privileged Access Manager and LDAP, you can transfer user names between them using scripts of your own design. Three sample scripts are provided.

## WARNING

**Warning:** To set up sebuildla and the required LDAP configuration settings, execute the ldapsearch command. We recommend that you read the man pages for ldap(1), ldapsearch(1), and the information about setting up in the documentation for your LDAP client.

Two of the provided scripts--ldap2seos and seos2ldap--export whole sets of users from Privileged Access Manager to an LDAP server and imports them from an LDAP server to Privileged Access Manager.

A third sample script, S50CREATE\_Ldap\_u.sh, automatically transfers new UNIX user names from Privileged Access Manager to LDAP as they are created.

The sample scripts require access to a TCL shell environment; they use the Language Client API (LCA) library extension, [tcllca.so](#).

**Note:** For more information about LCA and the TCL extension, see the Language Client API and the appendix the LCA Extension respectively in the *SDK Guide*.

If you do not have TCL, consult the FAQ posted monthly to comp.lang.t\_c\_l by Larry Virden. The FAQ is available on the MIT website and the Terafirm website.

You can also refer to the Sun website for TCL news, documentation, and resources.

### **S50CREATE\_Ldap\_u.sh**

S50CREATE\_Ldap\_u.sh uploads new UNIX users to LDAP as they are created.

Privileged Access Manager supplies a sample shell script to import new UNIX users automatically to an LDAP server. The script that you need can vary from the sample.

To employ the sample shell script, assuming that you are already using the provided exit script, follow these steps:

1. Copy the S50CREATE\_Ldap\_u.sh file to the directory *ACInstallDir/exits/USER\_POST*. In this directory, the script becomes a post-user exit.
2. In the seos.ini file in the [ldap], set the base\_entry token to the LDAP base entry.  
For example, for an organization that is named ServerWorld, located in Canada, the base entry might be:  
o=ServerWorld, c=CA.
3. In the same section, set the host name to the host name of the LDAP server. Set the path to the LDAP base directory.  
(The sample script looks for the line command utilities in the bin directory under that directory.)

Common Names (cn) are derived from the full name of the user. If the Privileged Access Manager database contains only the user name and surname, for example, these names comprise the Common Name. You are locked into the Common Name, so we recommend that you do not base it on a user name.

Each user then added to UNIX with selang is automatically uploaded to the LDAP server. If the user already exists in LDAP, an error message results.

When you add users with this script, the relevant LDAP replies and any warnings are collected in the /tmp/add\_User2Ldap.tcl.log file. You can examine this file, using vi or any other standard UNIX editor, to check for errors. The file is overwritten with the new set of replies and warnings each time you add new users.

## NIS Configuration

Privileged Access Manager intercepts requests to access system resources and decides whether to permit or deny these requests. The decision is based on access rules and policies that are defined in the database. The interception of requests to access system resources takes place at the kernel level.

To control hosts, groups, users, and services, the kernel and the relevant system calls use codes or numbers instead of names. Examples: IP addresses, group IDs, service numbers. Privileged Access Manager defines access rules based on

names. Privileged Access Manager translates names into codes recognizable by the kernel. This process is called name resolution.

On stand-alone stations, except for stations running Sun Solaris 2.5 or higher, name resolution is completed directly through the local user, group, and host files (`/etc/passwd`, `/etc/group`, and `/etc/hosts`). When Privileged Access Manager resolves a name, it simply calls a system function that in turn reads the relevant file.

On larger networks, however, this information is seldom stored locally. When you use NIS, DNS, or both, there are no local files that you can consult during name resolution. The information is requested and received from a server over the network.

## Avoid Deadlocks with the Lookaside Database

The setting of the `under_NIS_server` token in the `seos.ini` configuration file has a default setting of yes to avoid deadlocks. The token tells Privileged Access Manager to use its own internal name resolution tables instead of NIS, DNS, or the `nsdc` cache. Unless otherwise specified, these tables reside in memory.

Privileged Access Manager internal name resolution is much faster than NIS name resolution and even faster than using files. Using Privileged Access Manager internal name resolution improves performance even in an environment where there is no danger of deadlocks.

### NOTE

No cache exists for the internal name resolution tables in the lookaside database. Privileged Access Manager uses an open file handle to read data from the tables.

## Store Resolution Tables on Disk

Privileged Access Manager name resolution tables are generated while it is starting up. Maintain the tables on disk, not in memory, because storage in memory can lead to memory overload. Also, when the information is read into memory, it is static. Because it is static, Privileged Access Manager would not know of any changes made to user, group, or host information. The only way to update the tables in memory is to restart Privileged Access Manager.

To keep data current, Privileged Access Manager provides a lookaside database that ensures internal name resolution tables are stored on disk.

### NOTE

To implement the lookaside database, use `seos.ini` configuration settings. For more information about `seos.ini` configuration settings, see the *Reference Guide*.

## Set Up the Lookaside Database

The four tables in the lookaside database are `userdb.la`, `groupdb.la`, `hostdb.la`, and `servdb.la`. These four tables handle user, group, host, and service name resolution requests. The tables are located in the directory specified by the `lookaside_path` token in the `seos.ini` file, which by default is `/opt/CA/PAMSC/ladb`.

### Lookaside Database with Four Tables

To set up the lookaside database with four tables, do one of the following:

- If you are installing Privileged Access Manager, answer yes when asked if you want to create the lookaside database.
- If you already installed Privileged Access Manager:
  - a. In the `[seosd]` section of `seos.ini` change the following tokens to **yes**:
    - a. `under_NIS_server`
    - b. `use_lookaside`
  - b. Run `sebuildla -a` to create all four tables.

## Lookaside Database with Less Than Four Tables

You can also create one, two, or three tables. For example, if you want to use the lookaside database to resolve hosts only, complete the following steps:

1. After you install Privileged Access Manager, change the following tokens in the [seosd] section of the seos.ini file:
  - Set under\_NIS\_server to blank.
  - Set HostResolution to ladb.
2. Run sebuildla -h to create a table of all hosts, including local and DNS hosts.  
or  
Run sebuildla -e to create a table of local hosts only (defined in /etc/hosts).

To create a lookaside database with other tables, use the appropriate tokens in the seos.ini file and then run the appropriate option with sebuildla.

### NOTE

For descriptions of these tokens, see the seos.ini initialization file in the *Reference Guide*. For more information about sebuildla, see the *Utilities Guide*.

### WARNING

Run sebuildla whenever you add a host.

## How the Lookaside Database Works

The four tables in the lookaside database (groupdb.la, hostdb.la, servdb.la, and userdb.la) contain resolution information for groups, hosts, services, and host names. The tables are located in the directory specified by the lookaside\_path token in the seos.ini file, which by default is /opt/CA/PAMSC/ ladb.

Privileged Access Manager internal name resolution is much faster than NIS name resolution and even faster than looking up the files.

## Implement the Lookaside Database

### NOTE

The problems and solutions outlined here are for informational purposes only. Actual settings are correct upon installation and most users need not take any action.

Here is a broad overview of how Privileged Access Manager implements the lookaside database:

- The relevant tokens in the seos.ini file are set.
- The relevant symbolic links in the /opt/CA/PAMSC/exits directory are defined.
- The command /opt/CA/PAMSC/bin/sebuildla -a was issued to build the lookaside database.

The sebuildla utility taps into the native resolution mechanisms such as the files and NIS to build the lookaside database.

No security-sensitive information (such as password, location of the home directory, or gecost) is kept in the lookaside tables. The lookaside database tables contain only a numeric ID number and a name.

Once the lookaside database is created, update it using the sebuildla utility. You do *not* need to restart Privileged Access Manager.

## Update the Hosts Lookaside Table

You must update the hosts' lookaside table. To do so, execute sebuildla -h at regular intervals (site-specific). Use cron jobs to do this.

Every time you change the UNIX user or group databases utilizing selang, you must run the sebuildla utility. Privileged Access Manager provides exit scripts for this purpose, which runs sebuildla with the appropriate parameters.

## Name Resolution on an NIS DNS Client

Privileged Access Manager performs name resolution on a client-only NIS or DNS station (which is not its own server) as follows:

1. Privileged Access Manager generates a network request to connect to the relevant server.
2. The Privileged Access Manager kernel extension intercepts the request.
3. The Privileged Access Manager kernel extension permits the request because it knows that the request was made internally.
4. A connection to the NIS or the DNS server is established and the information necessary for name resolution is retrieved.
5. Once the name is resolved, Privileged Access Manager continues the process of deciding whether to permit or deny the original access request.

A standard Privileged Access Manager configuration is sufficient to handle name resolution on a client server.

## Name Resolution on a Server Deadlock

Privileged Access Manager performs name resolution on a server that includes itself as a client as follows:

1. Privileged Access Manager generates a network request to connect to the relevant server.
2. The kernel extension intercepts this request.
3. The kernel extension permits the request because it knows that the request was made internally by the Privileged Access Manager process.
4. The NIS or DNS server (which is located on the same station) generates a request to accept the network connection.
5. The kernel extension intercepts this request.
6. The kernel extension knows that a Privileged Access Manager process did not make this request. It places this request on the queue of requests awaiting seosd decision.
7. The seosd daemon is now caught in a deadlock. It is waiting for the reply necessary to complete name resolution, but the process that should provide this reply cannot proceed until seosd gives it permission to accept the network connection. The first request generates the second, and creates a deadlock.

## Name Resolution on Sun Solaris Deadlock

Name resolution on Sun Solaris entails accessing the *nscd* cache. The *nscd* is a process that provides a cache for the most common name service requests. The *nscd* furnishes caching for the *passwd*, *group*, and *hosts* databases.

The cache is not permanent. It becomes invalid as changes are made to the *passwd*, *group*, and *hosts* databases, or as the time-to-live stamp expires.

The Sun Solaris setup can create a deadlock like the one described in the previous section. Here, the interaction between Privileged Access Manager and the *nscd* process causes the deadlock.

1. During name resolution, Privileged Access Manager accesses the *nscd* cache.
2. The *nscd* process can decide that the cache is too old. In this case, it attempts to refresh the information by accessing the *passwd*, *group*, and *hosts* databases (locally or on a server).
3. The request to access these databases is intercepted by the kernel extension. Since a Privileged Access Manager process is not making the request, it is placed on a queue awaiting seosd decision. But no such decision is possible because seosd is still engaged in the previous request. The first request generates the second, and creates a deadlock.

## Restricting Local Interprocess Communication over UNIX (LOCAL) Named Domain Sockets

**Note:** This functionality is not supported in the Endpoint-Management UI.

In addition to controlling interprocess communication (IPC) over TCP, Privileged Access Manager can also restrict local IPC which uses UNIX (or LOCAL) named domain sockets. Privileged Access Manager intercepts processes that attempt to connect to a socket using the named socket path. You can write Privileged Access Manager rules to authorize connections to the socket using the UNIX\_SOCKET class and connect (c) access.

### Example

This example enables the user root full access and enables the user John to run docker commands. Docker commands communicate with the docker daemon using UNIX domain sockets as the default communication through socket path /run/docker.sock

```
so class+(UNIX_SOCKET)

nr UNIX_SOCKET /run/docker.sock owner(nobody) defaccess(none) audit(all)

auth UNIX_SOCKET /run/docker.sock uid(root) access(all)

auth UNIX_SOCKET /run/docker.sock uid(john) access(c)
```

The user John can now run docker commands using docker default local communication. Example: `sudo docker run hello-world`. Another user, Chris, cannot run such docker commands, and root maintains full capabilities.

## Protect Process being Attached by Other Processes

**Note:** In this release, this functionality is not supported in the Endpoint-Management UI.

System-related processes can be tampered with without the knowledge of the administrator using malicious code. To overcome this issue, this release of the product has enhanced the PROCESS class with an attribute called ATTACH.

The ATTACH attribute of the PROCESS class protects the process from being attached by other processes through the ptrace system calls. With this attribute, you can authorize which process should access a specific process.

The following example describes the use of the ATTACH attribute:

### Follow these steps:

1. Consider top as an example process with the following executable path:

```
/usr/bin/top
```

2. Create a record for the process top using the following code:

```
PAMSC> nr process /usr/bin/top owner(nobody) defacc(n)
```

A record is created for the process /usr/bin/top using the PROCESS class with owner as nobody and default access as none. At this time, the process top /usr/bin/top cannot be attached by any other process.

3. You can authorize the process /usr/bin/top to be attached to any other process running under root using the following Selang rule:

```
PAMSC>auth process /usr/bin/top uid(root) access(attach)
```

## Endpoint Administration for Windows

This guide describes the concepts used by Privileged Access Manager for Windows--a product that provides a total security solution for open systems. The guide describes Windows endpoint management tasks and concepts.

## **Manage Endpoints (Windows)**

Privileged Access Manager is a software product that is an active, comprehensive security software solution for Open Systems, tied dynamically to the operating system. Each time a user requests a security-sensitive operation, such as

opening a file, substituting a user ID, or obtaining a network service, Privileged Access Manager can intercept the event in real time. The product evaluates its validity before passing control to the standard operating system (OS) functions.

### **What Is Privileged Access Manager? (Windows)**

Privileged Access Manager provides you with a powerful tool for managing security for your native platforms, making it possible to implement a security policy that can be customized entirely to the security requirements of the enterprise. Privileged Access Manager lets you provide security for users, groups, and resources beyond what is available in native operating systems. The product lets you centrally manage security across the organization and integrate your Windows and UNIX security policies in a heterogeneous environment.

### **What Is Protected? (Windows)**

Privileged Access Manager protects the following entities:

- **Files**

Is a user authorized to access a particular file?

Privileged Access Manager restricts the ability of a user to access a file. You can give a user one or more types of access, such as READ, WRITE, EXECUTE, DELETE, and RENAME. The access can be specified regarding an individual file or to a set of similarly named files.

- **Terminals**

Is a user authorized to use a particular terminal?

This check is done during the login process. Individual terminals and groups of terminals can be defined in the Privileged Access Manager database, with access rules that state which users, or groups of users, are allowed to use the terminal or terminal group. Terminal protection ensures that no unauthorized terminal or station can be used to log in to the accounts of powerfully authorized users.

- **Sign-on time**

Is a user authorized to log on at a particular time on a particular day?

Most users use their stations only on weekdays and only during work hours; the time-of-day and day-of-week login restrictions, as well as holiday restrictions, provide protection from hackers and from other unauthorized accessors.

- **TCP/IP**

Is another station authorized to receive TCP/IP services from the local computer? Is another station authorized to supply TCP/IP services to the local computer? Is another station permitted to receive services from every user of the local station?

An open system is a system in which both the computers and the networks are open. The advantage of an open system is also a disadvantage. Once a computer is connected to the outside world, you can never be sure who enters the system and what damage an alien user can do, intentionally or by mistake. Privileged Access Manager includes firewalls that prevent local stations and servers from providing services to unknown stations.

- **Multiple login privileges**

Is the user permitted to log in from a second terminal?

The term *concurrent logins* refers to a user's ability to be logged onto the system from more than one terminal.

Privileged Access Manager can prevent a user from logging in more than once. This prevents intruders from logging into the accounts of users who are already logged in.

- **User-defined entities**

You can define and protect both regular entities (such as TCP/IP services and terminals) and functional entities (known as *abstract* objects; such as performing a transaction and accessing a record in a database).

- **Aspects of administrator authority**

Privileged Access Manager provides the means to both delegate superuser authorities to operators and restrict the privilege of the superuser account.

- **Registry keys**

Is a user authorized to access a particular registry key?

Privileged Access Manager restricts the ability of a user to access registry keys. You can give a user one or more types of access, such as READ, WRITE, and DELETE. The access can be specified with regard to an individual registry key or to a set of similarly named registry keys.

- **Programs**

Can a particular program be trusted? Is the user authorized to invoke it? Can the user access a specific resource using a program?

The security administrator can test programs to ensure that they do not contain any security loopholes that can be used to gain unauthorized access. Programs that pass the test and are considered safe are defined as trusted programs. The Privileged Access Manager self-protection module (also referred to as the **watchdog**) knows which program is in control at a particular time and checks whether the program has been modified or moved since it was classified as trusted. If a trusted program is modified or moved, the program is no longer considered trusted and Privileged Access Manager does not allow it to run.

In addition, Privileged Access Manager protects against various deliberate and accidental threats, including:

- **Kill attempts**

Privileged Access Manager can be used to protect critical servers and services or daemons against kill attempts.

- **Password Attack**

Privileged Access Manager protects against various types of password attacks, enforces the password-definition policies of your site, and detects break-in attempts.

- **Password Delinquency**

Privileged Access Manager policies delineate rules that force users to create and use passwords of sufficient quality. To ensure that users create and use acceptable passwords, Privileged Access Manager can set maximum and minimum lifetimes for passwords, restrict certain words, prohibit repetitive characters, and enforce other restrictions. Passwords are not permitted to last too long.

- **Account Management**

Privileged Access Manager policies ensure that dormant accounts are dealt with appropriately.

### ***How Is It Protected? (Windows)***

Privileged Access Manager starts immediately after the operating system finishes its initialization. The product places hooks in system services that must be protected. In this way, control is passed to Privileged Access Manager before the service is performed. Privileged Access Manager decides whether the service can be granted to the user.

For example, a user may attempt to access a resource protected by Privileged Access Manager. This access request generates a system call to the kernel to open the resource. Privileged Access Manager intercepts that system call and decides whether to grant access. If permission is granted, Privileged Access Manager passes control to the regular system service. If Privileged Access Manager denies permission, it returns the standard permission-denied error code to the program that activated the system call, and the system call ends.

The decision is based on access rules and policies that are defined in the database. The database describes two types of objects: accessors and resources. *Accessors* are users and groups. *Resources* are objects to be protected, such as files and services. Each record in the database describes an accessor or a resource.

Each object belongs to a class—a collection of objects of the same type. For example, **TERMINAL** is a class containing objects that are terminals (workstations) protected by Privileged Access Manager.

### ***Class Activation (Windows)***

The information about class status (that is, whether the class was active or inactive) is held in the database. Every attempt to access a resource is intercepted by Privileged Access Manager, which checks the status in the database. If the class is inactive, access is allowed without further checking for authorization.

Privileged Access Manager issues a list of active classes when the engine starts and when a user changes the class activity status. If a class is inactive, access to the resource is not intercepted, which reduces overhead.

### ***Accessor Elements (Windows)***

Each user is represented by an *accessor element* (ACEE)—an in-memory reflection of the record for the user in the database. Privileged Access Manager builds the accessor element during the login process. The accessor element is associated with the process of the user. Whenever the process requests a system service that is protected by Privileged Access Manager, or issues an implicit request to access a resource, the product accesses the record of the resource. It then determines whether the information in the previously created accessor element—such as the user's security level, mode, and group—lets the user access the resource.

### How Instrumentation Works

*Instrumentation* is a method that enables Privileged Access Manager to monitor, track, and change the execution flow of applications. Instrumentation enables Privileged Access Manager to monitor system processes, intercept, and implement a proprietary module in the application address space.

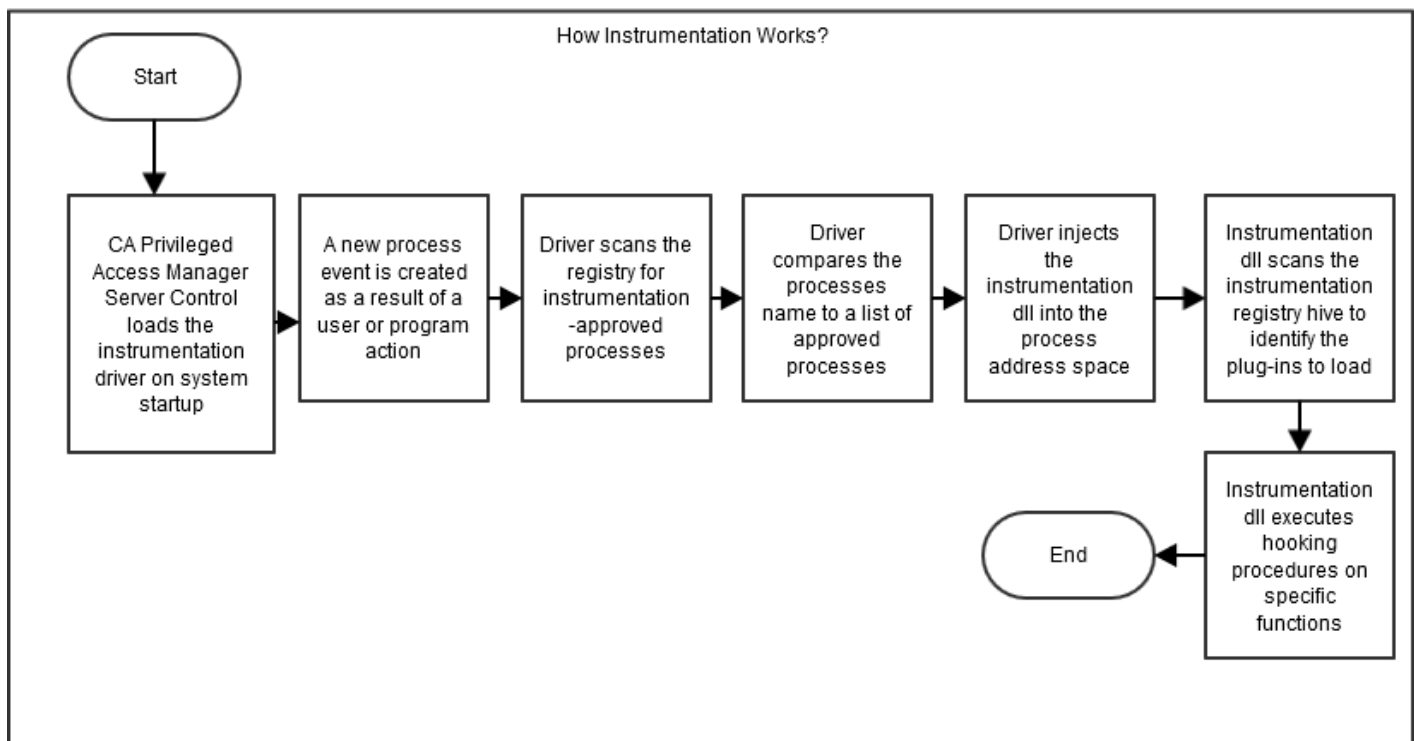

The instrumentation process consists of two phases: the *kernel instrumentation* phase and the *user-mode instrumentation* phase.

#### NOTE

For more information about kernel and user-mode interceptions, refer to the [User Impersonation Protection](#) chapter.

The following diagram illustrates the instrumentation process:

**Figure 44: Instrumentation\_Process**

In the kernel instrumentation phase, Privileged Access Manager performs the following actions:

1. Privileged Access Manager loads the instrumentation driver (cainstrm.sys) on system startup.
2. A new process event is created as a result of a user or program action.
3. In fixed intervals the instrumentation driver scans the registry hive for instrumentation-approved processes.  
You specify the list of instrumentation-approved processes using the instrumentation ApplyonProcesses [registry key](#).

4. When Privileged Access Manager identifies a new process event, it searches for the processes name in the list of approved processes. If found, the driver injects the instrumentation dll into the process address space.

In the user-mode instrumentation phase, Privileged Access Manager performs the following:

1. The instrumentation dll scans the instrumentation registry hive to identify the plug-ins to load into the process address space and does one of the following steps:
  - Loads all listed plug-ins in to the processes memory address. Continues to step 2.
  - Unloads itself if no plug-ins are listed.
2. Privileged Access Manager executes hooking procedures based on the specific functions that each plug-in contains using the Microsoft Detours library.  
Microsoft Detours is a library for instrumenting Win32 functions. For more information about Microsoft Detours, see the [Microsoft Detours web site](#).

### **WARNING**

If instrumentation is disabled, the following features or applications do not work:

- [STOP](#)
- WinService
- Configuration of Windows batch files as a PROGRAM object
- Database/IIS integration with SAM
- [RunAs](#)

## **Expand Native Security**

The following Privileged Access Manager features expand native security.

### **Superuser Account Limitations**

Users who administer and manage operating systems are typically members of predefined accounts. These accounts are automatically created during the system setup. Examples of these accounts are the root account on UNIX systems and the Administrator account on Windows systems. Each of the predefined accounts exists to perform a certain set of system functions.

For example, users acting as root or Administrator can create, delete, and modify users and lock, reconfigure, and shut down servers.

One of the major security risks is that an unauthorized user gains control of these accounts. If this happens, the user can seriously damage the system.

Privileged Access Manager lets you limit the rights that are granted to these accounts and limit the rights of members of user groups that have these accounts as members. These limits reduce the vulnerability of your operating system.

### **Privileged Access Manager Administrators**

When you install Privileged Access Manager, you are asked to name one or more product administrators. Administrators have the authority to modify all or part of the rules database. You need at least one full-authority administrator. This administrator can modify or create access rules freely and can designate other levels of administrators.

Once you have defined users for your system, assign administrative authority to other users by assigning the ADMIN attribute to them.

### **NOTE**

A user with the ADMIN attribute possesses powerful authority. Therefore, limit the number of ADMIN users. A good policy is to separate the roles of the native superuser and ADMIN. Remove the ADMIN attribute from the superuser after you have set up one or more Privileged Access Manager security administrators.

Because you need at least one user with authority to manage the database, Privileged Access Manager does not let you delete the last user that has the ADMIN attribute.

If you expect any of the product administrators to administer other hosts from this workstation, ensure that a rule in the database on that host gives them READ and WRITE access from this workstation.

### **Sub Administration**

Privileged Access Manager contains a *sub administration* feature. This feature lets administrators grant specific privileges that enable regular users to manage specific classes. These users are then named sub administrators.

For example, you can allow a specific user to manage users and groups only.

You can also specify a higher level of sub administration. To specify this level, grant access not only for specific classes, but for specified records in these classes.

### **Administration Rights for Regular Users**

Privileged Access Manager lets you grant ordinary users (non-administrators) the necessary rights and privileges to perform administrative tasks without being members of the Administrators group. The ability to delegate tasks by granting administrative privileges in this granular way is a significant advantage of Privileged Access Manager.

- A record in the SUDO class stores a command script to allow users to run the script with borrowed permissions.
- The data property value is the command script. This value can be modified by adding to it optional script parameter values.
- Each record in the SUDO class identifies a command for which a user can borrow permissions from another user.
- The key of the SUDO class record is the name of the SUDO record. This name is used instead of the command name when a user executes the commands in the SUDO record.

### **Enhanced File Protection**

Privileged Access Manager supports both logical and absolute file name formats. For example, if the file foo.txt is located under the directory \tmp on the logical drive D and the logical name D: is assigned to physical disk 1, partition 0, you can use either the logical or absolute file name to define a file to the product database:

```
nr file D:\tmp\foo.txt
```

or

```
nr file \Device\HardDisk1\Partition1\tmp\foo.txt
```

#### **NOTE**

If the second format is used, the file remains protected even if the logical name of the disk is changed. The absolute file name format is also supported for Privileged Access Manager generic file protection.

The product protects all file systems that are currently used in supported Windows operating systems. The two most commonly used are the Windows file system (NTFS) and the file allocation table (FAT).

The product also supports CDFS (a file system especially for CDs).

The product supplies a total security solution to the file allocation table (FAT) and an extra layer of security to other file systems including NTFS and CDFS.

### **Generic File Protection**

Privileged Access Manager supports both logical and absolute file names. The absolute file name format is also supported for Privileged Access Manager generic file protection.

Generic file protection lets you protect all the files that fit a specified wildcard pattern (regular expression). Any resource with a name matching the specified wildcard pattern is protected by the specified generic access rule. The product lets you protect files generically.

If a resource matches more than one generic access rule, Privileged Access Manager chooses the rule that most closely matches the file.

With generic file protection, no more than a handful of security rules must be defined to protect many of the files requiring protection.

## **Password Protection**

Native Windows security can protect passwords and can enforce password quality in a number of ways. Windows offers the ability to:

- Enforce a maximum password age
- Enforce a minimum password length
- Save up to 24 generations of the passwords of a user
- Lock out accounts after repeated login failures
- Force users to log in to Windows before changing their passwords

Privileged Access Manager also enforces the same rules but through its own unique mechanisms. In addition, the product implements two-way password synchronization with mainframe computers.

## **Enhanced Password Protection**

Native Windows security provides a significant amount of [protection for user passwords](#). However, Privileged Access Manager significantly extends password protection so that the likelihood of a hacker succeeding in stealing a password is greatly reduced.

When using Privileged Access Manager, you can create more rules that force users to choose safer, more secure passwords. For instance, you can demand that users select a minimum number of alphabetic, numeric, special, lowercase, or uppercase characters. You can also ensure that the new password that a user selects does not contain, and is not contained by, the password being replaced.

## **Program Pathing**

*Program pathing* is an access rule that is associated with a file that requires that the file is accessed only through a specific program. Program pathing greatly increases the security of sensitive files. Privileged Access Manager lets you use program pathing to provide more protection for the files in your system.

## **B1 Security Level Certification**

Privileged Access Manager includes the following B1 Orange Book features: security levels, security categories, and security labels.

- Accessors and resources in the database can be assigned a *security level*. The security level is an integer between 1 and 255. An accessor can gain access to a resource only if the accessor has a security level equal to or greater than the security level assigned to the resource.
- Accessors and resources in the database can belong to one or more *security categories*. An accessor can access a resource only if the accessor belongs to all of the security categories assigned to the resource.
- A *security label* is a name that associates a particular security level with a set of zero or more security categories. Assigning a user to a security label gives the user both the security level and any security categories associated with the security label.

### **NOTE**

For more information about B1 Orange Book features, see the *Implementation Guide*.

## Set Up Audit Procedures

Privileged Access Manager keeps audit records for events of access denial and access grants according to the audit rules defined in the database. The decision whether to log a certain event is based on the following rules:

- Every accessor and resource has an AUDIT property that can be set to indicate whether access successes, failures, or both, are logged. In addition, the AUDIT property for accessors can indicate whether login successes, failures, or both are logged.
- If the resource or the accessor has the AUDIT(ALL) attribute, all events concerning resources that are protected by Privileged Access Manager are logged, regardless of whether access failed or succeeded.
- If the access to a resource protected by Privileged Access Manager is successful and the user or the resource has AUDIT(SUCCESS), the event is logged.
- If the access to a resource protected by Privileged Access Manager fails and the user or the resource has AUDIT(FAIL), the event is logged.

Only a system auditor, a user to whom the AUDITOR attribute is assigned, can perform auditing tasks such as changing the auditing attribute that is assigned to users and resources.

If a resource is in warning mode, any access that violates access rules for the resource results in a warning mode audit record, which states that Privileged Access Manager permitted access to the resource.

The audit records constitute a file that is called the *audit log* (seos.audit). The location for the audit log is specified in the registry, as is the location for the error log.

The audit log (and also the error log) is specified under the following registry key:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\logmgr
```

The audit log is a binary file and cannot be edited or changed. However, you can use Privileged Access Manager Endpoint Management to view recorded events, to filter out events by time restrictions or event type, and so forth. (You can also use the seaudit utility to accomplish these same tasks.)

Consider archiving (backing up) old audit logs and error logs to let you scan the events at a later date.

## Components

Privileged Access Manager includes the following components:

- A database (seosdb)
- Two drivers (seosdrv and drveng)
- Several services, including the Watchdog, the Agent, the Engine (seosd), the Policy Model, and Task Delegation
- A graphical user interface

### Database

The database contains definitions of the following elements:

- Users and groups in your organization
- System resources that need protection
- Rules governing user and group access to system resources

### Drivers

The drivers protect all the Privileged Access Manager files and registry keys by performing the following tasks:

- Intercepting every request to open a file or registry key, terminate a process, and perform network activities.
- Passing these requests to the Privileged Access Manager Engine and receiving the decision about whether the request is granted or denied.
- Forwarding the decision to the original system call of the operating system. The operating system then continues its processing that is based on the answer it received from the drivers.

## **Services**

### ***Watchdog***

The Watchdog constantly checks that the other Privileged Access Manager services are running. On the rare occasion when the Watchdog discovers that another service has stopped, it immediately starts the service again.

### ***Agent***

The Agent is responsible for the following tasks:

- Communicating with Privileged Access Manager clients through a proprietary application protocol above TCP/IP
- Managing security for the Privileged Access Manager user

### ***Engine***

The Engine is responsible for the following tasks:

- Managing the database, including controlling all database updates
- Deciding whether to grant access requests that it receives from the Driver and the Agent
- Checking that the Watchdog service is running, and restarting the Watchdog if it discovers that the Watchdog has stopped running

The Engine handles database access requests *and* makes the access decision, creating an efficient service.

### ***Policy Model***

Managing tens or hundreds of databases individually is not practical. Therefore, Privileged Access Manager supplies the Policy Model service, a component that permits management of many computers from one computer. Using the Policy Model service is optional, but it greatly simplifies administration at large sites.

With the Policy Model service, use a Policy Model database (PMDB). Like other Privileged Access Manager databases, the PMDB contains users, groups, protected resources, and rules governing access to the resources. In addition, the PMDB contains a list of subscriber stations. A subscriber station is one linked to the PMDB so that any change to the PMDB is automatically sent to the subscriber database.

You can create a basic security policy for your organization and can implement all the necessary rules on a single database, the Policy Model database. The subscribers can include both Windows and UNIX stations, ensuring uniform rules with minimal administrative effort.

The system or security administrator updates the PMDB. The PMDB then propagates all updates from the PMDB to its subscribers in batch mode, freeing the administrator for other work.

A PMDB can have two types of subscribers: another PMDB or a local database. This PMDB also contains a list of subscribers to which it propagates database updates. This feature lets you build a hierarchy of PMDBs. The local database can be used to protect the users, groups, and resources that are defined on the station.

## **selang**

The command-line language, *selang*, performs all the functions of Privileged Access Manager. To use *selang* commands, open a Command Prompt window and start *selang*. You can also use *selang* in scripts.

For more information about *selang* and its commands, see the chapter "The *selang* Command Language" in the *Reference Guide*.

## Endpoint Management

Privileged Access Manager provides two ways to let you manage the resources in your enterprise and control who has access to them:

- **selang:** The Privileged Access Manager command language  
The selang command language lets you make definitions in the Privileged Access Manager database. The selang command language is the command definition language.

### NOTE

For more information about using selang, see the *selang Reference Guide*.

- **Privileged Access Manager Endpoint Management:** The endpoint administration interface  
The web-based interface lets you administer remote endpoints through a central administration server.

### NOTE

For more information about installing Privileged Access Manager Endpoint Management, see the *Implementation Guide*.

## Users and Groups

In Privileged Access Manager, every action and access attempt is performed on behalf of a user. The user is held responsible for submitting the request. Every process in the system is therefore associated with a certain user name. The user name identifies the user to Privileged Access Manager.

A *user* is a person who can log on, or can be the owner of a batch or daemon program. In Privileged Access Manager, a user performs every access attempt. Privileged Access Manager can use user information from the product database and from the enterprise user stores. The product stores user information in its database, in either a USER record or an XUSER record.

### NOTE

An *enterprise user store* is a store in the operating system that stores users or groups. Example: /etc/passwd and /etc/groups on UNIX systems, or Active Directory on Windows.

A *group* is a collection of users. A group defines common access rules for users in the group. Groups can be nested (belong to other groups). Privileged Access Manager can use group information from the Privileged Access Manager database and from the enterprise user stores. Typically, you create groups and assign users to them, based on a role; for example, database\_administrators.

The user records are the key accessor records. The main purpose for using groups in Privileged Access Manager is to assign access authorities to all users in group at one time. Assigning access authorities at one time is easier and less error prone than assigning them separately to each user.

## Where Information about Accessors Is Stored

The information that Privileged Access Manager uses about users and groups is stored both in the product database and in the host operating system. The host operating system information stores are called *enterprise user stores*, or just *enterprise stores*. By default, Privileged Access Manager is configured so that it does not use the enterprise stores. You can configure Privileged Access Manager so that it looks for information and uses information from the users and the group memberships defined in the enterprise store. This is useful if the product cannot find a user or group defined in its own database.

### NOTE

Privileged Access Manager uses information from the enterprise stores but only writes to them if you use selang commands in the native environment.

When checking for authorization, Privileged Access Manager always checks for accessors that are defined in its own database before it checks the enterprise store: if you have an enterprise user with the same name as a user defined in the product database, Privileged Access Manager ignores the enterprise user.

### **How Privileged Access Manager Finds a User Record**

When a user logs in, Privileged Access Manager conducts the search in the following order, until it finds a record associated with the user. Privileged Access Manager:

1. Searches for a user defined in its database.
2. Searches its cache for an enterprise user of that name. When the network is down, the operating system (OS) lets users log in using the OS cached credentials. The purpose of the Privileged Access Manager cache is to let the product use the records of enterprise users in these cases.
3. Uses the operating system to search the enterprise user stores for a user of that name.
4. If Privileged Access Manager does not find a record that is associated with the user in its database or in the enterprise stores, it assigns the user the attributes in the `_undefined USER` record.

### **Integration with the Enterprise User Stores**

Typically, you configure Privileged Access Manager to use the groups and users that are defined in the enterprise user stores. When you create an access rule that references an enterprise user or group, or when a user logs in to the operating system, Privileged Access Manager creates a record in its database for that user or group.

These records have the class `XUSER` (for enterprise users) or `XGROUP` (for enterprise groups). They hold the properties that Privileged Access Manager requires to enforce access rules. You do not need to manage them, because Privileged Access Manager creates them as required.

The only properties of an enterprise user or group that CA Access Control fetches from the enterprise user stores are the names and the group membership properties.

## **Guidelines for Managing Accessors in Enterprise Stores**

If you decide to manage your accessors in enterprise user stores, consider the following guidelines.

### **Users and Groups That Must Be Defined in the Database**

Privileged Access Manager needs some users and groups to be defined in its database, rather than in the enterprise user stores. These include:

- Predefined users
- Predefined groups
- Privileged Access Manager administrator
- Profile groups
- Logical users

### **Restrictions on the Use of Enterprise Users**

Privileged Access Manager imposes the following restrictions on the use of enterprise users:

- You cannot create, or cannot refer to, an enterprise user in Privileged Access Manager if it has the same name as a user defined in the database.
- You cannot create, delete, or modify an enterprise user using the selang AC environment.
- You cannot use an enterprise user as a logical user.
- By default, you cannot create an enterprise user in Privileged Access Manager unless the user is already defined in the enterprise user store. However, you can enable or disable this behavior on UNIX systems.

## **Restrictions on the Use of Enterprise Groups**

Privileged Access Manager imposes the following restrictions on the use of enterprise groups:

- You cannot create or delete an enterprise group within the selang AC environment.
- You cannot change the membership of an enterprise group within the selang AC environment.
- You cannot use an enterprise group as a Profile Group.

## **Enable or Disable the Use of Enterprise Users and Groups**

By default, Privileged Access Manager does not use the groups and users who are defined in the enterprise user stores. We recommend that you enable this feature. Only if you need compatibility with previous versions of Privileged Access Manager, disable this feature by setting `osuser_enabled` to "no".

### **Example: Enable the Use of Enterprise Users and Groups on Windows**

The following registry setting enables the use of enterprise users and groups on Windows:

Key: HKLM\SOFTWARE\ComputerAssociates\AccessControl\OS\_user

Name: `osuser_enabled`

Type: REG\_DWORD

Value: yes

### **Example: Enable the Use of Enterprise Users and Groups on UNIX**

The following commands stop Privileged Access Manager, enable the use of enterprise users and groups on UNIX, and restart Privileged Access Manager:

```
secons -s

seini -s OS_User.osuser_enabled yes

seload
```

## **Enable or Disable the Creation of XUSER Records at Enterprise User Login**

If Privileged Access Manager is enabled to use enterprise users, by default it creates a record (in the XUSER class) for a user when that user logs in. Sometimes you do not want this, for example, if thousands of users log on at the same time each day.

To prevent Privileged Access Manager creating XUSER records when users log in, change the value of the configuration setting `create_user_in_db` to 0 (zero). To re-enable this behavior, set the value to 1 (one).

### **Example: Disable the Automatic Creation of XUSER Records on Enterprise User Login on Windows**

The following registry setting disables the automatic creation of an enterprise user record in Privileged Access Manager on Windows:

- Key: HKLM\Software\ComputerAssociates\AccessControl\OS\_user
- Name: `create_user_in_db`
- Type: REG\_DWORD
- Value: 0

### **Example: Disable the Automatic Creation of XUSER Records on Enterprise User Login on UNIX**

The following commands stop Privileged Access Manager, disable the automatic creation of a XUSER record on UNIX, and restart Privileged Access Manager:

```
secons -s

seini -s OS_User.create_user_in_db 0

seload
```

### **Enable or Disable Checking Enterprise Store Before Creating XUSER Records on UNIX**

Sometimes you may want to create an enterprise user in Privileged Access Manager when the user is not defined in the enterprise user store. On Windows, you cannot create an enterprise user in Privileged Access Manager unless the user exists in the Windows user store. On UNIX, the default behavior is the opposite to Windows. However, on UNIX, you can enable or disable this default behavior.

To disable checking (and therefore allow Privileged Access Manager to create XUSER records when there is no enterprise user equivalent), change the value of the configuration setting `verify_osuser` to 0. To enforce checking, set the value to 1.

#### **Example: Enable Creation of XUSER Records without Checking the Enterprise User Store**

The following set of commands stops Privileged Access Manager, enables the creation of XUSER records with no enterprise store equivalents, and restarts Privileged Access Manager:

```
secons -s

seini -s OS_User.verify_osuser 0

seload
```

### **Recycled Enterprise Store Accounts on Windows**

*Recycled accounts* are enterprise store users or groups that have been deleted and recreated. For example, a user resigns and you remove the user from the user store, and later you create another account with the same name.

Recycled accounts are a security concern because you do not want new accessors to have the same access permissions as the old account with the same name. To solve this problem, Privileged Access Manager authorization is based on the SID. When you create an accessor, it does not automatically receive the permissions of a deleted accessor with the same name.

#### **WARNING**

Recycled account accessors *do not* inherit the old access permissions. However, database access rules, which mention the accessor name (not SID), make it seem like these rules still apply. Use the `secons -checkSID` command to resolve this issue.

### **Resolve Recycled Enterprise Accounts on Windows**

If an enterprise account (user or group) with associated database rules is recycled (deleted and created with the same name), the old database rules appear to apply to the new account. However, as Privileged Access Manager authorization is based on SID, these rules no longer apply, and you must create rules for the new group. Before you can create the rules, you have to resolve recycled accounts.

**Follow these steps:**

1. Open a command prompt and run the following commands:

```
secons -checkSID -users
```

```
secons -checkSID -groups
```

Privileged Access Manager works through all the enterprise user accounts it has (XUSER records) and then all the group accounts (XGROUP records) and identifies accounts with an SID that differs from the SID of the enterprise account. It renames these accounts in Privileged Access Manager using the following naming convention: *SID (accountName)*

2. Create the rules for the recycled account.

**Note:** Recycled user accounts are resolved in this way when the user logs in or tries to access a resource. We recommend that you run the `secons -checkSID` command as a scheduled task when you create an enterprise account.

**Example: A Recycled Group Account**

Company ABCD has a group that is called *interns* in its enterprise store. The group has nine members and they are working on productA. The administrator makes the group that is known to Privileged Access Manager and assigns it with access permissions to the files group members must access, as follows:

```
nxg interns owner(msmith)
```

```
auth file c:\products\productA\materials\* xgid(interns) access(all)
```

```
auth file c:\HR\interns\* xgid(interns) access(read)
```

When the interns complete their tenure with ABCD, the enterprise store administrator deletes the group. Three months later, a new group of interns with six members is created in the enterprise store, with the same name. The old rules in the Privileged Access Manager database still exist so it seems like the new *interns* group inherited the permissions of the old group. However, these rules apply to the old interns group and the Privileged Access Manager administrator must create rules for the new group.

To do this, the administrator has to identify and resolve the recycled interns account, as follows:

```
secons -checkSID -groups interns
```

This renames the XGROUP resource, and any access rules references to it, to "*SID (domain\interns)*". Now, the administrator can create rules for the new interns group that works on productB:

```
nxg interns owner(msmith)
```

```
auth file c:\products\productB\materials\* xgid(interns) access(all)
```

```
auth file c:\HR\interns\* xgid(interns) access(read)
```

## Database Accessors

No matter how you manage your users, define some accessors in the product database, as described in the following sections.

### Predefined Users

Privileged Access Manager predefines the following users, which you cannot delete:

- **+devcalc**  
(Windows) The user name under which Privileged Access Manager runs the deviation calculation process, devcalc.
- **\_dms**  
Installed on the advanced policy management server components' databases (DMS, DH reader, and DH writer), the \_dms user is used by policyfetcher and devcalc to communicate with the DH and DMS.
- **nobody**  
The nobody user is a user record that cannot correspond to a real user. Use this record to create rules that do not give the associated permissions to any user. For example, you can set *nobody* as the owner of resources, meaning that no user gets the permissions associated with owning that record.
- **+reportagent**  
The user name under which Privileged Access Manager runs the Report Agent.
- **\_seagent**  
\_seagent is the user name under which Privileged Access Manager runs some internal processes, such as:
  - The PMDB process, sepmdd
  - (UNIX) The deviation calculation process, devcalc
  - The user and group record update exit processes
 The \_seagent user has the SERVER attribute.
- **\_sebuildla**  
(UNIX) The \_sebuildla user is the user name under which Privileged Access Manager runs the sebuildla utility to create a lookaside database for the Privileged Access Manager Control daemon, seosd.
- **\_seoswd**  
(UNIX) \_seoswd is the user name that is used to run the seoswd watchdog daemon to monitor the file information and digital signatures of programs that are defined in the database as trusted programs.
- **\_undefined**  
\_undefined represents all users that are undefined in Privileged Access Manager. You can use \_undefined to include undefined users in ACLs.

### Predefined Groups

Privileged Access Manager comes with predefined groups. Except for the \_interactive and \_network groups, you add users to these groups in the same way as you do for any other group.

- **\_abspath**  
If a user is in the \_abspath group when logging in, that user must use absolute path names to invoke programs.
- **\_interactive**  
A user is a member of the \_interactive group only for the purposes of an access attempt. Users are members of the \_interactive group if they are logged into the same host as the resource they are trying to access. Privileged Access Manager dynamically and automatically manages the membership of the \_interactive group; you cannot change the membership.
- **interactive\_restricted**  
The users in the interactive\_restricted group need strong authentication before they can modify files. Users in the Interactive\_restricted group can read files and can execute commands. They cannot modify any files except for a

predefined list of non-files that they are authorized to modify. A message reminds users to run the sepromote utility to authenticate when they must remove the restriction.

- **\_network**

This is the complementary group to \_interactive. A user is a member of the \_network group for the purposes of access only. Users are members of the \_network group if they are trying to access a resource from a different host than the resource belongs to. Privileged Access Manager dynamically and automatically manages the membership of the \_network group; you cannot change the membership.

- **\_restricted**

For users in the \_restricted group, all files, and on Windows registry keys too, are protected by Privileged Access Manager. If a file or a Windows registry key does not have an access rule that is explicitly defined, access permissions are covered by the \_default record for that class (FILE or REGKEY).

**Note:** Users in the \_restricted group may not have sufficient authorization to do their work. If you plan to add users to the \_restricted group, consider using Warning mode initially.

- **\_surrogate**

When a user uses a member of the \_surrogate group as a surrogate, Privileged Access Manager writes a full trace in the audit trail of the surrogate's actions, tagged with the original user's name.

### Example: Adding a User to the \_restricted Group Using selang

The following selang command adds the enterprise user john\_smith to the \_restricted group:

```
joinx john_smith group(_restricted)
```

## Profile Groups

A *profile group* is a group that is defined in the product database that contains default values for user properties. When you assign a user to a profile group, the profile group provides those values to the user unless they have already been set for the user.

You can specify a profile group for a user when you create the user, or you can assign the user to the profile group afterwards.

Profile groups let administrators efficiently create a standard setup with specific permissions for any new user who is assigned to that group. This setup can specify such things as the home directory of the user, the audit properties, the PMDB that defines the access authorities, and various password rules affecting a user who is associated with a profile group.

### How the Product Uses Profile Groups to Determine User Properties

The following process describes how the product uses profile groups to determine user properties:

1. The product checks if the user's record in the USER or XUSER class has a value for the property. If the user's record has a value for the property, then the product uses that value.
2. The product checks if the user is assigned to a profile group. If the user is assigned to a profile group, the process continues. If the user is not assigned to a profile group, then the product assigns the default property value to the user.
3. The product checks if the profile group has a value for that property. If the profile group has a value for the property, The product assigns that value to the user. If the profile group does not have a value for the property, The product assigns the default property value to the user.

**Note:** If the audit property of a user or profile group is not set, the audit property of a group can affect the audit property of a user.

## Accessor Management

You can create, modify, and delete database or enterprise user or group records by using Privileged Access Manager Endpoint Management or by using selang.

## Manage Users or Groups

If you want to view or modify the properties of a particular accessor, or if you want to delete an accessor, you must first find that accessor.

### To manage users or groups

1. In Privileged Access Manager Endpoint Management, do as follows:
  - a. Click Users.
  - b. Click either the Users or Groups subtab.
 Depending on your selection, the Users or the Groups page appears.
2. Complete the following fields in the Search section:
  - **User/Group Name**  
Defines a mask for the accessors you want to find. You can enter the full name of the accessor you are after or you can use a mask. For example, use \*admin\* to list accessors whose name contains "admin". Use an \* (asterisk) to list all accessors and a ? (question mark) to replace a single character.
  - **User/Group Repository**  
Specifies the source from which you want to fetch a list of accessors. The source can be either:
    - a. **Internal Accounts** - accessors that are defined in the database
    - b. **Enterprise Accounts** - accessors that are defined in specific enterprise user stores
  - **Show only AC accounts/profiles**  
Specifies whether to list only those accounts that have records in the Privileged Access Manager database as follows:
    - a. If you chose Internal Accounts, the application lists only those accounts that exist in the database (no native accounts).
    - b. If you chose Enterprise Accounts, the application lists only those accounts that have a Privileged Access Manager enterprise profile (XUSER or XGROUP records).
3. Click Go.  
A list of accessors that exist in the repository you chose appears.
4. Do *one* of the following:
  - Click  in the View column to view the properties of the accessor.
  - Click  in the Delete column to delete the accessor.
  - Click the name of the accessor to modify the properties of the accessor.
  - Select the accessors that you want to delete and click Delete.
  - Click Create User or Create Group to create a user or group record in the product database.

### Example: Search for Enterprise Users in a Repository

The following graphic shows you the result of looking for all users in the ABC-DM1 enterprise user store.

**Search** **Create User**

**Required**

**User Name:**  For multiple entities please use the wildcard \*

**User:**  **Go**

**Repository:**

**Options:** ☐ Show only AC accounts/profiles

**User Environment**

- With AC Profile

- Without AC Profile

---

**Users list for: COMP001** **Create User**

Here are the results for XUSER with name: \* at 08/07/09 00:22

## User Management Using Selang

Use the following selang commands for records of enterprise users:

- **newxusr** and **editxusr** - define a new enterprise user record
- **chxusr** and **editxusr** - change the properties of an enterprise user
- **find xuser** - list enterprise users that have a Privileged Access Manager record
- **rmxusr** - delete a user
- **show xuser** - display the properties of an enterprise user

Use the following selang commands for Privileged Access Manager database user records:

- **newusr** and **editusr** - define a new user record
- **chusr** and **editusr** - change the properties of a user
- **rmusr** - delete a user
- **find user** - list database users
- **show user** - display the properties of a user

### Example: Define a User in the Database Using selang

The following selang command defines a new user in the Privileged Access Manager database with security level 100:

```
newusr internalUser level(100)
```

### Example: Change a Property of an Enterprise User Using selang

The following selang command gives the AUDITOR property to an enterprise user Terry:

```
chxusr Terry auditor
```

## Group Management Using selang

You can change any property of any group, except that you cannot change the name or the membership of enterprise groups (from within Privileged Access Manager).

To change group properties or to assign access rights associated with groups, you can use Privileged Access Manager Endpoint Management Console or the following `selang` commands:

- **join[-]** and **joinx[-]**  
Change the membership of an internal group  
Use `join` to add internal accessors to the group. Use `joinx` to add enterprise groups and users to an internal group. Use the `-` (minus) form of the commands to remove accessors.
- **editgrp**, **newgrp**, **chgrp**  
Change the non-membership properties of an internal group
- **editxgrp**, **newxgrp**, **chxgrp**  
Change the non-membership properties of an enterprise group
- **rmgrp**, **rmxgrp**  
Remove a user group

#### Example: Define a Group in the Database Using `selang`

The following `selang` command defines a new group `sales` in the database. The full name of the group is `Sales Department`:

```
newgrp sales name('Sales Department')
```

#### Example: Change a Property of a Group Defined in the Database Using `selang`

The following `selang` command makes Privileged Access Manager audit all events for members of the group `AC_admins`:

```
chgrp AC_admins audit(all)
```

#### Example: Add an Enterprise Group to an ACL Using `selang`

The following `selang` command adds the enterprise group `mygroup` to the ACL of the `myfile`:

```
Authorize FILE (myfile) xgid(mygroup)
```

#### Example: Add an Enterprise User to a Group Defined in the Database Using `selang`

The following `selang` command adds the enterprise user `mydomain\administrator` to the group `AC_admins` which is defined in the database:

```
joinx mydomain\administrator group(AC_admins)
```

#### Example: Add an Enterprise Group to a Group Defined in the Database Using `selang`

The following `selang` command adds the enterprise group `Guests` to the `_restricted` group:

```
joinx Guests group(_restricted)
```

## Classes

In Privileged Access Manager, the *class* of a record defines the properties that the record can have. All records in a class have the same properties, though different values for these properties.

Examples of classes are:

- **TERMINAL** class - This class contains records for terminals, such as `tty1`, `tty`.
- **FILE** class - This class contains records for files.
- **PROGRAM** class - This class contains records of programs.

Each record contains values for the properties appropriate to the record class. For example, a record in the `XUSER` class includes such properties as the location and working hours of the enterprise user. A record in the `HOSTNET` class includes such properties as net services and IP address data.

Privileged Access Manager includes predefined classes. You can also define new classes, named user-defined classes. This article describes a default record for class and new user-defined classes.

### Default Record for Class

Most classes can include a default record (`_default`) specifying access types for resources of that class that are not defined in database records of their own.

Like other resource records, the `_default` record can include an ACL and a `defaccess` field. You can create a `_default` record for all classes except `USER`, `GROUP`, `CATEGORY`, `SECLABEL`, and `SEOS`.

### UACC Class (Deprecated)

The UACC class is no longer recommended. To specify the default values for records in a class, use the `_default` record.

Some earlier versions of Privileged Access Manager used a separate class, called UACC, for records resembling the `_default` records of other classes. The UACC class is no longer recommended, and if you use a `_default` record, the equivalent record in the UACC class is not checked. In future versions, the UACC class may no longer be supported.

For example, suppose user Henderson tries to kill process `store_log`. Privileged Access Manager checks for authorization in the following order. The primary question is this: Is the process `store_log` defined in the database? Privileged Access Manager searches the database for a record that is named `store_log` in the `PROCESS` class.

- If no such record can be found, the process is not defined to Privileged Access Manager. In that case, the product uses either the `_default` record of class `PROCESS`, or the `PROCESS` record in the UACC class, to determine whether Henderson is allowed to kill `store_log`.
  - If user Henderson appears in the `_default` record's ACL, the authority specified in it is applied.
  - If Henderson does *not* appear in the `_default` record's ACL, the authority specified in the `defaccess` property of the `_default` record is applied. This authority is applied to all users who do not appear explicitly in the `_default` ACL.
- If process `store_log` is defined in the database, then the question is whether user Henderson appears in the ACL for process `store_log` in the database.
  - If user Henderson appears in the ACL for process `store_log`, the authority specified there is applied.
  - If Henderson does *not* appear in the ACL, Privileged Access Manager applies the authority specified in the default access property of the `store_log` resource. This authority is called the resource's default access.

**Note:** If the default access (`defaccess`) of `_default` is set to `NONE`, or if `_default` is not specified and the default of the corresponding resource in the UACC class is `NONE`, then any accessor attempting to access a resource not defined in the class is denied access to the resource.

**Note:** If the default access of `_default` (or UACC) is set to the highest authority (`ALL`, or in some cases `READ` or `EXECUTE`), then any resource that is not explicitly protected is accessible to everyone.

### Predefined Classes

The predefined classes can be categorized into the following types:

| Class Type   | Purpose                                                                                |
|--------------|----------------------------------------------------------------------------------------|
| Accessor     | Defines objects that access resources, such as users and groups.                       |
| Definition   | Defines objects that define security entities, such as security labels and categories. |
| Installation | Defines objects that control the behavior of Privileged Access Manager.                |
| Resource     | Defines objects that are protected by access rules.                                    |

The following table contains a list of all predefined classes.

| Class      | Class Type | Description                                                                                                                                                                                                                                  |
|------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADMIN      | Definition | Lets you delegate administrative responsibilities to users who do not have the ADMIN attribute. You give these users global authorization attributes and limit their administration authority scope.                                         |
| AGENT      | Resource   | Not applicable                                                                                                                                                                                                                               |
| AGENT_TYPE | Resource   | Not applicable                                                                                                                                                                                                                               |
| APPL       | Resource   | Not applicable                                                                                                                                                                                                                               |
| AUTHHOST   | Accessor   | Not applicable                                                                                                                                                                                                                               |
| CATEGORY   | Definition | Lets you define a security category.                                                                                                                                                                                                         |
| CONNECT    | Resource   | Lets you protect outgoing connections. The records in this class define which users can access which Internet hosts.<br><br>Before you activate the CONNECT class, be sure that the streams module is active.                                |
| CONTAINER  | Resource   | Lets you define a group of objects from other resource classes, thus simplifying the job of defining access rules when a rule applies to several different classes of objects.                                                               |
| FILE       | Resource   | Lets you protect a file, a directory, or a file name mask.                                                                                                                                                                                   |
| GAPPL      | Resource   | Not applicable                                                                                                                                                                                                                               |
| GAUTHHOST  | Definition | Not applicable                                                                                                                                                                                                                               |
| GFILE      | Resource   | Each record in this class defines a group of files or directories. Grouping is accomplished by explicitly connecting files or directories (resources of the FILE class) to the GFILE resource in the same way users are connected to groups. |
| GHOST      | Resource   | Each record in this class defines a group of hosts. Grouping is accomplished by explicitly connecting hosts (resources of the HOST class) to the GHOST resource in the same way users are connected to groups.                               |
| GROUP      | Accessor   | Each record in this class defines an internal group.                                                                                                                                                                                         |
| GSUDO      | Resource   | Each record in this class defines a group of commands that one user can execute as if another user were executing it. The sesudo command uses this class.                                                                                    |
| GTERMINAL  | Resource   | Each record in this class defines a group of terminals.                                                                                                                                                                                      |

|               |            |                                                                                                                                                                                                                                                                                                          |
|---------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HNODE         | Definition | The HNODE class contains information about the organization's Privileged Access Manager hosts. Each record in the class represents a node in the enterprise.                                                                                                                                             |
| HOLIDAY       | Definition | Each record in this class defines one or more periods when users need extra permission to log in.                                                                                                                                                                                                        |
| HOST          | Resource   | Each record in this class defines a host. The host is identified by either its name or its IP address. The object contains access rules that determine whether the local host can receive services from this host.<br><br>Before you activate the HOST class, be sure that the streams module is active. |
| HOSTNET       | Resource   | Each record in this class is identified by an IP address mask and contains access rules.                                                                                                                                                                                                                 |
| HOSTNP        | Resource   | Each record in this class defines a group of hosts, where the hosts belonging to the group all have the same name pattern. Each HOSTNP object's name contains a wildcard.                                                                                                                                |
| LOGINAPPL     | Definition | Each record in the LOGINAPPL class defines a login application, identifies who can use the program to log in, and controls the way the login program is used.                                                                                                                                            |
| MFTERMINAL    | Definition | Each record in the MFTERMINAL class defines a Mainframe Privileged Access Manager administration computer.                                                                                                                                                                                               |
| POLICY        | Resource   | Each record in the POLICY class defines the information required to deploy and remove a policy. It includes a link to the RULESET objects that contain a list of the selang commands for deploying and removing the policy.                                                                              |
| PROCESS       | Resource   | Each record in this class defines an executable file.                                                                                                                                                                                                                                                    |
| PROGRAM       | Resource   | Each record in this class defines a trusted program that can be used with conditional access rules. Trusted programs are setuid/setgid programs that are monitored by the Watchdog to ensure they are not tampered with.                                                                                 |
| PWPOLICY      | Definition | Each record in the PWPOLICY class defines a password policy.                                                                                                                                                                                                                                             |
| RESOURCE_DESC | Definition | Not applicable                                                                                                                                                                                                                                                                                           |
| RESPONSE_TAB  | Definition | Not applicable                                                                                                                                                                                                                                                                                           |

|            |              |                                                                                                                                                                                                                                                                                                                                                              |
|------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RULESET    | Resource     | Each record in the RULESET class represents a set of rules which defines a policy.                                                                                                                                                                                                                                                                           |
| SECFILE    | Definition   | Each record in this class defines a file that must not be altered.                                                                                                                                                                                                                                                                                           |
| SECLABEL   | Definition   | Each record in this class defines a security label.                                                                                                                                                                                                                                                                                                          |
| SEOS       | Installation | The one record in this class specifies your active classes and password rules.                                                                                                                                                                                                                                                                               |
| SPECIALPGM | Installation | Each record in the SPECIALPGM class registers backup, DCM, PBF and PBN functions in Windows or xdm, backup, mail, DCM, PBF, and PBN programs in UNIX or associates an application that needs special authorization protection with a logical user ID. This allows you to set access permissions according to what is being done rather than who is doing it. |
| SUDO       | Resource     | This class, used by the sesudo command, defines commands that one user (such as a regular user) can execute as if another user (such as root) were executing them.                                                                                                                                                                                           |
| SURROGATE  | Resource     | Each record in this class contains access rules for an accessor that define who can use that accessor as a surrogate.                                                                                                                                                                                                                                        |
| TCP        | Resource     | Each record in this class defines a TCP/IP service, for example, mail or http or ftp.                                                                                                                                                                                                                                                                        |
| TERMINAL   | Resource     | Each record in this class defines a terminal-a device from which a user can log in.                                                                                                                                                                                                                                                                          |
| UACC       | Resource     | Defines default access rules for each resource class.                                                                                                                                                                                                                                                                                                        |
| USER       | Accessor     | Each record in this class defines an internal user.                                                                                                                                                                                                                                                                                                          |
| USER_ATTR  | Definition   | Not applicable                                                                                                                                                                                                                                                                                                                                               |
| USER_DIR   | Resource     | Not applicable                                                                                                                                                                                                                                                                                                                                               |
| XGROUP     | Accessor     | Each record in this class defines an enterprise group to Privileged Access Manager.                                                                                                                                                                                                                                                                          |
| XUSER      | Accessor     | Each record in this class defines an enterprise user to Privileged Access Manager.                                                                                                                                                                                                                                                                           |

**Note:** Privileged Access Manager database classes TCP and SURROGATE are not active by default.

If you upgrade from an earlier release where the TCP class is active but you do not have any TCP records and have not changed the \_default TCP resource, Privileged Access Manager deactivates the class during upgrade. The same is true for the SURROGATE class.

**Note:** If you upgrade from an earlier release where the SURROGATE class is active and you have defined SURROGATE records or have changed the value of any SURROGATE record from its default, Privileged Access Manager retains the SURROGATE class configuration after the upgrade. The class remains active and kernel mode interception remains enabled.

**Note:** For more information about Privileged Access Manager classes, see the *selang Reference section*.

## **User-Defined Classes**

Privileged Access Manager enables you to define new classes, so that you can protect abstract objects by creating appropriate records for them.

### **Example: User-Defined Class for a Database View**

A site may use a database to store and display proprietary data.

You can define a user-defined class DATABASE\_VIEWS, and can define each database view to be a resource member of that class. Give the resource an ACL that defines the access authority that is required to create that database view. When a user attempts to create a database view, Privileged Access Manager checks the access authority of the user, and permits or disallows the creation based on the ACL.

### **Wildcards in User-Defined Classes Resources**

By using wildcards in the name of a resource in a user-defined class, you can create a resource record that corresponds to multiple physical resources: any physical resource with a name that matches the wildcard pattern is protected by the access authorities associated with the resource record.

Following are the wildcards that you can use:

- \* for any number of any characters
- ? for any one character

If a physical resource name matches more than one resource record name, the longest non-wildcard match is used for that resource.

Privileged Access Manager does *not* accept the following wildcard patterns as resource names:

- \*
- /\*
- /tmp/\*
- /etc/\*

### **User-Defined Class Example**

Suppose that your system serves a bank and you want to protect transfers of large amounts between accounts. You can use the following outline to set up this security.

1. Define a class to contain the records that describe transfers, named, for example, TRANSFERS.
2. For each monetary level transfer that you want to protect, define a record in the TRANSFERS class.  
For example, you might define records that are named Upto.\$1K, Upto.\$1M, Upto.\$10M, and Over.\$10M.  
Define any other resources to control transfers as members of the TRANSFERS class.
3. To give different users permission to perform different maximum transfers, grant or deny them access to the various records in the TRANSFERS class.
4. In addition, to handle programmatic transfers, insert in the bank's money-transfer program a call to the Privileged Access Manager API. This call checks the permission of the user before it allows a transfer to proceed.

## Windows Services Protection

### NOTE

The rules that are created using the selang CLI are not displayed properly in the Endpoint Management UI. The display name is shown incorrectly in the UI. You can edit the display name to the correct service name. Do not use the Endpoint Management UI to browse for the services, since the UI shows the display name of the service instead of the service name. If you want to use the UI to create the rule, ensure that you specify the correct name for the service.

Privileged Access Manager lets you protect Windows services. A *Windows service* is a program that runs in the background on Windows. A Windows Service is the Windows equivalent to a daemon on UNIX.

The Privileged Access Manager Windows service protection intercepts service access events that originate from one of the following sources:

- Service management and information events  
Privileged Access Manager intercepts the services.exe process for each service access. This includes starting or stopping a service. For example, net start *service* and net stop *service* are protected. Intercepted events in this case are audited using the name of the protected service.
- Service database management events  
Privileged Access Manager intercepts registry calls to the service control management database to protect against service state queries or changes. This means that the product automatically protects the registry areas that are associated with the protected service. Effectively, Privileged Access Manager protects the following registry keys when you define service protection:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\service_name
```

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\service_name
```

Intercepted events in this case are audited using the full registry path.

You protect a Windows service in the same way as you protect other resources. You assign a resource to the service and add accessors to the access control lists of the resource. The resource class for a Windows service is WINSERVICE. A WINSERVICE resource has two access control lists: an ACL and an NACL. Valid access types for an entry in a WINSERVICE access control list are:

- Read
- Modify
- Start
- Stop
- Pause
- Resume

### WARNING

Windows 2012, Windows 2012 R2, and Windows 2016 do not support the GID and UID attributes that are associated with logical groups and users, respectively. So, these attributes that were supported in Windows 2008 R2 and earlier are no longer supported from this release.

This article contains the following sections:

### Review Considerations

Consider the following points if the endpoint operating system is Windows 2012, Windows 2012 R2, or Windows 2016:

- The rules that are created to protect the Windows services do not apply to the critical services such as eventlog and dnscient.
- Rules that are created for third-party services work only if those services are not controlled by any security product/suite other than Privileged Access Manager. Else, conflict between Privileged Access Manager and other security product/suite can result in an undefined behavior of Privileged Access Manager. To avoid this issue, ensure that no other security suite products are installed on the host that has Privileged Access Manager installed.
- To modify the startup type of a non-critical Windows service, the rule must contain both the Start and Modify permissions. However, the sc utility lets you update the startup type of a service even if the rule is created with only the Modify permission. By default, the sc utility provides the Start permission.
- A rule that is created for a service can include auditing. In such cases, when you run the seaudit utility, the audit results are displayed with a delay of few seconds as all the Windows event logs must be scanned. Wait until the results are displayed before you rerun the utility.
- If a service has an active rule, do not delete the Windows event logs that are available under Security. If you want to delete the Security-related Windows event logs, delete the rule and then delete those event logs.
- Rules can be applied only to those users who are part of the administrators group.

### **Enable and Disable Windows Services Protection**

You can enable or disable the Privileged Access Manager protection of Windows services.

To enable protection of Windows services, set the configuration setting OperationMode in the Instrumentation\PlugIns\WinServiceplg section of the Privileged Access Manager registry to 1. To disable protection, set OperationMode to 0.

By default, Privileged Access Manager enables protection of Windows services.

For Privileged Access Manager to protect a Windows service, enable protection and ensure that the WINSERVICE class is active.

### **Protect a Windows Service**

You can protect a Windows Service and so provide extra protection to Windows operations.

#### **Follow these steps:**

1. Ensure that you have [enabled Windows services protection](#).
2. Ensure that the WINSERVICE class is active. (It is active by default.)
3. Create a WINSERVICE record in Privileged Access Manager, with the same name as the Windows service you want to protect.

**Note:** The Windows service name is shown on the General tab of the Windows service properties dialog. However, the Windows service name is not the same as the "display name" on that tab.

4. Assign the accessors and their access authorization to the service.  
The service is now protected.

### **Example: Restrict Access to the Print Spooler**

On Windows, the print spooler has the service name spooler. The following selang commands ensure that the WINSERVICE class is active and sets the default access to the spooler to *read*.

```
setoptions class+(WINSERVICE)

editres WINSERVICE(spooler) defacc(R)
```

### **Example: Authorize users of a group to access the Spooler service**

You can create a group and provide access to a Windows service to the members of that group.

**Follow these steps:**

1. Create a native user using the following command:  

```
nu <hostname>\testuser password(XXX) nt
```
2. Create a logical group without an owner using the following command:  

```
ng <hostname>\xgroup owner(nobody) nt
```
3. Associate the group that was created with the database using the following command:  

```
nxg <hostname>\xgroup
```
4. Associate the user with the group using the following command:  

```
join <hostname>\testuser group(<hostname>\testgroup) nt
```
5. Enable the Spooler service with default access set to no user using the following command:  

```
er winservice spooler owner(nobody) defacc(n)
```
6. Authorize the group's users to access the Spooler service, using the following command:  

```
auth winservice spooler XGID(<hostname>\xgroup) access(start,stop,r)
```

**Non-IPv4 Telnet Connections Are Not Secured on Windows Server 2008**

On Windows Server 2008, Privileged Access Manager cannot secure a telnet connection unless it uses IPv4.

To protect a localhost telnet connection from the localhost to the localhost on Windows Server 2008, modify the /etc/HOSTS file as follows:

```
127.0.0.1      localhost

#           ::1          localhost

127.0.0.1##    <your server name without domain suffix>
```

If your computer is on an IPv6 domain, add the following line:

```
127.0.0.1    <your server name with domain suffix>
```

**View Access Attempts to a Protected Windows Service**

When Privileged Access Manager protects a Windows service, it intercepts, and records in the audit log, access attempts that are related to the service. These access attempts can be a result of using the services.exe process to manage the service (start, stop, and so on). They can also be the result of registry access to the service database management area of the protected service. While the former access is audit contains only the service name, the latter (registry access) contains the full registry path. To view all access attempts related to a Windows service, use wildcards.

To view access attempts to a protected Windows service, create an audit filter that filters audit records of class WINSERVICE and resource name *\*myService\**

Privileged Access Manager displays all audit records for the WINSERVICE resource you defined (whether access was attempted through the registry or through a service management interface).

**WARNING**

Seaudit log entries for WinService class interception are created in the Japanese and Korean environments only if the audit parameter is explicitly specified in the rule.

**Example: View All Access Attempts to the Print Spooler Service**

This example assumes that you defined the Print Spooler service to Privileged Access Manager with no access as follows:

```
er winservice spooler defaccess(none) owner(nobody) audit(all)
```

where audit can have the following values:

- **All**  
Displays all logs including success and failure attempts
- **None**  
No logs are displayed
- **S**  
Displays only the successful attempts
- **F**  
Displays only the failure attempts

You can then use the seaudit utility to list all access attempts to the Print Spooler service as follows:

```
seaudit -resource WINSERVICE *spooler* *
```

This command lists all audit records for the class WINSERVICE that were recorded for access attempts to the Print Spooler service. The resulting output can look as follows:

```
seaudit - Audit log lister
03 Apr YYYY 16:53:48 D WINSERVICE    bigHost1\Administrator Read      69  2 Spooler
    c:\WINDOWS\system32\services.exe bigHost1.comp.com
03 Apr YYYY 16:53:48 D WINSERVICE    bigHost1\Administrator Read      69  2 Spooler
    c:\WINDOWS\system32\services.exe bigHost1.comp.com
03 Apr YYYY 16:53:50 D WINSERVICE    bigHost1\Administrator Read      69  2 Spooler
    c:\WINDOWS\system32\services.exe bigHost1.comp.com
03 Apr YYYY 16:53:50 D WINSERVICE    bigHost1\Administrator Read      69  2 Spooler
    c:\WINDOWS\system32\services.exe bigHost1.comp.com

    C:\WINDOWS\regedit.exe bigHost1.comp.com
03 Apr YYYY 16:54:26 D WINSERVICE    bigHost1\Administrator Modify    69  2 HKEY_LOCAL_MACHINE\SYSTEM
\CurrentControlSet\Services\Spooler
    C:\WINDOWS\regedit.exe bigHost1.comp.com
```

Total records displayed 11

## Windows Registry Protection

Privileged Access Manager lets you protect entries in the Windows registry.

You provide protection to a registry key by assigning a resource of class REGKEY to the key. You can then specify access authorities on the key, as with other resources.

Specifying access rights on a key does not affect access to subkeys of the key, except for enumeration (listing) of subkeys. Enumeration of subkeys requires read access to the key.

Privileged Access Manager only supports the REGVAL resource in the AC environment on Windows Server 2003 and subsequent Windows systems. On these systems, Privileged Access Manager protects registry values with the REGVAL class. The REGKEY access authorization does not affect access to the values of the key.

On earlier systems, Privileged Access Manager does not support the REGVAL resource in the AC environment. The access authorization that is applied on a REGKEY record does affect access to the values of the key.

REGKEY and REGVAL records have identical structures. Each record contains the following access control lists:

- ACL
- CALACL
- NACL
- PACL

REGVAL and REGKEY records both allow the same access types, which are as follows:

- READ
- WRITE
- DELETE
- NONE

### NOTE

Privileged Access Manager registry protection does not protect the registry operations of loading and unloading a hive. On Windows Server 2008 and subsequent systems, Privileged Access Manager returns a value of REG\_NONE if an accessor tries to access a protected registry value with access NONE. A value of REG\_NONE confirms that a value is present but does not specify the value.

## Protect a Windows Registry Entry

You can protect a Windows registry entry, and so provide extra protection to Windows operations.

### To protect a Windows registry entry:

1. If you want to use the REGKEY and REGVAL class records, ensure that these classes are active. (They are active by default.)
2. Create a REGKEY or a REGVAL record with the name of the registry key or value you want to protect.

### NOTE

Use the full registry path name to specify the key or value. You can use a wildcard to specify all subkeys or subkey values that are nested under a key.

The registry entry is now protected with the default access that Privileged Access Manager provides for the record.

3. (Optional) Assign the users and groups, with their access authorization, to the appropriate access control list in the REGKEY or REGVAL record.

### Example: Provide default access of NONE to a Registry Key

The following selang command provides default access of NONE to a registry key:

```
er REGKEY HKEY_LOCAL_MACHINE\SOFTWARE\Test\Key1 defacc(NONE) owner(nobody)
```

As a result, the default access to key1 is as follows:

| Action                                   | Systems earlier than Windows Server 2003 | Windows Server 2003 systems and later | Windows Server 2008 systems and later |
|------------------------------------------|------------------------------------------|---------------------------------------|---------------------------------------|
| Enumerate subkeys                        | Deny                                     | Deny                                  | Deny                                  |
| Query, modify, rename, or delete key     | Deny                                     | Deny                                  | Deny                                  |
| Load or unload hive to key               | Deny                                     | Deny                                  | Deny                                  |
| Enumerate values                         | Deny                                     | Deny                                  | Permit                                |
| Read, create, rename, or delete values   | Deny                                     | Permit                                | Permit                                |
| Enumerate subkeys of subkeys             | Deny                                     | Permit                                | Permit                                |
| Create subkeys                           | Permit                                   | Permit                                | Permit                                |
| Query, modify, rename, or delete subkeys | Permit                                   | Permit                                | Permit                                |
| Load or unload hive to subkeys           | Permit                                   | Permit                                | Permit                                |

#### Example: Provide default access of READ to a Registry Key

The following selang command provides default READ access to a registry key:

```
er REGKEY HKEY_LOCAL_MACHINE\SOFTWARE\Test\Key1 defacc(READ) owner(nobody)
```

As a result, the default access to Key 1 is as follows:

| Action                                   | Systems earlier than Windows Server 2003 | Windows Server 2003 and later | Windows Server 2008 and later |
|------------------------------------------|------------------------------------------|-------------------------------|-------------------------------|
| Enumerate subkeys                        | Permit                                   | Permit                        | Permit                        |
| Read key                                 | Permit                                   | Permit                        | Permit                        |
| Modify, rename, or delete key            | Deny                                     | Deny                          | Deny                          |
| Load or unload hive to key               | Deny                                     | Deny                          | Deny                          |
| Enumerate values                         | Permit                                   | Permit                        | Permit                        |
| Read values                              | Permit                                   | Permit                        | Permit                        |
| Create, rename, or delete values         | Deny                                     | Permit                        | Permit                        |
| Enumerate subkeys of subkeys             | Permit                                   | Permit                        | Permit                        |
| Create subkeys                           | Permit                                   | Permit                        | Permit                        |
| Query, modify, rename, or delete subkeys | Permit                                   | Permit                        | Permit                        |
| Load or unload hive to subkeys           | Permit                                   | Permit                        | Permit                        |
| Enumerate subkey values                  | Permit                                   | Permit                        | Permit                        |
| Create subkey values                     | Permit                                   | Permit                        | Permit                        |

#### Example: Provide default access of NONE to a Registry Key Wildcard

The following selang command provides default access of NONE to all subkeys in a registry key:

```
er REGKEY HKEY_LOCAL_MACHINE\SOFTWARE\Test\Key1\* defacc(NONE) owner(nobody)
```

The wildcard (\*) does not apply to Key1, but to all subkeys of Key1. This rule means that any form of access is denied to all subkeys of Key1. Access is also denied to rename or delete Key1, due to the parent protection rule.

This command permits access to the values of Key1. The access to values of subkeys of Key1 (for example, values of Key1\subkey1\ ) varies between different Windows systems:

- On Windows Server 2003 and subsequent systems, this command denies access to enumerate the values of any subkey of key1. However, the command grants access to create, rename, delete, and read the values.
- On systems earlier than Windows Server 2003, this command denies all access to the values of subkeys of Key1.

### Example: Provide default access of NONE to a Registry Value

The following selang command protects a specific registry value with access NONE on Windows Server 2003 and subsequent systems:

```
er REGVAL HKEY_LOCAL_MACHINE\SOFTWARE\TestKey\value1 defacc(NONE) owner(nobody)
```

#### NOTE

On Windows Server 2008 and subsequent systems, Privileged Access Manager returns a value of REG\_NONE if an accessor tries to access a protected registry value with access NONE. A value of REG\_NONE confirms that a value is present but does not specify the value.

## Protect File Streams

A stream is a sequence of bytes. File streams contain file data, and provide additional information about a file. For example, you can create a stream that contains keywords or metadata.

#### NOTE

File streams are only available on the NTFS file system. For more information on file streams, see the Microsoft Developer Network (MSDN) Library website.

When you create a FILE rule, Privileged Access Manager automatically protects the default data stream for the file. For example, a rule that protects the file c:\foo.txt also governs permissions to c:\foo.txt::\$DATA. However, Privileged Access Manager does not automatically protect any non-default data streams. Create extra file protection rules for these data streams.

To protect file streams, do either *one* of the following procedures:

- To protect a specific stream, create a file rule in the format:  
drive:\path\filename.ext:stream
- To protect a specific stream type of a particular stream, create a file rule in the format:  
drive:\path\filename.ext:stream:type
- To protect all streams, create a generic file rule in the format:  
drive:\path\filename.ext:\*

### Example: Protect All File Streams

The following selang command creates a generic file rule that protects all the streams in the file c:\foo.txt:

```
er file c:\foo.txt:* owner(nobody) defaccess(none)
```

### Example: Protect a Specific Stream

The following selang command creates a file rule that protects the stream *mystream* in the file c:\foo.txt:

```
er file c:\foo.txt:mystream owner(nobody) defaccess(none)
```

## Internal File Protection (Windows)

During installation, Privileged Access Manager writes rules to protect two types of internal files:

- Internal rules: Protect configuration files, log files, and database files.  
You cannot delete internal rules.
- Default rules: Protect sensitive files such as root and server certificates that you use to encrypt and authenticate communication.  
You can delete default rules after installation.

### Internal File Rules

Internal file rules protect configuration files, log files, and database files. Internal file rules are not visible in selang and cannot be deleted. However, you can write FILE rules to override the internal file rules. If you delete these FILE rules, Privileged Access Manager reverts to the internal file rules.

Except for database files, files that the product protects with internal file rules have the following access rights:

- Full access for Privileged Access Manager internal processes
- Read and execute (where relevant) access for all other accessors

Database files that the product protects with internal file rules have the following access rights:

- Privileged Access Manager internal processes have full access to the database.
- The NT AUTHORITY\System user has read access to the database.
- All other accessors have no access to the database.

#### NOTE

The default access rights for all other accessors were changed in r12.5 SP3. In previous releases, all other accessors had read access by default to the database files.

Privileged Access Manager protects the following files with internal file rules. The second column of the table lists the registry subkey and entry that specifies the file location, where applicable. Privileged Access Manager creates its registry entries under the following registry key:

HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl

#### NOTE

Some file locations are defined internally and do not have a corresponding registry entry. You cannot configure the location of these files.

| File                 | Registry Subkey and Entry | Default File Location                      |
|----------------------|---------------------------|--------------------------------------------|
| seosdrv.sys          | -                         | %SystemRoot%\system32\drivers\seosdrv.sys  |
| cainstrm.sys         | -                         | %SystemRoot%\system32\drivers\cainstrm.sys |
| drveng.sys           | -                         | %SystemRoot%\system32\drivers\drveng.sys   |
| pwdchange.dll        | -                         | %SystemRoot%\system32\pwdchange.dll        |
| SUSRAUTH.dll         | -                         | %SystemRoot%\system32\SUSRAUTH.dll         |
| eACSubAuth.dll       | -                         | %SystemRoot%\system32\eACSubAuth.dll       |
| eACPasswordFiltr.dll | -                         | %SystemRoot%\system32\eACPasswordFiltr.dll |
| All database files   | SeOSD\dbdir               | ACInstallDir\Data\seosdb                   |

|                   |                            |                        |
|-------------------|----------------------------|------------------------|
| All help files    | lang\help_path             | ACInstallDir\Data\help |
| All binaries      | -                          | ACInstallDir\bin       |
| seosd.trace       | SeOSD\trace_file           | ACInstallDir\log       |
| seos.audit        | logmgr\audit_log           | ACInstallDir\log       |
| seos.audit.bak    | logmgr\audit_back          | ACInstallDir\log       |
| seos.error        | logmgr\error_log           | ACInstallDir\log       |
| seos.error.bak    | logmgr\error_back          | ACInstallDir\log       |
| seos.msg          | message\filename           | ACInstallDir\Data      |
| stop.ini          | STOP\STOPIniFileName       | ACInstallDir\Data      |
| stopsignature.dat | STOP\STOPSignatureFileName | ACInstallDir\Data      |
| response.ini      | SeOSD\ResponseFile         | ACInstallDir\Data      |
| audit.cfg         | logmgr\AuditFiltersFile    | ACInstallDir\Data      |

Privileged Access Manager creates the following registry keys during installation and protects them with internal file rules under REGKEY, REGVAL class:

**Under HKLM\SYSTEM\\*ControlSet\*\Services:**

- CA Access Control Agent Manager
- CA Access Control Report Agent
- CA Access Control Web Service
- SeOS Agent
- SeOS Engine
- SeOS Policy Model(DH\_\_)
- SeOS Policy Model(DH\_\_WRITER)
- SeOS Policy Model(DMS\_\_)
- SeOS TD
- SeOS Watchdog
- cainstrm
- driveng
- seosdrv

**Under HKLM\SYSTEM\\*ControlSet\*\Enum\Root:**

- LEGACY\_CAINSTRM
- LEGACY\_DRVENG
- LEGACY\_SEOSDRV

**NOTE**

For more information about configuration settings, see the *Reference Guide*.

**Default File Rules**

Privileged Access Manager creates default file rules during installation to protect sensitive files. Default file rules are visible in selang and can be deleted.

The following table lists the sensitive files that the product protects with default file rules, and the access rights and permitted accessors for the files.

In the table, *PMDBDir* is the directory in which the policy model databases (PMDBs) reside, and *pmd\_name* is the name of each policy model. By default, *PMDBDir* is located at *ACInstallDir\Data*. The location of *PMDBDir* is defined in the following registry entry:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Pmd\_Pmd_directory_
```

| File                                          | Default Access | Permitted Accessors |
|-----------------------------------------------|----------------|---------------------|
| <i>ACInstallDir\data\crypto\crypto.dat</i>    | None           | sechkey             |
| <i>ACInstallDir\data\crypto\def_root.pem*</i> | None           | sechkey             |
| <i>ACInstallDir\data\crypto\sub.key</i>       | None           | sechkey             |
| <i>ACInstallDir\data\crypto\sub.pem</i>       | None           | sechkey             |
| <i>ACInstallDir\log\policyfetcher.log</i>     | Read           | +policyfetcher      |
| <i>PMDBDir\pmd_name</i>                       | Read, Chdir    | -                   |
| <i>PMDBDir\pmd_name\*</i>                     | Read, Execute  | -                   |

## Manage PAM SC Authorization

### Access Authorities

The main purpose of Privileged Access Manager is to assign and enforce access authorities, also known as access rights.

An access authority always has the following components:

- The resource that the access applies to, for example, a file, host, or terminal
- The type of access, for example, read, write, delete, log in, run
- The accessor, which is either a user or a group

A user has the authority to access a resource in a certain way because one or more of the following circumstances are true:

- The user has the access authority, as granted by the resource ACL
- The user is a member of a group that has access authority.
- The user is running a program that has the access authority. For example, the user has the authority to run a program in the SPECIALPGM class, or to run a command in the SUDO class.

#### NOTE

For more information about access authority by class, see the *selang Reference Guide*.

### Setting Access Authority - Examples

#### Example: Give an internal User Read Access

The following *selang* command adds the internal user *internal\_user* to the ACL of terminal *tty30*, to give read access to the terminal:

```
authorize TERMINAL tty30 access(READ) uid(internal_user)
```

#### Example: Give an Enterprise User Read Access

The following *selang* command adds the enterprise user *Terry* to the ACL of terminal *tty30*, to give read access to the terminal:

```
authorize TERMINAL tty30 access(READ) xuid(Terry)
```

**Example: Change an Access Authority of an Enterprise User to a Resource**

The following selang command sets Terry's access to terminal tty30 to none, and so denies Terry access:

```
authorize TERMINAL tty30 access(NONE) xuid(Terry)
```

**Example: Remove the Access Authority of an Enterprise User from a Resource**

The following selang command removes Terry from the ACL in the terminal tty30:

```
authorize- TERMINAL tty30 xuid(Terry) access-
```

Terry now has the default access to the terminal.

**Example: Give an Enterprise User Sub-administrator Access**

The following selang commands set up the enterprise user Terry as a sub-administrator with the authority to manage users and files:

```
authorize ADMIN USER xuid(Terry)
authorize ADMIN FILE xuid(Terry)
```

**Access Control Lists**

The access authorities to a resource are specified in an access control list. Every resource record has at least two access control lists:

- **ACL**  
Specifies the accessors that are granted access to the resource, together with the type of access that they are granted.
- **NACL**  
Specifies the accessors that are denied authorization to the resource, together with the type of access that they are denied.

The access authority can also depend on the circumstances around the access, such as whether the user is logged in locally or not.

***Conditional Access Control Lists***

Conditional Access Control Lists (CACLS) provide an extension to ACLs. When an accessor attempts to access a resource, if the resource's ACL and NACL do not define an access authority for the user, Privileged Access Manager examines the conditional access control lists.

The conditional access control lists specify access to resource where the access is by a particular method, for example by using a specified program.

For example you can use a conditional access control list to define a program pathing rule.

Privileged Access Manager allows the following conditional access control lists:

- Program Access Control Lists (PACLs)
- TCP class access control lists
- CALENDAR class access control lists

To define an entry in a conditional access control list entry, you can use the `via` option of the selang `authorize` command.

In common with other access control lists, each entry in a conditional access control list specifies the accessors that are granted access to the resource, together with the type of access that they are granted. In addition, an entry in a conditional access control list specifies the condition under which the authority is assigned. For a PACL, the condition is the name of a program which the accessor needs to run to have the access.

**Example: Using a PACL**

To allow the enterprise user sysadm1 to become superuser only by running the program secured\_su, you can specify the corresponding conditional access rule using the following selang command:

```
authorize SURROGATE user.root xuid(sysadm1) via(pgm(secured_su))
```

### **defaccess The Default Access Field**

The record for a resource can include a default access field, defaccess. The value of the defaccess field specifies the access authority that is allowed to accessors who are not covered by any of the resource access control lists.

### **How Access Authority to a Resource Is Determined**

When an accessor attempts to access a resource, Privileged Access Manager checks the access authority. The product runs one or more checks in a predetermined order, until it gets a result. If any check produces an access result (deny or allow access), Privileged Access Manager does not check any further. Instead, the product returns the result.

The order in which it runs through these checks is important. For each resource, Privileged Access Manager checks the access records in the following order by default:

1. The time-based restrictions of the resource
2. The ownership of the resource (owners are allowed access)
3. B1 checks
4. The NACL of the resource
5. The ACL of the resource
6. The PACL of the resource
7. The defaccess field of the resource

The setting of the accpac option determines the order of the last two checks. You can disable the use of resource PACL by using the selang command setoptions setpacl-.

#### **NOTE**

One access control list can contain more than one entry that affects a user. For example, it can contain an entry that mentions a user explicitly, and also entries for each of the groups to which the user belongs. Privileged Access Manager checks all the possible entries at each level before it goes to the next level. For more information about how it resolves conflicting rules at each level, see Interaction Between User and Group Access Authorities.

### **Example: The Resultant Permission on a File**

For the following table, assume that an accessor named user1 attempts to read the resource file1.

In the following table Privileged Access Manager is following the default setting of the accpac option to use the PACL.

| Entry in NACL for user1 | Entry in ACL for user1 | Entry in PACL for user1 | Entry in defaccess | Resulting Permission                          |
|-------------------------|------------------------|-------------------------|--------------------|-----------------------------------------------|
| Read                    | (Any)                  | (Any)                   | (Any)              | Read denied                                   |
| (Not defined)           | None                   | (Any)                   | (Any)              | Read denied                                   |
| (Not defined)           | Read                   | (Any)                   | (Any)              | Read granted                                  |
| (Not defined)           | (Not defined)          | via pgm securereader    | (Any)              | Read allowed through the securereader program |
| (Not defined)           | (Not defined)          | (Not defined)           | Read               | Read granted                                  |

Where an entry is shown as *(Not defined)*, no entry for user1 exists in that access control list.

Where an entry is shown as *(Any)*, the entry in that access control list does not matter, because Privileged Access Manager does not check it.

The order that Privileged Access Manager checks is from left to right. Notice that for all rows, the cells to the right of a cell with a defined access have the value *(any)*. Conversely all the cells to the left of a cell that contains a defined access have the value *(not defined)*.

### **Interaction Between User and Group Access Authorities**

You can explicitly grant or deny access authorities to a user, and also to groups to which the user belongs. Sometimes these can conflict. The following example shows what results if conflicting access authorities are assigned to the same resource when a user is a member of two groups (Group 1 and Group 2).

It assumes that the accumulative group rights option is set (the default setting).

| Access Authority for User | Access Authority for Group 1 | Access Authority for Group 2 | Resulting Access Authority |
|---------------------------|------------------------------|------------------------------|----------------------------|
| Access denied             | <i>(Any)</i>                 | <i>(Any)</i>                 | Access denied              |
| Access granted            | <i>(Any)</i>                 | <i>(Any)</i>                 | Access granted             |
| <i>(Not defined)</i>      | Access granted               | <i>(Not defined)</i>         | Access granted             |
| <i>(Not defined)</i>      | <i>(Not defined)</i>         | Access granted               | Access granted             |
| <i>(Not defined)</i>      | Access granted               | Access granted               | Access granted             |
| <i>(Not defined)</i>      | Access denied                | <i>(Any)</i>                 | Access denied              |
| <i>(Not defined)</i>      | <i>(Any)</i>                 | Access denied                | Access denied              |

Where an entry is shown as *(Not defined)*, this means that no entry for the user or group is defined.

Where an entry is shown as *(Any)*, this means that the access authority does not matter, because Privileged Access Manager does not check it.

### **Accumulative Group Rights (ACCGRR)**

The *accumulative group rights* option (ACCGRR) affects how Privileged Access Manager checks the ACL of the resource. If ACCGRR is enabled, Privileged Access Manager checks the ACL for the authorities that are granted from all the groups to which the user belongs. If ACCGRR is disabled, Privileged Access Manager checks the ACL to see if any of the applicable entries contain the value none. If so, access is denied. Otherwise Privileged Access Manager ignores all group entries except the first applicable one in the access control list. By default the option is enabled.

To enable the ACCGRR option, you can use the following `selang` command:

```
setoptions accgrr
```

To disable the ACCGRR option, you can use the following `selang` command:

```
setoptions accgrr-
```

### **Security Levels, Categories, and Labels**

Security levels and security categories provide additional ways to restrict access to a resource, complementary to the use of access control lists.

Security labels are a means to bundle security levels and categories together, to manage them more easily.

#### **Security Levels**

A *security level* is an integer between 0 and 255 that you can assign to accessors and resources. An accessor cannot access a resource if the accessor has a security level less than the security level assigned to the resource, even if the user is granted access authority in the resource's access control list. If a resource has a zero security level, security level checking is not checked for that resource.

An accessor with a security level of zero cannot access any resource that has a non-zero security level.

### **Security Categories**

A *security category* is the name of record in the CATEGORY class. You can assign a security category to accessors and to resources. An accessor can access a resource only if the accessor is assigned to all of the security categories assigned to the resource.

### **Security Labels**

A *security label* is the name of a record in the SECLABEL class. A security label bundles together a security level and a set of security categories. Assigning a security label to an accessor or a resource gives the accessor or resource the combined security level and security categories associated with the security label. A security label overrides any specific security level and category assignments in an accessor or resource.

#### **Example: Use of a Security Label High\_Security**

Assume High\_Security is a security label that contains a security level 255 and the security categories MANAGEMENT and CONFIDENTIAL.

If you assign a user user1 to the security label High\_Security, user1 has a security level of 255 and also has the security categories MANAGEMENT and CONFIDENTIAL.

## **User Impersonation Protection**

When you enable the SURROGATE class in Privileged Access Manager, you enable user impersonation protection. User impersonation protection lets you specify that a user or group can only change their SID (security identifier) to another SID if a specific rule permits the change. This protection prevents a user from impersonating the identity of another user if they are not authorized to do so.

### **NOTE**

A security identifier is a numeric value that identifies a user or group to the operating system.

For example, you define a Privileged Access Manager rule that prevents any user from impersonating Administrator. User Tom tries to run a program that performs some tasks as Administrator. Privileged Access Manager does not permit the program to execute because Tom does not have permission to impersonate Administrator.

You can run user impersonation protection in two modes:

- User mode interception
- Kernel mode interception

### **User Mode Interception**

If you enable user mode interception, Privileged Access Manager intercepts only the impersonation requests that originate from the Windows RunAs utility. User mode interception is available on all supported Windows versions.

### **NOTE**

User mode interception is enabled by default when you enable user impersonation protection: that is, when you enable the SURROGATE class.

The advantages of user mode interception include:

- Privileged Access Manager identifies the user who made the original impersonation request.  
In many Windows applications, including the RunAs utility, the NT AUTHORITY\SYSTEM user impersonates the requesting user and makes the impersonation request. User mode interception identifies the user executing the utility, not the NT AUTHORITY\SYSTEM user who makes the request. For example, if Tom executes RunAs to impersonate

Administrator, the NT AUTHORITY\SYSTEM user makes the impersonation request. Privileged Access Manager identifies Tom as the requesting user.

- Privileged Access Manager intercepts impersonation requests only when a user executes the RunAs utility. This process minimizes performance impact.

A disadvantage of user mode interception is that Privileged Access Manager does not intercept every impersonation request from every Windows process.

### **Kernel Mode Interception**

If you enable kernel mode interception, Privileged Access Manager intercepts every impersonation request from all Windows processes. Kernel mode interception is not available on all supported Windows versions.

#### **NOTE**

For more information about the Windows versions for which kernel mode interception is not available, see the *Release Notes*.

An advantage of kernel mode interception is that it lets you protect every impersonation request that is made on a Windows computer.

The disadvantages of kernel mode interception include:

- If the NT AUTHORITY\SYSTEM user impersonates the requesting user and makes the impersonation request, Privileged Access Manager does not identify the user who made the original impersonation request. For example, RunAs, ftp, and telnet requests are all made by the NT AUTHORITY\SYSTEM user. If Tom executes RunAs to impersonate Administrator, the NT AUTHORITY\SYSTEM user makes the impersonation request. Privileged Access Manager identifies NT AUTHORITY\SYSTEM as the requesting user.
- Privileged Access Manager intercepts every impersonation request that the OS makes as part of its normal operation, which can have a performance impact. Although Privileged Access Manager caches impersonation requests, the authorization engine must still authorize many impersonation events.

### **How Privileged Access Manager Responds to User Impersonation Requests**

Each record in the SURROGATE class defines restrictions that protect a user from impersonation attempts. Privileged Access Manager treats an impersonation request as an abstract object that only authorized users can access. A record in the SURROGATE class represents each user or group who has surrogate (impersonation) protection.

When a user or group makes a request to impersonate another user or group, Privileged Access Manager follows these steps:

1. Checks the access authority of the SURROGATE record for the user or group. Depending on the SURROGATE record, *one* of the following happens:
  - The SURROGATE record for the user or group specifically permits or denies the impersonation. Privileged Access Manager uses the access authority of the SURROGATE record to permit or deny the impersonation request.
  - The user or group does not have a SURROGATE record. The process goes to Step 2.
2. Checks the access authority of the default SURROGATE record for the user or group, as follows:
  - If the requester is a user, Privileged Access Manager gives the user the access type that is defined in the USER.\_default SURROGATE record.
  - If the requester is a group, Privileged Access Manager gives the user the access type that is defined in the GROUP.\_default SURROGATE record.

**NOTE**

The default access authority of the USER.\_default, GROUP.\_default, and \_default SURROGATE records are read. This means that Privileged Access Manager permits any request to impersonate a user or group, unless a SURROGATE record for the user or group prohibits the impersonation request. To change this behavior, change the access authority of the USER.\_default and GROUP.\_default records. You can also set the same default for users and groups by changing the access authority of the \_default SURROGATE record.

**Enable User Impersonation Protection**

User impersonation protection lets you set rules to permit or deny requests to impersonate specific users and groups.

**To enable user impersonation protection**

1. (Optional) Enable kernel mode interception, as follows:

- a. Stop Privileged Access Manager.

- b. Change the value of the following registry value to 1:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\
SeOSD\SurrogateInterceptionMode
```

- c. Restart Privileged Access Manager.

**NOTE**

User mode interception is enabled by default.

2. Open a selang command prompt window.

3. Enable the SURROGATE class:

```
setoptions class+(SURROGATE)
```

4. Define selang rules for SURROGATE records for your Privileged Access Manager implementation.

5. (Kernel mode interception only) Define a rule that lets the SYSTEM user impersonate the user that makes the impersonation request:

```
auth SURROGATE USER.Administrator uid("NT AUTHORITY\SYSTEM") acc(R)
```

Windows identifies many utilities and services (for example, Run As) as user "NT AUTHORITY\SYSTEM" and not as the user running the utility. Define a rule for the SYSTEM user to let users who run these utilities impersonate another user.

**Example: Permit Any Impersonation Request**

The following selang rule lets any user impersonate another user, unless a record in the database explicitly prevents the impersonation:

```
editres SURROGATE _default defaccess(READ)
```

**Example: Prevent Impersonation of a Specific User**

The following selang rule prevents any user impersonating Administrator, unless a record in the database explicitly permits the user impersonation:

```
newres SURROGATE USER.Administrator defaccess(NONE)
```

**Example: Permit a Group to Impersonate a User**

The following rule permits members of the Administrators group to impersonate Administrator:

```
authorize SURROGATE USER.Administrator gid("Administrators")
```

## Set Up the Surrogate DO Facility

Operators, production personnel, and end users must often perform tasks that only the superuser can perform.

The traditional solution is to supply all these users with the password of the superuser, which compromises the security of the site. The secure alternative, keeping the password secret, results in the system administrator being overloaded with legitimate requests from users to perform routine tasks.

The Surrogate DO (`sesudo`) utility solves this problem. The utility allows users to perform actions that are defined in the SUDO class, where each record contains a script. The utility specifies which users and groups can run the script, and it lends them the necessary permissions for the purpose.

For example, to define a SUDO resource that starts the "Print Spooler" service as if the user were System, enter the following `selang` command:

```
newres SUDO StartSpooler data("net start spooler")
```

This `newres` command defines `StartSpooler` as a protected action that some users may receive System authority to perform.

### WARNING

In the data property, use a full absolute path name. A relative path name could accidentally execute a Trojan horse program that is planted in an unprotected directory.

In addition, users can be authorized to perform the `StartSpooler` action by using the `authorize` command. For example, to allow the user *operator1* to start the "Print Spooler" service, enter the following `selang` command:

```
authorize SUDO StartSpooler uid(operator1)
```

You can also explicitly prevent a user from performing the protected action by using the `authorize` command. For example, to prevent the user *operator2* from starting the "Print Spooler" service, enter the `selang` command:

```
authorize SUDO StartSpooler uid(operator2) access(None)
```

Executing the `sesudo` utility performs the protected action. For example, the user *operator1* would start the "Print Spooler" service using the following command:

```
sesudo -do StartSpooler
```

The `sesudo` utility first checks whether the user is authorized to perform the SUDO action. If the user is authorized to the resource, the utility executes the command script defined in the resource. In the example, `sesudo` checks whether *operator1* is authorized to perform the `StartSpooler` action. The utility then invokes the command "net start spooler" with System credentials.

### NOTE

For more information about the `sesudo` utility, see the *Reference Guide*.

## Define SUDO Records (Task Delegation)

A record in the SUDO class stores a command script so that users can run the script with borrowed permissions. The SUDO record controls the ability to borrow permissions, as does the `sesudo` command that executes the scripts.

### NOTE

If you create a SUDO record for an interactive Windows application, set the interactive flag for the SUDO record. If you do not set the interactive flag, the application runs in the background and you cannot interact with it. For more information, see the *Troubleshooting Guide*.

In a SUDO record, the comment property is used for a special purpose. This property is often known by its alternate name: the data property.

The value of the comment property is the command script, with the optional addition of one or more script parameter values that are to be prohibited or permitted. The entire comment property value must be enclosed in single quotes. Reference executables by their complete path names to prevent Trojan horses from taking their place.

The comment property has this format:

```
comment('cmd[;[prohibited-values][;permitted-values]]')
```

Because the lists of prohibited and permitted values are optional, a simple comment property value can be the following:

```
newres SUDO NET comment('net use')
```

The simple value in the command means that the command `sesudoNET` executes the command `'net use'`. No particular script parameter values are prohibited; all are permitted.

Wildcards and powerful variables give you flexibility in specifying prohibited and permitted parameters. The wildcards that you can use are the standard Windows wildcards. Prohibited and permitted parameters can also contain the following variables:

| Variable | Description                                                                                  |
|----------|----------------------------------------------------------------------------------------------|
| \$A      | An alpha value                                                                               |
| \$G      | An existing Privileged Access Manager group name                                             |
| \$H      | (UNIX only) A parameter that starts with the home directory of the user                      |
| \$N      | A numeric value                                                                              |
| \$O      | The Privileged Access Manager name of the user running <code>sesudo</code>                   |
| \$U      | An existing Privileged Access Manager user name                                              |
| \$e      | An empty entry.<br>Use this entry to specify a SUDO command with no parameters for the rule. |
| \$f      | An existing file name                                                                        |
| \$g      | An existing Windows group name                                                               |
| \$h      | An existing host name                                                                        |
| \$r      | An existing file with Windows read access                                                    |
| \$u      | An existing Windows user name                                                                |
| \$w      | An existing file with Windows write access                                                   |
| \$x      | An existing file with Windows execute access                                                 |

If you append a list of the prohibited parameter values to the script:

- Separate the script from the prohibited parameter values with a semicolon, but keep them all inside the single quotes. For example, if you want to prevent the user from using `-start` but you permit the user to use all other parameters, enter the following command:

```
newres SUDO scriptname comment('cmd;-start')
```

where *cmd* represents your script.

Alternatively, if you do not allow any parameter values, but you want all parameters defaulted, define the SUDO record as follows:

```
newres SUDO scriptname comment('cmd;*')
```

- If a script parameter has more than one prohibited value, use the space character as a separator. For example, if you want to prevent the user from using `-start` and `-stop` but you permit the user to use all other parameters, enter the following command:

```
newres SUDO scriptname comment('cmd;-start -stop')
```

- If more than one script parameter has prohibited values, use the pipe character (|) as a separator between sets of prohibited values. For example, if you want to prevent the user from using -start and -stop for the script's first parameter, and from using any existing Windows user name for the second parameter (see the previous list of variables), enter the following command:

```
newres SUDO scriptname comment('cmd;-start -stop | $u')
```

If the script has more parameters than you list, then your last set of prohibited parameters applies to all the remaining parameters.

If you append a list of the permitted parameter values to the script,

- The sesudo utility checks that the parameter values:
  - Do *not* match any of the corresponding *prohibited* values.
  - Match at least one of the corresponding *permitted* values.

This means that if a parameter value is in the prohibited list, it is not permitted even if it is also specified in the permitted list.

Separate the list of *permitted* values from the list of *prohibited* values with a semicolon, but keep them all inside the single quotes. Even if you have no list of prohibited values, you still need the semicolon. Otherwise, what you intend to permit is prohibited. For example, if you want to allow only the value NAME as a parameter value for the script, enter the following command:

```
newres SUDO scriptname comment('cmd;;NAME')
```

- Just as in the other list,
  - If a script parameter has more than one permitted value, use the space character as a separator.
  - If more than one script parameter has permitted values, use the pipe character (|) as a separator between sets of permitted values.

For example, if you have two parameters, and the first must be numeric but must not be a Windows user name, and the second must be alphabetic but must not be a Windows group name, enter the following command:

```
newres SUDO scriptname comment('cmd;$u | $g ;$N | $A')
```

If the script has more parameters than you list, then your last set of permitted parameters applies to all the remaining parameters.

Thus, the overall format for the comment property is this: first the script; then the prohibited values, parameter by parameter; then the permitted values, parameter by parameter:

```
comment('cmd; \
param1_prohib1 param1_prohib2 ... param1_prohibN | \
param2_prohib1 param2_prohib2 ... param2_prohibN | \
...
paramN_prohib1 paramN_prohib2 ... paramN_prohibN ; \
param1_permit1 param1_permit2 ... param1_permitN | \
param2_permit1 param2_permit2 ... param2_permitN | \
...
paramN_permit1 paramN_permit2 ... paramN_permitN')
```

The sesudo utility checks each parameter that the user enters in the following manner:

1. Test if parameter N matches permitted parameter N. (If permitted parameter N does not exist, the last permitted parameter is used.)
2. Test if parameter N matches prohibited parameter N. (If prohibited parameter N does not exist, the last prohibited parameter is used.)

If all the parameters match permitted parameters, and none match prohibited parameters, sesudo executes the command.

**Example: Set Up Task Delegation that Permits a User to Run net send**

The following procedure shows you how you let user Takashi execute the net send command and prevent him from executing the net start command:

1. In Privileged Access Manager Endpoint Management click the Users tab, then click the Authorization and Delegation subtab.  
The Authorization and Delegation menu options appear on the left.
2. Click Task Delegations.  
The Task Delegations page appears.
3. Click Create Task.  
The Create Task page appears.
4. Complete the dialog fields as follows:

| Field                | Value                           |
|----------------------|---------------------------------|
| Name                 | NET                             |
| Data                 | net;start;send *                |
| Owner                | nobody                          |
| Default Access       | None (option cleared)           |
| Authorized Accessors | USER: Takashi<br>Allow: Execute |

1. 1. 1. Click Save.  
The new task delegation (SUDO) record is created.
2. Test the task delegation rule:
  - a. Log in as Takashi.
  - b. Open the command prompt and execute the following:

```
sesudo -do NET start
```

```
sesudo: you are not allowed to use 'start' as parameter number 1.
sesudo: you are not allowed to use 'start' as parameter number 1.
sesudo -do NET send comp message
sesudo -do NET send comp message
```

The following message appears:

#### NOTE

*net start* does not execute because it was defined as a prohibited value.

3. Execute the following value: NET send
4. The command executes.

### Example: Authorize a User to Execute Privileged Operations using an Interactive Application

A user can perform highly privileged operations using any snap-in MSC module, as the following example shows:

1. In Privileged Access Manager Endpoint Management click the Users tab, then click the Authorization and Delegation subtab.  
The Authorization and Delegation menu options appear on the left.
2. Click Task Delegations.  
The Task Delegations page appears.
3. Click Create Task.  
The Create Task page appears.

## 4. Complete the dialog fields as follows:

| Field                | Value                         |
|----------------------|-------------------------------|
| Name                 | services                      |
| Data                 | c:\winnt\system32\mmc.exe     |
| Owner                | nobody                        |
| Options              | Interactive (option selected) |
| Default Access       | None (option cleared)         |
| Authorized Accessors | USER: Tori<br>Allow: Execute  |

## 1. Click Save.

The new task delegation (SUDO) record is created. The Interactive option provides the desktop user interface that can be used by whoever is logged in when the service is started. This is available only if the service is running as a LocalSystem account.

## 2. Test the task delegation rule:

- a. Log in as Tori.
- b. Open the command prompt and execute the following:

```
sesudo -do services
```

- a. mmc.exe will start.

## Check User Inactivity

The inactivity feature protects the system from unauthorized access through accounts whose owners are away or no longer employed by the organization. An inactive day is a day in which the user does not log in. You can specify the number of inactive days that must pass before the user account is suspended and cannot log in. Once an account is suspended, you must manually reactivate it.

### NOTE

Password changes count as activities, in terms of inactivity checks. If a user's password changes, that user cannot become suspended due to inactivity.

You can set the number of inactive days with the inactive property of a USER class record or a GROUP class record. The latter affects only users that have that group as a profile group. You can also set inactivity for all users systemwide with the INACT property of the SEOS class.

In selang, use the following command to specify inactivity globally:

```
setoptions inactive (numdays)
```

To set the number of days for a group (which overrides the systemwide inactive setting for that group), use the following command:

```
editgrp groupName inactive (numdays)
```

To set the number of days for a user (which overrides group and systemwide settings for that user), use the following command:

```
editusr userName inactive (numdays)
```

To reactivate a suspended user account, use the following command:

```
editusr userName resume
```

To reactivate a suspended profile group, use the following command:

```
editgrp userName resume
```

To disable inactive login checking at the systemwide level, use the following command:

```
setoptions inactive-
```

To disable inactive login checking for a group, use the following command:

```
editgrp groupName inactive-
```

To disable inactive login checking for a user, use the following command:

```
editusr userName inactive-
```

## Security Auditors

One of the most important tasks of security auditors and system administrators is auditing or monitoring system activity to detect suspicious or malicious activity. Security auditing plays an essential role in a secure environment, and the security auditing features in Privileged Access Manager include the following:

- Providing a reliable indication of who has accessed the system, what resources have been accessed, how the resource has been accessed (for example, read a file), and when resources have been accessed
- Notifying and alerting appropriate users in case of an attempted security breach, even if the attempt failed
- Indicating what changes have been made to the security rules, and by whom
- Providing a means to test the effect of access rules before they are enforced

Privileged Access Manager auditing is modeled after real-world auditing: security auditors act independently of system and security administrators, although you can change your implementation so that this is not the case if some other model is more appropriate for your environment.

A security auditor is a user to whom the AUDITOR attribute is assigned. Users defined as security auditors are permitted to perform auditing tasks such as changing the audit rules that are assigned to users and resources. They are also authorized to use the Privileged Access Manager auditing utilities without being required to have the ADMIN attribute.

## Events Interception

Privileged Access Manager intercepts an event if the following two conditions are met:

- The appropriate class is active.
- A rule anticipating this event exists in the database.

For example, you can use the following generic rule to audit all file accesses to files that reside in c:\data\payroll:

```
newres FILE c:\data\payroll\*
```

Ensure that the FILE class is active (the default).

## Types of Intercepted Events

Privileged Access Manager intercepts two types of events:

- Interception Events  
Information from an interception event is cached as part of the process for future use by an audit event.
- Audit Events

## **Interception Modes**

Based on the interception mode, Privileged Access Manager intercepts, checks for authorization, and logs audit records of access request events. Privileged Access Manager has the following modes of interception:

- Full Enforcement mode
- Audit Only mode
- No Interception mode

### **NOTE**

Warning mode is not an interception mode. Warning mode works in Full Enforcement mode only and is designed for short-term use during implementation.

## **Audit Only Mode**

*Audit Only mode* records all intercepted events without checking or enforcing access rules. Use this mode to collect data for compliance requirements or regulations. In Audit Only mode, Privileged Access Manager intercepts the event and writes an audit event but does not process the request for authorization and does not enforce rules. As a result, Privileged Access Manager permits all access requests that it intercepts. This means that the authorization result recorded in the audit log for all events is *P* (permitted).

The following restrictions apply to Audit Only mode: The audit properties of the resource and the user are *not* considered. Audit Only mode records *all intercepted* events regardless of resource- or user-specific settings.

## **Set Up Audit Only Mode**

*Audit Only mode* records all intercepted events without checking or enforcing access rules. Use this mode to collect data for compliance requirements or regulations.

To set up Audit Only mode, set the SeOSD\GeneralInterceptionMode Privileged Access Manager registry entry to 1.

### **WARNING**

If you use Audit Only mode, ensure that you have enough disk space for the audit logs and that the size limit of the audit log is large enough. Also consider options for [audit log backup](#).

## **Warning Mode**

*Warning Mode* is a property that you can apply to a resource, and an option that you can apply to a class. If Warning mode is applied to a resource or a class and an access violates an access rule, Privileged Access Manager writes an audit log entry with the return code W. However, the product permits the access to the resource. If a class is in Warning mode, all the resources in that class are in Warning mode.

Warning Mode only has an effect if Privileged Access Manager is in Full Enforcement mode.

### **NOTE**

Full Enforcement mode is the only mode Privileged Access Manager for UNIX supports. Privileged Access Manager for Windows also supports Audit Only mode.

You can use Warning mode when you introduce or modify an access policy. If you do this, you can examine the audit log to preview the results of your intended policy before you put that policy into effect. You can display the audit log by using the `seaudit` command.

If a class has the property *warning*, you can put the class into Warning mode. If a resource group or class is in Warning mode when an access rule is violated, Privileged Access Manager follows these steps:

- Allows the access
- Writes an entry in the audit log that references the resource (not the resource group or class)

The Warning mode settings on a resource and on a class are independent: if you put a resource into Warning mode, it remains in Warning mode, even if it belongs to a class and you remove Warning mode from that class.

#### NOTE

You can only put resources or classes into Warning mode if they have the property *warning*; not all resources or classes have this property.

### **Put a Resource into Warning Mode**

You put a resource into Warning mode to monitor the effects of access rules, without needing to enforce these rules.

To put a resource into Warning mode:

1. In Privileged Access Manager Endpoint Management, edit the resource that you want to put into Warning mode.  
The appropriate Modify page appears.
2. Click the Audit tab.  
The Audit Modes page for the resource appears.
3. Select Warning Mode, and click Save.  
The resource that you modified is now in Warning mode.

#### NOTE

In Warning mode, Privileged Access Manager always writes warning records to the audit log when access is permitted but access rules are violated: you do not need to set the audit property on the resource for this to happen.

**Example:** Put a file into Warning Mode:

The following selang example puts the file c:\myfile into Warning mode:

```
chres FILE c:\myfile warning
```

**Example:** Clear Warning Mode from a file:

The following selang example takes the file c:\myfile out of Warning mode:

```
chres FILE c:\myfile warning-
```

Warning mode is now not active for the myfile, so Privileged Access Manager enforces the access rules for myfile.

**Example:** Put a terminal into Warning Mode:

The following selang example puts the terminal myterminal into warning mode:

```
chres terminal myterminal warning
```

Privileged Access Manager permits access by any authorized user from the terminal myterminal. However, the product logs an audit record for any user that typically would be denied access from that terminal.

### **Put a Class into Warning Mode**

Rather than putting individual records into Warning mode, you can put all records in a class into Warning mode. You might use Warning mode to monitor the effects of access rules, without needing to enforce these rules.

#### **To put a class into Warning mode**

1. In Privileged Access Manager Endpoint Management, do as follows:
  - a. Click Configuration.
  - b. Click Class Activation.
 The Class Activation page appears.

2. Select the check box in the Warning column for the class you want to put into Warning mode.
3. Click Save.  
A confirmation message appears, letting you know that Privileged Access Manager options have been successfully updated.

### **Find Out Which Resources Are in Warning Mode**

Use Warning mode as a temporary measure when implementing Privileged Access Manager. Once you are comfortable that users have the required access to the resources they require, turn off Warning mode and Privileged Access Manager starts enforcing the associated rules.

To find out which resources are in Warning mode, create a report that shows all resources with Warning mode.

To create a report, enter the following command:

```
sereport -f pathname.html -r 6
```

Privileged Access Manager creates the report.

#### **NOTE**

For more information about the sereport utility, see the *Reference Guide*.

### **Find Out Which Classes Are in Warning Mode**

You should use Warning mode as a temporary measure when implementing Privileged Access Manager. Once you are comfortable that users have the required access to the resources they require, turn off Warning mode and Privileged Access Manager starts enforcing the associated rules.

To find out which classes are in Warning mode, you can get Privileged Access Manager to display this data.

To display this data, enter the following selang command:

```
setoptions cwarnlist
```

Privileged Access Manager displays a table showing the classes that are in Warning mode.

#### **NOTE**

For more information about setoptions, see the *selang Reference Guide*.

### **How to Perform System Maintenance**

At certain times you might need to perform system maintenance to upgrade the system, install a new application, and so on. During system maintenance set Privileged Access Manager rules in Warning mode. Once you are comfortable that the maintenance did not affect user access to resources that they require, turn off Warning mode and Privileged Access Manager startd enforcing the associated rules.

To use Warning mode when you perform system maintenance, do the following:

1. Set the appropriate classes to Warning mode before you start the maintenance, using the following selang rule:

```
setoptions class(NAME) flags(W)
```

2. Perform the maintenance.
3. Run the sereitrust utility after you perform the maintenance.  
The sereitrust utility generates the selang commands required to retrust programs and secure files defined in the database.
4. Run the selang command to retrust the programs defined in the database.
5. Remove the Warning mode from the classes to enable policy enforcement, using the following selang rule:

```
setoptions class(NAME) flags-(W)
```

6. Review Privileged Access Manager audit log files.

The audit log contains warnings for the resources that were affected by the maintenance.

#### NOTE

For more information about the `seretrust` utility, see the *Reference Guide*.

## Monitor Access Control Activity

The Privileged Access Manager trace is a real-time log that can show every action taken by the product. Trace records are accumulated in `ACInstallDir\log\seosd.trace` (where `ACInstallDir` is the directory where you installed Privileged Access Manager).

Or they are accumulated in whatever file you specify as the `trace_file` value in the registry subkey:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\SeOSD\
```

Although you can filter the records from the trace file, the trace mechanism is designed for system monitoring and not for security auditing.

By default, Privileged Access Manager only generates trace messages during product initialization. Once Privileged Access Manager is initialized, it stops the trace mechanism and trace messages are not generated.

### Trace Record Filters

Privileged Access Manager generates two types of trace records:

- User trace records: Records actions completed by the user. Example: user1 accessed file `c:\tmp\tmp.exe`
- General trace records: Records actions completed by the system. Example: the Watchdog set a program to be nontrusted

Trace records are written to the `seos.trace` file, and can be filtered using the `trcfilter.ini` file.

If you set a user to be traceable, each time a trace record is written for that user, a matching audit record is written to the `seos.audit` file. The `audit.cfg` file filters the audit records.

#### NOTE

Audit records generated by trace events are not cached, and always go through the full enforcement flow.

The following `selang` command sets a user to be traceable:

```
editusr userName audit(trace)
```

To view trace or audit records, use the `seaudit` utility.

### Filter Trace Records

Using a trace filter file, you can specify that certain types of activity should not appear in the trace file. The trace filter file is specified with the `trace_filter` value in the registry key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\SeOSD
```

The default value is `ACInstallDir\log\trcfilter.ini` (where `ACInstallDir` is the directory where you installed Privileged Access Manager).

#### WARNING

Privileged Access Manager creates the trace filter file at installation with the single line: `*seosd.trace*`. Never delete this record.

Each line in the trace filter file represents an access or an activity that should *not* be traced. For example, to eliminate tracing the users' access to Microsoft Word, add the following line to the trace filter file:

```
*winword.exe*
```

## What Privileged Access Manager Server Control Audits

For security auditing, Privileged Access Manager keeps audit records for intercepted events according to the audit rules defined in the database and the enforcement mode it operates in. The records in the audit log accumulate according to these audit rules.

Full auditing provides audit records for all intercepted events of the following types:

- File access (FILE class)
- Program execution (PROGRAM class)
- Registry access (REGKEY and REGVAL classes)
- Impersonation control (SURROGATE class)
- Network control (CONNECT, TCP, HOST, GHOST, HOSTNET, and HOSTNP classes)
- Log in (TERMINAL class)

### NOTE

Intercepted login events are not cached; they always follow the auditing process for interception events.

- Service protection (WINSERVICE class)
- Password verification failure (PASSWORD class)
- Process termination (PROCESS class)

The decision whether to log an event depends on the Privileged Access Manager interception mode.

## Login Interception Limitations

Login interception on Windows is supported only by Privileged Access Manager sub-authentication method.

You cannot set login interception through the kernel. As a result, consider the following:

- Since the sub-authentication component works on the Domain Controller (DC) level, and it is up to the OS to decide which DC authenticates the user's login events (and triggers the Privileged Access Manager sub-authentication module), in a Windows domain environment, the product needs to be installed on every DC. When working in a Windows domain environment, Privileged Access Manager login policy (TERMINAL rules) need to be located on the DCs and not necessarily on the target server. For example, to protect or audit login events that are made by domain users on a file server, which is part of the Windows domain but is not a DC, define the Privileged Access Manager login policy on the DC and not on the target file server. This is because when a domain user accesses the shared file directory, a login authorization occurs on the DC, not the file server.
- When there is more than one DC, Privileged Access Manager login authorization could be processed on any one of the DCs. As a result, we recommend that you synchronize Privileged Access Manager login policy between all DCs. You can implement this synchronization through one of these methods:
  - The Policy Model mechanism, where all DCs are subscribers to a PMDB
  - Add all DCs into a host group and deploying a common policy using advanced policy management
- Some user properties, which correspond to login events, are updated at runtime during event authorization. These properties might be out-of-sync because the login authorization happens only on one of the DCs. These properties are *Gracelogins*, *Last accessed*, and *Last access time*. However, it is possible that the property *Last access time* value of the user is different between DCs because Privileged Access Manager sub-authentication was triggered on one of the DCs, not on all of them.
- To enforce local users' (that is, not domain users') login events, install Privileged Access Manager on the local computer that the local user needs access to. This is because the local computer is used as the domain computer (the domain is the local computer).
- Remote Desktop Protocol (RDP)/Terminal Services login events are enforced on the target server as it was in previous Privileged Access Manager versions. However, for RDP login events, Privileged Access Manager login policy should be defined on the target server.

### **What Privileged Access Manager Audits in Full Enforcement Mode**

In Full Enforcement mode (regular operation), Privileged Access Manager logs events as follows:

- If Warning mode is turned *off* for the intercepted resource, Privileged Access Manager enforces rules and logs the events based on the *audit* property of the resource or user.

| Audit Property | Events Logged    |
|----------------|------------------|
| ALL            | <i>All</i>       |
| SUCCESS        | Access permitted |
| FAIL           | Access denied    |

- If Warning mode is turned *on* for the intercepted resource, a record is written to the audit log if an access request violates an access rule (if the rules were enforced, the request would have failed). The audit record mentions that the violation was permitted because Warning mode is in effect.  
Rules are not enforced in this mode.

### **What Privileged Access Manager Audits in Audit Only Mode**

In Audit Only mode, Privileged Access Manager does not process requests for authorization or enforce rules. All intercepted login events for the accessor and all intercepted events for resources that are protected by Privileged Access Manager are logged, regardless of whether access failed or succeeded.

### **How to Change What Privileged Access Manager Writes to the Audit Log**

You can change what Privileged Access Manager writes to the audit log in two ways:

- Use the AUDIT property of the resources or accessors to define the audit events that Privileged Access Manager writes to the audit log.

#### **NOTE**

You can use the AUDIT property for a GROUP or XGROUP to set the audit property for all members of the group. However, you cannot use the AUDIT property to set the audit mode for group members if the audit mode of a user is defined in a USER record, XUSER record, or profile group.

- Use the audit configuration file audit.cfg to filter the events Privileged Access Manager sends to the audit log. You cannot use the audit.cfg file to add events to the audit log.

To reduce the number of audit records, you can also control consecutive audit events written to the log file. This customization is based on a time interval between consecutive matching audit events. That is, an access attempt to a resource with the same process ID, thread ID, rule ID, user ID, and access mask. The time interval, in seconds, can be set by setting the value of the AuditRefreshPeriod registry entry. By default, the AuditRefreshPeriod is set to zero (0), which means that all events are written to the log file.

### **Setting Audit Rules**

For security auditing, Privileged Access Manager keeps audit records for events of access denial or access grants according to the audit rules defined in the database.

Every accessor and resource has an AUDIT property that can be set to one or more of the following values:

- **FAIL**  
Logs access failures by the accessor to the resource.
- **SUCCESS**  
Logs successful accesses by the accessor to the resource.
- **LOGINFAIL**

Logs every logon failure by the accessor. (This value does not apply to resources.)

**NOTE**

Two types of login events are available: Password Attempt Event(A LOGIN) and Login Event(P/D/W LOGIN). For more information, see the *Reference Guide*.

**WARNING**

The Password Attempt Event is valid on UNIX only.

- **LOGINSUCCESS**

Logs every successful logon by the accessor. (This value does not apply to resources.)

- **ALL**

Logs the same information as FAIL, SUCCESS, LOGINFAIL, and LOGINSUCCESS for accessors or FAIL and SUCCESS for resources.

- **NONE**

Logs nothing concerning the accessor or resource.

Whenever you create or update an accessor or resource record in the database, you can specify the AUDIT property. You can also specify whether email notification of logged events should be sent and to whom.

The records in the audit log accumulate according to these audit rules. The decision whether to log an event is based on the following circumstances:

- If the resource or accessor has AUDIT(ALL), all login events for the accessor and all events concerning resources that are protected by Privileged Access Manager are logged. This logging occurs regardless of whether access failed or succeeded.
- If access to a resource protected by Privileged Access Manager is successful and the accessor or resource has AUDIT(SUCCESS), the event is logged.
- If access to a resource protected by Privileged Access Manager fails and the accessor or resource has AUDIT(FAIL), the event is logged.

In addition, if you set a user to be traceable, each time a trace record is written for that user, a corresponding audit record is written to the audit log.

### **Defining the Audit Events That Privileged Access Manager Writes to the Audit Log**

Privileged Access Manager writes access success and failures to the audit log. You define which access events Privileged Access Manager writes to the audit log, by changing the value of the AUDIT property for the resource or accessor that you want to audit. You can also use this method to specify that Privileged Access Manager logs every trace event to the audit log.

You use the AUDIT property to specify the audit events that Privileged Access Manager writes to the audit log. Use selang or Privileged Access Manager Endpoint Management to set the AUDIT property for resources and accessors as follows:

| Value of AUDIT | What Privileged Access Manager Logs                               | Applicable Objects  |
|----------------|-------------------------------------------------------------------|---------------------|
| FAIL           | Access failures                                                   | Users and resources |
| SUCCESS        | Access successes                                                  | Users and resources |
| LOGINFAIL      | Login failures                                                    | Users               |
| LOGINSUCCESS   | Login successes                                                   | Users               |
| ALL            | Equivalent to FAIL, SUCCESS, LOGINFAIL, LOGINSUCCESS, INTERACTIVE | Users and resources |
| TRACE          | Equivalent to ALL plus all system events                          | Users               |
| INTERACTIVE    | User sessions on UNIX computers                                   | Users               |

|      |            |                     |
|------|------------|---------------------|
| NONE | No logging | Users and resources |
|------|------------|---------------------|

**NOTE**

If the audit property of a user is not set, the AUDIT value of a group or profile group can affect the audit mode Privileged Access Manager uses for the user.

**How Privileged Access Manager Determines the Audit Mode for a User**

The audit mode for a user specifies which audit events Privileged Access Manager sends to the audit log for that user. The following process describes how Privileged Access Manager determines the audit mode for a user:

1. Privileged Access Manager checks if the record of the user in the USER or XUSER class has a value for the AUDIT property.  
If the record of the user has a value for the AUDIT property, Privileged Access Manager uses that value as the audit mode for the user.
2. Privileged Access Manager checks if the user is assigned to a profile group. If the user is assigned to a profile group, Privileged Access Manager checks if the record of the profile group in the GROUP class has a value for the AUDIT property.  
If the user is assigned to a profile group and the record of the profile group has a value for the AUDIT property, Privileged Access Manager uses that value as the audit mode for the user.
3. Privileged Access Manager checks if the user is a member of a group. If the user is a group member, Privileged Access Manager checks if the record of the group in the GROUP or XGROUP class has a value for the AUDIT property.  
If the user is group member and the record of the group has a value for the AUDIT property, Privileged Access Manager uses that value as the audit mode for the user. If the user is not a member of a group, or if the record of the group does not have a value for the AUDIT property, Privileged Access Manager assigns the systemwide audit mode to the user.

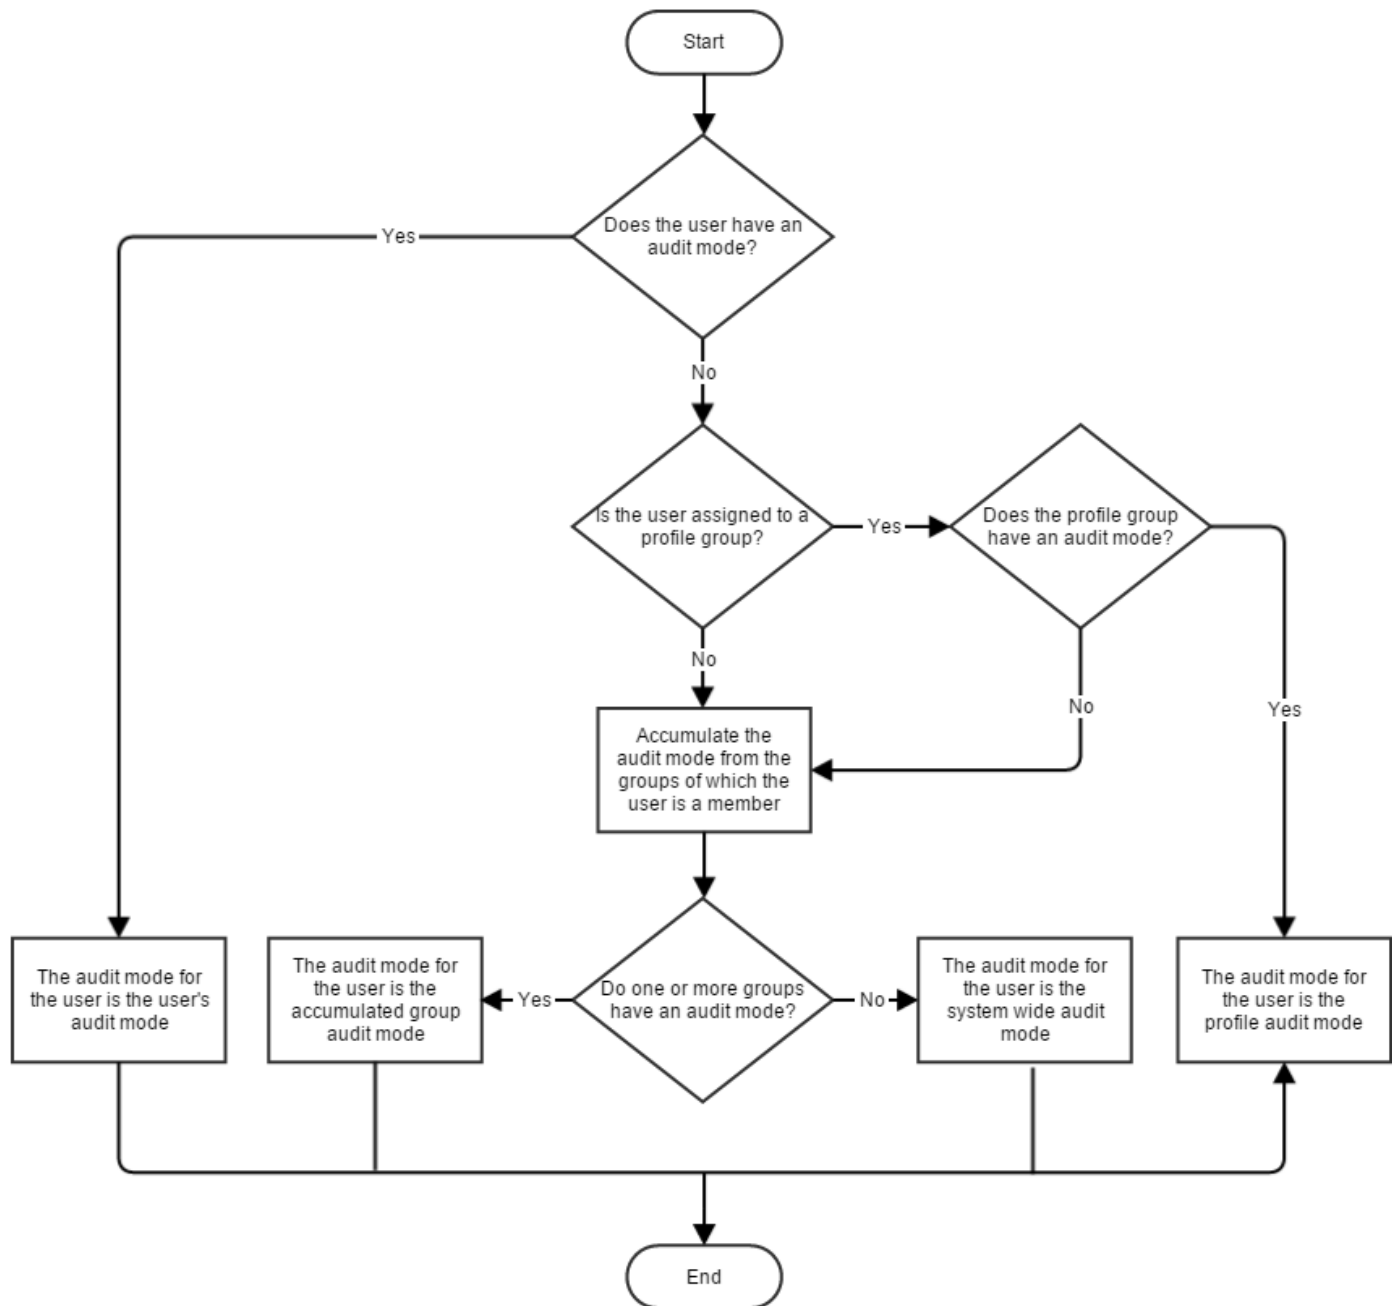

**NOTE**

The audit mode of the user accumulates if a user is a member of more than one group and the groups have different audit modes. The audit mode for the user is the sum of all the audit modes for the groups of which they are members.

**NOTE**

If Privileged Access Manager uses the value of a group's AUDIT property to determine the audit mode for a user, and you change the group's audit mode while the user is logged in, the audit mode for the logged-in user also changes. The user does not have to log off for the change in group audit mode to take effect.

The following diagram shows how Privileged Access Manager determines the audit mode for a user:

**Figure 45: Determine\_the\_Audit\_Mode\_for-a\_user****Example: Audit by Groups**

User Jan is a member of Group A and Group B. Group A has an audit mode of FAIL and Group B has an audit mode of SUCCESS. Because Jan is a member of both groups, Jan has the accumulated audit mode of FAIL and SUCCESS.

**Changing the Value of AUDIT Property for GROUP Records**

If you have a GROUP record that has two functions:

- A profile that defines an audit policy for one set of users
- A container for a second set of users

From r12.0 SP1 CR1 onwards, the GROUP record also defines the audit policy for the second set of users. To avoid problems that this behavior change may cause, create a separate GROUP for the second set of users.

### **Setting Audit Policies in Windows**

In addition to setting access rules for accessors and resources, you can specify Windows events that you want to write to the audit log. You can specify such audit policies for the entire organization, on a group basis, on a profile group basis, or on a user-by-user basis.

#### **Example: Set an Audit Policy for All Members of a Profile Group**

The following example sets an audit policy for all users that are part of a profile group:

1. Create a new profile group with the audit mode you require. For example:  

```
newgrp profileGroup audit(failure) owner(nobody)
```
2. Create a new user and attach it to the profile group you created. For example:  

```
newusr user1 profile(profileGroup) owner(nobody)
```
3. Remove the audit setting of the user. For example:  

```
chusr user1 audit-
```

You can now check whether this setting is effective:

1. Log on as the new user:  

```
runas /user:user1 cmd.exe
```
2. From the command prompt window of user1, enter the following command:  

```
secons -whoami
```

This command displays the information that is used for authorization and is held in the ACEE for user1.

```
ACEE audit mode is: Failure; Originated from Profile group definition
```

This message confirms that the audit policy is derived from the profile group the user is attached to.

#### **Example: Set a Audit Policy for Group Members**

In this example, a fictional company that is named Forward Inc wants to use Privileged Access Manager to protect all files in the /production directory. The /production directory has full access permissions in the native environment.

Forward Inc wants to deny and audit any attempts to access the /production directory. However, Forward Inc permits read access to the /production directory for developers. This access is not audited. An attempt by a developer to write to the /production directory is denied and audited.

Developers can request full access to the /production directory. Forward Inc audits any activity that a user with full access performs in the /production directory.

The following process describes the steps Forward Inc takes to implement the previous scenario:

1. Create a group named Developers in the native environment. Join all the developers to this group.
2. Create a group named Dev\_Access\_All in the native environment. Do not join any users to this group.
3. Define a generic access rule for the /production directory, as follows:

```
authorize FILE /production/* access(none) uid(*)
```

This rule sets the default access as none.

4. Define a generic audit rule for the /production directory, as follows:

```
editres FILE /production/* audit(failure)
```

This rule audits any failed attempt to access the /production directory.

5. Define an access rule for the Developers group, as follows:

```
authorize FILE /production/* access(read) xgid(Developers)
```

This rule permits members of the Developers group to have read access to the /production directory.

**NOTE**

The rule that you set in Step 4 ensures that Privileged Access Manager audits any failed access attempt by any user, including members of the Development group.

6. Define an access rule for the Dev\_Access\_All group, as follows:

```
authorize FILE /production/* access(all) xgid(Dev_Access_All)
```

This rule permits members of the Dev\_Access\_All group to have full access to the /production directory.

7. Define an audit rule for the Dev\_Access\_All group, as follows:

```
chxgrp Dev_Access_All audit(all)
```

This rule audits every action a member of the Dev\_Access\_All group performs.

8. When a member of the Developers group needs full access to the /production directory, add the user to the Dev\_Access\_All group in the native environment.

The user has full access to the /production directory, and Privileged Access Manager audits every action the user performs.

**NOTE**

The user must start a new logon session for the change in group membership to take effect.

9. When the user has completed their task in the /production directory, remove the user from the Dev\_Access\_All group in the native environment.

The user now has read access to the /production directory. Privileged Access Manager denies and audits any other access attempt on the /production directory by the user.

**NOTE**

The user must start a new log in session for the change in group membership to take effect.

## The Auditing Process

To configure Privileged Access Manager for your auditing requirements, you must first understand how auditing works. Auditing lets you keep track of access requests (events) that Privileged Access Manager intercepted. You can use this data to meet with compliance requirements, to analyze and refine your access rules for your security requirements, or to monitor access requests.

The process Privileged Access Manager follows to record audit events in the log depends on the type of event it intercepts:

- Interception events

**NOTE**

Intercepted login events (TERMINAL class), and audit records generated by user traces, are not cached; they always follow the auditing process for interception. events.

- [Audit events](#)

**NOTE**

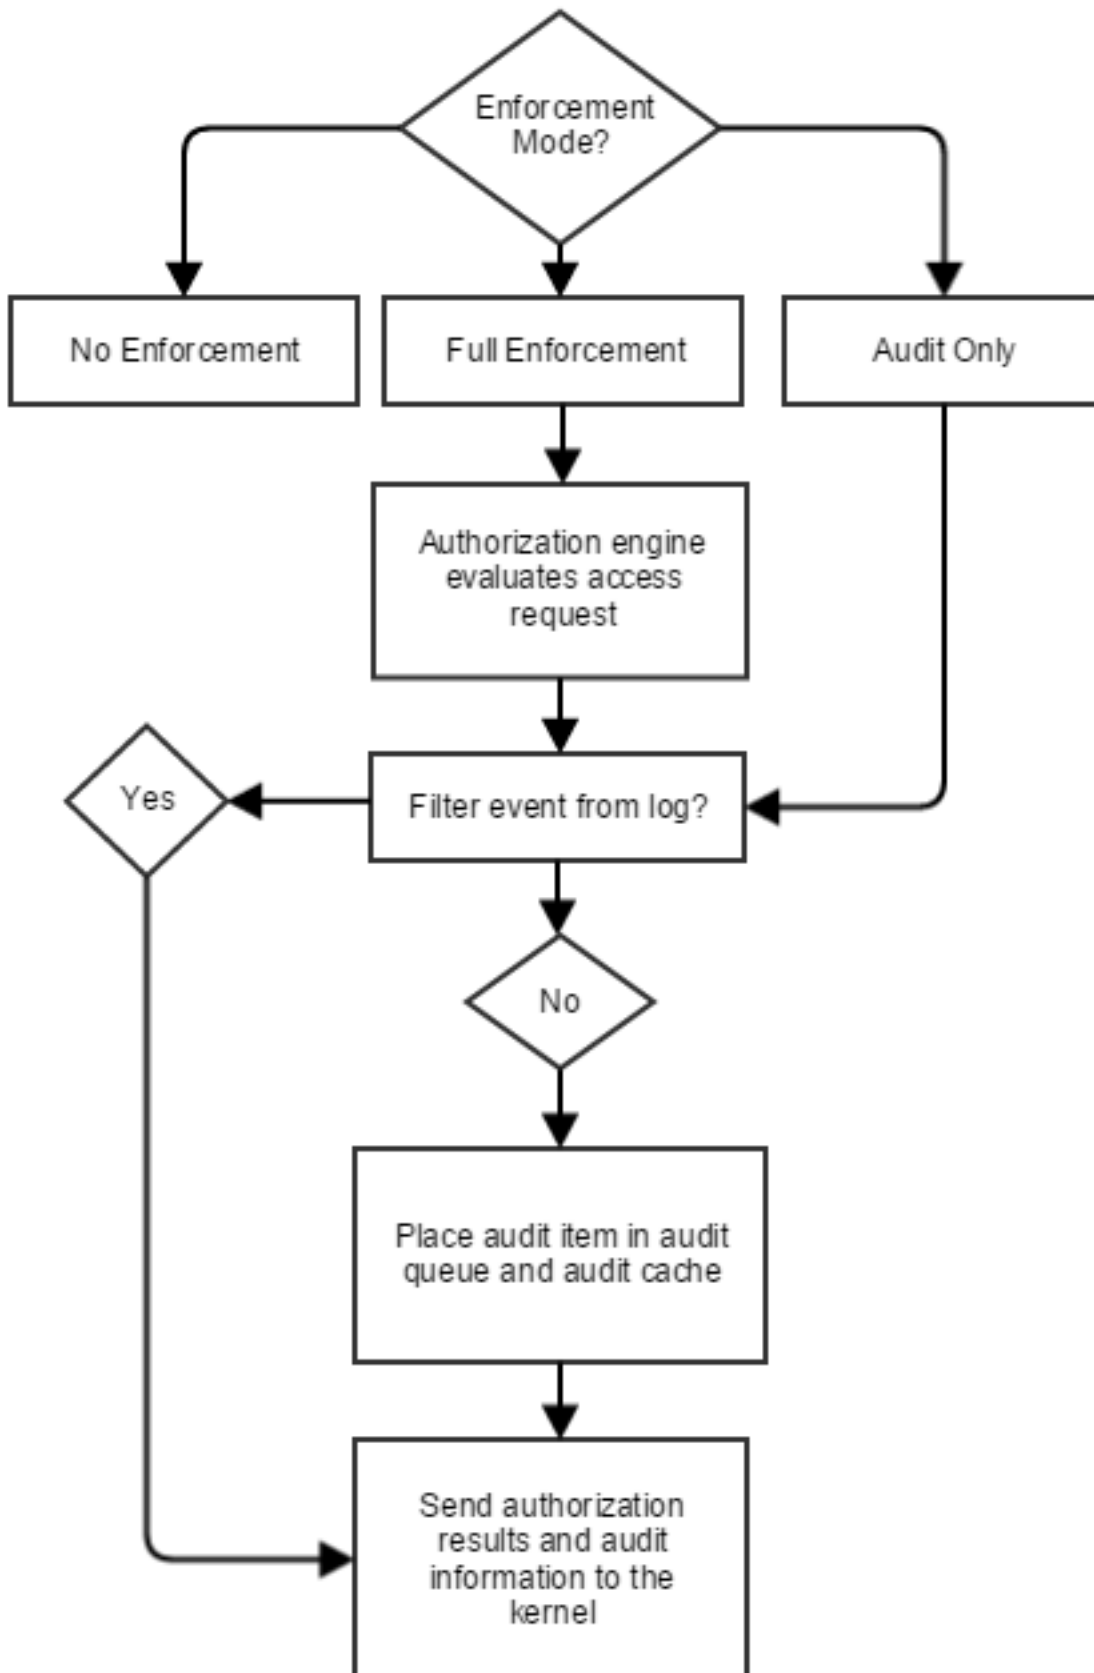

Privileged Access Manager intercepts an event only if the appropriate class is active, and the database contains a rule anticipating this event.

## How Auditing Works for Interception Events

An *interception event* is an event that Privileged Access Manager encounters for the first time and for which no authorization information or audit information exists in the kernel cache.

To log audit records, Privileged Access Manager performs the following actions and causes these effects for an interception event:

Figure 46: Audit Record Interception Events

- In No Enforcement mode, events are not intercepted or audited.
- In Full Enforcement mode, Privileged Access Manager follows these steps:
  - a. The authorization engine places an audit item that is based on the authorization result in the audit queue and in the audit cache.  
Privileged Access Manager writes an audit item only if the audit property for the resource or accessor is set to audit the resulting event and the audit filter file is not set to filter this event.
  - b. The authorization engine returns an informative answer on the authorization result and the audit-related information to the kernel.
- In Audit Only mode, Privileged Access Manager does not process the request for authorization. Audit information is always written, regardless of the audit property of the resource and user.  
Privileged Access Manager writes an audit item only if the audit filter file is not set to filter this event. The authorization result in this mode is always *P* (permitted).

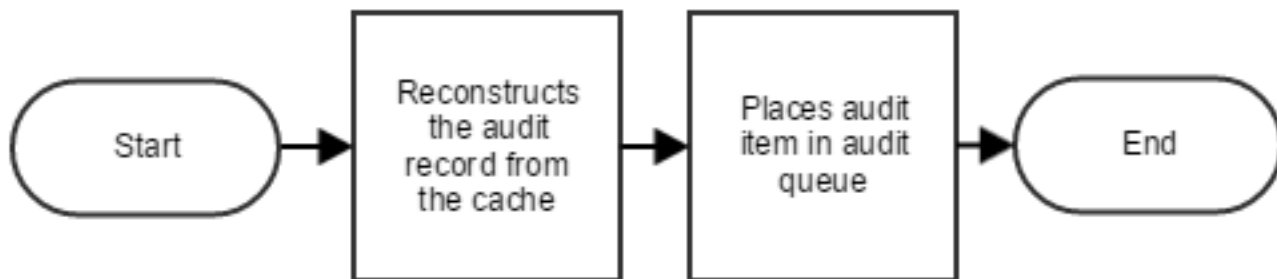

**NOTE**

Intercepted login events (TERMINAL class), and audit records that user traces generate are not cached. The authorization engine always writes audit records for these events.

**How Auditing Works for Audit Events**

The following diagram and steps demonstrate how auditing works for audit events:

**Figure 47: How Auditing Works for Audit Events**

Once the kernel notifies Privileged Access Manager about the cached interception event, Privileged Access Manager performs the following actions to log the audit event:

1. Reconstructs the audit data using the audit cache out of the information that the kernel sends.
2. Puts the audit item in the audit queue

**Kernel and Audit Caches**

The *kernel cache* contains data about previously intercepted events. The kernel identifies such cached intercepted events (audit events) and sends them to Privileged Access Manager for processing. Essentially, Privileged Access Manager uses the kernel cache to intercept events that follow the same pattern as a previously intercepted event.

The *audit cache* contains data that lets Privileged Access Manager reconstruct reoccurring audit records and send them to the audit queue without needing to follow the authorization process. This means that intercepted events, for which enough information already exists in the cache (audit events), are processed quickly and added to the audit queue. The authorization engine provides the data that is stored in the kernel and audit caches from the result of the initial event it intercepted (the interception event).

**Cache Reset**

Privileged Access Manager clears both the kernel and audit caches in the following cases:

- Database changes  
Privileged Access Manager clears the entire cache when database information changes. New or modified access rules make an existing cache potentially inaccurate.
- Time checkpoint reached  
Privileged Access Manager clears the entire cache when a time checkpoint affects an authorization result for any event. At the time that a DAYTIME restriction property or a HOLIDAY class record changes, the authorization result may change too and the cache becomes potentially inaccurate.
- PROGRAM resource change  
Privileged Access Manager clears the entire cache when the watchdog identifies that a PROGRAM resource has changed and become untrusted. An untrusted program affects the result of an authorization request regarding that program. This makes the cache potentially inaccurate.
- Audit cache filling  
Privileged Access Manager clears 10 percent of cache items (the least recently used items) when the audit cache fills up.

Once the cache is cleared, information from new interception events is needed to refill the cache and let Privileged Access Manager intercept an audit event.

## View Audit Event Logs

Privileged Access Manager sends audit events to the audit logs. You view the audit logs using the following Privileged Access Manager tools:

- Privileged Access Manager Endpoint Management
- The seaudit utility

You can configure Privileged Access Manager to send audit events to the Windows event log. The event log stores audit events from various applications in a single collection. You use the Windows Event Viewer to view audit events in the event log.

### Audit Events in the Windows Event Log

The Windows event log stores audit events from various sources in a single collection. If you configure Privileged Access Manager to route audit events to the event log, each time seosd writes an audit event to the Privileged Access Manager audit log, a corresponding event is sent to the event log.

The audit.cfg file filters audit events from both the audit log and the event log. If an audit event is not written to the audit log, it is not sent to the event log.

The Windows 2008 event log also routes audit events into containers that are called channels, depending on the volume, audience, and originating application of the audit events. The Privileged Access Manager channel is named CA-AccessControl-AuthorizationEngine/Audit.

If you have deployed Privileged Access Manager on a Windows 2008 server, you can choose to send audit events to:

- The event log
- The channel
- Both the event log and the channel
- Neither the event log or the channel

### Route Audit Events to the Windows Event Log

If you configure Privileged Access Manager to route audit events to the Windows event log, each time seosd writes an audit event to the Privileged Access Manager audit log, a corresponding event is sent to the event log. You can also configure Privileged Access Manager to send Policy Model audit events to the event log.

## To route events to the event log

1. Stop Privileged Access Manager using the following command:

```
secons -s
```

Privileged Access Manager stops.

2. Set the value of the SendAuditToNativeLog configuration setting in the logmgr section to 1.  
Audit events are sent to the Windows event log.
3. (Optional) Set the value of the SendAuditToNativeLog configuration setting in the Pmd section to 1.  
Audit events for policy models are sent to the Windows event log.
4. Restart Privileged Access Manager using the following command:

```
seosd -start
```

Privileged Access Manager restarts.

### Example: Route Audit Events to the Event Log

The following example routes audit events to the event log. You must be in the remote configuration environment (env config) to use this command:

```
er config ACROOT section(logmgr) token(SendAuditToNativeLog) value(1)
```

### Example: Route Policy Model Audit Events to the Event Log

The following example routes Policy Model audit events to the event log. You must be in the remote configuration environment (env config) to use this command:

```
er config ACROOT section(Pmd) token(SendAuditToNativeLog) value(1)
```

## Route Audit Events to the Windows Event Log Channel

### Valid for Windows Server 2008 only

If you configure Privileged Access Manager to route audit events to the Windows event log channel, each time seosd writes an audit event to the Privileged Access Manager audit log, a corresponding event is sent to the event log channel. The Privileged Access Manager event log channel is named CA-AccessControl-AuthorizationEngine/Audit.

You can also configure Privileged Access Manager to send Policy Model audit events to the event log channel. The Policy Model event log channel is named CA-AccessControl-Policy Models/Audit.

## To route events to the event log channel

1. Stop Privileged Access Manager using the following command:

```
secons -s
```

Privileged Access Manager stops.

2. Set the value of the SendAuditToNativeChannel token in the logmgr registry subkey to 1.  
Audit events are sent to the Windows event log channel.
3. (Optional) Set the value of the SendAuditToNativeChannel token in the Pmd registry subkey to 1.  
Policy Model audit events are sent to the Windows event log channel.
4. Restart Privileged Access Manager using the following command:

```
seosd -start
```

Privileged Access Manager restarts.

### Example: Route Audit Events to the Event Log Channel

The following example routes audit events to the event log channel. You must be in the remote configuration environment (env config) to use this command:

```
er config ACROOT section(logmgr) token(SendAuditToNativeChannel) value(1)
```

### Example: Route Policy Model Audit Events to the Event Log Channel

The following example routes Policy Model audit events to the event log channel. You must be in the remote configuration environment (env config) to use this command:

```
er config ACROOT section(Pmd) token(SendAuditToNativeChannel) value(1)
```

### The Audit Log (Windows)

The audit log is stored in a file. The value *audit\_log* in the following Windows registry subkey specifies the location of the audit log file:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\logmgr
```

The default value for this key is:

```
C:\Program Files\CA\PAMSC\log\seos.audit
```

By default, Privileged Access Manager automatically backs up the audit log when it reaches 1024 KB. You can change this size by changing the value *audit\_size* in the subkey:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\logmgr
```

You can also back up the audit log periodically (daily, weekly, or monthly). To do so, change the value *BackUp\_Date* in the Windows registry subkey:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\logmgr
```

#### NOTE

For more information about these registry subkeys, see the *Reference Guide*.

### Using Audit Logs

Privileged Access Manager provides two built-in tools for viewing, filtering, and searching the audit logs:

- Privileged Access Manager Endpoint Management
- The seaudit utility

You can display every record in the audit log. You can also use filters to select particular records from the audit log.

The remainder of this topic describes how to view the records in the audit log when using audit filters in Privileged Access Manager Endpoint Management.

### Audit Record Filters

The audit.cfg file filters audit records on a host by defining records that should not be sent to the audit file. Each line in the file represents a rule for filtering out audit information. The records that match the criteria in the line do not appear in the audit file. This filter helps to limit the size of the seos.audit file by keeping only the records needed. You can edit the audit.cfg file to suit your enterprise requirements.

By default, the audit.cfg file is located in the *ACInstallDir/etc* directory (UNIX) or *ACInstallDir\data* directory (Windows). You can change the location of the audit.cfg file by editing the [logmgr] AuditFiltersFile token in the seos.ini file (UNIX), or the AuditFiltersFile entry in the logmgr registry key (Windows).

The Privileged Access Manager Engine, seosd, reads the audit.cfg file at startup. When a message is sent to the audit file, seosd checks if the message matches one of the rules in the audit.cfg file. If the message matches a rule, the message is not written to the audit file.

#### NOTE

For more information about the audit.cfg file, see the *Reference Guide*.

### Audit Display Filters

The number of records in the audit log can become enormous. To reduce the number of records that *display*, use filters to specify the types of records for display. You can filter events by various criteria, including time or event type.

#### NOTE

You can also filter the audit records Privileged Access Manager *writes* to the audit file using the audit configuration settings (audit.cfg file).

You can create a filter in Privileged Access Manager Endpoint Management simply by giving it a name and choosing at least one switch. You can then select more switches, and have the option of assigning one or more options. You can also filter records with the seaudit utility.

Privileged Access Manager Endpoint Management provides several predefined filters, and you can create your own filters.

#### **Filter Wizard, Choose Name and Switches Page**

The Choose Name and Switches page of the Filter Wizard lets you define the following parameters:

- The name of the audit display filter you want to create
- The switches that you want to apply to this filter

This window contains the following fields:

- **Filter Name**  
Defines the name of the audit display filter you want to create.
- **Audit Event Records**  
Specifies whether you want the filter to display all audit records or only those switches that are selected. If you select to list all records, the switches on this page do not apply.
- **List INET audit records of Host and Service**  
Specifies whether to list the INET audit records of the TCP requests received from the specified hosts for the specified services. Host and service are masks that identify which set of hosts and services are searched for.
- **Show LOGINs for user on terminal**  
Specifies to list the following information:
  - LOGIN records for the specified user on the specified terminal. Both *user* and *terminal* are masks that you define.
  - Records created by the authorization engine when an invalid password is entered multiple times.
- **List RESOURCES audit of class on resource for users**  
Specifies whether to list resource records. You can define the following later:
  - *Class*, a mask that identifies the class to which the accessed resource belongs.
  - *Resource*, a mask that identifies the names of the resources that were accessed.
  - *User*, a mask that identifies the name of the users who accessed the resources.
- **List updates to database**  
Lists database update audit records. You can define:

- *Cmd*, a mask identifying the selang commands to search for.
- *Class*, a mask identifying the classes to search for.
- *Object*, a mask identifying the records to search for.
- *User*, a mask identifying the users who executed the commands.
- **List startup/shutdown messages**  
Specifies whether to list the startup and shut down messages from the Privileged Access Manager services.
- **List WATCHDOG audit records**  
Specifies whether to list the Watchdog audit records.
- **Show only trace records**  
Specifies whether to only list records sent to the audit log by the tracing facility.

### ***Filter Wizard, Edit Options Page***

The Edit Options page of the Filter Wizard lets you define the options that you want to apply to audit display filter.

This window contains the following fields:

- **Listing's Starting Today**  
Specifies today as the start date. Records that are logged before today are not listed.
- **Listing's Starting Date**  
Specifies the start date. Records that are logged before the specified date are not listed.
- **Listing's Starting Time**  
Specifies the start time. Records that are logged before the specified time are not listed.
- **Listing's Ending Date**  
Specifies the end date. Records that are logged after the specified date are not listed.
- **Listing's Ending Time**  
Specifies the end time. Records that are logged after the specified time are not listed.
- **Show Internet address not host name**  
Specifies that Internet addresses be listed instead of host names in TCP/IP records.
- **Hide failures**  
Specifies that failures are not listed.
- **Hide any granted accesses**  
Specifies that successful (granted) accesses are not listed.
- **Hide logout records**  
Specifies that logout records are not listed.
- **Hide NOTIFY audit records**  
Specifies that NOTIFY audit records are not listed.
- **Hide passwords attempts and actions**  
Specifies that password attempt records are not listed.
- **Hide warning records**  
Specifies that warning records are not listed.
- **Show port numbers not names**  
Specifies that port numbers be listed instead of service names.
- **Show only records originated from *host***  
Specifies that only records originating from the specified host are listed. This option is applicable only when connected to a UNIX workstation.

### ***Predefined Filters***

Privileged Access Manager comes with the following predefined filters:

- **All records**  
Displays every record in the audit log. No filtering takes place.
- **Today's records**

Shows every record created today.

- **Last 2 days records**

Shows every record created yesterday and today.

- **Last 7 days records**

Shows every record created during the last seven days.

- **Connections to Privileged Access Manager services**

Shows records that indicate when users connect to Privileged Access Manager services such as Privileged Access Manager Endpoint Management or selang.

**NOTE**

When connecting to a UNIX workstation, the name for this filter becomes Login Records. The records represent user logins.

- **Administration activity**

Shows all records that update the Privileged Access Manager or operating system databases. Updates to the databases include adds, deletes, and changes to all types of records.

### **Create a User-Defined Filter**

You can build as many filters as you need. Create a custom filter when you want to view only a particular set of audit records.

#### **To create a user-defined filter**

1. In Privileged Access Manager Endpoint Management, click the Audit Events tab.  
The Audit Records Viewer's Filter Settings section shows the list of Saved Filters.
  2. In the Saved Filters section, click Create Filter.  
The Audit Filter Wizard appears.
  3. Complete the wizard pages.
    - **Choose Name and Switches**  
Specifies the [switches that you want](#) to use in your filter.
    - **Edit Switches**  
Specifies settings for the switches you selected. These settings are masks that you can define for the audit events you want to filter.
    - **Edit Options**  
Specifies the [options that you want](#) to set for audit filtering.
- Click **Finish**.  
The new audit filter that you defined is saved and loaded.

### **Audit Log Backup**

Privileged Access Manager lets you automatically backup the audit log file for archiving.

The name of the audit log backup file is set in the logmgr\audit\_back Privileged Access Manager registry entry.

You can use the following methods for backing up the audit log file:

- Size-triggered backups
- Date-triggered backups

The method and settings you choose for backing up your audit log file depend on:

- Whether you need backup copies of the log file
- How much auditing data is likely to be generated in your environment
- System performance issues (for example, larger audit log files increase processing time)

**NOTE**

By default, Privileged Access Manager protects audit log backup files if you configure settings to keep timestamped backups. This is the same default protection that the size-triggered audit backup file receives. To remove these files, set permissive rules in the database.

**Set the Size at which the Audit Log is Backed Up Automatically**

You can set a limit on the size of the audit log file. When the file reaches the defined size, Privileged Access Manager automatically creates a backup copy of the file and clears the log. This means that the file is automatically backed up regularly.

To set the size at which the audit log is backed up automatically, set the maximum size that you require, in KB, in the logmgr\audit\_size Privileged Access Manager registry entry.

**NOTE**

You can define the name of the backup file by setting the logmgr\audit\_back Privileged Access Manager registry entry.

**WARNING**

If the logmgr/BackUp\_Date Privileged Access Manager registry entry is set to yes (no is the default), each size-triggered backup copy of the audit log is suffixed with a timestamp. In all other cases, including when date-triggered backups are configured, each backup copy *overwrites* the previously written backup copy.

**Example: Set automatic backup of audit log file when it reaches 5 MB**

This example shows you how you set your audit log file to be backed up when it reaches 5 MB (5120 KB). To do this, set the logmgr\audit\_size Privileged Access Manager registry entry to **5120**.

When the audit log file reaches 5 MB, Privileged Access Manager creates a backup copy of the file, named seos.audit.bak by default, and clears the log.

**Example: Set automatic backup of audit log file when it reaches 1 MB with a custom name and a timestamp**

This example shows you how you set your audit log file to be backed up when it reaches 1 MB (1024 KB), using a custom name for the backup file and adding a timestamp to the name.

To do this, set the following Privileged Access Manager registry entries as shown:

- logmgr\audit\_size=1024
- logmgr\audit\_back=log\ac\_audit.old
- logmgr\BackUp\_Date=yes

When the audit log file reaches 1 MB, Privileged Access Manager creates a backup copy of the file, and clears the log. The name of the backup log file name is: ac\_audit.old.*timestamp*, where *timestamp* is the date and time in the format DD-Mon-YYYY.hhmmss. For example:

```
ac_audit.old.06-Feb-2007.144330
```

**Set the Time Interval at Which the Audit Log Is Backed up Automatically**

You can define a time interval (daily, weekly, or monthly) at which Privileged Access Manager automatically creates a backup copy of the audit log file and clears the log.

To set the time interval at which the audit log is backed up automatically, set the interval in the logmgr\BackUp\_Date Privileged Access Manager registry entry. The interval can be one of the following:

- **daily**  
Backs up the audit log file once a day.
- **weekly**

Backs up the audit log file once a week.

- **monthly**

Backs up the audit log file once a month.

**NOTE**

You can define the name of the backup file by setting the logmgr\audit\_back Privileged Access Manager registry entry.

**WARNING**

If the audit log reaches the size limit that is defined in the logmgr\audit\_size Privileged Access Manager registry entry before the backup interval is reached, the product creates a backup copy of the file without a timestamp.

Each such backup copy can potentially overwrite any previous copy.

**Example: Set a daily backup of the audit log file**

This example shows you how you set your audit log file to be backed up daily. To do this, set the logmgr\BackUp\_Date Privileged Access Manager registry to **daily**.

Once a day Privileged Access Manager creates a backup copy of the file, and clears the log. The backup log file name has the *.timestamp* suffix, where *timestamp* is the date and time in the format DD-Mon-YYYY.hhmmss. For example:

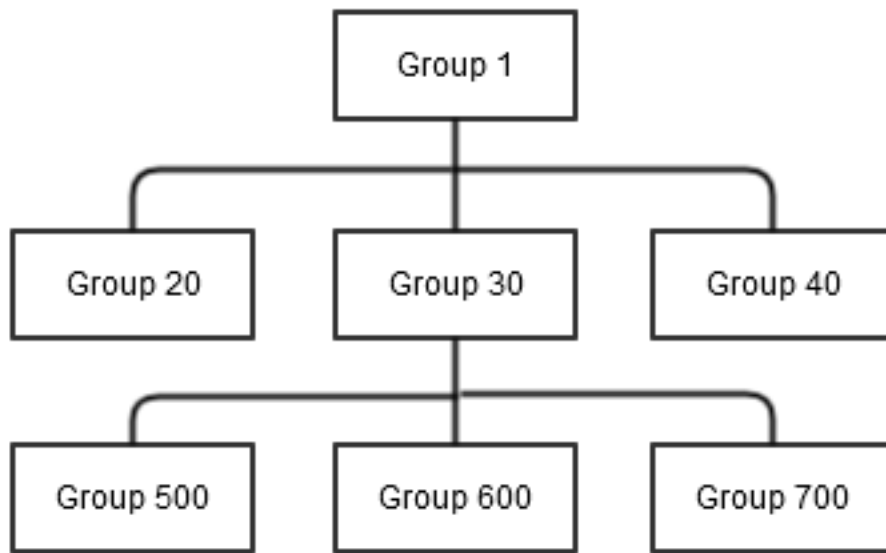

```
seos.audit.bak.06-Feb-2007.144330
```

## Group Authorization

It is necessary to understand the concept of parentage before discussing group authorization attributes.

### Parentage

The concept of subordinate and superior groups, also known as parentage, is important when discussing group administration privileges. One group can be the parent-superior-of one or more groups. A *child* or subordinate group can have only one parent. Assigning a parent to a group is optional. Consider the following diagram:

**Figure 48: parentage**

Group 1 is the parent of the three Groups 20, 30, and 40. Group 30 is also the parent of three groups-500, 600, and 700. Group 600 has only one parent-Group 30. Group 1 has no parent.

### **Group Authorization Attributes**

All records, including resource records and accessor records alike, have owners. Owning a record means having authorization to view, edit, and remove it.

A group can own its own records. However, within a group that owns records, only certain privileged users can manage the records. These special users have a group authorization attribute set in their own user records. The group authorization attributes are the following:

- GROUP-ADMIN
- GROUP-AUDITOR
- GROUP-OPERATOR
- GROUP-PWMANAGER

The join command-which only a properly authorized user can issue-sets these attributes. The join command serves the purpose of both putting a user into a group, and specifying the user's group authorization attribute (if any).

The privileged members of the group may or may not be authorized to manage the user records that define the members of the group, depending on who owns those records.

### ***GROUP-ADMIN Attribute***

Users with a group administration authorization attribute can create a certain set of records. In order to create a record, the group administrator has to specify the owner of the record.

The owner of the records must be the group in which the user has a group authorization attribute. If that group is the parent of other groups, the owner can also be from one of the sub groups. The whole set of records is called the group scope. The authorization examples provided illustrate the concept of group scope.

Users with the GROUP-ADMIN attribute have the following access authority for the records within their group scope:

| Access  | Description                                                     | Commands                            |
|---------|-----------------------------------------------------------------|-------------------------------------|
| Read    | Show the properties of the record.                              | showusr, showgrp, showres, showfile |
| Create  | Create new records in the database. You must specify the owner. | newusr, newgrp, newres, newfile     |
| Modify  | Change the properties of the record.                            | chusr, chgrp, chres, chfile         |
| Delete  | Remove records from the database.                               | rmusr, rmgrp, rmres, rmfile         |
| Connect | Join a user to a group or separate a user from a group.         | join, join-                         |

The GROUP-ADMIN attribute also has limits:

- GROUP-ADMIN users cannot make resources inaccessible to themselves, so:
  - GROUP-ADMIN users cannot assign a security level that is higher than their own security level.
  - GROUP-ADMIN users cannot assign a security category or security label that they do not have.
- GROUP-ADMIN users cannot delete the user superuser (the root account on UNIX or the Administrator account on Windows) from the database.
- Several limitations concern the global authorization attributes described in Global Authorization Attributes in this chapter:
  - A GROUP-ADMIN user cannot delete the only ADMIN user record in the database.
  - A GROUP-ADMIN user cannot remove the ADMIN attribute from the record of the last ADMIN user in the database.
  - GROUP-ADMIN users without the AUDITOR attribute cannot update the audit mode. Only a GROUP-ADMIN user with the AUDITOR attribute can update the audit mode.
  - GROUP-ADMIN users cannot set the global authorization attributes-ADMIN, AUDITOR, OPERATOR, PWMANAGER, and SERVER-for any user.

### **GROUP-AUDITOR Attribute**

A user with the GROUP-AUDITOR attribute can list the properties of any record within the group scope. The group auditor can also set the audit mode for any record within the group scope.

### **GROUP-OPERATOR Attribute**

A user with the GROUP-OPERATOR attribute can list the properties of any record within the group scope.

### **GROUP-PWMANAGER Attribute**

A user with the GROUP-PWMANAGER attribute can change the password of any user whose record is within the group scope.

## **Ownership**

Every record in the database—including both accessor records and resource records—has an owner. When you add a record to the database, you can either explicitly assign its owner by using the owner parameter or let Privileged Access Manager assign the user who defines the record as the owner of the record.

Accessors own a record if *any* of the following are true:

- They are defined as the owner of the record.
- They are members of a group that is defined as the owner of the record *and* they have joined the group with the GROUP-ADMIN property.
- They are owners of a resource group record that the resource is a member of.

If you remove a user or group that owns records from the database, the records no longer have an owner.

Users who own records have the following access authority for the records they own:

| Access  | Description                                             | Commands                            |
|---------|---------------------------------------------------------|-------------------------------------|
| Read    | Show the properties of the record.                      | showusr, showgrp, showres, showfile |
| Modify  | Change the properties of the record.                    | chusr, chgrp, chres, chfile         |
| Delete  | Remove the record from the database.                    | rmusr, rmgrp, rmres, rmfile         |
| Connect | Join a user to a group or separate a user from a group. | join, join-                         |

If you do not want a user or group to have ownership authority over a particular record, assign the owner *nobody* to the record and to any resource group record that the record is a member of.

The limits of the ownership privileges are as follows:

- The owner of the last ADMIN user in the database cannot delete that user record.
- Owners who do not have the AUDITOR attribute cannot update the audit mode. Only an owner with the AUDITOR attribute can update the audit mode.
- The owner of a superuser (the root account on UNIX or the Administrator account on Windows) cannot delete root from the database.
- Owners cannot set the global authorization attributes—ADMIN, AUDITOR, OPERATOR, and PWMANAGER—for the users they own.
- Owners cannot make resources inaccessible to themselves, so:
  - Owners cannot assign a security level that is higher than their own security level.
  - Owners cannot assign a security category or security label that they do not have.

## File Ownership

Privileged Access Manager allows the owner of a file to protect the file by defining a record in the FILE class. The owner of the file has full authority over the record of that file, so the owner can use the newfile, chfile, showfile, authorize, and authorize- commands with all parameters for the record that protect the file.

On UNIX, when a user creates a file, UNIX assigns the user as the owner of the file. Privileged Access Manager allows UNIX file owners to define FILE records, unless this feature is explicitly disabled. If you do not want file owners to define FILE records, make sure that the use\_unix\_file\_owner token in the [seos] section of the seos.ini file is set to no. (This is the default setting.)

## Authorization Examples

Following are diagrams that illustrate the concepts of group authorization attributes, parentage, ownership, membership, and group scope. These diagrams only contain users and groups, but the concept of ownership also applies to resource and file records.

### Single Group Authorization

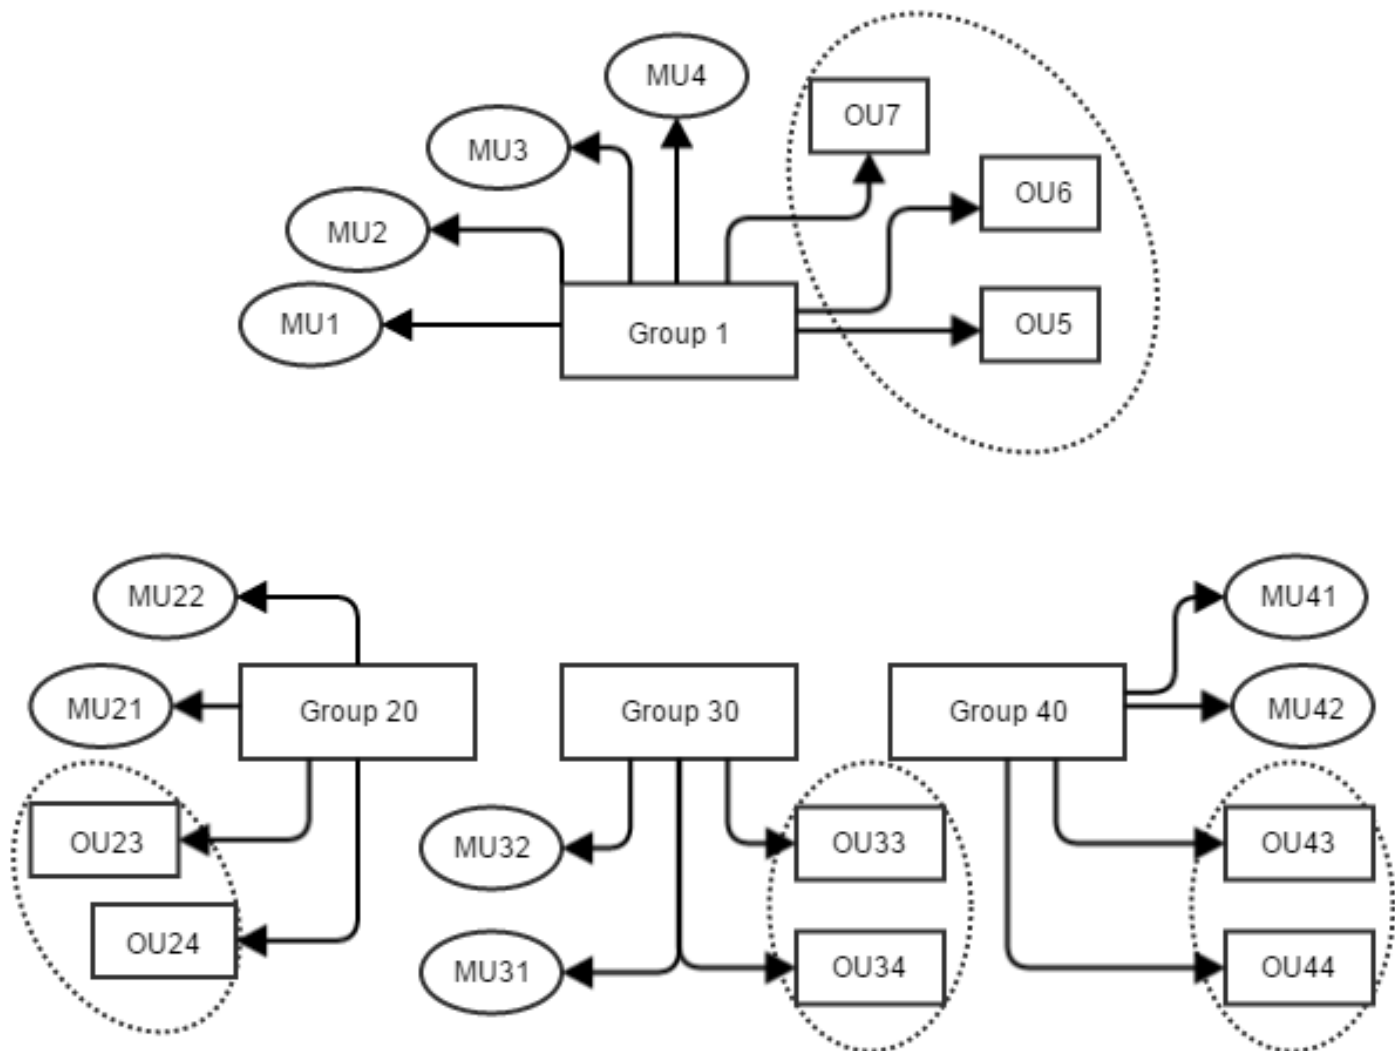

In the following diagram, four users are members of Group 1: MU1, MU2, MU3, and MU4. Group 1 also owns three users—OU5, OU6, and OU7. The member MU4 has the GROUP-ADMIN attribute.

**Figure 49: Single group authorization**

The ellipse indicates the group scope of the commands executed by user MU4. It includes all the users owned by Group 1-OU5, OU6, and OU7.

#### **Parent and Child Groups**

In the following diagram, four users are members of Group 1: MU1, MU2, MU3, and MU4. Group 1 also owns three users-OU5, OU6, and OU7. The member MU4 has the GROUP-ADMIN attribute set in its record.

**Figure 50: Parent and child groups**

Group 1 is also the parent of three groups—20, 30, and 40. Each of these subordinate groups has two users who are members of the group and two users who are owned by the group.

The four ellipses indicate the group scope of the commands executed by user MU4. It includes all the users owned by Group 1, as well as the users owned by the groups subordinate to Group 1. The users in the group scope of MU4 are OU5, OU6, OU7, OU23, OU24, OU33, OU34, OU43, and OU44.

If there were groups subordinate to Groups 20, 30, or 40 that owned users, groups, or resources, the records owned by these groups would also be in the group scope of commands executed by user MU4.

## **Windows Environment**

### **Valid in the native Windows environment**

When Privileged Access Manager is running, if you use `selang` to change a resource in the native Windows environment, the Privileged Access Manager Agent changes the resource in the appropriate Windows repository. You do not need any additional Windows permissions to change the resource. This means that when users in Privileged Access Manager with

global or group authorization attributes perform `selang` commands in the native Windows environment, they have the same privileges and limits for Windows as they do for Privileged Access Manager.

When Privileged Access Manager is not running, if you use `selang` to change a resource in the native Windows environment, you must follow these rules:

- You must include the `l` option in the `selang` command
  - You must have the ADMIN attribute or sub administration privileges
  - You must have sufficient Windows permissions to change the resource
- This restriction occurs because a `selang` process, not the Privileged Access Manager Agent, changes the resource in the Windows repository.

For example, user Emma wants to use the `chfile` `selang` command in the native Windows environment to change the owner of the file `C:\tmp.txt`. If Privileged Access Manager is running, Emma requires sufficient Privileged Access Manager permissions to change the file owner, but does not require additional Windows permissions. If Privileged Access Manager is not running, Emma requires both Privileged Access Manager and Windows permissions to change the file owner.

## **UNIX Environment**

For managing users and groups in UNIX, users in Privileged Access Manager with global or group authorization attributes have the same privileges and limits for UNIX as they do for Privileged Access Manager.

If you use `selang` while the `seosd` daemon is *not* running (for example, at installation time), you must follow these rules:

- You must include the `-l` option in the `selang` command.
- The user of `selang` must be root. (This exclusive root privilege complies with regular UNIX restrictions.)

## **Manage Sub Administrators**

Security administrators (users with the ADMIN attribute) can grant specific administrative privileges to regular users. These regular users are then called sub administrators. Sub-administrators have privileges to manage only specified Privileged Access Manager classes or objects. For example, a sub administrator can be authorized to manage only user and group objects. You can set a higher level of sub administration by authorizing the sub admin user the administrative privileges for specific objects in a class.

Sub administrators of users, groups and resources can use `selang` to perform administrative tasks related to these resources.

## **How to Grant Specific Administrative Privileges to Regular Users**

Because administrator users with the ADMIN attribute can execute almost all actions in Privileged Access Manager, you may want to delegate specific administrative tasks to sub administrators. To do this, grant those users with privileges to classes in the Privileged Access Manager database that control the specific administrative tasks the user needs to perform as follows:

1. Identify one or more classes that control the tasks you want to delegate.  
For example, Privileged Access Manager uses the USER and GROUP classes to create accessor resources. If you want to delegate accessor management, you need to use the USER and GROUP records of the ADMIN class.
2. Authorize one or more sub administrator to the applicable resource of the ADMIN class.  
For example, to let a sub administrator view and modify user records, grant the user with *read* and *modify* access to the USER record of the ADMIN class.

## **The ADMIN Class**

Sub administrator users listed in the access control list (ACL) of records in the class ADMIN have privileges similar to users with the ADMIN attribute. However, the privileges of users in the ACL for records in the class ADMIN are limited

to the particular class represented by the record. For example, the SURROGATE record in the ADMIN class determines which users can administer records of the SURROGATE class.

#### NOTE

For more information about Privileged Access Manager classes, see the *Reference Guide*.

A user in the ACL for a particular record in class ADMIN can execute the following commands:

| Access   | Description                                                                                                                                                                                                                             | Commands                                  |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| Read     | Show the properties of the record in the class.                                                                                                                                                                                         | showusr, showgrp, showres, showfile, find |
| Create   | Create new database records in the class.                                                                                                                                                                                               | newusr, newgrp, newres, newfile           |
| Modify   | Change properties in the class.                                                                                                                                                                                                         | chusr, chgrp, chres, chfile               |
| Delete   | Remove existing class records from the database.                                                                                                                                                                                        | rmusr, rmgrp, rmres, rmfile               |
| Connect  | Add users to and remove users from groups. This access is valid only in the ACL of the GROUP record.                                                                                                                                    | join, join-                               |
| Password | Control the password of all users within the database, and their password attributes. This access grants the same authority as the access permitted a user with the PWMANAGER attribute. This is valid only in the ACL for record USER. | chusr                                     |

Users with ADMIN class privileges have the following limitations:

- Users defined in the ACL of the USER record in class ADMIN cannot delete the last ADMIN user in the database.
- ADMIN class users cannot set the global authorization attributes-ADMIN, AUDITOR, OPERATOR, and PWMANAGER- for the users they own.
- ADMIN class users cannot necessarily update the audit mode. Only an ADMIN class user with the AUDITOR attribute can update the audit mode.
- ADMIN class users cannot delete superuser (the root account on UNIX or the Administrator account on Windows), but they can set root to be NOADMIN.
- ADMIN class users cannot make resources inaccessible to themselves, so:
  - ADMIN class users cannot assign a security level to a resource that is higher than their own security level.
  - ADMIN class users cannot assign a security category or security label that they do not have.

These limitations are part of the B1 security level certification.

## Environmental Considerations

One of the factors governing whether you can update information in your database is the position you occupy in the environment.

### Remote Administration Restrictions

You can access a remote station over a network and can update the database on the remote station. To update the database on the remote station, both you and your terminal need permission.

- You must be explicitly defined as a user in the database of the remote station. For whatever commands you want to execute, set the appropriate attribute in your user record in the database of the remote station.
- Explicitly mention the needs of your local terminal in a rule granting it WRITE permission for accessing the remote station. Otherwise, you cannot perform Privileged Access Manager administration there.  
With WRITE permission through a default access field (`_default`), or through the UACC class, you can enter the `selang` command shell at the remote station. However, you *cannot* execute any `selang` commands or otherwise access to the remote database. With READ permission, you can log in to the remote station but you cannot perform Privileged Access Manager administration there.

Here is an example of this distinction between WRITE and READ permission:

- To specify a new terminal with READ as default access, where administrators can log in from the terminal but cannot manipulate the database from it, issue the following command:

```
newres TERMINAL tty13 defacc(read)
```

- To grant user ADMIN1 permission to manipulate the database from the new terminal (that is, grant WRITE permission and READ permission), issue the following command:

```
authorize TERMINAL tty13 uid(ADMIN1) access(r,w)
```

## UNIX Environment

For managing users and groups in UNIX, users in Privileged Access Manager with global or group authorization attributes have the same privileges and limits for UNIX as they do for Privileged Access Manager.

If you use `selang` while the `seosd` daemon is *not* running (for example, at installation time), follow these rules:

- Include the `-l` option in the `selang` command.
- The user of `selang` must be root. (This exclusive root privilege complies with regular UNIX restrictions.)

## Windows Environment

### Valid in the native Windows environment

When Privileged Access Manager is running, the Privileged Access Manager Agent changes the resource in the appropriate Windows repository if you use `selang` to change a resource in the native Windows environment. You do not need any additional Windows permissions to change the resource. This means that when users in Privileged Access Manager with global or group authorization attributes perform `selang` commands in the native Windows environment, they have the same privileges and limits for Windows as they do for Privileged Access Manager.

When Privileged Access Manager is not running, if you use `selang` to change a resource in the native Windows environment, follow these rules:

- Include the `l` option in the `selang` command
- You must have the ADMIN attribute or sub administration privileges
- You must have sufficient Windows permissions to change the resource  
This restriction occurs because a `selang` process, not the Privileged Access Manager Agent, changes the resource in the Windows repository.

For example, user Emma wants to use the `chfile` `selang` command in the native Windows environment to change the owner of the file `C:\tmp.txt`. If Privileged Access Manager is running, Emma requires sufficient Privileged Access Manager permissions to change the file owner, but does not require more Windows permissions. If Privileged Access Manager is not running, Emma requires both Privileged Access Manager and Windows permissions to change the file owner.

## Default Permissions to Access the Database

Privileged Access Manager protects the internal database, `seosdb`, with internal file rules when it is running. Internal file rules are not visible in `selang` and cannot be deleted. You can write FILE rules to override the internal file rules. If you delete these FILE rules, Privileged Access Manager reverts to the internal file rules.

The following internal file rules protect the database when Privileged Access Manager is running:

- Privileged Access Manager internal processes have full access to the database.
- The NT AUTHORITY\System user has read access to the database.
- All other accessors have no access to the database.

#### NOTE

The default access rights for all other accessors were changed in r12.5 SP3. In previous releases, all other accessors had read access by default to the database files.

By default, Privileged Access Manager services run automatically after you install Privileged Access Manager or reboot the endpoint. Consequently, the only user who can access the database out of the box is NT AUTHORITY\System. The Privileged Access Manager administrators that you define during installation can also use a utility such as `selang` to update the database.

## Native Permissions to Access the Database

When Privileged Access Manager is stopped, access rights to the database files are determined by native Windows permissions. Permissions are inherited from the parent directory in which Privileged Access Manager is installed. Because of this inheritance, the default access to the database files is read when Privileged Access Manager is stopped.

To protect Privileged Access Manager when it is stopped, you can change the Windows permissions for the database files to suit your enterprise requirements. Before you change the permissions, consider the following:

- The NT AUTHORITY\System user *must* have Windows permissions to read and write to the database files. The Privileged Access Manager authorization engine inherits privileges from the NT AUTHORITY\System user. If this user cannot access the database, the engine does not have sufficient native privileges to update the database.
- Users who need read and write access to Privileged Access Manager when it is stopped must have Windows permissions to read and write to the database files. Users who need read and write access include users who back up, restore, or upgrade Privileged Access Manager.
- Users that can use `selang` when Privileged Access Manager is stopped (`selang -l` option) must have the following permissions:
  - The ADMIN attribute or sub-administration privileges
  - Windows permissions to read and write to the database files
  - Windows permissions to change native repositories, if required
 For example, to use the config environment to change Privileged Access Manager registry entries when it is stopped, you must have sufficient Windows privileges to change the registry.

Only Privileged Access Manager administrators (users with the ADMIN attribute or with sub-administration privileges) can use `selang` to maintain the database when it is stopped. If the Privileged Access Manager administrators cannot access the database when it is stopped, no user can perform offline database maintenance and a deadlock may occur.

## Policy Model Database (Windows)

Managing tens or hundreds of databases individually is not practical. Privileged Access Manager supplies the Policy Model service, a component that lets you manage many databases from one central database. Using the Policy Model (PMD) service is optional, but it greatly simplifies administration at large sites.

#### NOTE

In Windows Task Manager, the Policy Model service appears as `sepmdd.exe`.

The Policy Model service uses a Policy Model database (PMDB). Like other Privileged Access Manager databases, the PMDB contains users, groups, protected resources, and rules governing access to the resources. In addition, the PMDB contains a list of *subscriber* databases. Each subscriber is a Privileged Access Manager database that resides on a separate computer, or another PMDB that resides on the same or another computer. A PMDB that updates a subscriber is the *parent* of the subscriber.

The PMDB is a useful tool for managing many databases that have similar authority restrictions and access rules.

Policy Model names are case-sensitive on Windows for compatibility with UNIX. When specifying PMDB names in commands, ensure that you use the correct case. The first character for a PMDB name consists of the alphanumeric characters "-" and "\_".

#### NOTE

You cannot use non-English characters in PMDB and host names.

#### NOTE

Although PMDB names are case-sensitive, you cannot have two PMDBs on the same computer with only the letter case being different. Privileged Access Manager uses the PMDB name as part of the file path but Windows is case-insensitive and so does not permit this. For example, myPMDB and MYpmdb are two different Policy Model databases but cannot live on the same system.

#### NOTE

For information about administering a PMDB (sepmcmd utility), see the *Reference Guide*. For information about managing PMDBs remotely using selang, see the *selang Reference Guide*.

### **PMDB Location on Disk**

All PMDBs on a computer reside in a common directory. The `_pmd_directory_` value in the following subkey of the Windows registry specifies the name of the directory:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\Pmd
```

The default value of `_pmd_directory_` in the NTFS root directory is: `ACInstallDir\data`, where `ACInstallDir` is the directory where you installed Privileged Access Manager (by default `C:\Program Files\CA\AccessControl`).

Each PMDB occupies a subdirectory in the common directory. The files in the subdirectory contain all the data that is required to define the Policy Model. Policy Model configuration settings are stored in a `Pmd` subkey of the Privileged Access Manager registry settings. The name of the subkey is the name of the Policy Model.

### **Managing Local PMDBs**

Privileged Access Manager offers a utility for administering PMDBs:

- **sepmcmd**  
A PMDB administration utility that lets you:
  - Administer subscribers
  - Truncate the update file
  - Administer Dual Control
  - Manage the Policy Model log file
  - Perform other administrative tasks

#### NOTE

For more details about `sepmcmd`, see the *Reference Guide*.

### **Managing Remote PMDBs**

Privileged Access Manager also offers you a range of `selang` commands that you can use in the `pmd` environment. These commands let you manage PMDBs remotely:

- **backuppmd**  
Backs up a PMDB.
- **createpmd**

Creates a PMDB.

- **deletepmd**  
Deletes a PMDB.
- **findpmd**  
Displays the names of all PMDBs on the computer.
- **listpmd**  
Lists the following information about a PMDB:
  - Subscribers and their status
  - PMDB description and its status
  - Commands in the update file and their offsets
  - Contents of the error log
- **pmd**  
A PMDB administration command that lets you:
  - Remove a subscriber from the list of unavailable subscribers
  - Clear the Policy Model error log
  - Start and stop the Policy Model service
  - Lock and unlock the Policy Model
  - Truncate the update file
- **restorepmd**  
Restores a PMDB from its backup files.
- **subs**  
A PMDB subscription command that lets you:
  - Add an existing subscriber to a parent PMDB
  - Add a new subscriber to a parent PMDB
  - Assign a parent PMDB to a database (Privileged Access Manager or another PMDB)
- **subspmd**  
Assigns a parent PMDB to the local database.
- **unsubs**  
Removes a subscriber from the PMDB.

**Note:** For a comprehensive explanation of *selang* commands you can use in the *pmd* environment, see the *selang Reference Guide*.

### **Architecture Dependency**

When deploying Privileged Access Manager, consider the hierarchy of your environment. At many sites, the network includes various architectures. Some policy rules, such as the list of trusted programs, are architecture-dependent. On the other hand, most rules are independent of the architecture of the system.

You can cover both kinds of rules by using a hierarchy. You can define a global database for architecture-independent rules, and can give it subscriber PMDBs that define architecture-dependent rules.

#### **NOTE**

The root PMDB and all its subscribers can reside on the same computer or on separate computers, depending on the physical needs of your environment.

### **Example: A Two-Tiered Deployment Hierarchy**

The following UNIX example also applies to a Windows architecture with small modifications.

In the example, the site consists of IBM AIX and Sun Solaris systems. Because the list of trusted programs on IBM AIX differs from the one on Sun Solaris, the PMDBs need to consider architecture dependency.

To set up a multiple-architecture PMDB, set up your PMDBs as follows:

1. Define a PMDB named `whole_world`, to contain the users, groups, and all other architecture independent policies.
2. Define a PMDB named `pm_aix`, to contain all the IBM AIX-specific rules.
3. Define the PMDB `pm_sol` to contain all the Sun Solaris specific rules.

The PMDBs `pm_aix` and `pm_solaris` are subscribers of the PMDB `whole_world`. All IBM AIX computers at the site are subscribers of `pm_aix`. All Sun Solaris computers at the site are subscribers of `pm_sol`. The concept is illustrated in the following chart.

**Figure 51: Architecture\_Dependency**

4. When you enter platform-independent commands in `whole_world`, such as adding a user or setting a SURROGATE rule, all databases at the site are automatically updated.
5. When you add a trusted program to `pm_aix`, only IBM AIX computers are updated, without affecting the Sun Solaris systems.

### **Methods for Centrally Managing Policies**

Privileged Access Manager lets you manage several databases from a single computer in the following ways:

- **Automatic rule-based policy updates:** Regular rules that you define in a central database (PMDB) are automatically propagated to databases in a configured hierarchy.

**NOTE**

Dual control is only available with this method and on UNIX only. Information about dual control for automatic rule-based policy updates is found in the *Endpoint Administration Guide for UNIX*. Information about automatic rule-based policy updates can also be found in the *Endpoint Administration Guide for Windows*.

- **Advanced policy management:** Policies (groups of rules) you deploy are propagated to all databases based on host or host group assignment. You can also undeploy (remove) policies and view deployment status and deployment deviation. Install and configure extra components to use this functionality.

**NOTE**

Information about advanced policy management is found in the *Enterprise Administration Guide*.

## Automatic Rule-based Policy Updates

Single-rule policy updates (regular selang rules) you make in a central database are automatically propagated to the subscriber databases. By subscribing several computers to the same database, and by subscribing one database to another, you can create a hierarchy. You configure your environment for automatic rule-based policy updates after installation.

**NOTE**

This method of managing policies is limited to letting you make single-rule policy updates across your hierarchy. Other functionality is only available through implementing advanced policy management and reporting.

### How Automatic Rule-Based Policy Updates Work

When you configure your environment for automatic rule-based policy updates, each rule you define in the central database is automatically propagated to all its subscribers in the following way:

1. A rule is defined for any PMDB with at least one subscriber.
2. The PMDB sends the command to all subscriber databases.
3. The subscriber database applies the propagated command.
  - a. If the subscriber database does not respond, the PMDB sends the command at a regular interval (by default, every 30 minutes) until the subscriber database has been updated.
  - b. If a subscriber database is responding, but refuses to apply the command, the PMDB places the command in the [Policy Model error log](#).
4. If the subscriber database is a parent to other subscribers, it then sends the command to its subscribers.

### **Example: Removing a user from all computers in a hierarchy**

If a user is deleted from a PMDB using the `rmusr` command, the same `rmusr` command is sent to all the subscriber databases. In this way, a single `rmusr` command can remove a user from many databases on various computers.

### How You Use a PMDB to Propagate Configuration Settings

When you edit a Policy Model's configuration, the new configuration values are propagated to the Policy Model's subscribers.

The following process describes how configuration updates are propagated to a Policy Model's subscribers:

1. You edit one or more of the Policy Model's configuration values.
2. The Policy Model writes the new configuration values to the virtual configuration file.

**NOTE**

The virtual configuration file does not contain values for the `audit.cfg` file. The Policy Model does not write any changes you make to this file to the virtual configuration file.

3. The Policy Model sends the new configuration values to its subscribers.

4. `selang` commands update each subscriber with the new configuration values.

### **Virtual Configuration File**

Each Policy Model has a virtual configuration file that contains the configuration values for its subscribers. The virtual configuration file is located in the PMD directory, and is named `cfg_configname`, where *configname* is the name of the Policy Model configuration.

The virtual configuration file does not contain the configuration values held in the `audit.cfg` file.

### **How New Subscribers Are Configured**

The Policy Model configures each new subscriber with the existing configuration values. The existing configuration values are stored in the virtual configuration file.

#### **NOTE**

The virtual configuration file does not store configuration values from the `audit.cfg` file. Any changes you make to the `audit.cfg` file prior to creating a new subscriber are not propagated to the new subscriber.

The following process describes how a Policy Model configures new subscribers:

1. You create a new subscriber to the Policy Model.
2. The Policy Model reads the values in its virtual configuration file.
3. The Policy Model adds the configuration values from its virtual configuration file to the `updates.dat` file. The `updates.dat` file also contains the access rules for the Policy.
4. The Policy Model sends the `updates.dat` file to the new subscriber.
5. `selang` commands configure the new subscriber with the values in the `updates.dat` file.

### **How You Can Set up a Hierarchy**

Privileged Access Manager uses the Policy Model service to propagate rule-based policy updates across the configured hierarchy. By subscribing several Privileged Access Manager computers to the same PMDB, and by subscribing one PMDB to another, you create a hierarchy.

The most straightforward way to set up the PMDB hierarchy is as you install Privileged Access Manager, so it is worth thinking through how you want to structure the hierarchy before you begin the installation. Ensure that all the hosts in the PMDB hierarchy are part of the same network. The parent PMDB and its subscribers must be able to communicate with each other. The parent must be able to connect with each of its subscribers by name, and every subscriber must be able to connect to the parent PMDB by name.

**Note:** For more information about installing Privileged Access Manager, see the *Implementation Guide*.

If you want to change the configuration that you created during installation or if you did not create a PMDB structure during installation, you can change or create the PMDB configuration at any time. You can do this in one of the following ways:

- With Privileged Access Manager Endpoint Management
- With the `sepmdb` utility

To create a PMDB hierarchy and enable automatic rule-based policy updates after installation, follow these steps:

1. Create and configure the master PMDB.
2. (Optional) Create and configure subscriber PMDBs.
3. Define parent PMDBs for the subscribing computers, named *endpoints*.

## Update Subscribers

When updating subscribers, the Policy Model performs the following actions:

1. The Policy Model tries to fully qualify subscriber names as they are added or deleted from the Policy Model.
2. The PMDB service, sepmdd, attempts to update a subscriber database.
3. If the maximum time elapses and the service does not succeed in updating a subscriber, it skips that particular subscriber and tries to update the rest of the subscribers on its list.
4. After it completes its first scan of the subscriber list, sepmdd then performs a second scan, in which it tries to update the subscribers that it did not succeed in updating during its first scan.

### NOTE

Whenever a PMDB encounters an error while propagating updates to subscribers, the sepmdd service creates an entry in the [Policy Model error log file](#). This file, ERROR\_LOG, is located in the [PMDB directory](#).

## Update a Policy Model Database

Working at the computer where the PMDB resides does not automatically update the PMDB itself. To update a PMDB, you need to specify it as your target database.

You can specify the PMDB using selang or Privileged Access Manager Endpoint Management. To specify a target database using selang, use the hosts command in the selang command shell:

```
hosts pmd_name@pmd_host
```

All selang commands now update the policy model database specified. The commands then automatically propagate to the active databases on this computer and of all subscriber computers.

### Example: Specify a target PMDB

To set the target database to policy1 on myPMD\_host, use the following command:

```
hosts policy1@myPMD_host
```

If you now enter the newusr command, the new user is added to the policy1 database as well as the active databases on this computer and of all subscriber computers.

## Clean Up the Update File

The sepmdd utility automatically writes each update it receives in the updates.dat file. To prevent the file from growing too large, we recommend that you delete processed updates from the file periodically.

To clean up the update file, use the following command:

```
sepmdd -t pmdbName auto
```

sepmdd calculates the offset of the first update entry that has not been propagated and deletes all the update entries before it.

### NOTE

For more information about sepmdd utility, see the *Reference Guide*.

## Propagate and Synchronize Passwords

Once you set up a PMDB hierarchy, you can use it to keep user passwords synchronized throughout your system when the user passwords are changed with the Windows User Manager or software other than Privileged Access Manager.

### NOTE

Privileged Access Manager also supports mainframe password synchronization.

**Follow these steps:**

1. Create a PMDB Hierarchy.
2. Enter the name of the appropriate parent PMDB as the passwd\_pmd entry value in the registry on every station on which users or administrators may change passwords.

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\AccessControl\passwd_pmd
```

The PMDB then propagates the password change to all its subscribers.

**NOTE**

If the PMDB sends a user password to a subscriber in which the user is not defined, settings are not changed and the user remains undefined for the subscriber.

**Remove a Subscriber**

If you no longer want to propagate updates to a particular subscriber, you should remove it.

**To remove a subscriber**

1. Remove the computer from the subscription list:

```
secmd -u PMDB_namecomputer_name
```

The computer is removed from the Policy Model subscription list.

2. Shut down seosd on the computer that you removed from the subscription list:

```
secons -s
```

The seosd service is shut down.

3. Delete the value of the parent\_pmd registry value in the following registry key on the computer you removed from the subscription list:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\AccessControl
```

The computer will stop accepting updates from the parent PMDB.

4. Restart seosd.

The active database on the computer that you removed from the subscription list, is no longer a subscriber of the specified PMDB.

**NOTE**

Once the database is unsubscribed from the PMDB, the PMDB no longer sends commands.

**Filter Updates**

If you want your PMDB to update different subsets of data at different subscriber databases, you need to define which records are sent to subscriber databases.

**To filter updates:**

1. Configure PMDBs to serve as parents to subsets of subscribers.
2. Modify the *Filter* registry entry in the registry key of the parent PMDB, to point to a filter file you set up on the same computer.  
Updates to the subscriber databases are then limited to the records that pass the filter.

**Policy Model Filter File**

A filter file consists of lines, each with six fields. The fields contain information on:

- The form of access permitted or denied.  
For example, EDIT or MODIFY
- The environment affected.

For example, AC or native

- The class of the record.  
For example, USER or TERMINAL
- The objects, within the class, that the rule covers.  
For example, User1, AuditGroup, or COM2
- The properties that the record grants or cancels.  
For example, OWNER and FULL\_NAME in the filter line means that any command having those properties is filtered.  
You must enter each property exactly as it appears in the *Reference Guide*.
- Whether such records should be forwarded to the subscriber database or not:  
PASS or NOPASS

The following rules apply to each line in the filter file:

- You can use an asterisk (\*) to denote all possible values in any field.
- If more than one line covers the same records, the *first* applicable line is used.
- Spaces separate the fields.
- In fields with more than one value, semicolons separate the values.
- Lines beginning with # are considered a comment line.
- Empty lines are not allowed.

### Example: Filter file

The following example describes a line from a filter file:

|                |             |       |                      |                    |           |
|----------------|-------------|-------|----------------------|--------------------|-----------|
| CREATE         | AC          | USER  | *                    | FULL_NAME;OBJ_TYPE | NOPASS    |
| form of access | environment | class | record name( * =all) | properties         | treatment |

In this example, if we name the file with this line Printer1\_Filter.flt and edit the registry for PMDB PM-1 so that filter=C:\Program Files\CA\AccessControl\Printer1\_Filter.flt, then PMDB PM-1 will not propagate to its subscribers any records that create new users with the FULL\_NAME and OBJ\_TYPE property.

### Policy Model Error Log File

The Policy Model error log, which is organized chronologically, looks similar to this:

| Error Text                                                                                                                                                                           | Error Category       |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| <pre>20 Nov 03 11:56:07 (pmdbl): fargo nu u5 0 Retry ERROR: Login procedure failed (10068) ERROR: Cannot accept update from a non-parent PMDB (pmdbl@name.company.com) (10104)</pre> | Configuration Errors |
| <pre>20 Nov 03 19:53:17 (pmdbl): fargo nu u5 0 Retry ERROR: Connection failed (10071) Host is unreachable (12296)</pre>                                                              | Connection Errors    |

|                                                                                                                                                                                                                                        |                        |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <pre>20 Nov 03 11:57:06 (pmdbl): fargo nu u5 560 Cont ERROR: Failed to create USER u5 (10028) Already exists (-9)  20 Nov 03 11:57:06 (pmdbl): fargo nu u5 1120 Cont ERROR: Failed to create USER u5 (10028) Already exists (-9)</pre> | Database Update Errors |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|

The Policy Model error log is in binary format; you can view it only by entering the following command:

```
ACInstallDir/bin sepmd -e pmdname
```

#### NOTE

Do not manually delete an error log (for example, with the UNIX `rm` command). To delete the log, only use the following command:

```
ACInstallDir/bin sepmd -c pmdname
```

#### WARNING

The error log in Privileged Access Manager r5.1 and later versions has a format that is not compatible with the format of earlier versions. `sepmd` cannot handle error logs from these earlier versions. When you upgrade to a version that has this format, the old error log is copied to `ERROR_LOG.bak`; a new log file is created when you start `sepmd`.

#### Example: PMDB Update Error Message

The following example shows a typical error message:

```

date      time      pmdb name      subscriber      command      offset      flag
  ↓           ↓           ↓           ↓           ↓           ↓           ↓
20 Nov 03 19:53:17 (pmdbl): fargo nu u5 0 Retry
ERROR: Connection failed (10071) ← major level (type of error)
Host is unreachable (12296) ← minor level (cause of error)
                        ↑
                    return code

```

- The top line always consists of the date, time, and subscriber. The command that generated the error appears next, followed by the offset (in decimal format), which indicates the location of the failed update inside the updates file. Lastly, the flag indicates whether the PMDB retries the update automatically or continues without it.
- The second line shows an example of a major level message (what type of error occurred) and its return code.
- The third line displays an example of a minor level message (why the error occurred), and its return code.

#### Example: Error Message

A command may generate and display more than one error. Also, an error may consist of a major level message, a minor level message, or both.

The following error has only one message level:

```
Fri Dec 29 10:30:43 2003 CIMV_PROD:Release failed. Return code = 9241
```

This message occurs when `sepmd` pull attempts to release a subscriber that is already available.

## Native Policy Model Repositories

You can store all native environment user and group object types in the PMDB. By storing this information in the PMDB, you can receive information about objects using show commands (such as show user or show group). The returned objects are an image of the actual objects that are defined in Windows or UNIX subscribers.

After connecting to a Policy Model, a user can choose the following environments:

- AC
- Native
- NT
- UNIX
- Config

### NOTE

Native operates exactly as Windows while you are working in a Windows operating system, or exactly as UNIX while you are working on a UNIX operating system.

To use native environment repositories, use the following commands:

- Enter the following commands at the selang prompt:

```
env NT; find
```

Your results list all the native environment object types.

### NOTE

For descriptions of these object types, see the Windows environment classes and properties in the *Reference Guide*.

- Enter the following commands to receive a list of NT and Active Directory USER properties:

```
env NT; ruler user
```

- Enter the following commands to receive a list of NT and Active Directory GROUP properties:

```
env NT; ruler group
```

If a Policy Model is a subscriber of another (parent) Policy Model, it receives data from a parent through propagation and saves in the database all user and group properties, so you can see them and change them.

### NOTE

For more information, see the sepmd utility in the *Reference Guide*.

## Mainframe Password Synchronization

Privileged Access Manager supports password synchronization among mainframes running CA Top Secret, CA ACF2, or RACF security products (and CA Common Services CAICCI package) and Windows or UNIX computers running Privileged Access Manager. Synchronization is accomplished using the standard Privileged Access Manager password Policy Model method.

Any password change a mainframe user makes is propagated to all the machines in the password Policy Model hierarchy.

### Mainframe Password Synchronization Prerequisite

To work with Mainframe Password Synchronization on the server that has TNG/TND/NSM installed, Privileged Access Manager requires a prerequisite TNG/TND/NSM fix: T129430. Please contact support for getting the fix.

## Toggle Driver Interception

You can activate or deactivate the interception of the Privileged Access Manager filter driver.

**NOTE**

When the interception is deactivated, Privileged Access Manager protection that is not enforced by the filter driver still applies. This includes password quality checks, login events, Windows services events, STOP, and so on.

To activate interception, set UseFsiDrv to 1; to deactivate, set UseFsiDrv to 0.

You can find this configuration setting in the AccessControl section of the Privileged Access Manager registry.

After you change this registry value, restart Privileged Access Manager services.

## Disable CA Privileged Access Manager Server Control Kernel Interceptions

You can disable the following Privileged Access Manager interceptions at the kernel level:

- network interception
- process interception
- registry interception
- file interception

Even when the network, process, registry, and file classes are disabled and you are not using those classes to intercept kernel activity, the network, process, registry, and file interception processing code is initiated at boot time and working at run time, affecting performance. To improve performance, you can disable one or more interceptions from initiating at boot time.

### To disable Privileged Access Manager interceptions at the kernel level

1. Create one or more of the following registry entries of type REG\_DWORD and set the value of one or more entries to 1.
  - DisableNetworkInterceptiondisables network interception.
  - DisableProcessInterceptiondisables process interception.
  - DisableRegistryInterceptiondisables registry interception.
  - DisableFileInterceptiondisables file interception.

The entries must be created under the following registry key:

`HKLM\SYSTEM\CurrentControlSet\Services\drveng\Parameters`

2. Reboot the computer.  
Privileged Access Manager reloads without initializing the disabled interception types.

## Stack Overflow Protection

Stack Overflow Protection (STOP) is a feature that prevents hackers from creating and exploiting stack overflow to break into systems. Stack overflow enables hackers to execute arbitrary commands on remote or local systems, many times as the administrator. They do this by exploiting bugs in the operating system or other programs. These special types of bugs permit users to overwrite the program stack, changing the next command to be executed.

STOP works by intercepting crucial operating system calls to each application on the computer. Each call is then given an initial analysis before being sent for further analysis if it seems suspicious. Further analysis is performed using data from the STOP configuration and signature files.

### Enable STOP

STOP lets you prevent hackers from creating and exploiting stack overflow to break into your systems. You can enable STOP when installing Privileged Access Manager. Alternatively, you can enable STOP manually.

**To enable STOP:**

1. Enter the following command:

```
secons -s
```

Privileged Access Manager shuts down.

2. Set the *STOP OperationMode* registry entry to 1.  
The registry entry can be found in the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Instrumentation\PlugIns\StopPlg
```

When Privileged Access Manager is started, STOP modules will load and STOP will be enabled on the computer.

3. (Optional) Adjust STOP configuration using registry entries in the following keys:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Instrumentation\PlugIns\StopPlg
```

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\STOP
```

**NOTE**

For more information about STOP registry settings, see the *Reference Guide*.

4. Start Privileged Access Manager by entering the following command:

```
seosd -start
```

Privileged Access Manager starts up.

**Configure STOP for Receiving Signature File Updates**

You can make sure that all computers in your environment have the latest STOP information required for preventing stack overflow. You can do this by updating the STOP signature file on a central computer and setting up your computers to regularly retrieve the file.

**To configure STOP for receiving signature file updates**

1. Enter the following command:

```
secons -s
```

Privileged Access Manager shuts down.

2. Set the *STOPSignatureBrokerName* registry entry to the host name the computer you want to Privileged Access Manager to retrieve the signature file from.  
The registry entry can be found in the following key:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\STOP
```

When you start Privileged Access Manager (and then at a defined interval), it retrieves the STOP signature file from the specified computer.

3. Set the *STOPUpdateInterval* registry entry to the interval at which you want the signature file updated.  
Privileged Access Manager retrieves the signature file from the specified computer at the specified interval.
4. (Optional) Adjust STOP configuration using registry entries in the following key:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\STOP
```

**NOTE**

For more information about STOP registry settings, see the *Reference Guide*.

5. Start Privileged Access Manager by entering the following command:

```
seosd -start
```

Privileged Access Manager starts up.

**NOTE**

You can retrieve the signature file from any host using the eACSigUpdate utility. For more information about this utility, see the *Reference Guide*.

## Configure Settings

Privileged Access Manager lets you manage endpoint configuration settings remotely using Privileged Access Manager Endpoint Management or the selang config environment.

### Configuration Settings

Privileged Access Manager stores endpoint and Policy Model configuration settings it uses in:

- The Windows registry on Windows computers
- Initialization files (.ini) on UNIX computers

#### **NOTE**

For information about the configuration settings you can make and what they mean, see the *Reference section*.

### Change Configuration Settings

To affect how Privileged Access Manager and any Policy Models work, change the configuration settings.

#### **Follow these steps:**

1. In Privileged Access Manager Endpoint Management, do as follows:
  - a. Click Configuration.
  - b. Click Remote Configuration.
 The Remote Configuration page appears.
2. In the Remote Configuration Sections pane on the left, expand the configuration tree as required to reveal the section that contains the configuration setting you want to modify, then click that section.  
The Section: *sectionName* System Tokens page appears, displaying all the configuration settings in it.
3. Locate and edit the configuration settings as required, then click Save Tokens.  
The changed configuration setting is saved.

### Change Audit Configuration Settings

To affect how Privileged Access Manager generates and stores audit records, change the settings in the audit configuration files. You use selang commands to change the settings in the audit configuration files.

#### **Follow these steps:**

1. (Optional) If you are using selang to connect to a remote host, connect to the host using the following command:  
`host host_name`
2. Move to the config environment using the following command:  
`env config`
3. Use the editres config command to modify the configuration settings as required.  
The audit configuration settings are changed.

#### **Example: Modify Audit Configuration File**

The following example adds a line to the audit configuration file:

```
er CONFIG audit.cfg line+("FILE;*;Administrator;*;R;P")
```

## Track User Behavior Activities on Server Control Endpoints Using an SIEM Tool

To track all activity and events performed on your Server Control endpoints (devices) for IT governance purposes, configure PAM to report them to a *Security information and Event Management (SIEM)* tool such as Splunk or ArcSight

The following diagram illustrates the typical SIEM architecture, including these important components:

- The Report Agent is a service that exists on all the Server Control endpoints. The Reporting Agent feeds all the events/activities performed on each Server Control Device to the Utility Appliance.
- The Utility Appliance collects and stores all the events that are performed on all the Server Control endpoints.
- The Event Forwarder is a service that helps to track all the activities/events performed on all the Server Control endpoints. These events are viewed in a third-party tool such as Splunk, CA UARM, Arc sight, or similar. The Event Forwarder is installed on the Utility Appliance.

**Figure 52: PAM SIEM Architecture**

To track all activity and events performed on your Server Control endpoints for IT governance purposes, configure PAM to report them to a *Security information and event management (SIEM)* tool such as Splunk or ArcSight

**To set up the SIEM tool and view reports:**

1. In the PAM UI, select **Configuration**, expand **Logs**, and then select **Syslog**. The **Syslog** panel appears.
2. Configure the following options:
  - a. Set the **Enable Syslog to the specified server** option.
  - b. Enter the IP address of the SIEM tool in the **Remote Server** field.
  - c. Enter the port number of the SIEM tool in the **Remote Port**; for example, 5141.
3. Select **Update** to commit your changes.
4. Configure the connection between the embedded endpoint and the Utility Server, using the following procedures:
  - a. Perform a few events on the endpoint to act as a resource.
  - b. Run the following command to stop the Access Control Services:

```
secons -sk
```

- c. Configure the Access Control Server settings using the appropriate procedures:

**For Windows:**

- a. In regedit, modify the following keys:
  - For Hkey\_Local\_Machine->Software->Computer Associates->Access Control->Common->Communication, edit the Distribution\_Server entry to point to the IP address of the Utility Server.
  - For Hkey\_Local\_Machine->Software->Computer Associates->Access Control->Report Agent, set the audit\_enabled entry to 1.
  - For Hkey\_Local\_Machine->Software->Computer Associates->Access Control->Report Agent, set the agent\_enabled entry to 1.
- b. Run the following command to set the password to N0tall0wed:

```
sechkey -t -pwd "N0tall0wed"
```

**For Linux:**

- a. Using a standard text editor such as vi, open the accommon.ini file. For PAM SC, the file resides in /opt/CA/PAMSCShared/. For PAM 12.8, the file resides in /opt/CA/AccessControlShared/.
- b. Modify the following flags:
  - Set reportagent\_enabled to 1.
  - Set Distribution\_Server to the IP address of the Utility Server.
  - Set audit\_enabled to 1.

- c. Run the following command to set the password to N0tall0wed:
 

```
seckey -t -pwd "N0tall0wed"
```
- d. Run the following command to start the Access Control Services:
 

```
seload
```
- e. Export the path by running the command. Use the appropriate library path for your implementation.
 

```
export LD_LIBRARY_PATH= /opt/CA/AccessControlShared/AccessControlShared/lib
```
5. Generate some audit events, to verify the SIEM integration. The following examples are for the Splunk UI.
  - a. Create a test file by running the command. Replace <student #> with a test value.
 

```
touch /work/file_splunk_<student #>
```
  - b. Go to selang and create an ACL. For example:
 

```
er file /work/file_splunk_<student #> defaces(none) owner(nobody)
```
  - c. Quit selang and try to access the file by running the following command. Replace <student #> with the appropriate value.
 

```
cat /work/file_splunk_<student #>
```
  - d. A permission denied message displays and the event is audited. Enter the following command to view the audit entry. Replace <student #> with the appropriate value.
 

```
Seaudit -a -st now-5 | grep "/work/file_splunk_<student #>"
```
  - e. Send the audit records to the SIEM tool using the following command:
 

```
/opt/CA/PAMDistServer/APMS/AccessControlShared/bin/ReportAgent -debug 0 -task 1
```
  - f. Log in to the Splunk UI and search for the events under **Search & Reporting**. Search for the name of the file that you used to generate the audit event. For example:
 

```
"/work/file_splunk_student1"
```

See the Splunk documentation for detailed procedures for your specific lab environments.

## Troubleshoot PAM SC

This content in this section describes how to troubleshoot PAM Server Control.

Use the table of contents to access the topics in this section.

### View Server Control Policy Deployment Audit Data

Use the **Deployment Audit** tab on the **Policies, Manage Server Control** page to view a descriptive list of Server Control policy deployment tasks. Each entry contains the following information (as applicable) about the associated deployment task:

To view the audit deployment tasks, follow these steps:

1. Log into the PAM UI using an account with the required privileges.
2. Navigate to **Policies, Manage Server Control**.
3. Select the **Deployment Audit** tab.

The **Deployment Audit** opens, displaying a sortable, filterable list of your policy deployment tasks. Each list entry contains the following information (as applicable):

- **Policy Name:** The name of the deployment task.
  - **Version:** The version of the deployment task.
  - **Device Name:** The device associated with the deployment task.
  - **Device Group:** The device group associated with the deployment task.
  - **Type:** The type of policy deployment task (one of Assign, Unassign, Upgrade, Downgrade, Device Group Deletion, Auto Assign, Direct Deploy, Direct Undeployed, Reset, or Restore)
  - **Status:** The status of the deployment task (one of Queued, Success, Failure, Warning, No Action, Prerequisite, Dependence, Fix, Already Assigned, Unknown)
  - **Comment:** Any selang output generated by the deployment task.
  - **Update Time:** The time at which the deployment task occurred
  - **Updated By:** The name of the administrator account that initiated the deployment task.
4. To view all the specifics of any deployment task in a dialog, select the associated entry in the list and select the View button.

## Troubleshoot Policies Deployed on Server Control Devices

This topic describes how to do the following operations to troubleshoot policies deployed on Server Control devices:

- [Troubleshoot policies deployed to Server Control devices](#)
- [Remove obsolete devices associated with uninstalled PAM Server Control Agents](#)

### Troubleshoot Policies Deployed to Server Control Devices

When you deploy a policy to a Server Control agent, the policy is not deployed on the assigned endpoint until policyfetcher retrieves the deployment task and runs the policy script. As a result, deployment errors can occur when the policy is transferred to or is deployed at the endpoint.

If such an error occurs, PAM provides the following troubleshooting actions to help you resolve the issue:

- **Redeploy Policies**  
Creates a deployment task that contains the policy script and deploys the task to the endpoint. Use this option when the policy deploys on the endpoint with errors, that is, the Selang policy script execution fails. Fix the command syntax of deploy or undeploy script manually before you can redeploy the policy.
- **Undeploy Policies**  
Undeploys a policy that was deployed on the endpoint successfully or with errors. For troubleshooting purposes, use this option when a policy deploys on an endpoint with errors and you want to remove the policy association with the device.
- **Reset Device**  
Resets an endpoint and undeploys all the effective policies on the specified host. Privileged Access Manager resets host status and deletes all GPOLICY, POLICY, and RULESET objects on the specified host by creating deployment tasks and sending the tasks to the host for execution.  
Use this option to clean an endpoint from all policy deployments and clean endpoint status.  
**NOTE**  
This option does not remove DEPLOYMENT or GDEPLOYMENT objects from the endpoint or from PAM, because you might need these objects for auditing purposes. After you reset an endpoint, you can assign policies to the endpoint as normal.
- **Restore Device**  
Undeploys any policies on the specified host, and then deploys all the policies that must be deployed (assigned or directly deployed) on the host by creating deployment tasks and sending the tasks to the host for execution. Use this option when you reinstall Server Control or the operating system on the endpoint, or when you restore an endpoint

from a backup, to redeploy all the policies that Server Control indicates are effective on that endpoint. This option does not change the endpoint status in PAM.

**To use the available troubleshooting actions, follow these steps:**

1. Log in to the PAM UI.
2. Navigate to the **Policies, Manage Server Control** panel.
3. Select the **Device Troubleshooting** tab.  
A sortable, filterable table of Server Control devices opens.
4. Select the entry for the device with an assigned policy that requires repair.
5. Optionally, to open a dialog containing details about the device including queued and assigned policies, select the **View** button.
6. To troubleshoot the policy that is assigned to the device, select the button that is associated with the troubleshooting action that you want to run (**Redeploy Policies**, **Undeployed Policies**, **Reset Device**, or **Restore Device**).

**NOTE**

You can also perform most of these actions using the [policydeploy utility](#).

**Remove Obsolete Devices Associated with Uninstalled PAM Server Control Agents**

When you uninstall a PAM Server Control Agent from a server, PAM does not automatically remove the device that is associated with that node. As a routine maintenance procedure, you should therefore remove these obsolete nodes from the PAM database.

**Follow these steps:**

1. Log in to the PAM UI.
2. Navigate to the **Devices, Manage Server Control** panel.
3. Select the entry for the PAM Server Control agent.
4. Select the **Delete** button.

**WARNING**

When you delete a node, Privileged Access Manager removes all the HNODE-related deployment tasks, removes all the deployment tasks packages (unless they have other deployment task members), then removes the HNODE object.

## Troubleshoot Policies Deployed on Server Control Device Groups

When you deploy a policy to a Server Control device group, the policy is not deployed on the group members until policyfetcher retrieves the deployment task and runs the policy script on each one. As a result, deployment errors can occur when the policy is being transferred to, or is being deployed at, any of the endpoints in the group.

If a deployment error occurs, PAM provides the following troubleshooting actions to help you resolve the issue:

- **Reset Device Group**

Resets the endpoints and undeploys all the effective policies on the hosts in the device group. PAM resets the host status and deletes all GPOLICY, POLICY, and RULESET objects on the hosts by creating deployment tasks and sending the tasks to the hosts for execution. Reset also removes device and device group associations.

Use this action to clean the endpoints in the group from all policy deployments.

**NOTE**

The reset device group action does not remove DEPLOYMENT or GDEPLOYMENT objects from the endpoint or from PAM, because you might need these objects for auditing purposes. After you reset an endpoint, you can assign policies to the endpoint as normal.

If you reset a PAM SC device group, PAM performs the following actions on all PAM SC devices in that group:

- Disassociates the PAM SC device from the PAM device.
- Creates a new PAM device that has a Server Control host but no Device Type set.
- Associates the disassociated PAM SC device with the newly created PAM device.
- Removes all device groups.
- Resets all device group policies and device policies.
- **Restore Device Group**  
Use the restore group action when you reinstall the PAM Server Control Agent or the operating system on the members of the device group members. Also use the restore group action to redeploy all the policies that are effective on members of the group when you restore an endpoint from a backup. This action does not change the endpoint status in PAM.  
The restore device group action performs the following tasks on each host in the device group:
  - a. Undeploys any policies on the specified host.
  - b. Deploys all the policies that must be deployed (assigned or directly deployed) on the host by creating deployment tasks.
  - c. Sends the tasks to the host for execution.

**To run the available troubleshooting actions, follow these steps:**

1. Log in to the PAM UI.
2. Navigate to the **Policies, Manage Server Control** panel.
3. Select the **Device Group Troubleshooting** tab.  
A sortable, filterable table of Server Control device groups opens.
4. Select the entry for the device group with an assigned policy that requires repair.
5. Optionally, to open a dialog containing details about the device group including its members, select the **View** button.
6. To troubleshoot the policy that is assigned to the device group, select the button that is associated with the troubleshooting action that you want to run (**Reset Device Group** or **Restore Device Group**).

## Troubleshoot Orphaned Data, Records, and Validation Errors

Orphaned data and records are possible with Policies, Policy Versions, Rulesets, and Deployments. Orphaned data and records usually occur if data and records that are inserted into the PIM Deployment Map Server using selang commands are not properly mapped among the entities (policies, rulesets, policy versions, deployments). Orphan records do not occur if they are inserted through the PIM User interface.

The following orphan types are possible:

- A Policy (GPOLICY) without a version (POLICY)
- A policy version (POLICY) without a Policy (GPOLICY)
- A Ruleset (RULESET) without a policy version (POLICY)
- A GDEPLOYMENT without a DEPLOYMENT
- A DEPLOYMENT without a GDEPLOYMENT

The utility identifies orphaned data and records that cannot be extracted until they are fixed on the PIM server, or that are analyzed and ignored. The utility displays the path to the JSON files that contain the orphan records. The Validate button is disabled, and a user cannot proceed with validation unless the errors are fixed or ignored.

To fix orphaned data or records, you can choose to correct or delete them on the PIM Server.

**To correct orphaned data or records:**

1. Check the console to find the paths of Orphan Policies, Orphan Rulesets, and Orphan Deployments at one of the following locations:

- <STAGINGLOCATION>\ExtractedData\6.OrphanPolicies.json
  - <STAGINGLOCATION>\ExtractedData\7.OrphanDeploymentsExt.json
  - <STAGINGLOCATION>\ExtractedData\8.OrphanRuleSets.json
2. Navigate to the paths and fix them.
  3. Re-run the utility to repeat the Extraction phase.

#### To delete orphaned data or records:

1. Check the console to find the paths of Orphan Policies, Orphan Rulesets, and Orphan Deployments at one of the following locations:
  - <STAGINGLOCATION>\ExtractedData\6.OrphanPolicies.json
  - <STAGINGLOCATION>\ExtractedData\7.OrphanDeploymentsExt.json
  - <STAGINGLOCATION>\ExtractedData\8.OrphanRuleSets.json
2. Navigate to the path <STAGING LOCATION>\ExtractedData\[OrphanFiles] and delete them if records are obsolete/unused and can be ignored.
3. Re-run the utility to repeat the Extraction phase. If the orphaned data or records are fixed, the utility lets you perform Validation directly.

After Validation, you may see the following issues and behaviors:

#### Validation Errors

To fix validation errors:

1. Navigate <STAGING LOCATION>\ExtractedData\error to find the errors.
2. Each error record mentions the error message. Review the reason for failure, and then review and fix the record in the JSON file.
3. Re-run the utility by clicking Start. The utility re-scans the data available in the Staging location.
4. Click Validate to re-validate the errors and finish the Validation phase.

#### Invalid Hosts

The utility identifies validation errors related to hosts during the Validation phase. If you think any of these hosts are invalid and can be ignored during migration, you can update the **invalidDevices.txt** file with all such invalid host names. You also must delete the corresponding JSON error from the validation hnode errors file named **1.HNodeExt.json**.

The utility will then ignore the records associated with the invalid hosts on re-validate, and lets the user proceed with further steps in the migration process.

The **invalidDevices.txt** file is located here:

```
<Migration Utility_INSTALL_PATH>/config
```

The **1.HNodeExt.json** file is located here:

```
<STAGING LOCATION>\ExtractedData\error
```

#### Follow these steps:

1. Update the **invalidDevices.txt** file with all such invalid host names.
2. Delete the corresponding JSON error from the validation host errors from the **1.HNodeExt.json** file.
3. Re-run the Migration Utility.

#### Invalid Host Groups

The utility identifies validation errors related to host groups during the Validation phase. If you think any of these host groups are invalid and can be ignored during migration, you can update the **invalidDeviceGroups.txt** file with all such invalid host group names. You also need to delete the corresponding error json from the validation Gnode errors file named **2.GHNodeExt.json**.

The utility will then ignore the records associated with the invalid host groups on re-validate, and lets the user proceed with further steps in the migration process.

The **invalidDeviceGroups.txt** file is located here:

`<Migration Utility_INSTALL_PATH>/config`

The **1.GHNodeExt.json** file is located here:

`<STAGING LOCATION>\ExtractedData\error`

**Follow these steps:**

1. Update the **invalidDeviceGroups.txt** file with all such invalid host group names.
2. Delete the corresponding JSON error from the validation host group errors from the **2.GHNodeExt.json** file.
3. Re-run the Migration Utility.

### **Invalid Policies**

The utility identifies validation errors related to policies during the Validation phase. If you think any of these policies are invalid and can be ignored during migration, you can update the **invalidpolicies.txt** file with all such invalid policy names. You also need to delete the corresponding error json from the validation errors file named **3.PolicyExt.json**.

The utility will then ignore the records associated with the invalid policies on re-validate, and lets the user proceed with further steps in the migration process.

The **invalidpolicies.txt** file is located here:

`<Migration Utility_INSTALL_PATH>/config`

The **3.PolicyExt.json** file is located here:

`<STAGING LOCATION>\ExtractedData\error`

**Follow these steps:**

1. Update the **invalidpolicies.txt** file with all such invalid policy names.
2. Delete the corresponding JSON error from the validation policy errors from the **3.PolicyExt.json** file.
3. Re-run the Migration Utility.

### **Invalid Deployment Data**

- No Trigger Name
- No Host Name or No Policy Name
- New Triggers

If the deployment contains invalid device or policy details, the invalid devices and invalid policies already appear in the **invaliddevices.txt** file under `<Migration Utility_INSTALL_PATH>/bin`. The migration ignores these deployments.

### **Invalid Users**

The utility identifies validation errors related to UNAB login policies when the user/group mentioned in the login policy is not present on PAM. If you think any of these users/groups are invalid and can be ignored during migration, you can update the **invalidusers.txt** file with all such invalid user/group names.

The migration utility will then create placeholder users for such invalid users/groups and migrate the login policies to PAM.

Post migration, to upgrade the migrated login policy, you need to delete the placeholder users and proceed with policy updates.

The migration utility creates the **invalidUsers.txt** file, located here:

`<Migration Utility_INSTALL_PATH>/config`

**Follow these steps:**

1. Update the **invalidUsers.txt** file with all such invalid host user/group names
2. Re-run the Migration Utility.

## Tune Performance

### MALLOC\_ARENA\_MAX=1 Not Working on Red Hat Linux 6.2

#### Valid on RedHat Linux 6.2

**Symptom:**

I noticed that the UNAB uxauthd agent process exceeds the permitted memory threshold and periodically restarts.

**Solution:**

The cause of the unstable behavior is related to the MALLOC\_ARENA\_MAX variable. To resolve the issue, do *one* of these procedures:

- Upgrade the glibc library.
- Set the memory threshold to 500-MB minimum:
  - Modify the agent\_vmemory\_max token value in uxauth.ini
  - Modify the ProcVSizeHigh token value in seos.ini if Privileged Access Manager is installed
- Decrease the number of used threads:
  - Modify the working\_threads token value in the uxauth.ini file to 2

### Performance Degrades When Privileged Access Manager Is Running

**Symptom:**

My computer slows when Privileged Access Manager is running. When I stop Privileged Access Manager, my computer performs as usual.

**Solution:**

To diagnose and correct the performance problem, [troubleshoot the performance problem](#).

### System Load on Privileged Access Manager Server Is Too High

**Symptom:**

I need to reduce system load on the Privileged Access Manager server.

**Solution:**

To reduce system load, do the following:

- Avoid deep hierarchies in the database.  
Deep hierarchies of users and resources require system loads to obtain and check all dependencies.
- Avoid generic rules for frequently used directories.  
If you define a generic rule for a frequently used directory, Privileged Access Manager checks many system actions. For example, if you write a generic protection rule that protects /usr/lib/\*, Privileged Access Manager checks every action in the system.
- (Solaris only) Specify that Privileged Access Manager bypasses file access checks when the file belongs to a process file system (/proc).

To specify that Privileged Access Manager bypasses file access checks when the file belongs to a process file system, verify that the value of the `proc_bypass` configuration setting is 1 in the `[SEOS_syscall]` section of the `seos.ini` file.

**Note:** For more information about `seos.ini` file tokens, see the *Reference* section.

## General UNAB Troubleshooting

This content describes how to perform general UNAB troubleshooting procedures.

### **Failed to Install UNAB**

#### **Symptom:**

I customized the installation package but when I attempt to install UNAB on the endpoint, the installation fails.

#### **Solution:**

Use the following procedure to troubleshoot the problem.

1. Review the UNAB installation log file, `uxauth_install.log` for errors. By default, the file is in the following directory:

```
/opt/CA/uxauth
```

2. Export the UNAB installation log file and send the file to CA Support.
3. Run the installation process in debug mode:
  - For native package installations, create a file that is named `seos_debug_on` in `/tmp` directory. Assign a debug level between 0-9 to the file.
4. Run the native package in debug mode:
  - AIX: Add `-e<log_file_name>` flag to the install command
  - HP-UX: Review the installation log file that the `swinstall` generates for `swjob`
  - Linux: Add `-vv` flag to the install command
  - Solaris: Add `-v` flag to the install command

### **Troubleshoot UNAB Registration**

The following section contains information that you can use to troubleshoot problems you encounter during UNAB registration with Active Directory.

#### ***UNAB Registration Failed Due to Incorrect Password***

##### **Symptom:**

When I try to register UNAB with Active Directory, registration fails with the following error message:

```
Preauthentication failed while getting initial credentials Kerberos preauthentication  
using <Administrator> failed
```

##### **Solution:**

UNAB registration failed due to an incorrect administrator password. To troubleshoot this issue, verify the administrator password and register UNAB.

#### ***UNAB Registration Failed Due to Incorrect Clock Skew***

##### **Symptom:**

When I try to register UNAB with Active Directory, I receive the following error message:

```
Clock skew too great while getting initial credentials Kerberos preauthentication using  
<Administrator> failed
```

**Solution:**

UNAB registration failed because the clock skew between Active Directory and the UNAB endpoint is larger than configured.

To resolve this issue, follow these steps:

1. Manually synchronize the UNAB endpoint clock with that of Active Directory.
2. Set `use_time_sync` token value to `yes` under the `[Agent]` section in `uxauth.ini` to configure time synchronization automatically.

***UNAB Registration Failed Due to Incorrect NTP Server Configuration*****Symptom:**

When I try to register UNAB with Active Directory, I receive the following error message:

```
WARNING: NTP service location is specified incorrectly
```

**Solution:**

The UNAB registration failed because the network time protocol server (NTP) is incorrectly configured.

To troubleshoot this issue, set the `ntp_server` token under the `[Agent]` section in `uxauth.ini` to point to the NTP server.

***UNAB Registration Failed Due to Invalid Configuration*****Symptom:**

When I try to register UNAB in Active Directory, I receive the following error message:

```
Error initializing Kerberos 5 library.Please check '/opt/CA/uxauth/uxauth.ini' Kerberos  
preauthentication using <Administrator> failed
```

***uxconsole -register Fails*****Valid on UNIX****Symptom:**

When I run `uxconsole -register` to register a UNAB endpoint, the following error message appears:

```
No server can be used as a DC for communicating with Active Directory.
```

```
Please check the lookup_dc_list and ignore_dc_list tokens in the [ad] section.
```

**Solution:**

When uxconsole registers the UNAB endpoint in Active Directory, the Active Directory site that is closest to the physical location of the endpoint is discovered. However, the ignore\_dc\_list configuration setting in the ad section of the uxauth.ini file lists domain controllers that the UNAB endpoint does not communicate with. If all domain controllers from the discovered Active Directory site are listed in the ignore\_dc\_list configuration setting, registration fails.

To fix this problem, delete the names of any domain controllers in the discovered Active Directory site from the ignore\_dc\_list configuration setting. Rerun the uxconsole utility.

**NOTE**

The uxconsole utility writes the name of the discovered Active Directory site to the ad\_site configuration setting in the ad section of the uxauth.ini file. For more information about UNAB Active Directory site support, see the *Implementation Guide*.

**UNAB Login Policy Not Distributed****Symptom:**

I attempted to deploy a UNAB login policy to the UNAB endpoints, but the policy is not distributed.

**Solution:**

To troubleshoot this issue, follow these steps:

1. Verify that UNAB is started on the endpoint:
  - a. Open a command prompt window on the endpoint.
  - b. Run the following command:

```
./uxauthd.sh status
```

A message informs you of the status of UNAB.

2. Verify that the policy was downloaded to the host:
  - a. From a command prompt window on the endpoint, run the following command:

```
./uxconsole -status -detail
```

The information includes the policy name, if deployed to the endpoint.

3. Review the policy authorization commands that the Enterprise Management Server sent to the UNAB endpoint.
  - From a command prompt window on the endpoint, run the following command:

```
./uxaudit -a
```

```
18 Jan 2011 11:03:23 S UPDATE          TERMINAL    ac_entm_pers  338 10 _default
      acmanager.forwardinc.com auth terminal _default xuid(yaeyu01)access(read) (OS
      user)
```

Verify that the rules were not modified.

4. Search the syslog file for Message Queue communication errors.
5. Verify the user account for login permissions and status.
6. Run the following command for a command prompt window:

```
uxconsole -manage -show -user <AD_user_account>
```

## **ReportAgent Fails to Send Reports to the Enterprise Management Server**

### **Symptom:**

I started UNAB and verified that the ReportAgent daemon is running but I cannot view reports in Privileged Access Manager Enterprise Management.

### **Solution:**

Use the following procedure to troubleshoot this issue:

1. Check the syslog for Message Queue server communication-related error messages in the 'UNAB EP communication problems with ENTM' section.
2. Verify that the audit\_enabled token under the [ReportAgent] section in the accommon.ini file is set to 1, if you want to send reports data to the Audit Log.
3. Enable ReportAgent debugging.
4. Set the debug token under the [ReportAgent] section in the accommon.ini file to 1
5. Review the UNAB reports debug file unab2xml.log. The file is located in the following directory:

```
/opt/CA/PAMSCShared/log
```

6. Run the ReportAgent manually to generate a UNAB database snapshot:

```
/opt/CA/PAMSCShared/bin/ReportAgent -debug 0 -task 2 -now
```

### **NOTE**

- Add the path '/opt/CA/PAMSCShared/lob' to \$LD\_LIBRARY\_PATH before you run the ReportAgent manually.
- Remove the .dat files from the /opt/CA/PAMSCShared/data/audit2txt/ directory before you manually run the ReportAgent.
- For more information about ReportAgent utility debug mode, refer to the *Reference Guide*.

## **Kerberos Preauthentication Fails When Registering a UNAB Host**

### **Valid on UNIX**

### **Symptom:**

When I use the uxconsole -register command, I receive the following error message:

```
krb5_set_config_files failed for /opt/CA/uxauth/uxauth.ini: Missing open brace in profile
```

```
Kerberos preauthentication using <Administrator> failed
```

### **Solution:**

There is an unset configuration setting in the uxauth.ini file. To fix this problem, verify that each configuration setting in the uxauth.ini file has a value.

**Receive Error Code 2803 When Registering or Starting UNAB****Valid on UNIX****Symptom:**

I receive the following error message when I try to register a UNAB host in Active Directory, or I try to start UNAB:

```
Unable to open nss or create nss cache. Error code 2803.
```

**Solution:**

Not enough memory exists in the /var directory. To fix this problem, verify that less than 95 percent of /var is used, and retry the command.

**Active Directory User Cannot Log in to UNAB Endpoint****Valid on UNIX****Symptom:**

An Active Directory user that has UNIX attributes cannot log in to a UNAB endpoint.

**Solution:**

To troubleshoot the problem, follow these steps:

1. Verify that the container of the user is one of the following:
  - The container that is specified in the user\_container configuration setting.
  - A sub-container under the container specified in the user\_container configuration setting.

**NOTE**

The user\_container configuration setting is located in the AD section of the uxauth.ini file.

2. Verify that the user has a UID and a GID in Active Directory.
3. Verify that the user is not suspended.
4. Verify that UNAB is started on the endpoint:
  - a. Open a command prompt window on the endpoint.
  - b. Run the following command:

```
./uxauthd.sh status
```

A message informs you of the status of UNAB.

5. Verify that the endpoint is registered in Active Directory.

**NOTE**

If the endpoint is not registered in Active Directory, use the uxconsole -register utility to register the host.

6. Stop the name or password caching daemon for your OS on the endpoint, as follows:
  - a. Stop UNAB:

```
./uxauthd.sh stop
```

- b. Delete the NSS cache database:

```
rm -rf /opt/CA/uxauth/etc/nss.db
```

- c. Check if the name or password caching daemon for your OS is running on the endpoint.  
For example, for a Linux or Solaris endpoint, check if the nscd daemon is running. For an HP-UX endpoint, check if the pwgrd daemon is running.
- d. If the name or password caching daemon for your OS is running, kill the process.
- e. Start UNAB:

```
./uxauthd.sh start
```

- 7. Obtain a Ticket Granting Ticket (TGT) using a different Active Directory user account.  
Run the following command to connect to Active Directory using the Administrator account:

```
./uxconsole -krb -init Administrator
```

#### NOTE

You can obtain a TGT using the agent keytab, for example:

```
./uxconsole -krb -init -k
```

- 8. Resolve the Active Directory user account directly:
  - Run the following search:

```
./uxconsole -ldap -search "(&(objectClass=user)(sAMAccountName=johndoe))"
```

Check for discrepancies between the expected and actual user account name.

- 9. Search for the user account in other domains, if applicable.
  - Run the following command:

```
./uxconsole -ldap -search -b DC=unabca,DC=test,DC=co,DC=il "(&(objectClass=user)
(objectCategory=person))"
```

- 10. Verify that the user account UNIX attributes are identical on the Active Directory and UNIX.

### **User Cannot Run Commands on a UNAB Endpoint**

#### **Symptom:**

I successfully log in to a UNAB endpoint, and UNAB creates a P (permitted) record in uxaudit, the UNAB audit file, that corresponds to my login. However, I cannot run any UNIX commands on the endpoint.

#### **Solution:**

The user has previously logged in to the same endpoint with the same username but with a different UID, so the user cannot access their /home directory.

To fix this problem, follow these steps:

- 1. Delete the /home directory for the user.

#### NOTE

The /home directory is often located at /home/userName.

- 2. Ask the user to log in to the endpoint.  
A new /home directory is created for the user. The user can now perform UNIX commands on the UNAB endpoint.

## **I Cannot View UNAB Endpoint in World View**

### **Valid on UNIX**

#### **Symptom:**

I use Privileged Access Manager Enterprise Management to manage UNAB endpoints, but a UNAB endpoint does not appear in World View.

#### **Solution:**

Verify that the UNAB endpoint can communicate with the Distribution Server. Do the following on the UNAB endpoint:

1. Verify that the value of the `Distribution_Server` configuration setting is set to the name of the Distribution Server computer.  
The `Distribution_Server` configuration setting is located in the communication section of the `accommon.ini` file.  
**Example:** `ssl://ds.comp.com:7243`  
**Note:** By default, the Utility Appliance is located on the Enterprise Management Server.
2. Verify that the Message Queue password is correct. The endpoint uses this password to communicate with the Utility Appliance. Do the following:
  - a. Open a command prompt window.
  - b. Run the following command:

```
acuxchkey -t pwd "password"
```

- *password*  
Defines the Message Queue password. By default, this password is the communication password that you define when you install Privileged Access Manager Enterprise Management.

3. Restart the UNAB agent, as follows:
  - a. Navigate to the UNAB `lbin` directory.  
By default, this directory is under `/opt/CA/uxauth`
  - b. Restart the UNAB agent:

```
./uxauthd.sh restart
```

4. Verify that the Message Queue server is running, as follows:
  - Windows: Verify that the PAM SC Message Queue service is running.
  - UNIX: Verify that the `tibemsd` process is running.
5. Check the syslog or event viewer for Message Queue server communication errors.
6. Set the Message Queue server to log communicated-related messages to a log file:
  - UNIX:
    - a. Open the `pmd.ini`.
    - b. Modify the `debug_mode` token in the `[endpoint_management]` section to 1.
  - Windows:
    - a. Navigate to the following registry key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Pmd\ DMS_NAME  
  \endpoint_management
```

- b. Modify the `debug_mode` token value to 1

7. Restart the Enterprise Management Server to apply the changes. Review the endpoint\_management.log file located in the DMS directory for communication messages.
8. You have verified that the UNAB endpoint can communicate with the Utility Appliance.

### **I Cannot Start Daemons on Linux s390 Endpoint**

**Valid on Linux s390 and Linux s390x**

**Symptom:**

I cannot start the uxauthd or ReportAgent daemon.

**Solution:**

UNAB cannot locate the Java environment on the endpoint. To fix this problem, follow these steps:

1. Verify that the java\_home configuration setting in the global section of the accommon.ini file contains the path to the Java environment.
2. Set the value of the LD\_LIBRARY\_PATH environment variable to the path to the shared libraries of the Java environment.

### **User Cannot Log in or Change Password**

**Valid on UNIX**

**Symptom:**

When I try to log in or change my password on a UNAB endpoint, the following error message appears:

```
passwd: Authentication token manipulation error
```

**Solution:**

The PAM module timed out while waiting for uxauthd to respond to the password change request.

To fix this problem, follow these steps:

1. Increase the value of the pam\_receive\_timeout configuration setting in the pam section of the uxauth.ini file. For example, pam\_receive\_timeout=100
2. Stop and restart UNAB.

**NOTE**

For more information about the uxauth.ini file, see the *Reference Guide*.

**NOTICE**

For information about troubleshooting policies deployed on Server Control and UNAB devices and device groups, see the following topics:

- [Troubleshoot Policies Deployed on Server Control Devices](#)
- [Troubleshoot Policies Deployed on Server Control Device Groups](#)
- [Troubleshoot Policies Deployed on UNAB Devices](#)
- [Troubleshoot Policies Deployed on UNAB Device Groups](#)

## **Troubleshoot Policies Deployed on UNAB Devices**

When managing UNAB devices, discrepancies between the policies that are deployed on the PAM server and the UNAB devices can occur over time. These discrepancies are typically due to policy deployment failures, issues on the target

UNAB devices themselves, or both. If such discrepancies occur, PAM provides the following UNAB troubleshooting actions to help you resolve the issues:

- **Redeploy Policies**

Redeploys the specified UNAB (config and login authorization) policies on the specified UNAB device.

- **Undeploy Policies**

Undeploys a login authorization policy that was deployed on the specified UNAB device successfully or with errors. For troubleshooting purposes, use this option when the login authorization policy deploys on the endpoint with errors and you want to remove the policy association with the device.

- **Reset Device**

Resets the specified UNAB device. After you reset a UNAB device, you can reassign policies to that device as normal. If you reset a UNAB device, PAM performs the following actions:

- Disassociates the UNAB device from the PAM device.
- Creates a new PAM device that has a Server Control host but no Device Type set.
- Associates the disassociated UNAB device with the newly created PAM device.
- Removes all device and device group associations.
- Undeploys all the associated login authorization policies on that device.

- **Restore Device**

Undeploys all policies (assigned or directly deployed) on the specified host and then restores those policies. Use this option when you reinstall the UNAB Agent, reinstall the operating system on the endpoint, or when you restore an endpoint from a backup to redeploy all the policies that are effective on that endpoint.

**To use the available troubleshooting actions, follow these steps:**

1. Log in to the PAM UI.
2. Navigate to the **Policies, Manage UNAB Policies** panel.
3. Select the **Device Troubleshooting** tab.  
A sortable, filterable table of UNAB devices opens.
4. Select the entry for the device with an assigned policy that requires repair.
5. Optionally, to open a dialog containing details about the device including queued and assigned policies, select the **View** button.
6. To troubleshoot the policy that is assigned to the device, select the button that is associated with the troubleshooting action that you want to run (**Redeploy Policies**, **Undeploy Policies**, **Reset Device**, or **Restore Device**).

## Troubleshoot Policies Deployed on UNAB Device Groups

When managing UNAB devices in device groups, discrepancies between the policies that are deployed on the PAM server and the UNAB devices in the device groups can occur over time. These discrepancies are typically due to policy deployment failures, issues on the target UNAB devices themselves, or both. If such discrepancies occur, PAM provides the following UNAB troubleshooting actions to help you resolve the issues:

- **Reset Device Group**

Resets the UNAB devices in the specified device group. After you reset a UNAB device group, you can reassign policies to that group as normal.

If you reset a UNAB device group, PAM performs the following actions on all UNAB devices in that group:

- Disassociates the UNAB devices from the PAM device.
- Creates a new PAM device that has a Server Control host but no Device Type set.
- Associates the disassociated UNAB device with the newly created PAM device.
- Removes all device and device group associations.
- Undeploys all the associated login authorization policies on those devices.

- **Restore Device Group**

Use the restore device group action when you reinstall the UNAB Agent or to reinstall the operating system on members of the device group. Also use the restore device group action to redeploy all the policies assigned to members of the device group when you restore an endpoint from a backup. This action does not change the endpoint status in PAM.

The restore device group action performs the following tasks on each UNAB device in the device group:

- a. Undeploys any policies on the specified device.
- b. Redeploys all the (assigned or directly deployed) policies on the device.

**To run the available troubleshooting actions, follow these steps:**

1. Log in to the PAM UI.
2. Navigate to the **Policies, Manage UNAB Policies** panel.
3. Select the **Device Group Troubleshooting** tab.  
A sortable, filterable table of UNAB device groups opens.
4. Select the entry for the device group with an assigned policy that requires repair.
5. Optionally, to open a dialog containing details about the device group including its members, select the **View** button.
6. To troubleshoot the policy that is assigned to the device group, select the button that is associated with the troubleshooting action that you want to run (**Reset Device**, or **Restore Device Group**).

## Troubleshoot the Reporting Service

The topics that are discussed in this article help you troubleshoot the problems faced while working with the reporting service:

### Troubleshoot the Report Agent on a UNIX Computer

#### **Valid on UNIX**

The Report Agent collects scheduled snapshots of the local Privileged Access Manager database and any policy model databases (PMDBs) on the endpoint. The Report Server sends this snapshot in XML format to the report queue on the Utility Appliance.

#### **NOTE**

The Report Agent also performs other tasks. For more information about the Report Agent, see the *Reference facet*.

#### **To troubleshoot the Report Agent on a UNIX computer**

1. Verify that the library path environment variable is set correctly. Do the following actions:
  - a. su to root.
  - b. Set the library path environment variable to *ACSharedDir/lib*. By default, *ACSharedDir* is the following directory:

`/opt/CA/PAMSCShared`

- c. Export the library path environment variable.
2. Verify that the following configuration settings are correct. The configuration settings are located in the [ReportAgent] section of the accommon.ini file:

#### **NOTE**

You can use either Privileged Access Manager Endpoint Management or selang commands to verify the value of the configuration settings. However, for this procedure we recommend that you use selang commands in the config environment to change the value of configuration settings. Using selang commands lets you change the configuration settings in this procedure without having to stop and restart Privileged Access Manager.

– **reportagent\_enabled**

Specifies whether reporting is enabled (1) on the local computer.

**Default:** 0

**WARNING**

Set the value of this configuration setting to 1 to enable the Report Agent to run automatically. If the value of this configuration setting is 0, the Report Agent does not send scheduled snapshots of the database to the Utility Appliance. However, if the value of this configuration setting is 0 you can still run the Report Agent in debug mode.

– **schedule**

Defines the schedule of when reports are generated and sent to the Utility Appliance.

You specify this setting in the following format: time@day[,day2][...]

**Default:** 00:00@Sun,Mon,Tue,Wed,Thu,Fri,Sat

**Example:** "19:22@Sun,Mon" generates reports every Sunday and Monday at 7:22 pm.

– **send\_queue**

Defines the name of the Message Queue on the Utility Appliance to which the Report Agent sends snapshots of the local database.

**Default:** queue/snapshots

**WARNING**

Do not change the default value of this configuration setting.

3. Verify that the following configuration setting is correct. The configuration setting is located in the [communication] section of the accommon.ini file:

**NOTE**

You can use either Privileged Access Manager Endpoint Management or selang commands to verify the value of the configuration settings. However, for this procedure we recommend that you use selang commands in the config environment to change the value of configuration settings. Using selang commands lets you change the configuration settings in this procedure without having to stop and restart Privileged Access Manager.

– **Distribution\_Server**

Defines the Utility Appliance URL.

**Default:** none

**Example:** ssl://172.24.176.145:61616 This URL configures the Report Agent to communicate with the Utility Appliance at the IP address 172.24.176.145 on port 61616, using the SSL protocol.

4. Verify that the following line exists in the [daemons] section of the seos.ini file:

```
ReportAgent = yes, ACSharedDir/lbin/report_agent.sh start
```

This line enables the Report Agent daemon to execute automatically when Privileged Access Manager starts.

**NOTE**

By default, the *ACSharedDir* directory is located at /opt/CA/PAMSCShared

5. Stop Privileged Access Manager:

```
secons -s
```

Privileged Access Manager and the Report Agent stops.

6. Navigate to the following directory:

```
ACSharedDir/bin
```

7. Run the Report Agent in debug mode, using the following command:

```
./ReportAgent -debug 0 -task 0 -now
```

- **ReportAgent**  
Runs the Report Agent.
  - **-debug 0**  
Specifies to run the Report Agent in debug mode and to display the output on the console.  
**Note:** You cannot run the Report Agent in debug mode if the Report Agent daemon is enabled.
  - **-task 0**  
Specifies that the Report Agent collects and sends information about the Privileged Access Manager database, and any local PMDBs, to the Utility Appliance. This information is used to generate reports.
  - **-now**  
Specifies to run the Report Agent now.
8. Review the Report Agent output as follows:
- Review the output for errors.
  - Verify that the correct names are specified in the Send Queue and the Report File parameters in the Send report parameters section.
9. Start Privileged Access Manager:

```
seload
```

Privileged Access Manager and the Report Agent start.

### Example: Report Agent Output

The following Report Agent output shows the Send Queue and Report File parameters:

```
-----
Send report parameters:
-----
Send Queue..... queue/snapshots
Report File..... /work/opt/CA/PAMSCShared/data/db2xml/ACDB.xml
-----
start sending report to queue 'queue/snapshots'...
```

### Troubleshoot the Report Agent on a Windows Computer

#### Valid on Windows

The Report Agent collects scheduled snapshots of the local Privileged Access Manager database and any policy model databases (PMDBs) on the endpoint. The Report Agent sends this snapshot in XML format to the report queue on the Utility Appliance.

**NOTE**

The Report Agent also performs other tasks. For more information about the Report Agent, see the *Reference facet*.

**To troubleshoot the Report Agent on a Windows computer**

1. Verify that the following configuration settings are correct. The configuration settings are located in the following registry key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\ReportAgent
```

**NOTE**

You can use either Privileged Access Manager Endpoint Management or `selang` commands to verify the value of the configuration settings. However, for this procedure we recommend that you use `selang` commands in the config environment to change the value of configuration settings. Using `selang` commands lets you change the configuration settings in this procedure without having to stop and restart Privileged Access Manager.

- **reportagent\_enabled**

Specifies whether reporting is enabled (1) on the local computer.

**Default:** 0

**WARNING**

Set the value of this configuration setting to 1 to enable the Report Agent to run automatically. If the value of this configuration setting is 0, the Report Agent does not send scheduled snapshots of the database to the Utility Appliance. However, if the value of this configuration setting is 0 you can still run the Report Agent in debug mode.

- **schedule**

Defines the schedule of when reports are generated and sent to the Utility Appliance.

You specify this setting in the following format: `time@day[,day2][...]`

**Default:** 00:00@Sun,Mon,Tue,Wed,Thu,Fri,Sat

**Example:** "19:22@Sun,Mon" generates reports every Sunday and Monday at 7:22 pm.

- **send\_queue**

Defines the name of the Message Queue on the Utility Appliance to which the Report Agent sends snapshots of the local database.

**Default:** queue/snapshots

**WARNING**

Do not change the default value of this configuration setting.

2. Verify that the following configuration setting is correct. The configuration setting is located in the following registry key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Common\communication
```

- **Distribution\_Server**

Defines the Utility Appliance URL.

**Default:** none

**Example:** `ssl://172.24.176.145:61616` This URL configures the Report Agent to communicate with the Utility Appliance at the IP address 172.24.176.145 on port 61616, using the SSL protocol.

3. Verify that the Privileged Access Manager Report Agent service is started.

**NOTE**

Set the `reportagent_enabled` configuration setting to 1 to configure the Privileged Access Manager Report Agent service to start automatically.

4. Open a command prompt window and stop Privileged Access Manager:

```
secsns -s
```

Privileged Access Manager stops, including the Report Agent service.

5. Run the Report Agent in debug mode, using the following command:

```
reportagent -debug 0 -task 0 -now
```

- **reportagent**  
Runs the Report Agent.
- **-debug 0**  
Specifies to run the Report Agent in debug mode and to display the output on the console.  
**Note:** You cannot run the Report Agent in debug mode if the Report Agent service is started.
- **-task 0**  
Specifies that the Report Agent collects and sends information about the Privileged Access Manager database, and any local PMDBs, to the Utility Appliance. This information is used to generate reports.
- **-now**  
Specifies to run the Report Agent now.

6. Review the Report Agent output as follows:

- Review the output for errors
- Verify that the correct names are specified in the Send Queue and the Report File parameters in the Send report parameters section

7. Start Privileged Access Manager:

```
seosd -start
```

Privileged Access Manager starts and the Report Agent service starts.

### Example: Report Agent Output

The following Report Agent output shows the Send Queue and Report File parameters:

```
-----
Send report parameters:
-----
Send Queue..... queue/snapshots
Report File..... C:\Program Files\CA\PAMSC\data\db2xml\ACDB.xml
-----
start sending report to queue 'queue/snapshots'...
```

### Library Path Environment Variable Example

The following example sets and exports the library path environment variable on a Linux or Solaris computer:

```
LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:/opt/CA/PAMSCShared/lib
export LD_LIBRARY_PATH
```

The following example sets and exports the library path environment variable on an AIX computer:

```
export LIBPATH=$LIBPATH:/opt/CA/PAMSCShared/lib
```

The following example sets and exports the library path environment variable on an HP-UX computer:

```
export SHLIB_PATH=$SHLIB_PATH:/opt/CA/PAMSCShared/lib
```

### **Troubleshoot the Utility Appliance**

On the Utility Appliance, the Message Queue receives information that the Report Agents send from the endpoints. Message-driven Java beans (MDBs) then read the data in the Message Queue and write the data to the central database.

#### **To troubleshoot the Utility Appliance:**

1. Log in to the ActiveMQ Web Administration Console. The default address is <https://<hostname>:8161/admin>

#### **NOTE**

The default port number is 8161. However, you can configure another value during the ActiveMQ installation.

2. Enter your username and password.

#### **NOTE**

The default username is admin. You can change the username during the ActiveMQ installation. You specify the password during the ActiveMQ installation.

3. Click Queues at the top of the page. A list of queues on the Utility Appliance appears.
4. Open a command prompt window on an endpoint.
5. (UNIX) Set the library path environment as in the following example:
  - a. su to root.
  - b. Set the library path environment variable to ACSharedDir/lib. By default, ACSharedDir is in the following directory:

```
/opt/CA/PAMSCShared
```

- c. Export the library path environment variable.
6. (UNIX) Navigate to the following directory: ACSharedDir/bin
  7. Run the Report Agent on the endpoint. Run one of the following commands:
    - a. Windows

```
ReportAgent -report snapshot
```

- b. UNIX

```
./ReportAgent -report snapshot
```

8. The Report Agent sends a snapshot of the Privileged Access Manager database and any local PMDBs to the report queue on the Utility Appliance.
9. Review the *queue/snapshots* queue and refresh the page after the Report Server runs. If the number of Messages Enqueued grows, but the number of Messages Dequeued does not grow, WildFly may not be running. Troubleshoot WildFly.

### **JasperReports Server Is Down or Unreachable**

#### **Symptom:**

When I try to view a report in Privileged Access Manager, I receive the following error message:

```
Fatal: Failed to execute CreateReportInstance. ERROR MESSAGE: Exception:Connection
refused: connect
```

#### **Solution:**

To troubleshoot this problem, check the following points:

1. Verify that you have configured a successful connection to the JasperReports Server. To verify the connection status, do the following steps:
  - a. Log in to Privileged Access Manager.
  - b. Navigate to **System, Connection Management, Report Server Configuration, Manage Connection**.
  - c. Ensure that you have provided correct values in the configuration fields.
  - d. Click **Submit**. If you receive an error message, then recheck your configuration values.
2. Ensure that the Tomcat service is running on the JasperReports Server.

### **Report Execution Hangs**

#### **Symptom:**

When I run a report in the Privileged Access Manager web interface, I observe the following behavior:

- The report status shows *Pending/Deleted* for a long time.
- The report data is missing even though the report status shows *Complete*.

To view the report status, navigate to *Reports, Tasks, View My Reports* in the web interface.

#### **Solution:**

The cardinality Estimator(CE) that comes with Microsoft SQL 2014 database degrades the performance when compared to the earlier databases. If CE negatively influences the critical workloads, disable its use by reverting to a database compatibility level below 120.

1. Navigate to your application database.
2. Right-click the database and click **Properties**.
3. Click **Options**.
4. In the Compatibility Level drop-down list, change the compatibility level to *SQL Server 2012 (110)*.

## **General PAM SC Troubleshooting and Maintenance Procedures**

This topic describes general PAM SC troubleshooting and maintenance procedures.

## **How to Verify That Privileged Access Manager Is Correctly Installed on Windows**

Verify that Privileged Access Manager is correctly installed immediately after you install the product. The following process helps you verify that Privileged Access Manager is correctly installed.

If the installation is successful, you see the following changes:

- A new key is added to the Windows registry:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl
```

While Privileged Access Manager is running, the keys and subkeys are protected. You can modify the keys only through Privileged Access Manager Endpoint Management or with `selang` commands. However, you do not need to use Endpoint Management or `selang` commands to read the keys and values.

- When you restart your computer, several new Privileged Access Manager services start automatically. These services include the Watchdog, Engine, and Agent, which are always installed. Other services, such as Task Delegation, exist depending on the options you chose during installation. The Display name for all Privileged Access Manager services begins with "." You can check what services are installed, and can verify that these services are running, using Windows Services Manager.

## **How to Troubleshoot Resource Access Problems**

Incorrect access authorities are the most common cause of resource access problems. An example of a resource access problem is a root user that can still access a protected resource, but the protected resource has a default access authority of none. The following process helps you troubleshoot resource access problems:

1. Change the audit mode for the protected resource to audit all:

```
chres CLASS ResourceName audit(all)
```

Changing the audit mode to audit all makes the audit log easier to read.

2. [Run a trace](#) and recreate the problem.
3. Review the trace file and the audit log for occurrences of the protected resource. Try to troubleshoot the cause of the resource access problem from the information in the files.

### **NOTE**

SPECIALPGM objects provide bypasses that are not audited, but these bypasses appear in the trace file.

**Note:** For assistance, contact Broadcom Support at <http://ca.com/support>.

## **How to Troubleshoot Connection Problems**

Many factors affect connections between Privileged Access Manager computers. Connection problems include being unable to connect to a remote computer, or the connection to the remote computer timing out. The following process helps you identify the cause of the connection problem.

**Note:** For assistance, contact Broadcom Support at <http://ca.com/support>.

1. Check the Privileged Access Manager computers for recent changes to the following items:
  - Encryption key
  - Encryption method
  - TCP and UDP ports
2. Review any new rules or recently changed rules in the following classes: TCP, CONNECT, HOSTNET, or HOST.
3. Determine the port that has the connection problem.
4. [Run a trace](#) and review the trace file for:
  - Connections that Privileged Access Manager blocked due to TCP rules or other rules
  - A code other than P (permitted) next to the port number that has the connection problem
5. Review the Privileged Access Manager audit log for D (deny) records that refer to the problematic port.
6. Check that firewalls do not block the problematic port.

7. Review the log files for your OS for error messages that are caused by ports that cannot bind.

### **How to Troubleshoot Performance Problems**

The following process helps you identify the cause of performance problems:

**Note:** For assistance, contact Broadcom Support at <http://ca.com/support>.

1. Identify when the performance problem occurs. Does performance degrade:
  - When the OS starts?
  - When Privileged Access Manager starts?
  - When Privileged Access Manager has been running for some time?
  - When Privileged Access Manager or the OS run a scheduled process?
  - (UNIX) When the Privileged Access Manager kernel extension is loaded?
  - When Privileged Access Manager daemons or services are loaded?
2. If you have determined that Privileged Access Manager causes the performance problem, investigate the following questions:
  - What processes are using the most resources when performance degrades?
  - Are the Privileged Access Manager processes keeping the same process ID throughout their lifecycle?
  - Are there any third-party filter drivers installed on the computer?
  - Are there any system-monitoring applications installed on the computer?
3. Check the Privileged Access Manager database:
  - a. Stop the product.
  - b. Check the database:
 

```
dbmgr -util -all
```
  - c. [Reindex the database](#).
  - d. [Rebuild the database](#).
  - e. Restart Privileged Access Manager and check if the problem still exists.
4. (Windows) Disable driver interception:
  - a. Stop Privileged Access Manager.
  - b. Change the value of the UseFsiDrv registry entry to 0. The UseFsiDrv registry entry is in the following registry key:
 

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\AccessControl
```
  - c. Restart Privileged Access Manager and check if the problem still exists.
5. [Run a trace](#) and recreate the problem. Review the trace file for the following conditions:
  - Repeated events in a small period; for example, many file accesses in several seconds
  - Processes that have been killed
  - Either of the following values:
    - a. ACEEH = -1
    - b. U = a negative value
 These values can specify that Privileged Access Manager cannot resolve a user name or cannot assign a value to a resource.

### **NOTE**

For more information about improving Privileged Access Manager performance on your UNIX computer, see the Endpoint Administration Guide for UNIX.

### **Run a Trace**

Running a trace can help you troubleshoot problems. Privileged Access Manager writes trace records to the `seos.trace` file, which is located in the `ACInstallDir/log` directory.

**To run a trace:**

1. Remove all records from the trace file:

```
secons -tc
```

2. Start the trace:

```
secons -t+
```

3. Recreate the problem.

4. Stop the trace:

```
secons -t-
```

5. Review the trace file.

**NOTE**

The configuration settings in the seosd section configure the trace file. For more information about the seosd section, see the *Reference Guide*.

**Run a Trace on Privileged Access Manager Web Service Components****Valid on Windows**

Running a trace on the Privileged Access Manager web service components can help you troubleshoot problems. For example, if Privileged Access Manager Enterprise Management cannot connect to the DMS, run a trace to review the messages that these two components exchange.

Privileged Access Manager writes trace records for web service components to the file that is defined in the logFileName configuration setting in the WebService section. The default value for this configuration setting is C:\Program Files\CA\PAMSCServer\WebService\log\WebService.log.

**To run a trace on Privileged Access Manager web service components:**

1. Stop Privileged Access Manager and the Privileged Access Manager web service.

2. Create a registry key in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\WebService\TraceEnabled
```

3. Set the value of the key to 1.

4. Start Privileged Access Manager and the Privileged Access Manager Web Service.

Tracing starts on the web service components.

5. Recreate the problem.

6. Stop Privileged Access Manager and the Privileged Access Manager web service.

Tracing stops on the web service components.

7. Set the value of the key to 0.

8. Review the trace file.

**Reindex the Privileged Access Manager Database**

Because many updates are made to the Privileged Access Manager database, the database files can become fragmented. Reindexing and [rebuilding the database](#) ensures database optimization for speed and reliability. Reindex the database during your routine maintenance procedures every three to six months, and whenever you have a performance problem.

**NOTE**

In this procedure, the Privileged Access Manager database is installed in the default location, /opt/CA/PAMSC/seosdb (UNIX) and C:\Program Files\CA\PAMSC\Data\seosdb (Windows). To perform this procedure, you must log in as a root user (UNIX) or as an administrator (Windows).

### To reindex the Privileged Access Manager database

1. Stop Privileged Access Manager.
2. Navigate to the following directory:
  - (UNIX) /opt/CA/PAMSC/seosdb
  - (Windows) C:\Program Files\CA\PAMSC\Data\seosdb

3. Back up the database:

```
dbmgr -backup backup_directory
```

4. Index the database:

```
dbmgr -util -build seos_cdf.dat
```

```
dbmgr -util -build seos_odf.dat
```

```
dbmgr -util -build seos_pdf.dat
```

```
dbmgr -util -build seos_pvf.dat
```

#### NOTE

To reduce the size of the database on UNIX computers further, use the `sepurgdb` utility to delete references to undefined records from the database. For more information about the `sepurgdb` utility, see the *Reference Guide*.

### Rebuild the Privileged Access Manager Database

Because many updates are made to the Privileged Access Manager database, the database files become fragmented. [Reindexing](#) and rebuilding the database ensures database optimization for speed and reliability. Rebuild the database during your routine maintenance procedures every three to six months.

#### NOTE

In this procedure, the Privileged Access Manager database is installed in the default location, /opt/CA/PAMSC/seosdb (UNIX) and C:\Program Files\CA\PAMSC\Data\seosdb (Windows). To perform this procedure, you must log in as a root user (UNIX) or as an administrator (Windows).

### To rebuild the Privileged Access Manager database:

1. Stop Privileged Access Manager.
2. Navigate to the following directory:
  - (UNIX) /opt/CA/PAMSC/seosdb
  - (Windows) C:\Program Files\CA\PAMSC\Data\seosdb

3. Back up the database:

```
dbmgr -backup backup_directory
```

4. Export the existing rules and the user-related data from the database:

```
dbmgr -export -l -f exported_filename
```

```
dbmgr -migrate -r migrated_filename
```

5. Navigate to the following directory and create a directory in it named `seosdb_new`:

- (UNIX) /opt/CA/PAMSC
- (Windows) C:\Program Files\CA\PAMSC\Data

6. Create a database in the `seosdb_new` directory using the following command:

```
dbmgr -create -cq
```

7. Copy the *exported\_filename* and *migrated\_filename* files to the `seosdb_new` directory.

8. Import into the new database the existing rules and user-related data that you exported from the old database:

```
selang -l -d "absolute path for seosdb_new" -f exported_filename
```

```
dbmgr -migrate -w migrated_filename
```

**NOTE**

Selang does not use -d option. If you run the "selang -l -f exported\_filename" command after stopping the Privileged Access Manager service and move to the seosdb\_new directory, the exported rules are stored in \$SEOSDIR/seosd.

9. Rename the seosdb directory to seosdb\_old.
10. Rename the seosdb\_new directory to seosdb.
11. Start Privileged Access Manager.

**Change Port Number for Privileged Access Manager Agent Communication**

Privileged Access Manager client applications such as selang, policydeploy, and devcalc, and the Privileged Access Manager Agent communicate on port 8891. We do not recommend that you change this port. If you do change this port, use the following procedure.

**To change the port number for Privileged Access Manager Agent Communication:**

1. Open the following file in a text editor:
  - (UNIX) /etc/services
  - (Windows) %SystemRoot%\drivers\etc\services
2. Add the following file to the file:
 

```
seoslang2 port-number/ tcp
```
3. Save and close the file.
4. Restart Privileged Access Manager daemons or services.

**Configure the Message Queue TCP Port**

When you install Privileged Access Manager Enterprise Management, by default you configure the Message Queue to work with the SSL port. You can change this default behavior and can configure the Message Queue to use the TCP port.

**To connect to the Message Queue TCP port:**

1. Stop the WildFly Server, the Endpoint Services (secons -s), and the Privileged Access Manager ActiveMQ Broker.
2. Open the file C:\ActiveMQ\conf\activemq.xml for editing.

Replace this line of code:

```
<transportConnector name="nio+ssl" uri="nio+ssl://0.0.0.0:61616?
maximumConnections=1000&needClientAuth=false&transport.enabledProtocols=TLSv1.2&w
>
```

With this line of code:

```
<transportConnector name="nio" uri="nio://0.0.0.0:61615?
maximumConnections=1000&needClientAuth=false&wireFormat.maxFrameSize=104857600" /
>
```

3. Save the file and close the file.
4. Open the file standalone-full.xml for editing. The file is in the following location:

```
<WildFly_Home>\standalone\configuration
```

Replace the two instances of the following line of code:

```
ssl://localhost:61616?socket.enabledProtocols=TLSv1.1,TLSv1.2
```

With the following line of code:

```
tcp://localhost:61615
```

5. Save the file and close the file.
6. Open the registry editor. Edit the value in the following key:

```
HKEY_LOCAL_MACHINE>SOFTWARE>ComputerAssociates>AccessControl>Common>communications>Distribution_Server
Replace
```

```
ssl://localhost:61616
```

```
with
```

```
tcp://localhost:61615
```

7. Start the CA Privileged Identity Manager ActiveMQ Broker, Endpoint Services (seosd -start), and .WildFly

### **Information to Provide to Broadcom Support**

When you contact Broadcom Support, they will ask you to provide information about any changes to the environment to help them diagnose the cause of the problem. For example, host and user name changes and changes to the operating system can affect Privileged Access Manager. Broadcom Support might also ask you to use the Privileged Access Manager Support utility to provide more diagnostic information.

Broadcom Support asks you to provide the following information:

- Privileged Access Manager version
- Operating system name, version, architecture, and update level
- Details of any Privileged Access Manager patches installed on the computer
- Number of CPUs

#### **NOTE**

For more information about the operating systems, versions, architectures, and update levels that Privileged Access Manager supports, see the Compatibility Matrix that is available from the Privileged Access Manager product page on [Broadcom Support](#).

Broadcom Support might ask you the following questions:

- What is the impact of the problem?
- When did the problem first occur?
- Is the problem reproducible?
- Was anything added, removed, or changed in the environment before the problem occurred?
- Did you restart the computer before the problem occurred?
- How many times has the problem occurred?
- What happens on the system when the problem occurs? For example, does the problem occur when you execute a particular process or command?
- Does the problem occur consistently or randomly?
- Do any segmentation faults or access violations occur when you execute a Privileged Access Manager command?
- Why do you think Privileged Access Manager caused the problem?
- If the problem is an operating system problem, did you report the problem to the operating system vendor? If yes, can you provide a crash analysis from the operating system vendor?

### ***Generate Diagnostic Information About a Windows Endpoint***

When a customer contacts Broadcom Support to report a Windows endpoint issue, the support team often asks for customer environment information to help diagnose the issue. Privileged Access Manager provides a standalone utility that helps a customer collect relevant information (for example, the Event log, Dump files, System information) from an endpoint. The customer provides the output that the utility generates to the Broadcom Support so that they can troubleshoot the issue. The script is included in the customer endpoint implementation.

The utility lets you collect and report the following information about a Windows endpoint to Broadcom Support:

- System Information
- Export Event log
- Common Information
- Export Privileged Access Manager Registry
- Export Privileged Access Manager Audit
- Copy Privileged Access Manager Audit
- Export Privileged Access Manager Database
- Copy Privileged Access Manager Trace
- Copy Configuration Files
- List Privileged Access Manager Files
- Get Authentication and Cache Statistics
- Export APM Database
- Copy Dump Files
- Export Policy Management Database
- Export Policy Management Database Audit
- Copy Policy Management Database Audit
- Export APM Audit
- Copy APM Audit
- Copy Instrumentation Trace
- Copy APM Logs
- Copy Database

If you collect a copy of the Privileged Access Manager database, the Support utility stops the product before it takes a snapshot of the database. The Support utility restarts Privileged Access Manager when the snapshot is complete.

You can run the support utility in any of the following modes:

- **Interactive Mode**

Follow these steps to run the Support utility in the Interactive mode:

- a. Navigate to the directory where you have installed Privileged Access Manager endpoint: `ACInstallDir\bin`
- b. Double-click **ACSupport.exe**.
- c. In the **ACSupport** dialog that appears, select report types that you want the Support utility to collect and click **Proceed**.

The Support utility takes a snapshot and places the output in the `ACInstallDir\ACSupport` directory.

- **Silent Mode**

Follow these steps to run the Support utility in the Silent mode:

- a. Open a command prompt.
- b. Run the following command:

`ACSupport -s`

If you run the utility without a parameter, the utility starts in the interactive mode.

When you run this command, the utility collects information from a Windows endpoint based on the configuration tokens set in the **CFG\_support.ini** file. The configuration file is created during the endpoint installation, and placed in the Data directory of the installation path. By default, all the configuration tokens are set to "yes." Set the configuration token to "No" in case you do not want the utility to collect any information. The Support utility takes a snapshot and places the output in the `ACInstallDir\ACSupport` directory.

You find one-one correspondence between the Report types available from the **ACSupport** dialog and the tokens in the **CFG\_support.ini** file. Also, the meaning of each token is intuitive in the **CFG\_support.ini** file.

### **Generate Diagnostic Information About a UNIX Endpoint**

The Privileged Access Manager Support utility collects information about your installation to help Broadcom Support diagnose the cause of problems. If you include the Privileged Access Manager database in the snapshot, the Support

utility stops the product before it snapshots the database. The Support utility restarts Privileged Access Manager when the snapshot is complete.

The Privileged Access Manager Support utility always collects the following information about UNIX endpoints:

- `seos.ini` The Privileged Access Manager initialization file
- `tmpetc` The files from the Privileged Access Manager `/etc` directory, including the following:
  - `audit.cfg` The audit filter file
  - `auditroute.cfg` The audit route filter file
  - `nfsdevs.init` A file that contains the NFS defaults for the major device numbers for each operating system
  - `osver` The operating system version
  - `sereport.cfg` The sereport configuration file
  - `serevu.cfg` The serevu configuration file
  - `trcfilter.init` The trace filter file
- `versions.txt` A file that contains versions of key Privileged Access Manager binaries
- Some operating system files, for example, some variable files

If you specify that the Privileged Access Manager Support utility collects information about the database, it collects the following information:

- `seosdb` The Privileged Access Manager database
- `seosdb.tar` A compressed file of the Privileged Access Manager database
- The lookaside databases for groups, hosts, services, and users

If you specify that the Privileged Access Manager Support utility collects information about the logs, it collects the following information:

- `tmplog` The Privileged Access Manager log files
- `log.tar` A compressed file of the Privileged Access Manager log directory

### To generate diagnostic information about a UNIX endpoint

1. Navigate to the following directory, where *ACInstallDir* is the directory in which you installed Privileged Access Manager:

```
ACInstallDir/lbin
```

2. Execute the following command:

```
./support.sh [-db] [-log] [-all] [-none]
```

- **-db**  
Collects information about `seosdb`, the Privileged Access Manager database, but does not collect information about the audit logs.
- **-log**  
Collects information about the audit logs but does not collect information about `seosdb`.
- **-all**  
Collects information about both `seosdb` and the audit logs.
- **-none**  
Does not collect information about `seosdb` and the audit logs.

#### NOTE

If you do not specify an option, the Privileged Access Manager Support utility runs in interactive mode.

The Privileged Access Manager Support utility snapshots your installation and places the output in the *ACInstallDir* directory.

### Generate Diagnostic Information About The Enterprise Management Server

When a customer contacts Broadcom Support to report an Enterprise Management Server issue, the support team often asks for customer environment information to help diagnose the issue. Privileged Access Manager provides a Log Collector script that helps a customer collect relevant information (for example, the WildFly server log, installation logs) from the Enterprise Management Server. The customer provides the output that the script generates to the Broadcom Support so that they can troubleshoot the issue. The script is included in the customer Enterprise Management Server implementation.

Follow these steps to run the log collector script file:

#### [Windows]

1. Open a command prompt.
2. Navigate to *ACInstallDir\PAMSCServer\IAM Suite\Access Control\tools\LogCollector*.
3. Run the *log.bat* file.  
The script runs and collects the support information in a compressed file (ENTM\_supportfile\_<Date>.zip). The compressed file is placed in the **LogCollector** directory.

#### [Linux]

1. Open a terminal session.
2. Navigate to *ACInstallDir/PAMSC/Server/IAM Suite/Access Control/tools/LogCollector*.
3. Run the *log.sh* file.  
The script file runs and collects the support information in a compressed file (ENTM\_supportfile\_<Date>.zip). The compressed file is placed in the **LogCollector** directory.

## Install PAM Server Control Endpoints and Server Components

### Required packages are Missing for Linux Installation

#### Symptom:

The installation fails because required Linux packages are missing.

#### Solution:

Use the `rpm --requires` and the `rpm --which` provides commands to verify package dependencies, and install missing packages.

**Note:** For more information about required packages, see Required 32-bit Packages for installing the Enterprise Management Server on Red Hat Linux 6, in the Installation Considerations section of the *Privileged Access Manager Release Notes*.

#### ***rpm --requires Detect Library Dependencies***

When installing Enterprise Management on Linux, you want to know on which libraries the CAeAC package depends.

The command uses the following syntax:

```
rpm -qp --requires package
```

The command has the following parameters:

- **-q**  
Specifies that you want to query RPM package information.
- **-p**  
Query an RPM package file. Also retrieves information about packages that are not installed.
- **--requires package**

Retrieves the dependencies that are required by the package.

### Example

You want to retrieve dependency information about Privileged Access Manager 12.8 SP0.

```
root> rpm -qp --requires CAeAC-1280-0.0.1275.i386.rpm

rpm >= 4.0

libcrypt.so.1

libc.so.6

libdl.so.2

libgcc_s.so.1

libm.so.6

libnsl.so.1

libpam.so.0

libpthread.so.0

libresolv.so.2

libstdc++.so.6

rpmLib(PayloadFilesHavePrefix) <= 4.0-1

rpmLib(CompressedFileNames) <= 3.0.4-1
```

Continue running the rpm command on the listed packages one by one to retrieve further dependencies.

```
root> rpm -qp --requires libcrypt
```

### ***rpm --whatprovides Verify That a Library Exists***

Before installing Enterprise Management on Linux, verify that all required libraries are present on the target system.

The command uses the following syntax:

```
rpm -q --whatprovides capability
```

The command has the following parameters:

- **-q**

Specifies that you want to query RPM package information.

- `--whatprovides capability`

Specifies that you want to retrieve information which packages provide the capability.

### Example: Verify that a library is installed

In this example, you want to verify that `libcrypt.so.1` is installed. You receive a positive answer (`$?` is 0) and you learn that it is the `glibc-2.5-42` package that provides `libcrypt.so.1`.

```
root> rpm -q --whatprovides libcrypt.so.1

glibc-2.5-42

root> echo $?

0
```

### Example: Detect that a library is not installed

In this example, you want to find out whether `libexample.so.1` is installed. You receive a negative answer (`$?` is 1), because no package is installed that provides this capability.

```
root> rpm -q --whatprovides libexample.so.1

no package provides libexample.so.1

root> echo $?

1
```

If a required library is missing, install it before proceeding the installation.

## Modify the Oracle Database Host Settings After Installation

### Symptom:

After installing the Enterprise Management Server, I need to modify the Oracle database server settings to point to a different server.

### Solution:

You can modify the Enterprise Management Server to work with an Oracle database on a different host after installation:

1. Stop the WildFly service on the Enterprise Management Server.
2. Back up the Oracle database on the current host.
3. Restore the Oracle database on the new host.
4. Navigate to the following directory, where *WildFly\_HOME* indicates the directory where you installed WildFly:

```
WildFly_HOME/standalone/configuration
```

5. Locate and back up the following file:
  - `standalone-full.xml`

6. Open the file and locate the <connection-url> entry.
7. Modify the connection settings to specify the new Oracle database host name except the pool name **ExampleDS**.

**Example:**

```
<connection-url>jdbc:oracle:thin@//new_host_name:1521/sid_or_service_name</
connection-url>
```

8. Start the WildFly service.  
You have modified the Oracle database host settings.

**Enterprise Management Server Fails To Register Endpoints Type****Symptom:**

I cannot view the endpoint types when I attempt to register the endpoint, after installing the Enterprise Management Server.

**Solution:**

The componentregistration utility registers the endpoints with the Enterprise Management Server. When the installation fails to register the endpoints, you can manually run the componentregistration utility.

**Follow these steps:**

1. Log in to the Enterprise Management Server.
2. Open a Command Prompt window and navigate to the following bin directory:

```
\ProgramFiles\CA\PAMSCServer\APMS\PAMSC\bin\
```

3. Run the following command to execute the ComponentRegistration utility:

```
ComponentRegistration -comp jcs -register -userDN <user> -serverDN <server> -pwd
<communication_password> -port CA Portal -ssl yes
```

For example: ComponentRegistration -compjcs -register -userDNcn=root,dc=etasa -serverDN dc=im,dc=etasa -pwdpassword-port 20411 -ssl yes

4. Restart Privileged Access Manager Services.
5. Verify that the endpoint types are registered by logging in to Privileged Access Manager Enterprise Management.
6. Browse to Privileged Accounts, Endpoints, View Endpoints Types and check the listed endpoints types.

You have successfully registered the endpoint types.

**"Bad Interpreter" Error Message During CA Privileged Access Manager Server Control Enterprise Management Installation****Valid on UNIX and Linux****Symptom:**

When I try to install Privileged Access Manager Enterprise Management, I receive the following error message:

```
/bin/sh: bad interpreter: Permission denied
```

**Solution:**

In some UNIX or Linux releases, the operating system automounts the optical disc drive with the noexec option. To install Privileged Access Manager Enterprise Management, verify that the optical disc drive is not mounted with the noexec option.

### **Cannot Use '\$' Character for CA Privileged Access Manager Server Control Enterprise Management Database Password**

#### **Symptom:**

When I install Privileged Access Manager Enterprise Management, I enter the database password and I receive the following error message: "Database version could not be detected".

#### **Solution:**

Privileged Access Manager Enterprise Management installation displays this error message if you enter a '\$' character at the end of the password. If you must place a '\$' character at the end of the password, you must change the database password after the installation.

### **Cannot Open CA Privileged Access Manager Server Control Server Components**

#### **Symptom:**

I cannot open Privileged Access Manager Enterprise Management, Endpoint Management, or Password Manager in a web browser after I start all prerequisite services. I have installed WildFly and Oracle on the same server.

#### **Solution:**

Both Oracle and WildFly use a default port of 8080. To fix this problem, you must resolve the port conflict between Oracle and WildFly. You should consider which change is easiest to implement in your enterprise before you change the Oracle or WildFly port.

Use the following procedures to change the default WildFly and Oracle ports:

#### **Follow these steps:**

1. Stop WildFly.
2. Open the following file in a text editor:  
`<WildFly_Home>/standalone/configuration/standalone-full.xml`
3. Change the port number in the following section:  
`<socket-binding name="http" port="8080"/>`
4. Save and close the file.
5. Start WildFly.
6. (Windows) Change the Privileged Access Manager Enterprise Management, Endpoint Management, and Password Manager shortcuts, as follows:
  - a. Click Start, Programs, CA, Access Control, and right-click the appropriate shortcut.  
 For example, to change the Privileged Access Manager Enterprise Management shortcut, click Start, Programs, CA, Access Control, and right-click Enterprise Management.
  - b. Click Properties.
  - c. Change the port number in the URL field to the new WildFly port number.

#### **To change the default Oracle port:**

1. Start the SQL command line.
2. Connect to Oracle as sysdba:

```
connect / as sysdba
```

3. Check what port is currently used for HTTP communication:

```
select dbms_xdb.gethttpport from dual;
```

4. Set the port to the desired port number:

```
exec dbms_xdb.sethttpport('portNumber');
```

5. Stop and restart the database.

```
shutdown immediate
```

```
startup
```

## **No Tabs Visible in CA Privileged Access Manager Server Control Enterprise Management**

### **Valid for Active Directory user stores**

#### **Symptom:**

I successfully install Privileged Access Manager Enterprise Management. When I log in as the system user that I specified during installation, no tabs appear in the interface.

#### **Solution:**

When you install Privileged Access Manager Enterprise Management, you provide the following Active Directory parameters:

- Host
- Port
- Search root
- User DN (and the password for this user)
- System User

This problem occurs when the Active Directory search root is in the same node in the directory tree as the DNs (Distinguished Names) for User DN and System User. To fix this problem, specify a search root one or more nodes higher in the directory tree than the DNs for the specified User DN and System User.

#### **Example: The Active Directory Search Root**

This example uses the following DNs for User DN and System User:

- User DN: CN=MyQueryUser,OU=ENTERPRISE,OU=NFS,OU=ACCOUNTS,DC=EXAMPLE,DC=LAB
- System User: CN=MySystemManager,OU=ENTERPRISE,OU=NFS,OU=ACCOUNTS,DC=EXAMPLE,DC=LAB

The following search root is one node higher in the directory tree than the DNs for User DN and System User. If you specify the following search root, Privileged Access Manager Enterprise Management successfully installs and tabs appear in the interface:

```
OU=NFS, OU=ACCOUNTS, DC=EXAMPLE, DC=LAB
```

The following search root is in the same node in the directory tree as the DNs for User DN and System User. If you specify the following search root, Privileged Access Manager Enterprise Management successfully installs but no tabs appear in the interface:

```
OU=ENTERPRISE,OU=NFS,OU=ACCOUNTS,DC=EXAMPLE,DC=LAB
```

### Example: Set the Active Directory Search Root One Node Higher In the Directory Tree

This example uses the same DNs for User DN and System User as the previous example.

In this example, you specified the following search root when you installed Privileged Access Manager Enterprise Management:

```
OU=ENTERPRISE,OU=NFS,OU=ACCOUNTS,DC=EXAMPLE,DC=LAB
```

Because this search root is in the same node in the directory tree as the DNs for User DN and System User, specify a search root one node higher in the directory tree.

#### To set the Active Directory search root one node higher in the directory tree:

1. Enable the CA Identity Manager Management Console.
2. Open the CA Identity Manager Management Console.
3. Click Directories, and click the ac-dir directory.  
The Directory Properties dialog appears.
4. Click Export at the bottom of the Directory Properties dialog.
5. When prompted, save the XML file and open it for editing.  
**Note:** The file name is ac-dir.xml.
6. Locate the tag that contains the search root that you specified during installation. For example:

```
<LDAP searchroot="OU=ENTERPRISE,OU=NFS,OU=ACCOUNTS,DC=EXAMPLE,DC=LAB" secure="false"/>
```

7. Replace the existing search root with the new search root. For example:

```
<LDAP searchroot="OU=NFS,OU=ACCOUNTS,DC=EXAMPLE,DC=LAB" secure="false"/>
```

**Note:** Because you removed the Enterprise OU (Organizational Unit), this search root is one node higher in the directory tree than the previous search root.

8. Save and close the file.
9. In the CA Identity Manager Management Console, click Update in the Directory Properties dialog.  
The Update Directory page appears.
10. Click Choose File, navigate to the XML file that you edited, click Open, and click Finish.  
The CA Identity Manager Management Console validates the XML file and displays status information in the Directory Configuration Output field.  
**Note:** If you receive a "Failed to Import" error, see the Cannot Import ac-dir.xml Directory Configuration File topic.
11. Click Continue.  
The Directories page appears.
12. Click ac-dir, and click ac-env in the Environment(s) section.  
The Environment Properties page appears.
13. Click Restart.  
The CA Identity Manager Management Console restarts the environment and applies your changes.

**Note:** For more information about how to enable and start the CA Identity Manager Management Console, see the *Implementation* section.

## **Cannot Import ac-dir.xml Directory Configuration File**

### **Symptom:**

I exported the ac-dir.xml directory configuration file from the CA Identity Manager Management Console. When I try to import the file, the following error message appears in the Directory Configuration Output field:

```
Deploying directory configuration...
```

```
Parsing input stream...
```

```
Error: (140:67): cvc-complex-type.4: Attribute "value" must appear on element
"Container".
```

```
Error: Failed to import
```

```
*****
```

```
1 error(s), 0 warning(s)
```

### **Solution:**

The ac-dir.xml directory configuration file describes the structure and content of the user store. You use this file to change how Privileged Access Manager Enterprise Management interacts with the user store, for example, to change the user directory password or the Active Directory search root. You also edit the ac-dir.xml file when you configure Privileged Access Manager Enterprise Management for SSL communication and Active Directory for failover.

To fix this problem, do the following:

1. Open the ac-dir.xml file for editing.
2. Locate the following tag:

```
<Container objectclass="top,organizationalUnit" attribute="ou"/>
```

3. Replace the previous tag with the following tag:

```
<Container objectclass="top,organizationalUnit" attribute="ou" value=""/>
```

4. Save and close the file.

You can now import the directory configuration file in to the CA Identity Manager Management Console. To apply any changes that you made in the directory configuration file, you must restart the environment after you import the file.

## **CA Privileged Access Manager Server Control Enterprise Management Cannot Connect to DMS**

### **Symptom:**

When I log in to Privileged Access Manager Enterprise Management, I receive a message similar to the following:

```
Error: Login procedure failed
```

```
Error: Password on target does not match client's password
```

### **Solution:**

The user `ac_entm_pers` cannot log in to the DMS. This user authenticates communication and data flow between the Enterprise Management Server and the DMS.

**Note:** The `ac_entm_pers` user has the following authorization attributes: ADMIN, AUDITOR, IGN\_HOL, LOGICAL

To troubleshoot this problem, do the following:

1. Open `selang`.
2. Connect to the DMS:

```
host DMS__@entM_host_name
```

3. Change the password for `ac_entm_pers`:

```
eu ac_entm_pers admin auditor nonative password(password) logical nonative grace-
```

4. Authorize `ac_entm_pers` to log in to the host on which the Enterprise Management Server is installed:

```
authorize TERMINAL entM_host_name uid(ac_entm_pers) access(a)
```

5. Validate that `ac_entm_pers` can log in to the Enterprise Management Server:

```
host DMS_@entM_host_name uid(ac_entm_pers) password(password) logical
```

6. Update the Enterprise Management Server DMS connection settings with the new password for `ac_entm_pers`. The DMS authenticates `ac_entm_pers` and Privileged Access Manager Enterprise Management is connected to the DMS.

**Note:** For more information about how to configure the connection to the DMS, see the *Privileged Access Manager Enterprise Management Online Help*.

If you receive an error when you update the connection settings, the DMS cannot authenticate `ac_entm_pers`. To troubleshoot this problem, do the following:

1. Verify that you entered the same password in each step of the previous procedure.
2. Verify that the host name of the Enterprise Management Server (*entM\_host\_name*) in Step 4 of the previous procedure is correct.  
For example, if you specify the fully qualified host name of the Enterprise Management Server in Step 4, but the `TERMINAL` record for the Enterprise Management Server uses a short host name, the host names are not resolved. `ac_entm_pers` cannot log in to the Enterprise Management Server.
3. Review the Privileged Access Manager audit file:

```
seaudit -a
```

#### 4. Review the DMS audit file:

```
seaudit -a -fn DMS_log_file
```

**Note:** The audit records may provide information about the correct host name of the TERMINAL record for the Enterprise Management Server.

#### **Example: Display the DMS Audit File**

The following example displays the audit file for a DMS named DMS\_\_:

```
seaudit -a -fn "C:\Program Files\CA\PAMSCServer\APMS\PAMSC\Data\DMS__\pmd.audit"
```

### **Question Marks Appear in CA Privileged Access Manager Server Control Enterprise Management Tabs**

#### **Symptom:**

When I open Privileged Access Manager Enterprise Management, I see question marks in the tabs.

#### **Solution:**

To fix this problem, change the default language of your browser to US English.

### **Received "Null page" Error in InfoView**

#### **Symptom:**

When I try to access the Privileged Access Manager reports I get the following error in InfoView:

```
Null page: Unable to create page from report source
```

#### **Solution:**

On Windows, the Privileged Access Manager Universe may not be defined or installed properly. Test the connection for the Privileged Access Manager Universe. If the connection is not working, edit the connection; if the connection is working, replace the connection.

On Solaris, log in as bouser and edit the script \$CASHCOMP/CommonReporting/bobje/setup/env.sh as follows:

#### 1. Append the following LIBRARYPATH:

```
$MWHOME/lib-sunos5_optimized
```

#### 2. Restart BusinessObjects services:

```
cd $CASHCOMP/CommonReporting/bobje
```

```
./stopservers
```

```
./startservers
```

## **CA Privileged Access Manager Server Control Does Not Start Automatically After a UNIX Installation**

### **Valid on UNIX**

#### **Symptom:**

Privileged Access Manager does not start automatically after I install it on a UNIX endpoint.

#### **Solution:**

By default, Privileged Access Manager does not start automatically on a UNIX endpoint.

To configure the seosd daemon to start automatically upon startup on a UNIX computer, use the *ACInstallDir/samples/system.init/sub-dir* directory, where *sub-dir* is the directory for your operating system. Each sub-directory contains a readme file with instructions on how to start Privileged Access Manager automatically on your operating system.

**Note:** For more information about how to start Privileged Access Manager, see the *Implementation* section.

## **Cannot Start Daemons on Linux s390 Endpoint**

### **Valid on Linux s390 and Linux s390x**

#### **Symptom:**

I cannot start the seosd or ReportAgent daemon.

#### **Solution:**

Privileged Access Manager cannot locate the Java environment on the endpoint. To fix this problem, do the following:

1. Verify that the `java_home` configuration setting in the global section of the `accommon.ini` file contains the path to the Java environment.
2. Set the value of the `LD_LIBRARY_PATH` environment variable to the path to the shared libraries of the Java environment.

## **Cannot Connect to selang After Installation**

#### **Symptom:**

After I install Privileged Access Manager, I receive the following error when I try to start selang or connect to the Privileged Access Manager database:

```
ERROR: Initialization failed, EXITING!
```

```
(localhost)
```

```
ERROR: Login procedure failed
```

```
ERROR: You are not allowed to administer this site from terminal example.com
```

#### **Solution:**

Terminal rules are not correctly defined. Troubleshoot the terminal rules to determine the problem.

#### **To troubleshoot terminal rules:**

1. Stop Privileged Access Manager:

```
secons -s
```

2. Start `selang` in local mode:

```
selang -l
```

**Note:** You must be the root user to run `selang` in local mode on a UNIX computer.

3. Check that you have created a `TERMINAL` record for the local terminal (*terminal\_name*), and that the terminal access authorities are correctly defined:

```
showres TERMINAL terminal_name
```

- If a record does not exist, create a `TERMINAL` record for the local terminal:

```
editres TERMINAL terminal_name owner(name) defaccess(accessAuthority)
```

**Note:** The owner can be either a user or a group. Because the default access for a `TERMINAL` record is none, we recommend that you specify a default access when you create the record to avoid locking users out of the terminal.

- If the terminal access authorities are incorrect, define the correct access authorities for the terminal:

```
authorize TERMINAL terminal_name uid(name) access(accessType)
```

4. (UNIX) Check the value of the `terminal_default_ignore` configuration setting in the `[seosd]` section. This configuration setting determines if Privileged Access Manager considers the `defaccess` value of the `_default` `TERMINAL` and of the specific `TERMINAL` records when authorizing administrative access.

**Note:** For more information about the `terminal_default_ignore` configuration setting, see the *Reference* section.

5. (UNIX) Check that the lookaside database reflects the terminal, as follows:

- a. Build a hostname-specific lookaside database:

```
sebuilda -h
```

- b. Check that the terminal entry and the hostname are the same in the lookaside database:

```
sebuilda -H | grep hostname
```

The contents of the hosts lookaside database files are listed.

6. Start Privileged Access Manager:

- (UNIX) `seload`
- (Windows) `seosd -start`

**Note:** If you still cannot start `selang` or connect to the Privileged Access Manager database, you may have to modify the hosts file for your OS. Contact your system or network administrator for assistance.

### **Messages Appear in Solaris 10 Log File**

#### **Valid on Solaris 10**

#### **Symptom:**

When I stop Privileged Access Manager using "`secons -s`," messages appear in the `/var/adm/messages` log file on my Solaris 10 computer. The `SEOS_use_streams` configuration setting on my computer is set to yes.

**Solution:**

These messages are informational only and do not indicate any failure or error. You do not need to do anything. The messages and their interpretation follow:

- "SEOS: Restored tcp wput" "SEOS: Restored strthead rput"  
These messages indicate that the SEOS\_syscall function disabled network hooks.
- "SEOS: Replaced tcp wput" "SEOS: Replaced strthead rput"  
These messages indicate that the SEOS\_syscall function enabled network hooks.

**Received Error When Manually Deleting Registry Keys During Uninstall****Valid on Windows****Symptom:**

When I try to delete a registry key while uninstalling Privileged Access Manager, I receive the following error message:

```
Cannot open Data: Error while opening key.
```

**Solution:**

Run the RemoveAC.exe utility to remove Privileged Access Manager registry keys and directories. The RemoveAC.exe utility does not uninstall the product, but helps ensure that all Privileged Access Manager registry keys and directories are removed from the computer.

**ProductExplorer Not Started****Symptom:**

When I insert the Privileged Access Manager Server Components DVD for Windows into my optical drive, the ProductExplorer does not start.

**Solution:**

Do the following:

- Navigate to the optical disc drive directory and double-click the ProductExplorerrx86.EXE file.
- Enable autorun to startup the ProductExplorer automatically.

**The Path/Environment Variable Is Not Set In a Solaris Endpoint****Symptom:**

When I do `sesu` to root in a Solaris endpoint from any non-root user, the path/environment variable for the root user is not set.

Sample Error Message:

```
bash-2.05$ sesu -
Sun Microsystems Inc. SunOS 5.9 Generic May 2002
You have new mail.
/etc/profile[121]: grep: not found
/etc/profile[121]: uname: not found
/etc/profile[121]: test: argument expected
/etc/profile[121]: uname: not found
```

```

/etc/profile[121]: uname: not found
/etc/profile[121]: test: argument expected
.profile[5]: grep: not found
.profile[5]: uname: not found
.profile[5]: test: argument expected
.profile[5]: uname: not found
.profile[5]: grep: not found
.profile[5]: uname: not found
.profile[5]: test: argument expected

```

**Solution:**

1. Stop Privileged Access Manager services.  

```
#/opt/CA/PAMSC/bin/secons -s
```
2. Open seos.ini file for editing. You can find this file at /opt/CA/PAMSC/.
3. Modify the following lines in seos.ini as follows, and save the file.

```

old_sesu = no
request_target_password = no
UseInvokerPassword = no

```

4. Start Privileged Access Manager services.

```
#/opt/CA/PAMSC/bin/seload
```

**Login Procedure Failed Error in a UNIX Endpoint****Symptom:**

After a successful installation of a UNIX endpoint, I get the following error on starting selang or when I connect to SEOSDB.

```

"ERROR: Initialization failed, EXITING!"(localhost)
ERROR: Login procedure failed
ERROR: You are not allowed to administer this site from terminal 127.0.0.1

```

**Solution:**

Verify that the terminal rules are defined properly. If not, define the proper terminal and provide appropriate authorization for the terminal.

1. Stop Privileged Access Manager endpoint services.

```
/opt/CA/PAMSC/bin/secons -sk
```

2. Start Selang in local mode.

```
selang -l
```

3. Verify if the terminal with the host name is defined and proper authorizations are provided.

```
PAMSC> sr terminal *
```

If not, define the terminal and provide the appropriate authorization.

```
PAMSC> authorize TERMINAL <terminal name> uid(USER) access(Type of access to be
provided)
```

4. Quit selang
5. Check if the Look Aside Database (LADB) reflects the defined host name terminal according to your site. Use `sebuildla -h` to build the host name-specific LADB.
6. Use `sebuildla -H | grep <hostname>`, to match against the defined terminal entry. The terminal entry and the host name must be same in all aspects.
7. Check if the TERMINAL class is ON. If it is OFF, run "so CLASS+(TERMINAL)" from the Selang prompt.
8. Start Privileged Access Manager services.

### **Ungraceful Shutdown of a Process Causes Corruption**

#### **Symptom:**

The SIGKILL signal is sent to a process to terminate (kill) it immediately. In contrast to SIGTERM and SIGINT, this signal cannot be caught or ignored, and the receiving process cannot perform any clean-up upon receiving this signal.

#### **Solution:**

To protect programs from being killed while Privileged Access Manager is up and running, define relevant PROCESS rules for the binaries. Try **secons -S selogrd** or **kill -15 PID**, which gives the components a chance to shut down correctly and safely (closing socket connections, cleaning up temp files, and informing the child processes that it is going away).

### **Error Starting SEOS**

#### **Symptom:**

When I start Privileged Access Manager services through seload on a Linux endpoint, I get the following error message:

```
./seload
CA Privileged Access Manager Server Control seload <version> - Loader Utility
Copyright (c) 2013 CA. All rights reserved.
SEOS_load: Warning ! The system.map file does not exist
on this system. As a result CA Privileged Access Manager Server Control might
not be able to load
SEOS_load: Executing un/load exit file, /opt/CA/PAMSC/exits/LOAD/SEOS_load_int.always -
pre
SEOS_load: Executing un/load exit file, /opt/CA/PAMSC/exits/LOAD/SEOS_load_int.always -
post
SEOS_load: SEOS_syscall WASN'T loaded
```

#### **Solution:**

Run the following command to check if the **system.map** file is available:

```
ls -al /boot/System.map-`uname -r`
```

If the file is missing, install it. This file is required to load/get debug information from the kernel module.

## **Failed to Unload Privileged Access Manager Endpoint**

### **Symptoms:**

When I uninstall Privileged Access Manager endpoint, I get the following error messages:

```
Trying to unload CA Privileged Access Manager Server Control...
```

```
ERROR: Module seos is in use
```

```
Error: CA Privileged Access Manager Server Control kernel module could not be unloaded.
```

### **Solutions:**

You can troubleshoot this problem using the following two ways:

#### **Solution 1**

1. Run the following command to list all the dependent processes (intercepted system calls) on SEOS kernel module.

```
secons -scl'
```

Example:

```
# secons -scl
CA Privileged Access Manager Server Control secons v12.81.0.2627 - Console utility
Copyright (c) 2015 CA. All rights reserved.
Active system calls:
-Syscall 2 - PID: 14412 PPID: 27271 UID: 0 TIME: 10s PROGRAM NAME: /bin/cat
```

2. Stop the listed dependent processes:

```
# Kill -15 <pid>
```

Example:

```
# kill -15 14412
```

3. Run the following command to stop and kill the endpoint daemons or services:

```
# secons -skca c
```

4. Unload the kernel module using the following command.

```
# SEOS_load -u
```

5. Uninstall the endpoint, if necessary.

```
# ./uninstall_AC
```

**Note:** If the uninstall fails, run the following command to uninstall the endpoint.

- # rpm -e CAeAC (for native package installation)
- # ./uninstall\_AC -force (for install\_base installation)

#### **Solution 2:**

1. Reboot the endpoint so that the dependent processes on the kernel module are cleared from the system.
2. Run the following command to stop and kill the endpoint daemons or services:

```
# secons -sk
```

3. Unload the kernel module using the following command.

```
# SEOS_load -u
```

4. Uninstall the endpoint, if necessary.

```
# ./uninstall_AC
```

**Note:** If the uninstall fails, run the following command to uninstall the endpoint.

- # rpm -e CAeAC (for native package installation)
- # ./uninstall\_AC -force (for install\_base installation)

### **ORA-00955: Name Is Used by an Existing Object**

#### **Symptom:**

When I restart WildFly, the following error is shown in the **server.log** file:

```
ERROR [ims.tmt.CreateDatabaseSchema] Error in creating Report Snapshot database schema.
java.sql.SQLException: ORA-00955: name is already used by an existing object
    at oracle.jdbc.driver.T4CTTIoer.processError(T4CTTIoer.java:447)
    at oracle.jdbc.driver.T4CTTIoer.processError(T4CTTIoer.java:396)
    at oracle.jdbc.driver.T4C8Oall.processError(T4C8Oall.java:951)
    at oracle.jdbc.driver.T4CTTIfun.receive(T4CTTIfun.java:513)
    at oracle.jdbc.driver.T4CTTIfun.doRPC(T4CTTIfun.java:227)
    at oracle.jdbc.driver.T4C8Oall.doOALL(T4C8Oall.java:531)
```

#### **Solution:**

When you install the Enterprise Management Server, all the tables are created in the database. Post installation when WildFly starts, it tries to create some tables again. Because the tables already exist in the database, you see errors in the **server.log** file. You can ignore this error as it has no impact on the product.

## **Create Policies and Access Authorities**

### **Block Users Access to Network Drives and Shared Drives**

#### **Valid on Windows**

#### **Symptom:**

I am able to block users access to a system drive, but I cannot stop users access to network and shared drives.

#### **Solution:**

To block users access to network and shared drives on Windows 2008, add the following selang command to the policy:

```
newres FILE \Device\Mup\*
```

To block users access to network and shared drives on Windows 2003, add the following selang command to the policy:

```
newres FILE \Device\LanmanRedirector\*
```

### **User Can Access Protected Resources**

#### **Symptom:**

I created a default access authority of none for a resource, but the superuser can still access the resource.

#### **Solution:**

[Troubleshoot the resource access problem.](#)

### **Read Access Checks Bypass etc/passwd and etc/group Files**

#### **Valid on UNIX**

##### **Symptom:**

I created a rule that has a default access authority of none for the /etc/passwd and /etc/group files, but I still have read access to these files.

##### **Solution:**

By default, the Privileged Access Manager authorization engine bypasses read access checks for the /etc/passwd and /etc/group system files. To stop Privileged Access Manager bypassing read access checks for system files, change the value of `bypass_system_files` in the `[seosd]` section of the `seos.ini` file to `no`.

##### **WARNING**

If you stop Privileged Access Manager bypassing read access checks for system files, verify that correct authorizations are in place. If you do not set the correct authorizations and bypass read access checks, users including Privileged Access Manager administrations and the root user may not be able to access the system. A critical system processes may fail.

### **An Enterprise User or Group Cannot Access Resources but Correct Access Rules are Set**

#### **Valid on Windows**

##### **Symptom:**

I can see that an enterprise user or group has permissions to access a resource but they cannot access it.

##### **Solution:**

The enterprise account may have been recycled and the permissions in the database apply to the old account, not the new account that has the same name but a different SID. To check for this scenario, resolve recycled enterprise accounts.

##### **NOTE**

For more information about resolving recycled enterprise accounts, see the *Endpoint Administration Guide for Windows*.

### **Failed Login Does Not Lock Out User**

#### **Valid on UNIX**

##### **Symptom:**

I configure `serevu` to disable users in the password PMD after a specified number of failed login attempts. When a user fails to log in correctly, Privileged Access Manager does not lock out the user. When I start `serevu` with the `nodaemon` option to view the `pam_failed_logins.log` file, the server does not respond.

##### **Solution:**

The value of `passwd_pmd` in the `[seos]` section of the `seos.ini` file is incorrect. Set the value of `passwd_pmd` to the name of the password PMD to which `sepass` sends password updates.

### **Users Can Run Commands Outside Time Restrictions**

##### **Symptom:**

I set time restrictions on a group, but group members can run Privileged Access Manager commands outside the permitted times.

##### **Solution:**

During a restricted time period, Privileged Access Manager prevents users from starting a new login session but cannot force users to disconnect. To prevent users from accessing resources or commands in a restricted time period, change the resource record for the resource or command to include time restrictions.

**NOTE**

Privileged Access Manager checks if time restrictions exist in the USER or XUSER record for the user before it checks if time restrictions exist for GROUP or XGROUP to which the user belongs.

## **CA Privileged Access Manager Server Control Recognizes All Users as root**

### **Valid on UNIX**

#### **Symptom:**

When I run the `sewhoami` utility for a non-root user, Privileged Access Manager recognizes the user as root.

#### **Solution:**

To troubleshoot this problem, verify the following in the LOGINAPPL record of the login application:

- The name of the LOGINAPPL record is the name of the login application.
- The LOGINPATH parameter in the LOGINAPPL record specifies the correct, full path to the login application.

**NOTE**

To determine the path to the login application, [run a trace](#) and then use the login application to log in and log out of Privileged Access Manager. Review the trace to obtain the path.

The LOGINSEQUENCE parameter in the LOGINAPPL record specifies the correct login sequence for the login application. For assistance, contact CA Support at <http://ca.com/support>.

**NOTE**

Privileged Access Manager does not define LOGINAPPL records for third-party login applications. If you use a third-party login application, manually define the LOGINAPPL record for the application.

## **Cannot Add User as Password Manager to Only One Group**

#### **Symptom:**

I want to make a user a password manager for a specific group, but when I execute the following command the user becomes a password manager for all groups:

```
editusr userName pwmanager
```

#### **Solution:**

Specify the name of the group to which you want to add the user as a password manager, as follows:

```
join userName group(groupName) pwmanager
```

## **Windows Administrators Can Change Privileged Access Manager Server Control Passwords**

### **Valid on Windows**

#### **Symptom:**

Windows administrators can change Privileged Access Manager passwords in my Privileged Access Manager-protected Windows environment.

#### **Solution:**

To help ensure that only users that you specify in Privileged Access Manager can change passwords, set the value of the EnforceViaTrust registry entry to 1 in the following key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\passwd
```

This registry entry specifies to enforce that you can update or create user passwords through Privileged Access Manager only. The default value of the registry entry is 0, meaning that you do not have to use Privileged Access Manager to update or change a user password.

### **Global Password Policies Lock Users Out of Protected Systems**

#### **Symptom:**

When I implement a global password policy, the password policy locks users out of systems protected by Privileged Access Manager.

#### **Solution:**

Create a separate password policy for the users who must access the Privileged Access Manager-protected system. Use a profile group to create a password policy for these users.

The following process describes how to use a profile group to implement a password policy:

1. Create a profile group.
2. Set the password policy for the profile group.
3. Assign the users to the profile group.

The password policy that you set for the profile group now applies to the users associated with the profile group.

### **Task Delegation Hangs for Interactive Application**

#### **Valid on Windows**

#### **Symptom:**

I write a task delegation rule that lets a user run an interactive Windows application, for example, notepad.exe. When the user tries to run the application, the task delegation hangs.

#### **Solution:**

The interactive flag must be set for the SUDO class record that permits the user to run the application. If you use task delegation to run an interactive Windows application and the interactive flag is not set, the application runs in the background and you cannot interact with it.

To fix this problem, do the following:

1. Set the interactive flag for the SUDO record:

```
er SUDO resourceName interactive
```

#### **– resourceName**

Specifies the name of the resource record that lets the user run the application.

The interactive flag is set for the specified resource.

2. Restart the Task Delegation service, as follows:
  - a. Kill the interactive application.
  - b. If task delegation still hangs, restart Privileged Access Manager.

#### **NOTE**

For more information about task delegation and defining SUDO records, see the *Endpoint Administration Guide for Windows*.

## Manage the CA Privileged Access Manager Server Control Database

### selang Query Returns Maximum of 100 Records

#### Symptom:

When I run a selang query that should return more than 100 records, Privileged Access Manager displays the following message:

```
WARNING: Only 100 (query size limit) items are displayed.
```

#### Solution:

The default value of the query\_size configuration setting is 100. To increase the number of records that Privileged Access Manager returns for selang queries, change the value of the query\_size configuration setting.

The query\_size configuration setting is located in the:

- (UNIX) [lang] section of the seos.ini file
- (Windows) lang subkey, as follows:  
HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\lang

### UTimes and Denied Records in the Audit Log After Database Backup

#### Symptom:

When Privileged Access Manager is running and I back up the database with my OS backup tools, Privileged Access Manager sends an entry to the audit log similar to the following message:

```
03 Mar 2008 15:58:01 D FILE          UTimes      69 10
/opt/CA/PAMSC/seosdb/seos_pvf.fre /usr/sbin/fbackup
```

#### NOTE

The example above is written using UNIX pathnames, but the solution is also valid for Windows computers.

#### Solution:

The audit message means that Privileged Access Manager prevented the backup operation from updating the UTimes file date stamp. Privileged Access Manager did not prevent the backup itself.

To prevent this message from appearing in the audit log, complete the following tasks:

- If the backup program is executed by a non-superuser, verify that the user has the OPERATOR attribute.
- If the backup program is executed by a superuser, verify that the backup program has a SPECIALPGM record that has the pgmtype (backup) property.

To verify that the database is correctly backed up, use the dbmgr utility to perform the backup.

### The Privileged Access Manager Database Is Corrupt

#### Valid on UNIX

#### Symptom:

I notice messages similar to the following messages in the Privileged Access Manager error log:

```
seoswd: [ID 973226 auth.error] Communication time out to seosd. Executing seosd
FATAL!Inseosrt_InitDatabase (0x270)
WARNING: /Path of Access Control/seosdb/seos_cdf.dat was corrupted
```

**Solution:**

Use the following procedure to fix the database corruption:

**NOTE**

This procedure assumes that the database is installed in the default installation location, /opt/CA/PAMSC

**To fix the Privileged Access Manager database corruption:**

1. Stop Privileged Access Manager:

```
secons -s
```

2. (Optional) Back up the database to another location so that the database can be provided to Technical Support if necessary.

3. Verify that the database is marked as closed:

```
cd /opt/CA/PAMSC/seosdb
dbmgr -util -close
```

**NOTE**

If Privileged Access Manager is not shut down correctly, the database can be marked as open.

4. Check the database:

```
dbmgr -util -check
```

5. Do *one* of the following tasks:

- If you do not receive an error message when you check the database, go to Step 6.
- If you receive an error message when you check the database, do not complete Steps 6 and 7. Instead, [rebuild the database](#).

6. Build the database files:

```
dbmgr -util -build all
```

7. Check the database again:

```
dbmgr -util -check
```

8. Start Privileged Access Manager:

```
seload
```

**Note:** If the database is still corrupt, further investigation is required. For assistance, contact CA Support at <http://ca.com/support>.

## Connecting to Remote Computers

### Cannot Connect to Remote Computer

**Symptom:**

I cannot connect to a remote Privileged Access Manager computer.

**Solution:**

[Troubleshoot the connection problem.](#)

### Communication Time Out to seosd Appears Continuously in syslog

**Valid on Windows****Symptom:**

When I run Privileged Access Manager, the computer occasionally slows down and the following messages appear in syslog:

```
seoswd: Communication time out to seosd. Executing seosd
seoswd: Communication problem with seosd returned 5378 [Success]
seoswd: Description: Timeout communication with seosd.
```

**Solution:**

The antivirus software on the computer causes Privileged Access Manager to time out. Do the following in the antivirus software:

- Exclude the Privileged Access Manager directory from real-time scanning.
- Stop the real-time (on access) scan for the Privileged Access Manager directory.

Because Privileged Access Manager protects the Privileged Access Manager registry keys, files, and installation directory by default, the previous actions should not increase the virus threat to the computer.

We recommend that you create a SPECIALPGM record for the antivirus software. Set the PGMTYPE property to pbf for the SPECIALPGM record. The pbf program type bypasses database checks for file handling events.

**First Incoming ftp Connection Cannot Be Controlled****Valid on UNIX****Symptom:**

When I start Privileged Access Manager, it does not control the first incoming ftp connection from vsftpd. I have created a TCP rule for ftp and a HOST rule for vsftpd, and Privileged Access Manager controls all subsequent incoming ftp connections from vsftpd according to the TCP or HOST rule that I created.

**Solution:**

If you start vsftpd before you start Privileged Access Manager, vsftpd places a hook in the accept system call for incoming ftp connections. The hook means that vsftpd processes the first incoming ftp connection before Privileged Access Manager can intercept it.

After vsftpd processes the ftp connection, it tries to call the accept system call in preparation for the next ftp connection. However, Privileged Access Manager intercepts this system call and hence controls all subsequent ftp connections.

To intercept the first incoming ftp connection, use one of the following workarounds:

- Start Privileged Access Manager before you start vsftp.
- Use a super-server daemon such as inetd or xinetd to start vsftpd.

**NOTE**

For more information about configuring a super-server daemon, contact your OS vendor.

- Run the tripAccept utility after you start Privileged Access Manager.  
To run the tripAccept utility, you must enable the call\_tripAccept\_from\_seload token in the [SEOS\_syscall] section of the seos.ini file. We recommend that you define a SPECIALPGM record for the tripAccept utility before you run it.

**Target Pages on Local Host and Target Host Are Different****Valid on UNIX****Symptom:**

When I try to connect to a Privileged Access Manager host, I get the following message:

```
WARNING: Local machine's code page is different from target host's.
```

**Solution:**

Verify that the locale configuration setting in the [seos] section of the seos.ini file has the same value on the local host and the target host.

## **Cannot Connect to an Endpoint Using selang**

### **Symptom:**

When I try to connect to an endpoint using selang, I receive an error message similar to the following:

```
Unpacking of data failed
```

### **Solution:**

A problem exists with the encryption that is used to protect inter-component communication. Check Privileged Access Manager computers for recent changes to the encryption key and the encryption method.

#### **NOTE**

For more information about encryption methods, see the *Implementation Guide*.

## **Deploy Rules from a PMD**

### **Subscriber PMDB Cannot Receive Updates from the Master PMDB**

#### **Symptom:**

I have a hierarchical PMDB architecture. A subscriber PMDB does not receive updates from the master PMDB. The error log of the master PMDB has the following message:

```
Cannot receive update from non-parent PMDB
```

#### **Solution:**

When a subscriber PMDB does not receive updates from the master PMDB, use the following procedure to troubleshoot the problem.

#### **To troubleshoot PMDB update problems:**

1. List the subscribers of the master PMDB (*master\_pmdb\_name*) and their status:

```
sepmdb -L master_pmdb_name
```

#### **NOTE**

Run this command on the master PMDB computer.

2. Review the list of subscribers to determine which subscribers are unavailable.
3. Verify that the value of the parent\_pmd configuration setting is correct on each unavailable subscriber. The parent\_pmd configuration setting is located in:
  - (UNIX) The [seos] section of the seos.ini and the pmd.ini files
  - (Windows) The following registry key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\AccessControl
```

**Note:** The hostname that you specify in the parent\_pmd token must match the hostname of the master PMDB exactly. Verifying that hostname resolution is correctly configured may help troubleshoot this issue. If you use a UNIX computer, you can use the sehostinf utility to discover the hostname of the master PMDB. For assistance, contact CA Support at <http://ca.com/support>.

If the problem still exists, do the following:

1. Display the master PMDB error log:
 

```
sepmdb -e master_pmdb_name
```
2. Review the error log and note what error codes are reported for the unavailable subscribers.
3. For each unavailable subscriber, use the error code to troubleshoot the problem.

If the problem still exists, do the following:

1. Remove the problematic subscriber from the list of unavailable subscribers that the master PMDB maintains:

```
sepmdb -r pmdb_name subscriber_name
```

The parent PMDB tries to send updates to the subscriber.

2. Repeat the previous procedure.
3. If there are any changes to the list of subscribers or to the parent PMDB error log, use the changes to troubleshoot the problem.

### **Failed Events in Audit Log of Subscriber Endpoint**

#### **Symptom:**

A subscriber does not receive updates from a master PMDB. I notice *Failed* events in the Privileged Access Manager audit log of the subscriber.

#### **Solution:**

The PMDB user does not have the ADMIN attribute. To give the PMDB user the ADMIN attribute, edit the user record using the following selang command:

```
chusr userName admin
```

#### **NOTE**

You must have the ADMIN attribute to run this selang command. Privileged Access Manager bypasses TERMINAL rules when deploying PMDB updates to subscribers.

## **Collect Audit Records**

### **Some Audit Log Messages Are Not Received by the Collection Server**

#### **Valid on UNIX**

#### **Symptom:**

I configured the endpoints in my Privileged Access Manager installation to route their local audit logs to a central log collection server. However, the server does not receive all the audit logs. I configured selogrd to emit the audit records and selogrd to collect the audit records.

#### **Solution:**

To troubleshoot selogrd, the emitter daemon for the Privileged Access Manager log routing system, follow these steps:

- Review the selogrd.cfg file. This file configures which audit messages Privileged Access Manager routes to the central log collector.
- Review the audit log for each endpoint. If an audit event is missing from the audit log, review the audit.cfg file. The audit.cfg file configures which audit events Privileged Access Manager writes to the audit log. If the audit.cfg file prevents Privileged Access Manager from writing an audit event to the audit log, the audit event cannot be routed.
- Configure selogrd, the emitter daemon for the log routing system, to print debug messages then recreate the problem. Use the following command to configure selogrd to print debug messages:

```
selogrd -d
```

### **No Audit Log Messages Are Received by the Collection Server**

#### **Valid on UNIX**

**Symptom:**

I configured the endpoints in my Privileged Access Manager installation to route their local audit logs to a central log collection server. However, the server does not receive any audit logs. I configured selogrd to emit the audit records and selogrcd to collect the audit records.

**Solution:**

Verify that selogrcd is running on the log collection server.

**NOTE**

If selogrcd does not run for an extended timeframe, audit events may be discarded by the endpoints.

**SID Resolution Failed (Event Viewer Warning)****Valid on Windows****Symptom:**

When I view the Application log of the Windows Event Viewer, I find a Warning event from Privileged Access Manager that says that resolving a specific SID into an account name has failed.

**Solution:**

A *security identifier (SID)* is a numeric value that identifies a user or group to the operating system. Each entry in the discretionary access control list (DACL) has a SID. The SID identifies the user or group for whom access is allowed, denied, or audited.

This warning appears when the operating system was not able to convert the SID into an account name, for example, if the user or group that the SID refers to no longer exists. Ensure that the problematic system and its corresponding domain controller are configured correctly for SID resolution.

**SID Resolution Times Out (Event Viewer Warning)****Valid on Windows****Symptom:**

When I view the Application log of the Windows Event Viewer, I find a Warning event from Privileged Access Manager that says that resolving a specific SID into an account name has timed out.

**Solution:**

A *security identifier (SID)* is a numeric value that identifies a user or group to the operating system. Each entry in the discretionary access control list (DACL) has a SID. The SID identifies the user or group for whom access is allowed, denied, or audited.

This warning appears when the operating system was not able to convert the SID into an account name within the defined timeout. Ensure that the following conditions are true:

- The problematic system and its corresponding domain controller are configured correctly for SID resolution.
- Network settings are configured correctly.

You can also increase the timeout by changing the DefLookupTimeout configuration setting in the following registry key:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\SeOSD
```

**NOTE**

Increasing the SID resolution timeout may downgrade Privileged Access Manager performance.

---

## **Receive Error Code 4631 When Attempting to Start selogrd**

### **Valid on UNIX**

#### **Symptom:**

I attempt to start selogrd. selogrd does not start and I receive the following error message:

```
ERROR 4631 (0x1217) initializing /opt/CA/PAMSC/bin/selogrd
```

#### **Solution:**

Resolve the local host name before you start selogrd. To resolve the host name, add the host name to the operating system hosts file, or define the host name to NIS or DNS.

## **Audit Logging Stops When Audit File Size Exceeds 2 GB**

### **Symptom:**

Privileged Access Manager stops writing audit records to the audit file when the audit file size exceeds 2 GB.

#### **Solution:**

Privileged Access Manager cannot write audit records to the audit file when the size of the audit file exceeds 2 GB. The maximum size of the audit file is specified, in KB, by the audit\_size configuration setting in the logmgr section.

To set the maximum size of the seos.audit file to 2 GB, set the value of the audit\_size configuration setting in the logmgr section to 2097151.

## **System Slows When Privileged Access Manager Writes to Audit Log**

### **Symptom:**

My computer slows when Privileged Access Manager writes to the audit log.

#### **Solution:**

Most processes in the system could be blocked while Privileged Access Manager writes audit and trace data. To reduce the time it takes to write audit data and trace data, do the following:

- Set the audit mode only for resources and accesses you need.
- Open the trace only when you need to.
- Store audit file, trace file, and Privileged Access Manager database files on the fastest available file system.

## **Filter Not Applied If Host Is Assigned Multiple IP Addresses**

### **Symptom:**

I configured the audit.cfg to filter TCP events on a host that is assigned multiple IP addresses using the host name. After I applied the filter, I cannot see the TCP logs for all the IP addresses.

#### **Solution:**

When you apply the audit.cfg filter, the audit system resolves the host name to the IP address of the host and the host IP address to the host name. If you configure the host with more than one IP address, the audit.cfg filters the first IP address only.

To apply the audit.cfg filter to all IP addresses, specify all the IP addresses in the filter only and not the host name.

Example:

```
TCP;*;192.168.30.138;*;R;P
```

```
TCP;*;192.168.30.139;*R;P
```

## PAM SC reference

This section provides reference material for PAM Server Control.

Use the table of contents to access the topics in this section.

### Configuration Files

- [audit.cfg File Filter Audit Records](#)
- [auditrouteft.cfg File Filter Audit Records Routing](#)
- [The accommon.ini File](#)
- [The Audit Log Route Configuration File selogrd.cfg](#)
- [The lang.ini File](#)
- [The pmd.ini File](#)
- [The seos.ini Initialization File](#)
- [The uxauth.ini File](#)
- [trcfilter.init](#)

### audit.cfg File Filter Audit Records

The audit.cfg file filters audit records on a host by defining records that are not sent to the audit file. Each line represents a rule for filtering out audit information.

By default, the audit.cfg file is located in the following directories:

- (UNIX) /opt/CA/PAMSC/etc
- (Windows) C:\Program Files\CA\PAMSC\data

You can change the location of the audit.cfg file by editing the [logmgr] AuditFiltersFile token in the seos.ini file (UNIX), or the AuditFiltersFile entry in the logmgr registry key (Windows).

#### NOTE

Save the audit.cfg file using UTF-8 encoding if you filter the file that includes Japanese characters.

Use the audit.cfg file to filter out records in the following audit event types, each type by a different syntax:

- resource access
- [network connection](#)
- [login and logout events](#)
- [security database administration](#)
- trace message on a user

#### NOTE

A \* in any column in each type of syntax stands for "any value".

## audit.cfg File Resource Access Events Filter Syntax

Audit records that belong to a resource access event have the following filter format:

```
ClassName;ObjectName;UserName;ProgramPath;Access;AuthorizationResult
```

- **ClassName**  
Defines the name of the class that the accessed object belongs to.

### NOTE

Enter the name of the class in uppercase.

- **ObjectName**  
Defines the name of the object that was accessed.
- **UserName**  
Defines the name of the accessor.
- **ProgramPath**  
Defines the name of the program used to access the object.
- **Access**  
Defines the requested access to the object.

### NOTE

The following values are the values for this parameter that you use in the audit.cfg file to filter out an audit record. In some cases the value of this parameter in the audit.cfg file is different to the value that Privileged Access Manager writes in the audit record for that event. Any such differences are noted after the description of each value. Type the parameter in the same case as it appears in the following list.

### NOTE

#### Values:

- **\***  
A wildcard that represents any type of access.
- **Chdir**  
Change directory The accessor made a request to move the object to a different directory.
- **Chmod**  
Change mode The accessor made a request to change the mode of the object.
- **Chgrp**  
(UNIX) Change group The accessor made a request to change the group the object belongs to.
- **Chown**  
Change owner The accessor made a request to change the owner of the object.
- **Connect**  
Join user to group The accessor made a request to add a new user to a group.  
**Note:** The connect value is identical to the join value.
- **Control**  
(UNIX) Control The accessor requested Chown, Chmod, Utime, Sec, Chdir, and Update access to the object.
- **Cre**  
Create The accessor made a request to create an object.

### NOTE

#### Crdrwr

#### Crread

Create and Read The accessor requested Create and Read access to the object.

**Note:** Privileged Access Manager writes this value as CrRead in the corresponding audit record.

#### Crwrite

Create and Write The accessor requested Create and Write access to the object.

Note: Privileged Access Manager writes this value as CrWrite in the corresponding audit record.

– **Del**

DeleteThe accessor made a request to delete an object.

**NOTE**

Privileged Access Manager writes this value as Erase in the corresponding audit record.

– **Join**

Join user to groupThe accessor made a request to add a new user to a group.

**NOTE**

The join value is identical to the connect value.

– **Kill**

Kill The accessor made a request to kill a process.

Modify

Modify The accessor requested Modify access to the object.

OwnGrp

Change owner and Change groupThe accessor requested Chown and Chgrp access to the object.

**NOTE**

PW

– **R**

ReadThe accessor requested read access to an object.

**NOTE**

(UNIX) If STAT\_intercept is set to 1, this parameter includes *stat* interception.

– **Rename**

Change file nameThe accessor made a request to change the file name of an object.

– **Sec**

Change ACLThe accessor made a request to edit the ACL of the object.

**NOTE**

Privileged Access Manager writes this value as ACL in the corresponding audit record.

**Update**

Read, Write, and ExecuteThe accessor requested Read, Write, and Execute access to an object.

Note: The Update value also filters events when an accessor requested Read and Write access to an object.

– **Utime**

(UNIX)Change timeThe accessor made a request to change the modification time of an object.

**NOTE**

Privileged Access Manager writes this value as Utimes in the corresponding audit record.

– **W**

WriteThe accessor requested write access to an object.

– **X**

ExecuteThe accessor made a request to execute an object.

**NOTE**

Some values are not valid for every class. For example, kill is an invalid value for the FILE class, because the kill action is not available to objects in the FILE class. If you enter an invalid value for a class when you write a rule, Privileged Access Manager ignores that rule when it reads the file.

• **AuthorizationResult**

Defines the authorization result.

**Values:**

P - Permitted

D - Denied

O - Logout

I - Inactivate (Disable user) by serevu

E - Enable user login by serevu

A - Password attempt detected

\* - A wildcard that represents any value

### Example: Audit Filter Policy

- This example shows you what an audit filtering policy looks like:

```
env config
er config audit.cfg line+("FIEL;*;*;*;R;P")
```

- This policy writes the following line to the audit.cfg file. The line filters audit records that record a permitted attempt by any accessor to access any file resource for reading:

```
FILE;*;*;*;R;P
```

### audit.cfg File Network Connection Events Filter Syntax

Audit records that belong to a network connection event have the following filter format:

```
{HOST|TCP};ObjectName;HostName;ProgramPath;Access;AuthorizationResult
```

- HOST**  
Specifies that the rule filters records generated by objects in HOST class, that is, incoming TCP connections.
- TCP**  
Specifies that the rule filters records generated by objects in TCP class, that is, connect with service events.
- ObjectName**  
Defines the name of the object that was accessed. *ObjectName* can be a service name or port number.
- HostName**  
Defines the name of the host. *HostName* must be an object in the HOST class.
- ProgramPath**  
Defines the login program type.  
(Windows) For outgoing connections, this parameter defines the program path of the process trying to establish the connection.

#### NOTE

This parameter has no meaning for incoming connection events. Use \* for this parameter to filter audit records generated by incoming connection events.

- Access**  
Defines the type of attempted connection.

#### NOTE

##### Values:

- (HOST) \*
- (TCP) R (incoming connection), W (outgoing connection), \*

- AuthorizationResult**  
Defines the authorization result.  
**Values:** P (permitted), D (denied), \*

### Examples: Filter Network Connection Events

- This example filters all audit records from the host ca.com generated by successful incoming telnet connections:

```
HOST;telnet;ca.com;*;*;P
```

- This example filters all audit records from the host ca.com generated by incoming and outgoing login TCP connections that were denied:

```
TCP;login;ca.com;*;*;D
```

- This example filters all audit records from the host ca.com generated by outgoing telnet connections:

```
TCP;telnet;ca.com;*;W;*
```

## audit.cfg File Login and Logout Events Filter Syntax

Audit records that belong to a login or logout event have the following filter format:

```
LOGIN;UserName;UserId;TerminalName;LoginProgram;AuthorizationResultOrLoginType
```

- **LOGIN**  
Specifies that the rule filters audit records generated by login and logout events.
- *UserName*  
Defines the name of the accessor.
- *UserId*  
(UNIX) Defines the native user ID of the accessor.
- *TerminalName*  
Defines the terminal at which the event occurred.
- *LoginProgram*  
Defines the name of the program that attempted to log in or out.
- *AuthorizationResultOrLoginType*  
Defines the authorization result.

### NOTE Values:

- \*  
A wildcard that represents any type of authorization result.
- **D**  
The login attempt was denied.
- **P**  
The login attempt was permitted.
- **O**  
(UNIX) The accessor logged out.
- **I**  
(UNIX) The serevu daemon revoked the accessor's account.
- **E**  
(UNIX) The serevu daemon enabled the accessor's account.
- **A**  
(UNIX) The serevu daemon or Pluggable Authentication Module audited a user's attempt to log in with an incorrect password.

### NOTE Windows does not record logout events.

## Examples: Filter Login or Logout Events

- This example filters all audit records generated when root logs in to a permitted account:

```
LOGIN;root;*;*;*;P
```

- This example filters all audit records generated when root logs in successfully due to the system's CRON program:

```
LOGIN;root;*;*;SBIN_CRON;P
```

- This example filters all audit records generated when the `_CRONJOB_` process logs the root user out:

```
LOGIN;root;*;*_CRONJOB_*;O
```

## audit.cfg File Security Database Administration Events Filter Syntax

Audit records that belong to a security database administration event have the following filter format:

```
ADMIN;ClassName;ObjectName;UserName;EffectiveUserName;TerminalName;Command;CommandResult
```

- **ADMIN**  
Specifies that the rule filters audit records generated by events performed by an administrator.
- *ClassName*  
Defines the class on which the administrator executes the command.
- *ObjectName*  
Defines the object that the administrator's command updated.
- *UserName*  
Defines the name of the user who executed the command.
- *EffectiveUserName*  
(UNIX) Defines the name of the effective user to which the rule applies.  
(Windows) Defines the name of the native user to which the rule applies.
- *TerminalName*  
Defines the terminal at which the event occurred.
- *Command*  
Defines the command that the administrator executed.
- *CommandResult*  
Defines the authorization or command result.

### NOTE

**Values:** S (command succeeded), F (command failed), D (command denied), \*

### Example: Filter Security Database Administration Events

This example filters all audit records generated by successful FILE management commands by admin01:

```
ADMIN;FILE'*;admin01;*;*;S
```

## audit.cfg File Trace Messages On a User Events Filter Syntax

Audit records that belong to a trace message on a user event have the following filter format:

```
TRACE;TracedClassName;TracedObjectName;RealUserName;EffectiveUserName;ACUserName;AuthorizationResult;TraceMessage
```

### NOTE

The maximum limit for the trace filter is 1000 records.

- **TRACE**  
Specifies that the rule filters user trace records.
- *TracedClassName*  
Defines the name of the object class the user tried to access.

### NOTE

Enter the name of the class in uppercase.

- *TracedObjectName*

Defines the name of the object that the user tried to access.

- **RealUserName**  
(UNIX) Defines the name of the real user that generated the trace record.  
(Windows) Defines the name of the native user that generated the trace record.
- **EffectiveUserName**  
(UNIX) Defines the name of the effective user that generated the trace record.  
(Windows) Defines the name of the native user that generated the trace record. This parameter is identical to the RealUserName parameter. Use \* for this parameter.
- **ACUserName**  
Defines the user name Privileged Access Manager chose to authorize the event.
- **AuthorizationResult**

#### NOTE

Defines the authorization result. Values: P (permitted), D (denied), \*

- **TraceMessage**  
Defines the trace message that was generated.

### Example: Filter Trace On a User Message Events

This example filters all user trace records generated when the effective user is root, and root accessed an object in the FILE class:

```
TRACE;FILE;*;*;root;*;*;*
```

## auditrouteflt.cfg File Filter Audit Records Routing

The auditrouteflt.cfg file filters audit records routing by defining records that Privileged Access Manager should not send to the Distribution Server. Each line represents a rule for filtering out audit information. The file pathname is defined by the audit\_filter configuration setting in the ReportAgent section.

#### NOTE

Filtered audit events are written to the local audit file but Privileged Access Manager does not send them to the message queue on the Distribution Server. To filter out audit messages from the local audit file, modify filter rules in the file defined by the AuditFiltersFile configuration setting in the logmgr section (by default, audit.cfg).

You can use the auditrouteflt.cfg file to filter out records in the following audit event types, each type by a different syntax:

- resource access
- network connection
- login and logout events
- security database administration
- trace message on a user

#### NOTE

A \* in any column in each type of syntax stands for "any value".

### Resource Access Events Filter Syntax

Audit records that belong to a resource access event have the following filter format:

```
ClassName;ObjectName;UserName;ProgramPath;Access;AuthorizationResult
```

- **ClassName**  
Defines the name of the class that the accessed object belongs to.

#### NOTE

You must enter the name of the class in uppercase.

- **ObjectName**

Defines the name of the object that was accessed.

- *UserName*  
Defines the name of the accessor.
- *ProgramPath*  
Defines the name of the program used to access the object.
- *Access*  
Defines the requested access to the object.

#### **NOTE**

##### **Values:**

- **\***  
A wildcard that represents any type of access.
- **Chdir**  
Change directoryThe accessor made a request to move the object to a different directory.
- **Chmod**  
Change modeThe accessor made a request to change the object's mode.
- **Chgrp**  
(UNIX) Change groupThe accessor made a request to change the group the object belongs to.
- **Chown**  
Change ownerThe accessor made a request to change the owner of the object.
- **Cre**  
CreateThe accessor made a request to create a new object.
- **Del**  
DeleteThe accessor made a request to delete an object.
- **Join**  
Join user to groupThe accessor made a request to add a new user to a group.
- **Kill**  
KillThe accessor made a request to kill a process.
- **R**  
ReadThe accessor requested read access to an object.

#### **NOTE**

(UNIX) This parameter includes *stat* interception if STAT\_intercept is set to 1.

- **Rename**  
Change file nameThe accessor made a request to change the file name of an object.
- **Sec**  
Change ACLThe accessor made a request to edit an object's ACL.
- **Utime**  
(UNIX) Change timeThe accessor made a request to change the modification time of an object.
- **W**  
WriteThe accessor requested write access to an object.
- **X**  
ExecuteThe accessor made a request to execute an object.

#### **NOTE**

Some values are not valid for every class. For example, kill is an invalid value for the FILE class, because the kill action is not available to objects in the FILE class. If you enter an invalid value for a class when you write a rule, Privileged Access Manager ignores that rule when it reads the file.

- *AuthorizationResult*  
Defines the authorization result.

**NOTE**

**Values:** P (permitted), D (denied), \*

**Network Connection Events Filter Syntax**

Audit records that belong to a network connection event have the following filter format:

```
{HOST|TCP};ObjectName;HostName;ProgramPath;Access;AuthorizationResult
```

- **HOST**

Specifies that the rule filters records generated by objects in HOST class, that is, incoming TCP connections.

- **TCP**

Specifies that the rule filters records generated by objects in TCP class, that is, connect with service events.

- *ObjectName* Defines the name of the object that was accessed. *ObjectName* can be a service name or port number.

- *HostName*

Defines the name of the host. *HostName* must be an object in the HOST class.

- *ProgramPath*

Defines the login program type.

(Windows) For outgoing connections, this parameter defines the program path of the process trying to establish the connection.

**NOTE**

This parameter has no meaning for incoming connection events. Use \* for this parameter to filter audit records generated by incoming connection events.

- *Access*

Defines the type of attempted connection.

**NOTE**

**Values:**

- (HOST) \*
- (TCP) R (incoming connection), W (outgoing connection), \*

- *AuthorizationResult*

Defines the authorization result.

**NOTE**

**Values:** P (permitted), D (denied), \*

**Login and Logout Events Filter Syntax**

Audit records that belong to a login or logout event have the following filter format:

```
LOGIN;UserName;UserId;TerminalName;LoginProgram;AuthorizationResultOrLoginType
```

- **LOGIN**

Specifies that the rule filters audit records generated by login and logout events.

- *UserName*

Defines the name of the accessor.

- *UserId*

Defines the native user ID of the accessor.

- *TerminalName*

Defines the terminal at which the event occurred.

- *LoginProgram*

Defines the name of the program that attempted to log in or out.

- *AuthorizationResultOrLoginType*

Defines the authorization result.

**NOTE****Values:**

- **\***  
A wildcard that represents any type of authorization result.
- **D**  
The login attempt was denied.
- **P**  
The login attempt was permitted.
- **O**  
(UNIX) The accessor logged out.
- **I**  
(UNIX) The serevu daemon revoked the accessor's account.
- **E**  
(UNIX) The serevu daemon enabled the accessor's account.
- **A**  
(UNIX) The serevu daemon or Pluggable Authentication Module audited a user's attempt to log in with an incorrect password.

**NOTE**

Windows does not record logout events.

**Security Database Administration Events Filter Syntax**

Audit records that belong to a security database administration event have the following filter format:

```
ADMIN;ClassName;ObjectName;UserName;EffectiveUserName;TerminalName;Command;CommandResult
```

- **ADMIN**  
Specifies that the rule filters audit records generated by events performed by an administrator.
- *ClassName*  
Defines the class on which the administrator executes the command.
- *ObjectName*  
Defines the object that the administrator's command updated.
- *UserName*  
Defines the name of the user who executed the command.
- *EffectiveUserName*  
(UNIX) Defines the name of the effective user to which the rule applies.  
(Windows) Defines the name of the native user to which the rule applies.
- *TerminalName*  
Defines the terminal at which the event occurred.
- *Command*  
Defines the selang command that the administrator executed.
- *CommandResult*  
Defines the authorization or command result.

**NOTE**

**Values:** S (command succeeded), F (command failed), D (command denied), \*

**Trace Messages On a User Events Filter Syntax**

Audit records that belong to a trace message on a user event have the following filter format:

```
TRACE;TracedClassName;TracedObjectName;RealUserName;EffectiveUserName;ACUserName;AuthorizationResult;TraceMessage
```

- **TRACE**

Specifies that the rule filters user trace records.

- *TracedClassName*  
Defines the name of the object class the user tried to access.

#### NOTE

You must enter the name of the class in uppercase.

- *TracedObjectName*  
Defines the name of the object that the user tried to access.
- *RealUserName*  
(UNIX) Defines the name of the real user that generated the trace record.  
(Windows) Defines the name of the native user that generated the trace record.
- *EffectiveUserName*  
(UNIX) Defines the name of the effective user that generated the trace record.  
(Windows) Defines the name of the native user that generated the trace record. This parameter is identical to the RealUserName parameter. Use \* for this parameter.
- *ACUserName*  
Defines the user name Privileged Access Manager chose to authorize the event.
- *AuthorizationResult*  
Defines the authorization result.

#### NOTE

**Values:** P (permitted), D (denied), \*

- *TraceMessage*  
Defines the trace message that was generated.

### Examples: Filter Network Connection Events

- This example filters all audit records from the host ca.com generated by successful incoming telnet connections:  
`HOST;telnet;ca.com;*;*;P`
- This example filters all audit records from the host ca.com generated by incoming and outgoing login TCP connections that were denied:  
`TCP;login;ca.com;*;*;D`
- This example filters all audit records from the host ca.com generated by outgoing telnet connections:  
`TCP;telnet;ca.com;*;W;*`

### Examples: Filter Login or Logout Events

- This example filters all audit records generated when root logs in to a permitted account:  
`LOGIN;root;*;*;P`
- This example filters all audit records generated when root logs in successfully due to the system's CRON program:  
`LOGIN;root;*;*;SBIN_CRON;P`
- This example filters all audit records generated when the \_CRONJOB\_ process logs the root user out:  
`LOGIN;root;*;_CRONJOB_;*;O`

### Example: Filter Security Database Administration Events

This example filters all audit records generated by successful FILE management commands by admin01:

```
ADMIN;FILE'*;admin01;*;*;S
```

### Example: Filter Trace On a User Message Events

This example filters all user trace records generated when the effective user is root, and root accessed an object in the FILE class:

```
TRACE;FILE;*;*;root;*;*;*
```

## Example: Audit Filter Policy

This example shows you what an audit filtering policy looks like:

```
env config
er config auditrouteflt.cfg line+("FILE;*;*;R;P")
```

This policy writes the following line to the auditrouteflt.cfg file:

```
FILE;*;*;R;P
```

This line filters audit records that record a permitted attempt by any accessor to access any file resource for reading.

## The accommon.ini File

The accommon.ini configuration file contains tokens that control the initialization process of the Report Agent and tokens that control general communication settings. Example: UNAB registration settings with Privileged Access Manager.

The accommon.ini file is divided into the following sections:

Section	Description
AccountManager	Contains tokens that control the Agent Manager settings
communication	Contains tokens that control general communication settings
global	Contains Privileged Access Manager global settings
ReportAgent	Contains tokens that control the Report Agent settings
AgentManager	Contains tokens that control the Agent Manager settings
DiscoveryAgent	Contains tokens that control the Discovery Agent settings
PupmAgent	Contains tokens that control the Pupm Agent settings

## AccountManager

In the [AccountManager] section, the tokens control the behavior of the Account Manager plug-in.

- **INSTALL\_ACCOUNT\_MNG**

Specifies whether to configure Account Management on the endpoint.

**Values:** Yes, No

**Default:** No

**Example:** INSTALL\_ACCOUNT\_MNG="no"

**NOTE**

Configure the Distribution Server parameters to activate the AccountManager.

- **Interval**

Specifies the AccountManager plug-in interval in seconds.

**Default:** 300

**NOTE**

Applicable if you set the ScheduleType control value to 2.

- **JCS\_USER\_DN**

Specifies the Java Connector Server (JCS) administrator user DN.

**Values:** DN format string

**Default:** cn=root,dc=etasa

**Example:** JCS\_USER\_DN="cn=root,dc=etasa"

- **JCS\_USER\_PSSWD**

Specifies the JCS administrator password.

**Values:** any string.

**Default:** no default value.

**Note:** Asterisks (\*) replace the JCS\_USER\_PSSWD value after installation.

- **JCS\_SERVER\_DN**

Specifies the JCS server DN.

**Values:** DN format string

**Default:** dc=im,dc=etas

**Example:** JCS\_SERVER\_DN="dc=im,dc=etasa"

- **JCS\_SERVER\_PORT**

Specifies the JCS port.

**Values:** Port number

**Default:** 20411

**Example:** JCS\_SERVER\_PORT=20411

- **JCS\_SSL**

Defines the JCS communication protocol.

**Values:** 'yes' for SSL connection, otherwise 'no'.

**Default:** yes

**Example:** JCS\_SSL="yes"

- **max\_threads\_count**

Defines the number of working threads in the pool.

**Values:** 50

- **OperationMode**

Defines whether the AccountManager plug-in is enabled or disabled.

**Options:** 1plug-in enabled, 0plug-in disabled

**Default:** 1

- **PluginPath**

Defines the full pathname of the AccountManager plug-in.

**Default:** /opt/CA/PAMSCShared/lib/AccountManager.so

- **QueryFilter**

Specifies a custom value to add to the Message Queue receive queue filter.

**Options:**

- "ENDPOINT\_CUSTOM1="

a. "ENDPOINT\_CUSTOM2="

b. "ENDPOINT\_CUSTOM3="

c. "ENDPOINT\_CUSTOM4="

d. "ENDPOINT\_CUSTOM5="

e. "ENDPOINT\_OWNER="

f. "ENDPOINT\_DEPARTMENT="

**Default:** no value

**NOTE**

You can use more than one custom property, using the AND operand. Example:

"ENDPOINT\_DEPARTMENT='Finance' AND 'ENDPOINT\_CUSTOM1=Accounting'"

**WARNING**

When specifying the custom property, verify that:

- You use apostrophes to specify the property value.
- You use the AND, OR operands when specifying more than one property.
- You use the parenthesis when using the OR operand.

- **Schedule**

Specifies the AccountManager plug-in a schedule string.

**Default:** 00:00@Sun,Mon,Tue,Wed,Thu,Fri,Sat

#### **NOTE**

Applicable if you set the ScheduleType control value to 3.

- **ScheduleType**  
Defines the AccountManager plug-in scheduling type.  
**Options:**
  - 0 Run once
  - 1 Run on demand
  - 2 Run every N seconds
  - 3 Run according to the scheduling string: 00:00@Sun.Mon,Tue,Wed,Thu,Fri,Sat**Default:** 2

## **Communication (accommon.ini)**

In the [communication] section, the tokens control the communication and encryption options.

- **Distribution\_Server**  
Defines the Distribution Server URL. You can define more than one Distribution Server in a comma-separated list.  
**Example:** ssl://ds.comp.com:61616, ssl://ds\_dr.comp.com:61616  
**Default:** None
- **endpoint\_to\_server\_queue**  
Defines the name of the message queue that the endpoint uses to send information to Privileged Access Manager Enterprise Management.  
**Default:** ac\_endpoint\_to\_server
- **jvm\_gc**  
Defines the optional parameter for tuning the Garbage Collector. The JVM uses this parameter while communicating with the Distribution Server.  
**Values:** A string representing complete GC tunables  
**Example:** jvm\_gc = -XX:+UseConcMarkSweepGC -XX:+UseParNewGC  
**Default:** Empty value
- **jvm\_ms**  
Defines the optional parameter for the JVM initial heap size -Xms. The JVM uses this parameter while communicating with the Distribution Server.  
**Values:** The size is measured in MB.  
**Example:** jvm\_ms = 512  
**Default:** 0
- **jvm\_mx**  
Defines the optional parameter for a Java virtual machine (JVM) maximum heap size -Xmx. The JVM uses this parameter while communicating with the Distribution Server.  
**Value:** The size is measured in MB.  
**Example:** jvm\_mx = 1024  
**Default:** 0
- **jvm\_ps**  
Defines the optional parameter for the JVM permgen size -XX:MaxPermSize. The JVM uses this parameter while communicating with the Distribution Server.  
**Values:** The size is measured in MB.  
**Example:** jvm\_ps = 128  
**Default:** 0
- **server\_to\_endpoint\_broadcast\_queue**  
Defines the name of the message queue that Privileged Access Manager Enterprise Management uses to broadcast messages to all endpoints.

- Default:** ac\_server\_to\_endpoint\_broadcast
- **server\_to\_server\_broadcast\_queue**  
Defines the name of the message queue that the Enterprise Management Server uses to broadcast topics and authenticate using the reportserver user.  
**Default:** ac\_server\_to\_server\_broadcast
- **server\_to\_server\_queue**  
Defines the name of the message queue that the Enterprise Management Server uses to send messages and authenticate using the reportserver user.  
**Default:** ac\_server\_to\_server
- **ac\_server\_to\_endpoint\_queue**  
Defines the name of the message queue that Privileged Access Manager Enterprise Management uses to send messages to the endpoint.  
**Default:** ac\_server\_to\_endpoint
- **ServerVersion**  
Defines the Distribution Server version for forward compatibility.  
**Example:** 12.01.0648  
**Default:** None
- **ssl\_expected\_hostname**  
Specifies the expected server hostname. The client expects this name in the certificate of the server  
**Default:** None
- **ssl\_keystore**  
Defines the keystore location and the location of the client SSL certificate.  
**Limits:** The full pathname to the keystore location  
**Default:** None
- **ssl\_noverifyhost**  
Specifies whether to enable verification of the host certificate.  
**Limits:** 0, disable host certificate verification; 1, enable host certificate verification  
**Default:** 0
- **ssl\_noverifyhostname**  
Specifies whether to enable verification of the host name.  
**Limits:** 0, disable host name verification; 1, enable host name verification  
**Default:** 0
- **ssl\_truststore**  
Defines the truststore for server verification.  
**Limits:** The full pathname to the truststore  
**Default:** None

## global

In the [global] section, the tokens control the behavior of the Privileged Access Manager endpoint.

- **accommon\_path**  
Specifies the full path name of the acccommon directory.  
**Default:** /opt/CA/PAMSCShared/
- **AC\_Version**  
Defines the version of Privileged Access Manager installed on the endpoint.  
**Default:** none
- **java\_home**  
(Linux s390) Defines the path to the Java libraries.  
**Example:** For an IBM J2SE version 5.0 JRE installed on a Linux390 computer: /opt/ibm/java2-s390-50/jre  
**Default:** none

## ReportAgent

In the [ReportAgent] section, the tokens control the behavior of the Report Agent daemon (ReportAgent).

- **audit\_enabled**  
Specifies whether you want to send endpoint audit data to the Distribution Server.  
**Values:** 0 no; 1 yes  
**Default:** 0
- **audit\_filter**  
Defines the full pathname to the file that contains filtering rules for audit records that the Report Agent routes to an external source (such as the Audit Log). This file determines which records the Report Agent routes.  
**Default:** *ACSharedDir/etc/auditrouteflt.cfg*
- **audit\_queue**  
Defines the name of the queue to which the Report Agent sends endpoint audit data.  
**Default:** queue/audit
- **audit\_read\_chunk**  
Defines the maximal audit records the Report Agent tries to collect in a single read of the audit files.  
**Limits:** A positive integer  
**Default:** 300
- **audit\_send\_chunk**  
Defines the maximal audit records that the Report Agent sends to the Distribution Server in each connection. When the number of audit records the Report Agent collects reaches this number, it sends these records to the Distribution Server.  
**Limits:** A positive integer  
**Default:** 1800
- **audit\_sleep**  
Define the length of time the Report Agent sleeps between generating audit reports.  
**Limits:** A positive integer representing a number of seconds  
**Default:** 10
- **audit\_timeout**  
Defines the cycle at which the Report Agent must send endpoint audit data to the Distribution Server. If this amount of time passes from the last send, the Report Agent sends audit data to the Distribution Server. The Report Agent sends this data even if the number of records it collected is less than the audit\_send\_chunk value.  
**Limits:** A positive integer representing a number of seconds  
**Default:** 300
- **Debug**  
Specifies whether the Report Agent logs debug information.  
If you specify yes (1), the Report Agent logs the following reports:
  - Privileged Access Manager reports to *ACSharedDir/log/ac2xml.log*
  - UNAB reports (uxauthd) to *ACSharedDir/log/unab2xml.log*
  - Privileged Access Manager audit reports that are sent to the Audit Log to *ACSharedDir/log/ac2elm.log*
  - UNAB audit reports that are sent to the Audit Log to *ACSharedDir/log/unab2elm.log*
  - Keyboard Logger reports that are sent to the Audit Log to *ACSharedDir/log/kbl2elm.log***Limits:** 0, Report Agent does not log debug information; 1, Report Agent logs debug information  
**Default:** 0
- **elm\_event\_interval**  
Defines the interval in seconds, at which the Report Agent sends user sessions audit events to the Audit Log.  
**Limits:** 0; no interval, send audit events when messages size exceeds the value specified in the elm\_max\_msg\_size token; any positive integer.  
**Default:** 60
- **elm\_max\_msg\_size**

Defines the maximum size of Keyboard Logger messages, in bytes, that the Report Agent sends to the Audit Log.

**Value:** Any positive integer

**Default:** 300000

- **interval**

Defines the interval, in minutes, at which Privileged Access Manager generates and sends reports to the Distribution Server.

The *schedule* setting defines the interval start time and the days it operates on. If the Report Agent starts later than a scheduled occurrence, it sends a report at the next calculated interval (from the schedule) and then at the defined intervals after that on scheduled days.

**Example:** If you have *schedule=8:30@Mon,Tue, Wed*, and *interval=5* and the Report Agent loads on Tuesday at 8:47 am, the Report Agent generates and sends a report at 8:50 am. This is the earliest cycle calculated from the scheduled start using the 5-minute interval.

**Values:** 0 No interval (use scheduled occurrences only); *positive integer* number of minutes to use as interval

**Default:** 0

- **reportagent\_enabled**

Specifies whether reporting is enabled (1) on the local computer.

**Default:** 0

- **schedule**

Defines when reports are generated and sent to the Distribution Server.

You specify this setting in the following format: *time@day[,day2][...]*

For example, "19:22@Sun,Mon" generates reports every Sunday and Monday at 7:22 pm.

**Default:** 00:00@Sun,Mon,Tue,Wed,Thu,Fri,Sat

- **send\_queue**

Defines the name of the reporting queue on the Distribution Server to which the Report Agent sends snapshots of the local database and any PMDBs.

**Default:** queue/snapshots

- **restart\_enabled**

Specifies restart of the ReportAgent daemon. Specify 1 to enable the restart.

**Default:** 0

## AgentManager

In the [AgentManager] section, Privileged Access Manager controls the behavior of plug-ins.

```
Plugins = DiscoveryAgent
```

## DiscoveryAgent

In the [DiscoveryAgent] section, the tokens control the behavior of the Discovery Agent plug-in.

- **Interval**

Defines the plugin schedule in seconds.

**Default:** 600

**Note:** Applicable only when *ScheduleType* is set to 2.

- **max\_threads\_count**

Defines the threadpool threads count.

**Default:** 10

- **OperationMode**

Defines the plugin operation mode.

**Options:** 0 - plugin disabled, 1 - plugin enabled

**Default:** 0

- **PluginPath**

Defines the full pathname of the plugin.

**Default:** /opt/CA/PAMSCShared/lib/DiscoveryAgent.\*

- **QueryFilter**

Defines an additional value that is added to receive the message queue filter.

**Default:** empty value

- **Schedule**

Defines the plugin scheduling string.

**Default:** 00:00@Sun.Mon,Tue,Wed,Thu,Fri,Sat

**Note:** Applicable only when ScheduleType is set to 2.

- **ScheduleType**

Defines the plugin schedule type.

**Options:** 0 - execute once, 1 - execute on demand, 2 - execute on interval, 3 - execute on schedule

**Default:** 0

## PupmAgent (accommon.ini)

In the [PupmAgent] section, the tokens control the behavior of the Pupm Agent plug-in.

- **OperationMode**

Defines the plugin operation mode.

**Options:** 0 - plugin disabled, 1 - plugin enabled

**Default:** 0

- **PluginPath**

Defines the full pathname of the plugin.

**Default:** /opt/CA/PAMSCShared/lib/PupmAgent.[so|sl|o]

- **ScheduleType**

Defines the plugin schedule type.

**Options:** 0 - Execute once, 1 - Execute on demand, 2 - Execute every *n* seconds (*n* is defined in the **Interval** token), 3 - Execute by scheduler *string* (*string* is defined in the **Schedule** token). Example:

00:00@Sun,Mon,Tue,Wed,Thu,Fri,Sat

**Default:** 1

- **Interval**

Defines the plugin interval in seconds, when using **ScheduleType** = 2.

**Default:** 1

- **RegistrationInterval**

Defines the registration lifetime in days.

**Default:** 7

- **Schedule**

Defines the plugin scheduling string, when using **ScheduleType** = 3

**Default:** 00:00@Sun,Mon,Tue,Wed,Thu,Fri,Sat

- **AutoRegister**

Specifies whether to send a registration message to the server on agent startup.

**Options:** 0 - The Pupm agent does not send a registration message to the server, 1 - The Pupm agent sends a registration message to the server.

**Default:** 1

## The Audit Log Route Configuration File selogrd.cfg

Valid on UNIX

The following code is the format of the configuration file, followed by a detailed explanation.

```
section-name-1
routing-method destination
[{include|exclude} match-field(match-pattern) ...]
...
.
section-name-2
routing-method destination
[{include|exclude} match-field(match-pattern) ...]
...
.
...
```

- **Specifying Audit Records**

The configuration file is a list of which audit records to route-and which not to route-to various destinations. To specify audit records, you describe the contents of one or more particular fields. You can use the standard UNIX pattern matching (the wildcards \* and ?).

For example, to specify records that deal with users whose user names begin with the letters dbms, enter the following code:

```
User(dbms*)
```

This example matches users with names like dbms1, dbms\_mgr, and so on.

To specify the same users, but only the records that deal with their login attempts, enter:

```
User(dbms*) Class(LOGIN)
```

**NOTE**

When a line specifies records in terms of more than one field, it specifies only the records that match *all* those fields.

At the beginning of the same line that specifies the records, specify whether you want the records included or excluded. For example, to include those records in the routing enter the following code:

```
include User(dbms*) Class(LOGIN).
```

This type of line appears in the overall format as:

```
[{include|exclude} match-field(match-pattern) ... .]
```

Here, the ... means that the first match-field(match-pattern) pair can be followed by further pairs.

You can use any of the following for match-field(match-pattern):

- **Access(access-type)**  
For the type of access required; *access-type* is any one of the following:  
ACL, Chdir, Chgrp, Chmod, Chown, Connect, Control, Create, Erase, Exec, Kill, Modify, Owngrp, Password, Read, Rename, Replace, Update, Utimes, and Write.
- **Class(LOGIN)**  
For login records.
- **Class(LOGOUT)**  
For logout records.
- **Class(PWCHANGE)**  
For password administration.
- **Class(HOST)**  
For TCP/IP records.
- **Class(UPDATE CA ControlMinder-class)**  
For database administration. CA ControlMinder-class is any of the accessor or resource classes (such as USER, GROUP, FILE, HOSTNP...) or a pattern for the class name to match. Thus for all database administration, you can specify UPDATE \*.
- **Class(CA ControlMinder-class)**

For access to protected resources. For example, Class(FILE) refers to records reporting file access attempts. You can use an asterisk to combine Class(CA ControlMinder-class) and Class(UPDATE CA ControlMinder-class) as Class(\*CA ControlMinder-class). For example, specifying Class(\*FILE) is like specifying both Class(FILE) and Class(UPDATE FILE). It refers both to attempts to access files and to attempts to update records in the FILE class.

– **Code(return-code)**

For the Privileged Access Manager return code indicating what happened; return-code can take the following values. (See also Example 1 in this section.)

**A**-An attempt to log in failed because an invalid password was entered repeatedly.

**D**-Privileged Access Manager denied access to a resource, did not permit a login, or did not permit an update to the database because the accessor did not have sufficient authorization.

**E**-Serevu enabled a disabled user account.

**F**-An attempt to update the database failed.

**I**-Serevu disabled a user account.

**M**-The executed command started or shut down a daemon.

**O**-A user logged out.

**P**-Privileged Access Manager permitted access to a resource or permitted a login.

**S**-The database was successfully updated.

**T**-An audit record was written because all the actions of the user are being traced.

**U**-A Trusted program (setuid or setgid) was changed; therefore it is no longer Trusted.

**W**-Access to the resource violated the access rules for the resource. However, Privileged Access Manager allowed the access because warning mode is set in the resource.

– **Host(host-name)**

The host involved in a TCP/IP connection.

– **Object(resource-name)**

For the resource that the user is attempting to access.

– **Reason(reason-number)**

The reason that the audit record is triggered.

– **Service(service-name)**

The name of the service requested from the remote host, such as telnet, ftp, or port number.

– **Source Host(hostname)**

The name of the host that contributed the record to the consolidated audit.

– **Stage(stage-number)**

The stage at which access was granted or denied. (See the lists of stage codes in the *Reference Guide*.)

– **Terminalterminal-name)**

The terminal that is attempting access or administration.

– **Uid(uid-number)**

The uid of the user who is attempting access or administration.

– **User(username)**

Users attempting access or administration; username is a name or pattern.

**NOTE**

Although some variables are more likely to be specified as patterns, you can use a pattern for any variable—even for something like a stage number.

• **Refining with Further Lines**

To refine your specifications, you can filter by differing criteria at the same time. Simply add one include/exclude line after another. For example:

```
include User(dbms*) Class(*LOGIN*).
exclude Terminal(console_*)
```

The example specifies all login attempts by users whose names begin with dbms and who are at terminals that do not have names beginning with console\_.

• **Specifying the Destination**

Use a line *above* your sequence of include and exclude lines to specify the destination for the audit records you are including. For example:

```
mail weekwatch
include User(dbms*) Class(*LOGIN*).
exclude Terminal(console_*) .
```

The example specifies that the email address weekwatch receives a report on all login attempts by users whose names begin with dbms and who are at terminals that do not have names beginning with console\_.

This type of line appears in the format of the log route configuration file as:

```
routing-method destination
```

You can use any of the following methods:

– **mail *address***

To email the audit record; *address* is the destination address. If it is not in the form user@host, it is checked against local user lists and the NIS mail alias map.

**NOTE**

If address is a user name and surrogate requests to that user's account are audited, the audit records accumulate endlessly.

– **screen *username***

To display the audit record on the screen of the specified user, if that user is logged in at the current host when selogrd forwards the audit record. If the user is not logged in, the display is canceled, not postponed.

– **cons *hostname***

**NOTE**

To send the audit record to the Security Administrator GUI of the secmon utility on the specified host. If that host is not available, the display is terminated, not postponed.

- **file *textfilename*** To write the audit record in the specified ASCII file; *textfilename* must be an absolute path name and selogrd must have access to the file. Selogrd includes everything by default so you have to exclude everything and include what you want to be written to the file. For example:

```
LoginRule
file /data/audit_login_data.txt
include User(dbms*) Class(LOGIN) .
format filesize(10240000) .
.
```

– **host *hostname***

To send the audit record to the audit log collector on the specified host. If that host is not available, selogrd tries again later.

– **notify mail or notify default**

To email the audit record to the address that the audit record itself specifies.

– **notify screen**

To display the audit record on the screen of the user that the audit record itself specifies. If the user is not logged on, the display is canceled, not postponed.

– **syslog *priority***

To send the audit records to the syslog with a specified log priority:

- a. **LOG\_EMERG** System is unusable.
- b. **LOG\_ALERT** Action must be taken immediately.
- c. **LOG\_CRIT** Critical conditions
- d. **LOG\_ERR** Error conditions
- e. **LOG\_WARNING** Warning conditions
- f. **LOG\_NOTICE** Normal but significant condition

- g. **LOG\_INFO** Informational
- h. **LOG\_DEBUG** Debug-level messages

- **Proper Sequence for Lines**

It is important to arrange your include and exclude lines in proper sequence, properly delimited.

- Precede each sequence of lines (or single line) that you want to treat as a single complex filter with a title line. End it with a terminating line that consists of a single dot. Example:

```
dbms login from non-console
mail weekwatch
include User(dbms*) Class(*LOGIN*).
exclude Terminal(console_*) .
.
```

The full sequence, including the title line and terminating line, is called a *section* of the file.

- If both include and exclude lines match the same audit record in the same section, the last match overrides all others.
- If no lines match a particular audit record, then the first line of the section is the deciding line for that record. If the first line is an include line, then the failure to match excludes the record. If the first line is an exclude line, then the failure to match includes the record for routing.
- If the section includes no include and exclude lines, then it includes all audit records for routing.

- **How Sections Coexist**

Whereas the lines of a section work together to produce a single decision whether a record is to be sent, different sections in the configuration file work independently. Whether an audit record is sent by one section, has no influence on whether the same audit record is sent by another section.

You can send the same selection of audit records to more than one destination, and the same destination can receive more than one selection of audit records.

In your configuration file, the total of all the include lines and exclude lines, from all the sections together, must not exceed 64 lines.

- **Including Comments**

To add a comment line to the configuration file, begin the line with a semicolon.

## Example 1

The following code is a sample configuration file, followed by its explanation.

```
; Product : CA ControlMinder
; Module  : selogrd
; Purpose : route table for audit log routing daemon
;
;-----
Rule#1
mail jones@admhost
include      Class(*LOGIN*) Code(D) .
.
Rule#2
mail smith
include      Class(*SURROGATE*) Object(USER.root*) .
.
Rule#3
host venus
exclude      Class(UPDATE SU*) .
.
Rule#4
host venus
include      Class(*PROGRAM*) Object(/usr/bin/ps) .
```

The first five lines are comment lines.

The next four lines make up the first section, named Rule#1. They tell selogrd to mail a log record to the address jones@admhost whenever a login request is denied (code D reports denial):

```
Rule#1
mail jones@admhost
include      Class(*LOGIN*) Code(D) .
.
```

The next section is named Rule#2. It tells selogrd to mail a log record to the address smith whenever someone attempts to use the su command to enter the root account. The objects in the SURROGATE class are targets for the su command:

```
Rule#2
mail smith
include      Class(*SURROGATE*) Object(USER.root*) .
.
```

The next section is named Rule#3. It tells selogrd to send a log record to the collector on the host venus whenever someone attempts database administration, unless the class name begins with the letters SU (the matching classes are SURROGATE and SUDO):

```
Rule#3
host venus
exclude      Class(UPDATE SU*) .
```

The last section is named Rule#4. It tells selogrd to send a log record to the collector on the host venus whenever someone attempts to use the ps command:

```
(Code 1 8pt) Rule#4
host venus
include      Class(*PROGRAM*) Object(/usr/bin/ps) .
.
```

## Example 2

The following configuration file sends *all* audit records to the collector on the station named loghost:

```
; Product : CA ControlMinder
; Module  : selogrd
; Purpose : route table for audit log routing daemon
;
;-----
Rule#1
host loghost
.
```

- Return Codes**

You can associate each type of record in the configuration file with one or more Privileged Access Manager return codes. (For a complete list of the return codes see the description of *code(return-code)* in Specifying Audit Records in this section.) The following table describes the record types and their associated return codes.

Record Type	Class or Event	Associated Return Codes
Login	LOGIN LOGINDISABLE LOGINENABLE	D, P, W I E

Logout	LOGOUT	O
TCP/IP	HOST	D, P
Resource classes	<i>Class name</i>	D, P, W
Watchdog	PROGRAM SECFILE	U U
Password administration	PWCHANGE	D
Down	SHUTDOWN	D, S
Start	START	S
Privileged Access Manager database administration	UPDATE	D, F, S

### Manage JCS Connector Log File Names and Log Levels

You can use the following configuration file to manage log file names for SSH, Network-device, Sybase, ACF2, and RACF JCS log file connectors.

```
<JCS-directory>\conf\log4j.properties
```

This file is used to set the log file names for each of the preceding connectors. The log file names are:

ssh.log

- network\_device.log
- sybase.log
- acf2.log
- racf.log

You can configure the log detail level for each connector according to the following level scale:

Trace

- Debug
- Info
- Warn
- Error
- Fatal

The SSH connector collects only logs from the level that is set on the scale and lower. For example, the SSH connector collects logs only from the debug, info, warn, error, and fatal levels when set as follows:

```
log4j.logger.com.ca.jcs.sshdyn=INFO, ssh
log4j.logger.com.ca.sesame.conn.unix=INFO, ssh
```

#### NOTE

Each connector log file is saved to a back-up and a new log is started each day.

### kbldaudit.cfg Filter Keyboard Logger Audit Records

#### Valid on UNIX

The **kbldaudit.cfg** file filters Keyboard Loggers (KBL) audit records. The file filters KBL audit records depending on the filter rule that you configure in the [INCLUDE] and [EXCLUDE] sections.

You can locate the file at */opt/CA/PAMSC/etc*.

- [INCLUDE]

The format of the [INCLUDE] section is as follows:

```
[INCLUDE]
LOGIN;<UserName>;<UserId>;<TerminalName>;<LoginProgram>;<AuthorizationResult>
TRACE;<TracedClassName>;<TracedObjectName>;<RealUserName>;<ACUserName>;<AuthorizationResult>;
```

When you add a filter rule to the [INCLUDE] section, the *kblaudit.cfg* file logs audit records that match the rule. The *kblaudit.cfg* file logs all the audit records when you fail to define a rule in the [INCLUDE] section.

In the [INCLUDE] section, ensure that you include the LOGIN rule. Without the LOGIN records, the *seaudit* utility fails to display session IDs. Without session IDs, the *kblaudit.cfg* file fails to log KBL audit records.

- **[EXCLUDE]**

The format of the [EXCLUDE] section is as follows:

```
[EXCLUDE]
TRACE;<TracedClassName>;<TracedObjectName>;<RealUserName>;<ACUserName>;<AuthorizationResult>;
```

When you add a filter rule to the [EXCLUDE] section, the *kblaudit.cfg* file logs audit records that do not match the rule. The *kblaudit.cfg* file logs all the audit records when you fail to define a rule in the [EXCLUDE] section.

### Example:

The following snippet of the *kblaudit.cfg* file excludes from the *kbl.audit* file the *usermod* operation events that the *test-user* performs.

```
[EXCLUDE]

TRACE;*;*;test-user;*;test-user;*;*;usermod*
```

The following snippet of the *kblaudit.cfg* file includes in the *kbl.audit* file the *cat* operation events that the *test-user* performs.

```
[INCLUDE]
LOGIN;*;*;*;*;*
TRACE;*;*;test-user;*;test-user;*;*;cat*
```

### NOTE

A \* in the rule syntax stands for any value.

## Login Rule Syntax

### Valid on UNIX

The Login rule filters keyboard loggers login events depending on the arguments that you specify. The format of the login rule is as follows:

```
LOGIN;<UserName>;<UserId>;<TerminalName>;<LoginProgram>;<AuthorizationResult>
```

- **<UserName>** Specifies the login name of the user to filter login events.
- **<UserId>**  
Specifies the login Id of the user to filter login events.
- **<TerminalName>**

Specifies the name of the local host that the user logs in.

- **<LoginProgram>** Specifies the name of the program that the user attempts to log in or log out.

**Limits:** cmdlog

- **<AuthorizationResult>** Specifies the authorization criteria to filter user login events.

**Limits:** P (permitted), D (denied), O (logout), \* (A wildcard that represents any value)

## Trace Rule Syntax

### Valid on UNIX

The Trace rule filters trace messages on user events depending on the arguments that you specify. The format of the trace rule is as follows:

```
TRACE;<TracedClassName>;<TracedObjectName>;<RealUserName>;<ACUserName>;<AuthorizationResult>;<TraceMessageMask>;<KBLSessionID>;<Optional><InputCommandName>;
```

- **<TracedClassName>**  
Specifies the name of the object class that the user tries to access.  
**Limits:** KBL raw, KBL output, KBL input, KBL execargs
- **<TracedObjectName>**  
Specifies the host that the user tries to access.
- **<RealUserName>**  
Specifies the name of the logged in user that generates trace records.
- **<ACUserName>**  
Specifies the name of the effective user who checks the rule. An effective user can be a logical user or a *setuid* user.
- **<AuthorizationResult>** Specifies the authorization criteria to filter trace messages.  
**Limits:** P (permitted), D (denied), \*
- **<TraceMessageMask>**  
Specifies the trace message mask criteria to filter trace messages.
- **<KBLSessionID>**  
Displays the keyboard logger sessions ID.
- **[Optional] <InputCommandName>** Specifies that the utility filters audit records based on the command a user executes on the host. The input command argument is optional.

## The lang.ini File

### Valid on UNIX

This section describes the tokens in the lang.ini file, used by the selang utility.

The lang.ini file contains the following sections:

- **general**  
Contains default parameters that apply to more than one type of resource; that is, both new resources and new users.
- **history**  
Contains default parameters for the selang history mechanism.
- **newres**  
Contains the default values that are assigned to the properties of new resource records. The default value is assigned unless you explicitly set a different value.
- **newusr**

Contains the default values that are assigned to the properties of new user records. The default value is assigned unless a different value is explicitly set.

- **properties**  
Contains tokens that specify values for user-defined properties, such as file locations for user-defined properties. The tokens have no default values; you must set them explicitly.
- **unix**  
Contains the default values that are assigned when a new user is defined to UNIX from within the selang command shell. The default value is assigned unless you explicitly set a different value.

## general

The [general] section contains default parameters that apply to more than one type of resource.

- **defaultOwner**  
The name of the owner assigned to a new record.  
If you do not specify a value, the creator of the new record is assigned as owner.

## history

The [history] section contains default parameters for the selang history mechanism.

- **HistFile**  
The name of the file where the commands in the history list are stored. The command list is loaded at the beginning of each session.  
No default value; that is, the history list is not saved at the end of a session.
- **HistSize**  
The number of commands (a positive integer between 10 and 100) stored by the history mechanism.  
**Default:** 30

## newres

The [newres] section contains default values that are assigned by the newres command. The newres command creates new resource records in the database. Each token in this section represents a newres parameter. Parameters not represented in the lang.ini file are assigned default values that are hard-coded in Privileged Access Manager. If you do not specify a value for a token, the default value specified in the table is applied.

- **DefaultAudit**  
The default audit mode for the new resource. Valid values are: none, all, success, failure.  
**Default:** failure
- **DefaultDay**  
The default day restrictions that apply to the resource. Valid values are: anyday, weekdays, mon, tue, wed, thu, fri, sat, sun.  
**Default:** anyday
- **DefaultNotify**  
The default email address to which alert messages regarding the resource record are sent.  
No default value; that is, no notification message is sent.
- **DefaultTime**  
The default time restrictions that apply to the resource. Valid values are: anytime, startTime:endTime.  
**Default:** anytime
- **DefaultWarning**  
Whether warning mode is enabled by default. Valid values are: yes, no.  
**Default:** no

## newusr

The [newusr] section contains the default values assigned by the newusr command, which creates new user records in the database. Each token in this section represents a newusr parameter. Parameters not represented in the lang.ini file are assigned default values that are hard-coded in Privileged Access Manager. If you do not specify a value for a token, the default value specified in the table is applied.

- **DefaultAudit**  
The default audit mode for the new user. Valid values are: none, all, success, failure, loginsuccess loginfailure.  
**Default:** failure loginfailure loginsuccess
- **DefaultDay**  
The default day restrictions that apply to the user when logging in to the system. Valid values are: anyday, weekdays, mon, tue, wed, thu, fri, sat, sun.  
**Default:** anyday
- **DefaultExpire**  
The default expiry date for the user record. Valid values are: expire[dd/mm/yy], expire-.  
**Default:** expire-
- **DefaultLocation**  
The default location in which the user works.  
No default value
- **DefaultNotify**  
The default email address to which alert messages are sent when the user logs in.  
No default value; that is, no notification message is sent.
- **DefaultOrg**  
The organization for which the user works.  
No default value
- **DefaultOrgUnit**  
The organizational unit in which the user works.  
No default value
- **DefaultTime**  
The default time restrictions that apply to the user when logging in to the system. Valid values are: anytime, startTime:endTime.  
**Default:** anytime

## properties

The [properties] section contains parameters that apply to user-defined properties.

- **UserDefinedTokensFile**  
The path for a definition file that contains context information for user-defined properties.  
**Default:** none
- **UserDefinedAttributesFile**  
The path for a definition file that contains attribute information for user-defined properties.  
**Default:** none

## User-Defined Properties

This section is complimentary to the sepropadm utility. It defines the selang context by which database properties created with sepropadm are recognized. Two definition files that use a format similar to the one used by sepropadm accomplish this. The location of these files is specified in the two tokens of this section.

**NOTE**

The properties must be defined in the database (using the sepropadm utility), before the definition files are loaded by selang. The definition files are loaded automatically when selang is run, during the initialization phase.

When these properties are defined in both the appropriate definition files and the database, you can use them in selang commands like any other Privileged Access Manager defined property.

**WARNING**

Do **not** use the sepropadm utility with a description file that was **not** certified by your vendor's support personnel.

**The Definition Files**

To get selang to recognize the new user-defined properties, selang loads two \*.def files during its initialization: the Tokens file and the Attributes file.

**The Tokens File****User Defined Tokens File**

A definition file supplied by your vendor's support personnel. The definition file has the following format:

Lines that begin with a semicolon (;) are comments and are not processed.

One line must begin with the hash symbol (#). This line must precede the description lines.

The description line must conform to the following format:

```
TOKEN=%s DOMAIN=%d CLASS=%d COMMAND=%d
```

The following is a sample definition tokens file:

```
; Sample Token Definition File for user defined properties
; Copyright 2004 Computer Associates International, Inc.
; -----
; DO NOT USE THIS FILE UNLESS YOU KNOW HOW TO!
# token definition file ; Format is : TOKEN=EMAIL DOMAIN=1 CLASS=USER COMMAND=206
TOKEN=NOEMAIL DOMAIN=1 CLASS=USER COMMAND=206
TOKEN=EMAIL DOMAIN=1 CLASS=USER COMMAND=218
TOKEN=AGE DOMAIN=1 CLASS=USER COMMAND=206
TOKEN=AGE DOMAIN=1 CLASS=USER COMMAND=218
TOKEN=NOAGE DOMAIN=1 CLASS=USER COMMAND=206
TOKEN=TERMLOCATION DOMAIN=1 CLASS=TERMINAL COMMAND=217
TOKEN=NOTERMLOCATION DOMAIN=1 CLASS=TERMINAL COMMAND=205
TOKEN=TERMLOCATION DOMAIN=1 CLASS=TERMINAL COMMAND=205
```

**The Attributes File****User Defined Attributes File**

A definition file supplied by your vendor's support personnel. The definition file has the following format:

Lines that begin with a semicolon (;) are comments and are not processed.

One line must begin with the hash symbol (#). This line must precede the description lines.

The description line must conform to the following format:

```
PROPERTY=%s TYPE=%d FLAGS=%x
```

The following is a sample definition attributes file:

```
; Sample Attributes Definition File for user defined properties
; Copyright 2004 Computer Associates International, Inc.
; -----
; DO NOT USE THIS FILE UNLESS YOU KNOW HOW TO!
# attributes definition file ; Format is : PROPERTY=EMAIL TYPE=306 FLAGS=8000
PROPERTY=EMAIL TYPE=5 FLAGS=8000
PROPERTY=AGE TYPE=306 FLAGS=8000
PROPERTY=AGE TYPE=5 FLAGS=8000
PROPERTY=TERMLOCATION TYPE=306 FLAGS=8000
PROPERTY=TERMLOCATION TYPE=5 FLAGS=8000
```

### WARNING

Do **not** use `selang` with a definition file that was **not** certified by your vendor's support personnel.

## unix

The `[unix]` section contains the default values that are assigned by the `newusr` command when a user is added to UNIX. Each token in this section represents an argument of the `unix` parameter. UNIX arguments not represented in the `lang.ini` file are assigned default values that are hard-coded in Privileged Access Manager.

- **DefaultPGroup**  
The default group assigned to new users. If you specify a default shell in the server's `seos.ini` file, it overrides the value specified here.  
**Default:** `other`
- **DefaultShell**  
The default shell of new users. If you specify a default shell in the server's `seos.ini` file, it overrides the value specified here.  
**Default:** `/bin/sh`
- **DefaultHome**  
The default home directory of the system. If you specify a default shell in the server's `seos.ini` file, it overrides the value specified here. The user's home directory is a subdirectory of the specified system home directory. For example, if the system home directory is `/home`, the new user's home directory is `/home/userName`. If you specify a home directory prefix in the server's `seos.ini` file, it overrides the value specified here.  
For those familiar with earlier versions, the token `DefaultHome` replaces `HomeDirPrefix`.  
**Default:** `/home`

## The pmd.ini File

### Valid on UNIX

The `pmd.ini` file contains various setup and initialization settings Privileged Access Manager uses when building and maintaining a specific PMDB. It consists of several sections and each section contains multiple settings:

Section	Description
<code>endpoint_management</code>	Policy Model endpoint management settings.
<code>lang</code>	Privileged Access Manager management interface ( <code>selang</code> ) settings for working with a Policy Model.
<code>logmgr</code>	PMDB logging facility settings.
<code>passwd</code>	User and password data settings.
<code>pmd</code>	Policy Model daemon ( <code>sepmdd</code> ) settings.

seos	Generic PMDB settings.
------	------------------------

## endpoint\_management

The [endpoint\_management] section contains the parameters that define endpoint management settings for the Policy Model.

- **AutoSync**  
Specifies to automatically synchronize the DH with the Message Queue server.  
**Limits:** 0,1  
**Default:** 0 (disabled)
- **debug\_mode**  
Specifies if Privileged Access Manager writes debug messages to the endpoint\_management.log file in the DMS directory (1).  
**Limits :** 0,1  
**Default :** 0 (debugging is disabled)  
**Note:** The log file is located at *ACInstallDir/log/endpoint\_management.log*
- **deployment\_lifetime**  
Specifies the deployment lifetime in days. Older deployments are removed at 2 am. To disable deployment cleanup, set this value to 0.  
**Default:** 30 days
- **operation\_mode**  
Specifies whether central (DMS) endpoint management through the Privileged Access Manager Message Queue is enabled.  
**Limits:** 0,1  
**Default:** 1 (enabled)

## lang (pmd.ini)

The [lang] section contains the parameters used by the Privileged Access Manager language program (selang) when building and maintaining a PMDB.

- **pre\_user\_exit**  
Specifies the path of the exit program to be executed before Privileged Access Manager issues a language command to update the UNIX user database.
- **post\_user\_exit**  
Specifies the path of the exit program to be executed after Privileged Access Manager issues a language command to update the UNIX user database.
- **pre\_group\_exit**  
Specifies the path of the exit program to be executed before Privileged Access Manager issues a language command to update the UNIX groups database.
- **post\_group\_exit**  
Specifies the path of the exit program to be executed after Privileged Access Manager issues a language command to update the UNIX groups database.

## logmgr (pmd.ini)

The [logmgr] section contains the parameters used by the PMDB logging facility.

- **audit\_back**  
Specifies the name of the PMDB audit backup file.

**Default:** pmd\_audit.bak

- **audit\_log**  
Specifies the name of the PMDB audit log file.  
**Default:** pmd\_audit
- **audit\_group**  
Specifies the group that can read the PMDB audit files. If no group is specified, only root can read the audit files. Privileged Access Manager does not verify the value of this token, so if you enter an invalid group name, Privileged Access Manager does not assign any group permissions to the audit log files.  
To change the group ownership of an existing audit log file, do the following:
  - a. Use the selang command chgrp to set the group ownership of the files.
  - b. Change the UNIX permissions by entering:

```
chmod 640 /opt/CA/PAMSC/log/seos.audit
```

**Default:** none

- **audit\_size**  
Specifies the size of the PMDB audit log file, in KB. Do not specify a size less than 50 KB.  
**Default:** 50 KB
- **error\_back**  
Specifies the name of the PMDB error backup file.  
**Default:** pmd\_error.bak
- **error\_log**  
Specifies the name of the PMDB error log file.  
**Default:** pmd\_error
- **error\_group**  
Specifies the group that can read the PMDB error files. If no group is specified, only root can read the error files. Privileged Access Manager does not verify the value of this token, so if you enter an invalid group name, Privileged Access Manager does not assign any group permissions to the error log files.  
To change the group ownership of an existing error log file, do the following:
  - a. Use the selang command chgrp to set the group ownership of the files.
  - b. Change the UNIX permissions by entering:

```
chmod 640 /opt/CA/PAMSC/log/seos.error
```

**Default:** none

- **error\_size**  
Defines the maximum size, in KB, of the PMDB error log file (defined by error\_log).  
**Limits:** A minimum value of 50 KB.  
**Default:** 50
- **max\_log\_size**  
Specifies the size of the PMDB general log file in KB.  
**Default:** 50 KB
- **pmd\_log\_level**  
Determines the messages that are logged in the PMDB log file.  
Valid values include the following:
  - 0-Do not log any entries.
  - 1-List only error messages.
  - 2-List error and informational messages.**Default:** 2
- **use\_syslog**

Determines whether the policy model daemon should write syslog messages.

**Default:** yes

## passwd (pmd.ini)

The [passwd] section contains parameters for UIDs and GIDs.

- **AllowedGidRange**

Specifies reserved numbers.

The integers below the first number and above the second number are reserved GIDs, which Privileged Access Manager cannot update.

**NOTE**

If only one integer is specified, all integers between one and the specified integer are reserved GIDs. If you specify a number that is larger than the upper limit, the default upper limit is applied (30000). If you specify a negative number, the default lower limit is applied (1). The applied lower limit for any number is +1 of the specified lower limit. For example, if *AllowedGidRange* = 100, 3000, then 101 is treated as the lower limit.

**Limits:** -1 to 2147483647

**Default:** 100,30000

- **AllowedUidRange**

Specifies reserved numbers.

The integers below the first number and above the second number are reserved UIDs, which Privileged Access Manager cannot update.

**NOTE**

If only one integer is specified, all integers between one and the specified integer are reserved UIDs. The applied lower limit for any number is +1 of the specified lower limit. For example, if *AllowedGidRange* = 100, 3000, then 101 is treated as the lower limit.

**Limits:** -1 to 2147483647

**Default:** 100,30000

## pmd (pmd.ini)

The [pmd] section contains the attributes used by the sepmd daemon when building and maintaining a PMDB.

- **\_min\_retries\_**

Specifies the minimum number of attempts that sepmd should make to resend the next queued update to an unavailable subscriber. The sepmd loops through the list of subscribers for outstanding updates and increments the counter each time it cannot resend the update to an unavailable subscriber. The subscriber is marked unavailable after the minimum number of attempts specified in this token.

**Default:** 4

- **\_QD\_timeout\_**

Specifies the maximum time, in seconds, that the sepmd daemon waits while attempting to update a subscriber database during the first scan of its subscriber list. If the time elapses and the daemon does not succeed in updating a subscriber, it skips that particular subscriber and tries to update the remainder of the subscribers on its list. After completing the first scan of the subscriber list, sepmd then performs a second scan in which it attempts to update the subscribers it did not succeed in updating during the first scan. During the second scan, it tries to update a subscriber until the connect system call times out (approximately 90 seconds).

**Default:** 3

- **\_retry\_timeout\_**

Specifies the time, in minutes, to wait before trying to resend an update to an unavailable subscriber, after the minimum number of attempts specified in `_min_retries_` has been made. It marks the subscriber available after the number of minutes defined by this token elapses.

A subscriber is marked unavailable until:

- It is manually released.
- `sepmdd` is manually shutdown and restarted. The `sepmdd` is restarted if:
  - a. if a language facility attempts to connect to it.
  - b. if a parent PMDB wants to send an update.
  - c. the pull option is triggered by a subscriber. This optionally occurs when Privileged Access Manager starts on the subscriber.
- The pull option is triggered by the unavailable subscriber.

#### NOTE

Shutting down `sepmdd` too often is not desirable because it takes time to restart the daemon, which results in slowing the whole propagation process. Allowing it to be on all the time is also undesirable because there maybe some stability issues, but it is only a conjecture.

**Default:** 30

- **`_shutoff_time_`**

Specifies the time, in minutes of activities before `sepmdd` quits. If the token value is zero, `sepmdd` never quits.

**Default:** 0

- **`always_propagate`**

If this token is set to no, commands that failed to execute by the policy model are not propagated to the subscribers.

**Default:** none

- **`exclude_file`**

Specifies an exclude file.

The exclude file contains host names (one on each line) that should be excluded from receiving policy model updates.

**Default:** none

- **`exclude_localhost`**

Tells the `pmdb` to exclude the local host from receiving updates as a subscriber.

Possible values: yes, no.

**Default:** no

- **`exclude_method`**

Enables/disables the promote offset in update file when subscriber is excluded.

Values:

"pmdwaitdo not promote offset"

Otherwise "bypass"

**Default:** `pmdwait`

- **`filter`**

Specifies the name of the filter file.

- **`force_auto_truncate`**

Specifies whether Privileged Access Manager truncates the update file even if there are no subscribers to the Policy Model.

You can truncate the update file manually (`sepmdd -t`), and Privileged Access Manager also truncates the file automatically based on a separate configuration setting (`trigger_auto_truncate`) that defines the event that triggers automatic truncation.

**Note:** If all subscribers to the Policy Model are "Out of sync", the Policy Model effectively has no subscribers.

**Default:** Yes

- **`group_file_name`**

Specifies the name of the group file for a new UNIX group. `sepmdd` saves the group entry of the new UNIX group in this file.

**Default:** group

- **is\_maker\_checker**

Specifies whether to use Dual Control. The valid values for this token are yes and no.

If **yes** is selected, then the PMDB cannot be updated directly, but only through a transaction; and each transaction entered by one administrator must be processed by another administrator before the commands are implemented on the PMDB.

**Default:** no

- **password\_file\_name**

Specifies the name of the password file for new UNIX users. `sepmdd` stores the password entry of new UNIX users in this file.

**Default:** passwd

- **send\_unix\_env**

Indicates whether `sepmdd` sends the contents of Policy Model password files and group files.

If this token is set to **yes**, the `sepmdd -n` option sends the contents of the Policy Model password files and group files.

If this token is set to **no**, the `sepmdd -n` option does not send the contents of the policy model password files and group files.

**Default:** yes

- **synch\_uid**

Determines whether `sepmdd` attempts to synchronize UIDs between a Policy Model and its subscribers. The valid values for this token are yes and no.

If the token is **no**, `sepmdd` does not attempt to synchronize UIDs. Users are assigned the first available UID on each subscriber host.

If the token is **yes**, `sepmdd` attempts to synchronize UIDs. For example, if a new UNIX user is created on the PMDB with a UID of 1000, `sepmdd` transfers that UID to the subscribers. If UID 1000 is already in use on one of the subscribers, then the update on that subscriber fails.

`sepmdd` only tries to synchronize UIDs if the original command sent to the PMDB did not specify a UID for the user. If the original command did specify a UID, the specified UID is sent to all the subscribers.

**Default:** yes

- **TNG\_Environment**

Specifies whether the database is created with special TNG classes and resources.

Valid values are:

"0" to create the database without the special TNG classes

"1" to create the database with all the special TNG classes

**Default:** 0

- **transaction\_lib**

Specifies the path of the maker-checker policy.

**Default:** /opt/CA/eTrustAccessControl/policies/maker

- **trigger\_auto\_truncate**

Defines the size of the Policy Model update file, in megabytes, that triggers an automatic truncating of the update file.

If you use a value that is less than the lower limit, Privileged Access Manager uses the default value. If you use a value that is greater than the upper limit, Privileged Access Manager uses the upper limit value.

**Limits:** 1 - 2000 MB

**Default:** 1024 MB

- **update\_while\_processing**

Defines the frequency at which the Policy Model propagates commands to subscribers while it is processing incoming events.

The frequency is a factor of the `updates_in_chunk` setting, and determines how many commands the PMD processes before it sends the next subscriber in line one set of commands. For example, if you set this to 3 and `updates_in_chunk` is set to 10, the PMD will process 30 commands before it sends a set of commands (10) once to the next subscriber in line. A value of 0 means that the PMD does not propagate commands while processing incoming events.

**Default:** 1

- **updates\_in\_chunk**

Determines the maximum number of commands that the Policy Model sends to each of its subscribers in each cycle of a loop.

**Default:** 20

- **UseEncryption**

Specifies whether update information saved to the updates.dat file is encrypted.

**Default:** no

- **UseShadow**

Determines whether to use a shadow file when you reference the PMDB native environment.

**Default:** no

- **YpServerSecure**

Specifies the name of the password shadow file (a security file on an NIS server) that is used for building the NIS password map. This token is relevant only if you set UseShadow to yes.

**Default:** /etc/shadow

## seos (pmd.ini)

The token of the [seos] section, which contains the global settings that are used by Privileged Access Manager, is described in the following table.

- **parent\_pmd**

Defines a comma-separated list of policy model databases (PMDBs) from which this PMDB accepts updates. This PMDB rejects updates from any PMDB that is not specified in this list.

You can also specify a file path that contains a line-separated list of PMDBs.

Set this token to "\_NO\_MASTER\_" for this PMDB to accept updates from any PMDB.

If you do not set this token, this PMDB does not accept updates from any PMDB.

Each PMDB is specified in the following format: pmd\_name@hostname

For example:

```
parent_pmd = pmd1@host1,pmd2@host1,pmd3@host2
```

```
parent_pmd = /opt/CA/PAMSC/parent_pmdbs_file
```

**Default:** Token is not set (PMDb does not accept updates from any PMDB).

## The seos.ini Initialization File

### Valid on UNIX

The seos.ini file contains various setup and initialization tokens that are used by Privileged Access Manager. Each token occupies a line in the file, in the following format:

```
token=value
```

The lines containing the tokens for a particular utility, daemon, or other facility of Privileged Access Manager are grouped in sections. Each section starts with a header line that gives the section name inside square brackets. Every token belongs to a section. For example, the following line starts the section that governs the serevu utility:

```
[serevu]
```

The seos.ini file, as installed, is protected by Privileged Access Manager and cannot be updated while Privileged Access Manager is running. The file, as defined by default in Privileged Access Manager, has READ access because many utilities access this file during their processing. If they cannot read the seos.ini file, they fail.

Enter the following selang command to let an authorized user update the file while Privileged Access Manager is running:

```
newres FILE /opt/CA/PAMSC/seos.ini owner(authUser)
```

where *authUser* is the name of an authorized user. This command establishes that *authUser* is the owner of the file, and as the owner of the file, *authUser* can always update it.

You can use Privileged Access Manager Endpoint Management or the seini utility to read, add, modify, and delete tokens in initialization files.

#### NOTE

The seini utility can only update the seos.ini file when seosd is *not* running, or when a rule in the database specifically permits it.

Using the *secons -r* command, you can reload an seos.ini file with updated tokens without having to restart the seosd daemon.

The following table lists all the sections in the seos.ini file.

Section	Description
crypto	Cryptographic module library settings.
daemons	A list of Privileged Access Manager daemons the seload utility runs automatically.
Dependency	A list of products that use Privileged Access Manager as an embedded component, as defined by users.
devcalc	Policy deviation calculator (devcalc) settings.
kblaudit	Keyboard logging session tracking settings.
lang	Privileged Access Manager management interface (selang) settings.
ldap	LDAP server settings for the LDAP sample exit.
logmgr	Logging facility settings.
message	Message file settings.
mfsd	Mainframe synchronization daemon (mfsd) settings.
OS_user	Enterprise user store usage settings.
package	A list of installed Privileged Access Manager packages.
pam_seos	Pluggable Authentication Module (PAM) programming interface settings.
passwd	Password replacement and user-related services settings.
pmd	Common Policy Model database settings.
policyfetcher	Policy fetcher daemon (policyfetcher) settings.
seagent	seagent daemon settings.
segrace	User login information utility (segrace) settings.
seini	Configuration file management utility (seini) attributes.

selock	Desktop inactivity protection utility (selock) settings.
selogrd	Log routing daemons (selogrd and selogrcd) settings.
seos	Global configuration settings.
SEOS_syscall	SEOS_syscall kernel module settings.
seosd	Authorization daemon (seosd) settings.
seosdb	Database checking and rebuilding settings.
seoswd	Watchdog daemon (seoswd) settings.
serevu	Unsuccessful login attempts resolution utility (serevu) utility settings.
sesu	Privileged Access Manager switch user utility (sesu) settings.
sesudo	Privileged Access Manager substitute user do utility (sesudo) utility settings.
standalone	Standalone computer administration settings.
strong_auth	Strong authentication server settings.
tcp_communication	Common TCP connection settings.

## crypto

In the [crypto] section, the tokens control aspects associated with the cryptography module.

- **ca\_certificate**  
Defines the full pathname to the Certificate Authority (CA) certificate database.  
**Default:** *ACInstallDir/data/crypto/def\_root.pem*
- **communication\_mode**  
Specifies whether secure socket layer (SSL) protocols are enabled.  
If you set this token to *ssl\_only*, only SSL V2, SSL V3, and TLS connections are enabled. This means that this computer cannot communicate with computers that do not support SSL, and so cannot communicate with computers that are running versions of Privileged Access Manager earlier than r12.0, which do not support SSL.  
**Note:** Computers that are running Privileged Access Manager r12.0 and later do support SSL.  
If the *fips\_only* token is set to 1, the actual communication mode is set to *ssl\_only* in FIPS mode (TLS), and the *communication\_mode* token is ignored.  
Valid values are:
  - *all\_modes*
  - *ssl\_only*
  - *non\_ssl***Default:** *non\_ssl*
- **CAPKIHOM**  
Defines the installation directory of CAPKI.  
**Default:** */opt/CA/SharedComponents/CAPKI*
- **encryption\_methods**  
Specifies the encryption libraries that the Privileged Access Manager Agent uses to decrypt messages. The Agent attempts to use each library in the list, in turn, until the decryption is successful.  
**Limits:** *libaes256, libaes192, libaes128, libdes, libtripleDES, libscramble*  
**Default:** *libaes256, libaes192, libaes128, libdes, libtripleDES*
- **fips\_only**  
This token controls whether Privileged Access Manager works in FIPS only mode. In this mode, all non-FIPS functions are disabled.  
Valid values:

**1** Privileged Access Manager works in FIPS only mode

**0** Privileged Access Manager works in non-FIPS mode

**Default:** 0

- **LIBRARY\_PATH**

Defines the directory for the ETPKI cryptographic library.

- **private\_key**

Defines the full pathname to the subject private key.

**Default:** *ACInstallDir/data/crypto/sub.key*

- **sha\_mode** Defines the hashing mode of the sha signatures.

Values are: sha1, sha256, sha384, sha512

**Default:** sha512

- **ssl\_port**

Defines the port for SSL communications between Privileged Access Manager clients and services.

**Default:** 5249

- **subject\_certificate**

Defines the full pathname to the subject certificate.

**Default:** *ACInstallDir/data/crypto/sub.pem*

## daemons

In the [daemons] section, each token specifies whether (and if so, how) the seload utility executes a particular program from the Privileged Access Manager installation directory. Each token name corresponds to either a Privileged Access Manager daemon name or is a program nickname and can be assigned several values.

- *program-name*

Specifies one of two possibilities:

- The name of a daemon or other program to be matched with:
  - a *yes* value, so that seload runs the program with default parameters
  - a *no* value, so that seload does not run the program
  - a set of parameters, so that seload runs the program with those parameters

For example, enter the following to run serevu from the Privileged Access Manager installation directory with default parameters:

```
serevu=yes
```

Enter the following to refrain from running serevu; this is the same as using no serevu token

```
serevu=noEnter the following to run serevu from the CA ControlMinder installation directory
```

```
serevu=-f 3 -d 6m -t 1m -
```

s 5mA dummy string, to be matched with the absolute path name of a daemon or other program, f  
opt/CA/PAMSC/bin directory, with the specified parameters:

```
run_it=/opt/CA/PAMSC/bin/serevu -f 3 -d 6m -
```

t 1mTo include specifications for several programs, use the token once for each program.

serevu=yes

Enter the following to refrain from running serevu; this is the same as using no serevu token at all.

**Default:** no

#### NOTE

You do not need to specify the seosd daemon. seload always ensures that the seosd daemon is running.

- **seload\_wait\_timeout**

Specifies the time (in seconds) that seload waits until the main process is running.

**Default:** 45

## Dependency

In the [Dependency] section, each user-defined token specifies a product that uses Privileged Access Manager as an embedded component.

- *product-name*

Specifies a product that uses Privileged Access Manager as an embedded component. Valid values are:

**0** - Not an embedded product

**1** - An embedded product

**Default:** No default products specified

## devcalc

In the [devcalc] section, the tokens control aspects associated with the policy deviation calculator.

- **dms\_command\_retry\_interval**

Defines the number of seconds between each DMS notification command retry.

**Default:** 60

- **init\_ac\_db**

Obsolete.

- **max\_dms\_command\_retry**

Defines the maximum number of times the policy deviation calculator retries to send update notifications to the DMS before giving up.

**Default:** 3

- **max\_lines\_request**

Defines the maximum number of lines (from the policy deviation data file) that the *get devcalc* selang command returns at any one time. You then need to retrieve additional lines using the following command:

```
get devcalc params("offset=X")
```

XDefines the line offset returned by the previous *get devcalc* output.

```
get devcalc params("offset=X")
```

– X

Defines the line offset returned by the previous *get devcalc* output.

**Default:** 50

## kblaudit

The tokens in the [kblaudit] section control the behavior of the Keyboard Logger session tracking program.

- **audit\_back**

Specifies the name of the Keyboard Logger backup audit log file.

**Default:** *ACInstallDir/log/kbl.audit.bak*

- **audit\_group**

Specifies the group that can read the audit logs. If you set this token to **none**, only root can read the audit logs. This token does not verify the value of this token. If you enter an invalid group name, the token does not assign any group permissions to the audit log files.

To change the group ownership of an existing audit log file, complete the following steps:

Use the `selang` command `chgrp` to set the group ownership of the files.

Change the UNIX permissions by entering the following command:

```
chmod 640 ACInstallDir/log/seos.audit
```

**Default:** none

- **audit\_log**

Specifies the name of the Keyboard Logger audit log file.

**Default:** *ACInstallDir/log/kbl.audit*

- **audit\_max\_files**

Specifies the maximum number of audit log files to keep in backup mode. When reached, deletes the earliest backup file when the latest file is created.

**Limits:** a positive integer.

**Default:** 0

**NOTE**

When set to 0, accumulates backup files and does not delete earlier files.

- **audit\_size**

Specifies the maximum size, in KB, of the audit log file.

**Minimum value:** 50 KB

**Default:** 24000

**Note:** stops writing audit records to the audit file when the audit file size exceeds 2 GB.

- **BackUp\_Date**

Specifies the criterion by which the session backs up the audit log file, and if it adds a timestamp to the backup file name.

*Always* backs up the audit log file when it reaches the size that is specified in the `audit_size` configuration setting.

**Values:** none, yes, daily, weekly, monthly

- **yes:** The session backs up the audit log file when it reaches the size that is specified in `audit_size`. The session adds a timestamp to the backup file name.
- **none:** The session backs up the audit log file when it reaches the size that is specified in `audit_size`. The session does not add a timestamp to the backup file name.
- **daily, weekly, monthly:** The session backs up the audit log file whenever the specified interval has elapsed *and* when it reaches the size that is specified in `audit_size`. The session adds a timestamp to the backup file name. However, if no audit events are written to the audit log file in the specified interval, the session does not back up the file after the interval elapses.

**Note:** Counts the specified interval from the time that it creates the first audit log file, and backs up the file at midnight on the appropriate day.

**Example:** The configuration setting has a value of `weekly`, and creates the audit log file at 9:00 am on Friday April 1. Many audit events occur this week and the audit log file exceeds the `audit_size` configuration setting on Monday 4 April. backs up the audit log file on 4 April and adds a timestamp to the backup file name. A week after the audit log file was first created, at midnight Friday 8 April, again backs up the audit log file and adds a timestamp to the backup file name.

**Default:** NONE

- **cmd\_log**

Specifies the link to the Keyboard Logger `cmdlog` binary file.

**Default:** */etc/AC*

- **debug\_backup\_dir**

Specifies the location of the backup debug messages files.

**Default:** /opt/CA/PAMSC/log/kbl\_debug

- **debug\_backup\_num**

Specifies the number of debug files to backup.

**Default:** 2

- **debug\_file**

Specifies the location of the file that stores the Keyboard Logger debug messages.

**Default:** /opt/CA/PAMSC/log/kbl\_debug/cmdlog

- **debug\_level** Specifies the minimal level of debug messages to save.

**Values:**

- disabled: Messages are not saved
- critical: CRITICAL messages are saved, only
- very\_high: CRITICAL + VERY\_HIGH
- high: CRITICAL + VERY\_HIGH + HIGH
- normal: CRITICAL + VERY\_HIGH + HIGH + NORMAL
- low: CRITICAL + VERY\_HIGH + HIGH + NORMAL + LOW

**Default:** critical

- **debug\_size**

Specifies the maximum size (MB) of the debug messages file.

**Default:** 256 MB

- **error\_back**

Specifies the name of the Keyboard Logger error log backup file.

**Default:** *ACInstallDir*/log/kbl.error.bak

- **error\_group**

Specifies the group that can read the error log files. If you set this token to **none**, only root can read the error log files. Does not verify the value of this token, so if you enter an invalid group name, does not assign any group permissions to the error log files.

To change the group ownership of an existing error log file, complete the following steps:

Use the selang command `chgrp` to set the group ownership of the files.

Change the UNIX permissions by entering the following command:

```
chmod 640 ACInstallDir/log/seos.audit
```

**Default:** none

- **error\_log**

Specifies the name of the Keyboard Logger error log file.

**Default:** *ACInstallDir*/log/kbl.error

- **error\_size**

Defines the maximum size, in KB, of the error log file.

**Limits:** A minimum value of 50 KB

**Default:** 500

- **kbl\_enabled**

Specifies whether the Keyboard Logger is enabled.

**Values:** yes, no

**Default:** no

- **kbl\_flush\_timeout**

Specifies the user session inactivity interval, in seconds, after which the printable logged data is stored in the kbl audit file. Set the token to 0 to disable.

**Default:** 30

- **kbl\_output\_limit**

Specifies the limit (bytes) for storing the output that is collected after the last user input.

**Default:** 0 (no limit)

- **Kbl\_seos\_trace**  
Specifies whether seosd activates trace on session and sends user activity data to the Keyboard Logger.  
**Values:** yes, no  
**Default:** yes
- **kbl\_trace**  
Specifies whether to print the Keyboard Logger debug messages.  
**Values:** 0 (no tracing), 1 (use tracing)  
**Default:** 0
- **OS\_etc\_shells**  
Specifies the name of the operating system shells file.  
**Default:** /etc/shells
- **socket\_name**  
Specifies the socket name for the Keyboard Logger audit manager.  
**Default:** *ACInstallDir*/kblserver

## lang

In the [lang] section, the tokens specify the attributes used by the selang command language programs: selang, Security Administrator, and seadm.

- **check\_password**  
Determines whether selang requests users to specify their own passwords. Valid values include:  
**no**-selang does not require any passwords  
**yes**-Users are prompted to enter their passwords.  
**Default:** no
- **exit\_timeout**  
Specifies the maximum time, in seconds, that allows the exit program to execute. After this time has passed, the token kills the exit program.  
**Default:** 30
- **exits\_dir**  
Specifies the target directory where exits are installed by the *ACInstallDir*/bin/install\_exits.sh shell script.  
**Default:** *ACInstallDir*/exits
- **exits\_source\_dir**  
Specifies the source directory of the exits to be installed by the *ACInstallDir*/install\_exits.sh shell script.  
**Default:** *ACInstallDir*/samples/exits-src
- **help\_path**  
Specifies the directory in which lang help files are located.  
**Default:** *ACInstallDir*/data/langhelp
- **HNODE\_max\_events**  
Specifies the maximum number of health status events that the HNODE record writes. If events exceed the configured maximum number, then the oldest events are removed.  
**Default:** 10
- **language**  
Defines the language Privileged Access Manager installs in (for internal use).  
**Default:** english
- **max\_groups\_buffsize**  
Specifies the buffer size, in KB, that the security administrator uses when communicating with the database. This token is used when a UNIX update needs to be applied.  
**Default:** 128
- **no\_check\_password\_users**

Specifies users who are not asked to enter their passwords.

This token is relevant only if the token check\_password is set to **yes**.

Valid values include a list of users separated by commas.

**Default:** none

- **passwd\_copy**

Specifies how the password file (/etc/passwd) or PMDB password file (/PMDB\_Directory/policies/pmdb/passwd) is updated when you copy the temporary file back to the original after changing user information. Valid values include:

**fast\_copy** - Copies information over the file.

**rename** - Changes the directory to point to the new file.

**Default:** fast\_copy

- **post\_group\_exit**

Specifies the path of the exit program to be called after a group command is executed in the UNIX environment.

**Default:** ACInstallDir/exits/lang\_exit.sh

- **post\_user\_exit**

Specifies the path of the exit program to be called after a user command is executed in the UNIX environment.

**Default:** ACInstallDir/exits/lang\_exit.sh

- **pre\_group\_exit**

Specifies the path of the exit program to be called before a group command is executed in the UNIX environment.

**Default:** ACInstallDir/exits/lang\_exit.sh

- **pre\_user\_exit**

Specifies the path of the exit program to be called before a user command is executed in the UNIX environment.

**Default:** ACInstallDir/exits/lang\_exit.sh

- **query\_size**

Specifies the maximum number of records to be listed in a database query.

**Default:** 100

- **RecvTimeOut**

Specifies the maximum time, in seconds, that selang waits to receive information before timing out.

If you set the value to 0, there is no time-out.

**Default:** 60

- **SendTimeOut**

Specifies the maximum time, in seconds, that selang waits to send information before timing out.

If you set the value to 0, there is no time-out.

**Default:** 60

- **SetBlockRun**

Specifies whether to check if a program is trusted and block the execution of untrusted programs. The execution blocking is performed regardless whether the program is a setuid or a regular program.

Valid values include the following:

**yes**-All programs that are defined with viapgm authorization rules have the blockrun property set to yes.

**no**-All programs that are defined with viapgm authorization rules have the blockrun property set to no.

**suid**-All setuid programs have the blockrun property set to yes, and all other programs have the blockrun property set to no.

**Default:** yes

- **swap\_deletion\_order**

Defines the order in which the "ru *userName* unix" command (user deletion) is executed in selang. Typically, this command is first executed in the AC environment, and then in the UNIX environment. Sometimes (for example, a group administrator deleting a user) where you would want to reverse this order.

Valid values are:

**no** - remove the user from the AC environment before the UNIX environment.

**yes** - remove the user from the UNIX environment before the AC environment.

**Default:** no

- **timeout**

Specifies the maximum time, in seconds, the client waits for seosd daemon to respond. If seosd does not respond within this period, an error message is sent noting that seosd is not responding. The client then stops trying to connect to seosd.

**Default:** 90

- **use\_old\_commands**

Specifies whether to disable old ACF2 compatibility commands (ag, lg, rg, lu, au, and so on).

**Limits:** 0do not support old commands, 1support old commands

**Default:** 1 (support old commands)

- **use\_unix\_file\_owner**

Specifies whether a UNIX owner of a file can define the file. If the value is yes, an owner of a file in UNIX can define it using the newres or newfile command.

If the file is already defined, the user cannot change its parameters in the database unless the user is allowed to do so according to the normal authorization rules.

Valid values are yes and no.

**Default:** no

## ldap

In the [ldap] section, the tokens specify the attributes that are used to locate the LDAP server and input data. These parameters are used only by the ldap sample exit located in *ACInstallDir/samples/ldap/exits/S50CREATE\_Ldap\_u.sh*.

- **base\_entry**

Specifies the point in the LDAP directory tree to be used as the base entry point.

For example, you can use *o=organization\_name, c=country\_name*.

**Default:** Token not set

- **host**

Specifies the host name of the LDAP server.

**Default:** Token not set (localhost)

- **path**

Specifies the LDAP client base directory.

**Default:** Token not set (/usr/local/ldap)

- **port**

Specifies the LDAP server port (optional)

**Default:** Token not set (389)

## logmgr

In the [logmgr] section, the tokens control the behavior of the logging facility.

- **audit\_back**

Specifies the name of the audit log backup file. Only Privileged Access Manager can write to this file. Users can have READ access only to this file.

**Default:** *ACInstallDir/log/seos.audit.bak*

- **audit\_group**

Specifies the group that can read the audit logs. If you set this token to **none**, only root can read the audit logs.

Privileged Access Manager does not verify the value of this token. If you enter an invalid group name, the product does not assign any group permissions to the audit log files.

To change the group ownership of an existing audit log file, complete the following steps:

Use the selang command *chgrp* to set the group ownership of the files.

Change the UNIX permissions by entering the following command:

```
chmod 640 ACInstallDir/log/seos.audit
```

**Default:** none

- **audit\_log**

Specifies the name of the audit log file. When this file reaches the size that is specified in *audit\_size*, Privileged Access Manager does the following actions:

- Closes the file
- Renames it with the name in *audit\_back*
- Creates an audit log. Only Privileged Access Manager can write to this file. Users can have READ access only to this file.

**Default:** *ACInstallDir/log/seos.audit*

- **audit\_max\_files**

Defines the maximal number of audit log backup files accumulates when it performs date-triggered backups. When the BackUp\_Date configuration setting is set to anything other than *none*, continuously accumulates date-triggered backup files. This configuration setting lets you reduce disk space uses for audit log backups. When the number of audit log backup files reaches the limit that you set, Privileged Access Manager deletes the oldest backup file when it creates the newest.

**Values:**

- **0** keep all audit log backup files.
  - a. *na* positive integer greater than zero.

**Note:** You cannot remove redundant audit log backup files manually because Privileged Access Manager protects these files automatically. Also, if the audit reporting is enabled, Privileged Access Manager does not delete a backup file until the Report Agent finishes processing it.

**Default:** 0

- **audit\_size**

Specifies the maximum size, in KB, of the audit log file.

Minimum value: 50 KB

**Default:** 10240

**NOTE**

stops writing audit records to the audit file when the audit file size exceeds 2 GB.

- **BackUp\_Date**

Specifies the criterion by which Privileged Access Manager backs up the audit log file, and if it adds a timestamp to the backup file name.

*always* backs up the audit log file when it reaches the size specified in the *audit\_size* configuration setting.

**Values:** none, yes, daily, weekly, monthly

- **yes:** backs up the audit log file when it reaches the size that is specified in *audit\_size* and adds a timestamp to the backup file name.
- **none:** backs up the audit log file when it reaches the size that is specified in *audit\_size* and does not add a timestamp to the backup file name.
- **daily, weekly, monthly:** backs up the audit log file whenever the specified interval has elapsed *and* when it reaches the size that is specified in *audit\_size*, and adds a timestamp to the backup file name. However, if no audit events are written to the audit log file in the specified interval, Privileged Access Manager does not back up the file after the interval elapses.

**Note:** counts the specified interval from the time that it creates the first audit log file, and backs up the file at midnight on the appropriate day.

**Example:** The configuration setting has a value of weekly and Privileged Access Manager creates the audit log file at 9:00 a.m. Friday 1 April. Many audit events occur this week and the audit log file exceeds the *audit\_size* configuration setting on Monday 4 April. Privileged Access Manager backs up the audit log file on 4 April and adds a timestamp to the backup file name. A week after the audit log file was first created, at midnight Friday 8 April, the product again backs up the audit log file and adds a timestamp to the backup file name.

**Default:** NONE

- **error\_back**

Specifies the name of the error log backup file.

**Default:** *ACInstallDir/log/seos.error.bak*

- **error\_group**

Specifies the group that can read the error log files. If you set this token to **none**, only root can read the error log files. The product does not verify the value of this token. If you enter an invalid group name, the product does not assign any group permissions to the error log files.

To change the group ownership of an existing error log file, complete the following steps:

Use the `selang` command `chgrp` to set the group ownership of the files.

Change the UNIX permissions by entering the following command:

```
chmod 640 ACInstallDir/log/seos.audit
```

**Default:** none

- **error\_log**

Specifies the name of the error log file. When this file reaches the size that is specified in *error\_size*, Privileged Access Manager does the following actions:

- Closes the file
- Renames it with the name in *error\_back*
- Creates an error log. Only Privileged Access Manager can write to this file.

**Default:** *ACInstallDir/log/seos.error*

- **error\_size**

Defines the maximum size, in KB, of the error log file.

**Limits:** A minimum value of 50 KB.

**Default:** 50

- **irecorder\_audit**

Specifies whether the IR API library routes audit events of existing PMDs in addition to the local security daemon audit events.

all - routes audit events of Policy Models in addition to the local security daemon audit events.

localhost - routes audit events of the local security daemon only.

**Default:** all

- **logconnected**

Prevents TCP-CONNECTED records from being written to the audit log.

Set `logconnected` to No to use this feature.

**Default:** no

## message

In the [message] section, the tokens control the behavior of the message utility `semsgtool`.

- **dashboard\_messages** Indicates if the installation status was sent to the server for monitoring.

**Values:** Yes, No

**Default:** No

- **filename**

Specifies the location and name of the file that supplies most of the messages that appear in response to typed `selang` commands.

**Default:** *ACInstallDir/data/seos.msg*

- **MessagesDirectory**

Specifies the location of the messages file.

**Default:** *ACInstallDir/data/msg*

## mfsd

In the [mfsd] section, the tokens define the mainframe synchronization daemon options.

- **mfsd\_trace\_file**

Specifies the location of the file to which the mainframe synchronization daemon mfsd trace messages are written. If this token is set to **no**, the trace file is not created.

**Default:** *ACInstallDir/log/mfsd.trace*

## **OS\_user (seos.ini)**

The tokens in the [OS\_User] section define the settings used by Privileged Access Manager for enterprise users and enterprise groups.

- **create\_user\_in\_db**

Specifies whether creates an XUSER record for a user who is not defined to, when that user logs in.

Note: This setting applies only if you use enterprise users (osuser\_enabled is set to 1).

**Limits:** yes, no

**Default:** yes

- **nonunix\_unabgroup\_enabled**

Specifies whether supports non-UNIX groups of users in the UNAB database.

**Limits:** yes, no

**Default:** no

- **nonunix\_ldapgroup\_enabled**

Specifies whether supports non-UNIX groups of users, on LDAP servers.

**Limits:** yes, no

**Default:** no

- **osuser\_enabled**

Specifies whether enterprise users and groups are enabled.

**Limits:** yes, no

**Default:** yes

- **UserCache\_groups\_max**

Defines the maximum number of groups in the runtime user cache table.

**Default:** 1000

- **UserCache\_max**

Defines the maximum number of entries in the runtime user cache table.

**Default:** 20000

- **UserCache\_timeout**

Defines the interval (in minutes) before a record is removed from the runtime user cache table.

**Default:** 60

- **verify\_osuser**

Specifies whether verifies that a user exists in an enterprise store before it creates an enterprise user record (XUSER) in.

**Limits:** No - Lets you create an enterprise user record only if that user is defined in the enterprise user store. Yes - Always lets you create an enterprise user record.

**Default:** no

## **package**

In the [package] section, the tokens specify the packages you selected to install.

- **Client, Server, Admin, Mfsd, Tng, Stop, Api**

Indicates whether you selected to install the specified package.

**Default:** no

## pam\_seos

### NOTE

In the [pam\_seos] section, the tokens help you to more fully exploit the programming interface PAM (Pluggable Authentication Module).

- **api\_update\_lastacctest**  
Specifies whether the API libraries update the last access time and date of a user (through SEOS\_VerifyCreate).  
Valid values are:  
**0** - the last access time and date is not updated.  
**1** - the last access time and date is updated.  
**Default:** 0
- **bypass\_services**  
Defines which services PAM bypasses.  
**Default:** ftp, vsftpd
- **call\_segrace**  
Specifies whether to call the segrace utility with any login automatically.  
Valid values are yes and no.  
**Default:** no
- **call\_sepass**  
Specifies whether to use the sepass utility in the pam\_seos password management service.  
**Values:** No, Yes  
**Default:** No
- **debug\_mode\_for\_user**  
Specifies whether to inform the user of the reason for the login denial.  
Valid values are yes and no.  
**Default:** no
- **failed\_login\_file**  
Specifies the location of the failed login audit file pam\_seos.  
**Default:** *ACInstallDir/pam\_seos\_failed\_logins.log*
- **pam\_login\_events\_enabled**  
Specifies whether pam\_seos sends login events to seosd.  
**Values:** **0** - do not send login events; **1** - send login events  
**Default:** 1
- **pam\_get\_groups**  
Specifies whether pam\_seos retrieves user groups from operating system.  
**Values:** **0** - do not attempt to retrieve groups; **1** - attempt to retrieve groups  
**Default:** 1
- **pam\_groups\_timeout**  
Defines the timeout interval, in seconds, that Privileged Access Manager PAM uses for API to retrieve user groups.  
**Default:** 10
- **PamPassUserInfo**  
Specifies whether pam\_seos sends user information to seosd. This token is required when you use enterprise users, which Privileged Access Manager has no information for. Set this setting to 0 if you are not using enterprise users (osuser\_enabled = no).  
**Values:** **0** - do not send user information; **1** - send user information.  
**Default:** 1
- **pam\_surrogate\_events\_enabled**  
Specifies whether pam\_seos sends surrogate events to seosd.  
**Values:** **0** - do not send surrogate events; **1** - send surrogate events.  
**Default:** 1
- **process\_failed\_logins**

Specifies whether pam\_seos calls pam\_authenticate to authenticate user passwords and process failed logins.

Set this token to 0 if you do *not* want pam\_authenticate to be called twice.

**Values:** **0** - do not call pam\_authenticate from the Privileged Access Manager PAM module; **1** - call pam\_authenticate from the Privileged Access Manager PAM module.

**Default:** 1

- **serevu\_use\_pam\_seos**

Specifies whether serevu uses the pam\_seos login failure log file instead of the system file.

This feature increases the accuracy of serevu.

**Default:** yes

## passwd

In the [passwd] section, the tokens define password replacement and other user-related services.

- **AllowedGidRange**

Specifies the range of GIDs that the user can add, update, and delete. Values outside this range represent reserved GIDs that Privileged Access Manager cannot update.

**NOTE**

If only one integer is specified, all integers between the specified integer and the default upper limit (30000) are reserved GIDs. If you specify a number that is higher than the upper limit, the default upper limit is applied. If you specify a negative number that is less than the lower limit, the default lower limit (100) is applied. The applied lower limit for any number is +1 of the specified lower limit. The applied higher limit for any number is -1 of the specified higher limit. For example, if *AllowedUidRange* = 100, 3000, then 101 is treated as the lower limit and 2999 is treated as the higher limit.

**Limits:** -1 to 2147483647

**Default:** 100,30000

- **AllowedUidRange**

Specifies the range of UIDs that the user can add, update, and delete. Values outside this range represent reserved UIDs that Privileged Access Manager cannot update.

**NOTE**

If only one integer is specified, all integers between the specified integer and the default upper limit (30000) are reserved UIDs. If you specify a number that is higher than the upper limit, the default upper limit is applied. If you specify a negative number that is less than the lower limit, the default lower limit (100) is applied. The applied lower limit for any number is +1 of the specified lower limit. The applied higher limit for any number is -1 of the specified higher limit. For example, if *AllowedUidRange* = 100, 3000, then 101 is treated as the lower limit and 2999 is treated as the higher limit.

**Limits:** -1 to 2147483647

**Default:** 100,30000

- **AllowRootProp**

Specifies whether root password changes made using sepass -p or sepass -s are sent to the Policy Model. The PMD then propagates the password to its subscribers.

Valid values are yes and no.

**Default:** no

- **change\_pam**

Specifies whether the local host uses PAM for password authentication and changes in the LDAP database.

**Default:** no

- **Check\_Adm\_Rules**

Specifies whether to enforce password rules for ADMIN and PWMANAGER users.

**Default:** no

- **Check\_All\_User\_Rules**

Specifies whether `selang` checks the Password Rules for all the users.

Valid values are `yes` and `no`.

If this token is set to `yes`, `selang` checks the Password Rules for all the users.

If this token is set to `no`, `selang` checks the Password Rules only for the user who changes the password.

**Default:** `no`

#### NOTE

This token is supported when using the API only.

- **CreateHashedPasswdDatabase**

(DEC UNIX only). Specifies whether an exit script runs after each Privileged Access Manager command that creates, updates, or removes a user record, or after each user password changed with the `sepass` utility.

#### NOTE

For more usage instructions, see the README file in `ACInstallDir/samples/exits-src/USER_POST` directory.

**Default:** `no`

- **DefaultHome**

Specifies the default home directory of the system. The home directory of the user is a subdirectory of the specified system home directory. For example, if the system home directory is `/home`, the new home directory of the user is `/home/username`. If specified, the value for this token overrides the value in the client `lang.ini` file. If you specify `nohomedir`, then a home directory is not automatically set.

**Default:** `/home`

- **DefaultPasswdCmd**

Specifies the default password program. If specified, this password program is used when `sepass` is started and `seosd` is not running.

**Default:** `/bin/passwd`

- **DefaultPgroup**

Specifies the primary group that Privileged Access Manager assigns to a new UNIX user if no value is entered.

**Default:** `other`

- **DefaultShell**

Specifies the default shell that Privileged Access Manager assigns to a new UNIX user if no value is entered. If specified, the value for this token overrides the value in the client `lang.ini` file.

**Default:** `/bin/sh` (or `/sbin/sh` on HP-UX)

- **Dictionary**

Defines the full pathname of the file containing the words that *cannot* be used as passwords.

#### NOTE

To use this file, you must set the dictionary format password rule (`use_dbdict`) to *file* and set `UseDict` setting to `yes`. If the dictionary format is set to *db*, passwords that cannot be used are taken from the Privileged Access Manager database and this setting is ignored. This value is the default on UNIX.

#### WARNING

This token is obsolete. Use `dictionary` in the database instead.

**Default:** `/usr/dict/words`

- **GeneratePasswd**

Specifies whether `sepass` generates a new password by itself.

Valid values are `yes` and `no`.

**Default:** `no` (the user is asked to enter a new password.)

- **HomeDirUpd**

Specifies whether Privileged Access Manager updates the group ownership of the home directory of the user when the primary group of the user changes.

Valid values are **yes** and **no**

**Default:** `yes`

- **nis\_env**

Specifies whether the local host is an NIS or NIS+ client.

Valid values are no, nis, or nisplus.

**Default:** no

- **NisPlus\_server**

Specifies whether this station is an NIS+ server.

Valid values are yes and no.

If token value is yes, Privileged Access Manager treats password replacements as NIS+ password replacements.

**Default:** no

- **only\_local**

Determines whether the default setting for sepass includes the -l flag.

Valid values are yes and no.

If this token is set to yes, sepass replaces the password only in the local files. Example: the local password file (usually /etc/passwd), security files, and the local database

**Default:** no

- **only\_pmdb**

Specifies whether the default setting for sepass includes the -p flag. If token value is yes, it instructs sepass to change the password only on the PMDB at the host specified.

If no such database is defined, sepass does nothing.

**Default:** no

- **passwd\_distribution\_encryption\_mode**

Specifies which method is used to encrypt user passwords when passwords are distributed as part of the Policy Model service.

Valid values are:

**1** - Compatibility mode, to distribute passwords between Privileged Access Manager systems that do not use long passwords (This includes all machines running pre-r12.0 versions of Privileged Access Manager.)

**2** - MD5 mode, to distribute passwords between Privileged Access Manager systems that use long passwords and are also running Linux.

**3** - Bidirectional mode, to distribute passwords securely, as clear text within encrypted messages, between any Privileged Access Manager systems that use long passwords.

**Default:** 1

- **passwd\_format**

Indicates whether the password changes are propagated to an NT host.

Setting this token to **NT** means that one of the hosts you are administering is an NT host.

**Default:** none

- **passwd\_local\_encryption\_method**

Specifies which method is used to encrypt user passwords when storing these passwords locally.

Valid values are:

**crypt** - The standard one-way UNIX encryption that uses only the first eight characters of the password (as a DES key). Specifying crypt disables the use of long passwords.

**md5** - MD5 hash function that can encrypt passwords of indefinite length. Specifying md5 enables the use of long passwords.

**Default:** crypt

- **PromptOldPassword**

Specifies whether to prompt local users for their old password when sepass is invoked through /opt/CA/PAMSC/bin/segrace. (You must use the full path).

**Default:** yes (indicates that the users are prompted for their old passwords)

- **quiet\_mode**

Specifies whether sepass displays a copyright notice and a message about propagating passwords to Policy Models.

**Default:** no

- **RootPwAsOwn**

Specifies whether sepass lets a privileged user change the root password as if changed by root (using the -x option).

Valid Values are:

**yes**-Privileged users can use `sepass` to change the root password as if changed by root. They cannot change the root password as themselves (administrative change).

**no**-Privileged users can use `sepass` to change the root password only as themselves (administrative change).

For example, a privileged user can use the following command to change the root password if this token is set to **yes**:

```
sepass -x root
```

The same user cannot use the following command to change the root password:

```
sepass root
```

If this token is set to *no*, the opposite is true.

**Default:** no

- **SaveGroupAttrs**

Specifies whether the previous group file owner, group, and mode are preserved after an update of a group in the UNIX environment.

Valid values are yes and no.

**Default:** no (new values are set to 0, 0, 644 respectively)

- **SavePasswdAttrs**

Specifies whether the previous password file owner, group, and mode are preserved after an update of a user in the UNIX environment.

Valid values are yes and no.

**Default:** no (new values are set to 0, 0, 644 respectively)

- **Shadow\_Admin\_Change**

(AIX platforms only). Specifies whether the ADMCHG flag gets added to the user entry in the `/etc/security/passwd` file when an administrator changes the password from `selang` or using `sepass`.

**Default:** no

- **UIDAlgorithm**

Specifies which free UID algorithm to employ when adding new users. Setting it to any other value would select the older process. The *new* algorithm provides for UID numbers over 4 KB and is faster.

**Default:** new

- **UseDict**

Specifies whether to use the dictionary file (set with the Dictionary setting) when verifying a password.

**NOTE**

To use the dictionary file, you must also set the dictionary format password rule (`use_dbdict`) to *file*. If the dictionary format is set to *db*, passwords that cannot be used are taken from the Privileged Access Manager database and this setting is ignored.

**Default:** no

- **YpGrpCmd**

Specifies the command to use for generating the NIS group map.

**Default:** make group

- **YpMakeDir**

Specifies the name of the makefile directory to use when creating NIS maps.

**Default:** /var/yp

- **YpPassCmd**

Specifies the command to use for generating the NIS password map.

**Default:** make passwd

- **YpServerGroup**

Specifies the group file from which the NIS group map is made.

**Default:** /etc/group

- **YpServerPasswd**

Specifies the password file from which the NIS password map is made.

**Default:** /etc/passwd

- **YpServerSecure**

Specifies the name of the security file containing passwords that is used for building the NIS password map.

**Default:** Varies by platform:

- IBM AIX: /etc/security/passwd
  - HP-UX: /.secure/etc/passwd
  - Sun Solaris: /etc/shadow

- **YpTimeOut**

Specifies the time, in seconds, that a new client (selang, Security Administrator, and so forth) can run the ypbind test. The ypbind test determines whether the local host is connected to a NIS server. At expiration, the client exits and an error message appears.

The default value of zero (0) means that no ypbind test is conducted.

**Default:** 0

## pmd1

In the [pmd] section, the tokens are used to configure the generic Policy Model settings.

- **ClientOperationTimeout**

Defines the number of seconds a Policy Model client waits for a response from the Policy Model. If the Policy Model does not respond within this time frame, the client assumes that the Policy Model is non-responsive.

**Default:** 60 seconds

- **is\_maker\_checker**

Specifies whether to use Dual Control. If yes is selected, then the database cannot be updated directly, but only through a policy model database by a pair of administrators - a Maker and a Checker, who must collaborate on the update.

**Values:** yes, no

**Default:** no

- **min\_retries**

Specifies the minimum number of attempts that are made by sepmd to access an unavailable subscriber before giving up and temporarily shutting itself down.

**Default:** 4

- **pass\_auth**

Specifies whether sepass verifies the invoker password during a remote password change. The sepass utility compares the old password that the user enters with the password stored in the local database. If this token is set to yes, then sepass also compares the old password that the user running sepass enters with their own password as it is stored in the remote database (pmdb). This means that the sepass user must enter their own password even when changing the password for another user.

**Values:** yes, no

**Default:** yes

- **pmd\_backup\_directory**

Specifies the directory to store Policy Model backups. Each Policy Model backup is stored in a subdirectory named <pmd\_name>.

**Default:** /opt/CA/PAMSC/data/policies\_backup

- **pmd\_directory**

Specifies the directory in which the policy model database resides. Each policy model database resides in the <pmd\_directory>/<pmd\_name> subdirectory where <pmd\_name> is the policy model name.

**Default:** /opt/CA/PAMSC/policies

- **pull\_option**  
Specifies that the local host, and any policy model on this station, have a parent policy model to which they subscribe. When this station becomes temporarily unavailable to send updates, the pull\_option token enables Privileged Access Manager agent to send a message to these parent policy models when this station becomes available again. Then the parents start sending updates immediately, instead of waiting for the next retry.  
**Values:** yes, no  
**Default:** yes
- **QD\_timeout**  
Specifies the maximum time (seconds) that the daemon sepmd waits to update a subscriber database during the first scan of the subscribers. If the maximum time elapses and the daemon fails in updating a subscriber, then it skips to the remaining subscribers.  
**Default:** 3
- **retry\_timeout**  
Specifies the time (minutes) between consecutive attempts to access an unavailable subscriber.  
**Default:** 30 minutes
- **send\_unix\_env**  
Specifies the token when set to yes, the *sepmd -n* option sends the content of the policy model password files and group files.  
**Values:** yes, no  
**Default:** yes
- **ShutdownWaitingTimeout**  
Defines the number of milliseconds a Policy Model waits for its components to shut down gracefully. If Policy Model components do not shut down gracefully within this time frame, the Policy Model forces them to shut down.  
**Default:** 60 milliseconds
- **shutoff\_time**  
The time (in minutes) sepmd waits before shutting itself off. If this token is set to zero, sepmd never shuts itself off.  
**Default:** 0
- **updates\_in\_chunk**  
Specifies the maximum number of commands that the Policy Model sends to each subscriber every cycle. The Policy Model sends commands to its subscribers one by one in a loop.  
**Default:** 10

## policyfetcher

In the [policyfetcher] section, the tokens control the behavior of the policy fetcher daemon (policyfetcher).

- **check\_deployment\_tasks**  
Defines how often, in seconds, policyfetcher checks for new deployment tasks (DEPLOYMENT resources) on the Distribution Host.  
**Default:** 600 (every 10 minutes)  
**Limits:** A minimum value of 60
- **deploy\_timeout**  
Defines the number of seconds policyfetcher waits for a deployment or undeployment task to complete on the endpoint.  
**Default:** 900
- **devcalc\_command**  
Defines the selang command that policyfetcher uses to run the deviation calculation.  
**Default:** start DEVCALC params(-nonotify)

**Example:** start DEVCALC params(-nonotify -precise)

- **dh\_command\_retry\_interval**  
Defines the number of seconds between each DH notification command retry.  
**Default:** 60
- **endpoint\_heartbeat**  
Defines the frequency at which policyfetcher sends a heartbeat to the Distribution Host (DH). The frequency is a factor of the check\_deployment\_task setting, and determines how many times policyfetcher checks deployment tasks before it sends a heartbeat. For example, if check\_deployment\_task is set to the default 600 seconds (10 minutes) and you set this to 6, policyfetcher sends a heartbeat every 3600 seconds (1 hour).  
The policyfetcher runs the deviation calculator (start devcalc command) after sending the heartbeat, and then waits 60 seconds for the deviation calculation to complete. After 60 seconds, policyfetcher continues to check that local endpoint information is identical to DH information.  
**Default:** 6
- **max\_deployment\_errors**  
Defines the maximum number of deployment errors that the endpoint sends to the DMS.  
**Default:** 10
- **max\_dh\_command\_retry**  
Defines the maximum number of times policyfetcher retries to get update notifications from DH before giving up.  
**Default:** 10
- **max\_dh\_retry\_cycles**  
Defines the maximum number of cycles policyfetcher retries to get update notifications from production DHs before moving to disaster recovery DHs.  
**Default:** 5
- **policy\_verification**  
Specifies whether the policyfetcher daemon verifies new deployment tasks on a backup Privileged Access Manager database before executing the tasks.  
Valid values:  
1 - Run policy verification  
0 - Disable policy verification  
**Default:** 0
- **policyfetcher\_enabled**  
Specifies whether to run the policyfetcher daemon.  
Valid values:  
1 - Run policyfetcher  
0 - Disable policyfetcher  
**Default:** 0

#### NOTE

To run policyfetcher on UNIX, specify value 1 for policyfetcher\_enabled token. To run policyfetcher on Windows, specify value 1 for policyfetcher\_enabled token and enable the registry value at the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Applications\Policyfetcher
```

## PUPMAgent

In the [PUPMAgent] section, the tokens determine the functionality of the Privileged User Password Management Agent.

- **EnableLogonIntegration**  
Specifies that terminal integration is enabled.  
**Limits:** 0, terminal integration is disabled; 1, terminal integration is enabled.  
**Default:** 1
- **Endpointname**

Specifies the name of an endpoint on the local server used for the PUPM login integration.

**Default:** <Short local host name>

**IMPORTANT**

If the specified Endpointname value is greater than 15 characters, login integration fails.

- **InterfaceName**

Defines the communication interface name. This name is the UNIX socket name with which the SAM Agent handles requests. The socket file is located in the /opt/CA/PAMSC/data/PUPMAgent directory.

**Default:** PUPMAgentInterface

- **OperationMode**

Specifies the SAM Agent work mode.

**Limits:** 0, the SAM Agent is disabled and not running. 1, the SAM Agent is enabled, running but not logging data to trace files. 2, the SAM Agent is enabled, running, and logging data to trace files.

**Default:** 0

## seagent

In the [seagent] section, the tokens control the behavior of the seagent daemon.

- **debug\_backup\_dir** Specifies the backup debug files location.

**Default:** Privileged Access Manager product log directory

- **debug\_backup\_num**

Defines the number of backup debug files to save.

**Value:** A positive number

**Default:** 2

- **debug\_file**

Defines the name of the file to which Privileged Access Manager writes seagent debug messages.

**Default:** *ACInstallDir/log/seagent\_debug*

- **debug\_level**

Specifies the minimal level of debug messages that Privileged Access Manager writes to the debug file.

**Limits:**

- disabledno messages are written to the debug file
- criticalCRITICAL messages are written to the debug file
- very\_highCRITICAL and VERY\_HIGH messages are written to the debug file
- highCRITICAL, VERY\_HIGH, and HIGH messages are written to the debug file
- normalCRITICAL, VERY\_HIGH, HIGH, and NORMAL messages are written to the debug file
- lowCRITICAL, VERY\_HIGH, HIGH, NORMAL, and LOW messages are written to the debug file

**Default:** critical

- **watchdog\_check\_interval**

Defines the time interval, in seconds, at which seagent checks that seoswd exists.

**Note:** This token applies only if there is a high volume of incoming connections to seagent. If seagent is idle, it checks that seoswd exists every 3 seconds and this token is ignored.

**Default:** 30

## segrace

In the [segrace] section, the tokens determine the attributes of the segrace utility.

- **sepass\_command**

Specifies the location of the Privileged Access Manager password replacement command that is executed when a user has no remaining grace logins.

**Default:** *ACInstallDir/bin/sepass*

## seini

In the [seini] section, the tokens determine the attributes of the seini intelligent search feature.

- **get\_error\_warning**  
Specifies whether the error and warning messages for the intelligent search feature display.  
**Default:** yes
- **perform\_action**  
Specifies whether seini performs its operations on the token or section found by the intelligent search feature.  
Valid values are yes and no.  
If this token is set to **yes**, the section and token, found by the additional intelligent search, are used for the requested seini operation.  
**Default:** no
- **use\_intelligent\_search**  
Specifies whether to perform an intelligent search when you invoke the seini utility.  
**Default:** no

## selock

In the [selock] section, the tokens control the behavior of the selock utility.

- **unlocking\_user**  
Specifies the name of a user, other than the owner, who can unlock a locked screen.  
**Default:** root

## selogrd

In the [selogrd] section, the tokens control the behavior of the log routing daemons selogrd and selogrcd.

- **Caudit\_size**  
Specifies the maximum size, in KB, of the audit collection file, before selogrcd creates a backup file and opens a new file.  
The minimum value is 50 KB.  
**Default:** 1024
- **CBackUp\_Date**  
Sets the criterion by which selogrcd performs the backup.  
Valid values include: none, yes, daily, weekly, and monthly.  
If you specify **yes**, Privileged Access Manager performs backups according to the size limit token Caudit\_size and timestamps the file.  
If you specify **none**, Privileged Access Manager performs the backup according to the Caudit\_size token but it does not timestamp the file.  
If you specify **daily**, **weekly**, or **monthly**, selogrcd adds a timestamp when it first creates the file. When the current date passes the timestamp, Privileged Access Manager automatically creates a backup file and timestamps it. However, if the size of the file exceeds the value of the Caudit\_size token first, Privileged Access Manager creates a backup file without issuing a timestamp.  
**Default:** NONE
- **ChangeLogFactor**  
Specifies the factor applied to the value in the token *Interval* before testing whether the log file was changed to a backup file. For example, if the *Interval* token is set to 5 and the *ChangeLogFactor* token is set to 5 (the default), Privileged Access Manager waits 25 seconds before checking whether the log file was changed to a backup file.

**Default:** 5

- **CipherName**

Specifies the name of the file that contains the encryption functions used by selogrd if the UseEncryption token is set to eTrust.

This file must be placed in the *ACInstallDir/lib/* directory.

The CipherName is a symbolic link to a shared object file.

**Default:** adcipher

- **CollectFile**

Specifies the name of the file in which the audit collector daemon selogrcd stores the collected audit records.

**Default:** *ACInstallDir/log/seos.collect.audit*

- **CollectFileBackup**

Specifies the name that selogrcd uses when backing up and renaming the file of collected audit records when it receives the USR1 signal.

**Default:** *ACInstallDir/log/seos.collect.bak*

- **ConsolePort**

Specifies the name or port number for selogrd - secmon communication. This token is necessary only if you plan to run both selogrcd and secmon on the same host.

If specified, selogrd - secmon communication is done using the specified port. Otherwise, they use the port that is specified in the *ServicePort* token, or they use RPC portmapper to allocate a port dynamically if that token is also empty. The service name must be a UDP port because the log routing daemon uses UDP for communication.

If the token value is a number, daemons bind to the specified port number.

If the token value is a service name (string), /etc/services or NIS services maps are used to resolve the port number.

**Default:** Token not set (value taken from *ServicePort* token)

- **DataFile**

Specifies the name of the file to which the target routing information is written before being delivered to the specified targets.

**Default:** *ACInstallDir/log/logroute.dat*

- **Interval**

Specifies the time interval, in seconds, between each poll of the log file by the selogrd daemon.

**Default:** 5

- **KeyFile**

Specifies the name of the file that holds the audit encryption key.

This key is used when selogrd performs Privileged Access Manager audit encryption. The location of the key file is the *ACInstallDir/lib* directory.

The key can be changed by sechkey utility.

**Default:** adcipher.bin

- **Mailer**

Specifies the name of the program that selogrd uses to send email.

**NOTE**

This option is relevant only if you set the UseSmtplib token to yes.

**Default:** /bin/mail

- **MaxErrorSending**

Specifies whether selogrd sends error messages to syslog regarding difficulties sending audit records to selogrcd, only after the number of difficulties surpasses this token value.

The default value is 1: every time selogrd has difficulties sending to selogrcd, it sends a message to syslog.

**Default:** 1

- **MaxSeqNoSleep**

Specifies the maximum number of log records scanned by selogrd without sleeping.

**Default:** 50

- **RefuseUnencrypted**

Specifies whether selogrcd accepts unencrypted audit. It is used with the UseEncryption token and is redundant if UseEncryption is set to **no**. It is therefore applicable only if selogrcd uses encryption.

Valid values are:

**yes**- refuse unencrypted audit

**no**- accept both encrypted and unencrypted audit

**Default:** no

- **ReopenInterval**

Specifies the time (seconds) that selogrd waits to reopen the audit file.

**Default:** 20

- **RouteFile**

Specifies the name of the log routing configuration file. The file is used unless overridden by the -config option of the selogrd utility.

**Default:** *ACInstallDir/log/selogrd.cfg*

- **SavePeriod**

Specifies the time interval, in minutes, between saving information about the number of records sent.

**Default:** 2

- **sendmail\_header\_format**

Determines the user name format in the header of mail that selogrd sends.

**Note:** Change this token value only if selogrd cannot send mail. (That is, if you see an error 4634 from selogrd in your syslog.)

Valid values include the following:

**1**-The user name format is *SmtplibMailFrom*

For example: eTrust\_Admin

**2**-The user name format is *SmtplibMailFrom@hostname* (where *hostname* is the host which selogrd runs on).

For example: eTrust\_Admin@machine

**Default:** 1

- **ServicePort**

Specifies the name or port number that the log routing facility must use.

If specified, selogrd and selogrcd use the specified port. Otherwise selogrd and selogrcd use the RPC portmapper to allocate a port dynamically.

If the token has a value, selogrd and selogrcd use the specified port. Otherwise, selogrd and selogrcd dynamically allocate a UDP port using the RPC portmapper. The service name must be a UDP port because the log routing daemon uses UDP for communication.

If the token value is a number, daemons bind to the specified port number.

If the token value is a service name (string), /etc/services or NIS services maps are used to resolve the port number.

Only a UDP port/service can be specified.

**Default:** Token not set (selogrd and selogrcd use RPC portmapper to allocate a port dynamically).

- **SmtplibMailFrom**

Specifies the identity of the sender for UseSmtplibMail.

**Default:** AccessControl\_Admin

- **SmtplibMailServer**

Specifies the address of the remote mail server host. Use this token if UseSmtplibMail is set to yes. If you do not specify this token, the local computer is assumed to be the mail server.

**Default:** (blank - local server)

- **SmtplibTimeLimit**

Specifies the time limit, in seconds, that selogrd waits for the mail server to answer before timing out.

**Default:** 100

- **tec\_conf\_file**

Specifies the name of the configuration file that is used for the TEC event creation by the selogrd daemon.

**Default:** /etc/tecad\_seos.conf

- **UseEncryption**

Determines the type of encryption.

Valid values include the following:

**native**-selogrd uses Privileged Access Manager standard encryption.

**eTrust**-selogrd uses audit log encryption through adcipher.

**no**-selogrd does not use encryption.

**Default:** no

- **UseSmtplib**

Determines whether to use the direct mail feature or the previous Mailer.

**Default:** yes

## seos

In the [seos] section, the tokens determine the global settings that are used by Privileged Access Manager.

- **admin\_data**

Specifies the directory where the Privileged Access Manager Security Administrator rulers and other configuration files are stored.

**Default:** *ACInstallDir/data*

- **auth\_login**

Determines the login authority method. Valid values are:

**native** - login checks the user password against the UNIX passwd or shadow file.

**eTrust** - when the user does not exist in the Native environment, checks the user password against the Privileged Access Manager database.

**PAM** - when the user does not exist in the Native environment, checks the login through the PAM module. This is only supported on machines where PAM is supported. PAM is used to validate the user for users such as LDAP-defined users.

**Default:** native

- **auth\_module\_names**

Defines the language client module that is allowed to authenticate outside of native authentication. The client inside the lca API calls set this token before the authentication. Changing this token can affect other clients authenticating in non-native mode.

No default.

- **fast\_create\_db**

Specifies whether the PMDB uses the fast database copy device.

Valid values are:

**no** - Use the old device.

**yes** - Use the fast database copy device.

**Default:** yes

- **full\_year**

Specifies the format for displaying the year using four digits or last two digits.

For example, setting the token to yes displays 2000 instead of 00.

The following values are valid:

**yes**-four digits

**no**-two digits

This token influences the output that is produced by secons -tv, dbmgr -d, and the seaudit utility.

**Default:** yes (four-digit)

- **ldap\_base**

Defines the distinguished name of the search base for user data queries in the LDAP Directory Information Tree (DIT) by Privileged Access Manager LDAP-enabled utilities (such as sebuildla).

For example, use the following format, replacing inputs with your own:

```
o=organization_name,c=country_name
```

**Default:** Token not set

**WARNING**

To set up `sebuildla` and the required LDAP configuration settings, be familiar with LDAP and be able to execute the `ldapsearch` command. We recommend that you read the man pages for `ldap(1)`, `ldapsearch(1)`, and the information about setting up in the documentation for your LDAP client.

- **ldap\_hostname**

Defines a space-separated list of the host names where the LDAP servers are running for Privileged Access Manager LDAP-enabled utilities.

**Default:** Token not set (localhost).

- **ldap\_certdb\_path**

Defines the directory where the Netscape-style certificate database is located.

This token is required for `sebuildla` on platforms that use the Netscape LDAP SDK API for LDAP over SSL (Solaris).

For `sebuildla` to work, a certificate database must contain a valid certificate for the LDAP server.

**NOTE**

`sebuildla` uses LDAP over SSL with server authentication (that is, no client authentication). Consult your PKI toolkit documentation for details on setting up secure services.

**Default:** `/.netscape`

- **ldap\_keydb**

Defines the name of the key database file.

**NOTE**

This setting is for AIX only as an AIX key database can have an arbitrary name. In contrast, Netscape security databases have names like `certX.db` and `keyY.db` depending on the implementation version, and so only the `ldap_certdb_path` is required for finding them.

**Default:** Token not set

- **ldap\_method**

Specifies the bind method that Privileged Access Manager uses for LDAP-enabled utilities to access the LDAP service. By default, `sebuildla` uses *simple* authentication with all security mechanisms. In simple authentication, `ldap_userdn` and the corresponding credential are passed to the LDAP server. `sebuildla` stores user credentials in encrypted form in `ldapcred.dat` at `ACInstallDir/etc`. These two parameters approximate the account and password combination that the LDAP server requires.

**NOTE**

For SASL or TLSv.1/SSL, consult your LDAP server documentation. For a particular `ldap_method` setting to take effect, the corresponding mechanism must be supported and configured in the native LDAP client that is deployed on the computer where `sebuildla` is executed. That is, with TLS/SSL operations, valid certificates should be installed on the server and client side.

Valid values are:

**0-** Standard LDAP

**1-**SASL (RFC 2222)

**2-**LDAPS (LDAP over SSL - server authentication only.)

**NOTE**

The method that you use determines how you set up the `ldap_userdn` token and its corresponding credential (through `seldapcred` utility).

**Default:** 0

- **ldap\_port**

Defines the LDAP server port for Privileged Access Manager LDAP-enabled utilities. Change this token if your LDAP server is not using the standard LDAP port (389).

**Default:** Token not set (389).

- **ldap\_query\_size**

Defines the maximum number of LDAP entries sebuildla retrieves in each batch query.

Use this token when you do not want to change the LDAP server-side size limit parameter. Typically, sebuildla attempts to retrieve all data in one instance. If there are numerous user entries, the amount of data might exceed the size limit of the server and might cause the LDAP operation to fail. If you set `ldap_query_size`, sebuildla need not retrieve all entries for the operation to succeed. If the total number of user entries is greater than either the `ldap_query_size` or the server-side size limit, the number of entries that are retrieved corresponds with the lower number of these two settings.

**WARNING**

Enabling batch queries can affect sebuildla performance. Consider using this setting only where the LDAP environment has numerous user data (thousands of entries) in the DIT (Directory Information Tree).

**NOTE**

For information about server-side LDAP controls, for example, the OpenLDAP server (slapd) `sizelimit` parameter, consult your LDAP server documentation. **Default:** Token not set (empty)

- **ldap\_timeout**

Defines the maximum amount of time (in seconds) that Privileged Access Manager LDAP-enabled utilities wait when binding to the LDAP service and obtaining LDAP search results, before terminating the connection. The time that it takes to retrieve information from the LDAP service depends on how fast the LDAP service is, and how much user data is stored in the DIT. Use this token to account for these aspects.

**NOTE**

You might also need to adjust server-side LDAP controls to avoid truncated search results. For example, for the OpenLDAP server (slapd) adjust the `sizelimit` parameter. Consult your LDAP server documentation for more information.

**Default:** Token not set (15 seconds)

- **ldap\_uid\_attr**

Defines the name of the attribute that contains the user name in the LDAP DIT. RFC 2307 (An Approach for Using LDAP as a Network Information Service) prescribes *uid* as this attribute, which is the default value for this token. Change this token to let Privileged Access Manager LDAP-enabled utilities operate against LDAP DITs with nonstandard schemas.

**Default:** Token not set (uid).

- **ldap\_uidNumber\_attr**

Defines the name of the attribute that contains the UID number in the LDAP DIT. RFC 2307 prescribes *uidNumber* as this attribute, which is the default value for this token. Change this token to let Privileged Access Manager LDAP-enabled utilities operate against LDAP DITs with nonstandard schemas.

**Default:** Token not set (uidNumber).

- **ldap\_user\_class**

Defines the name of the object class that contains the user data in the LDAP DIT. RFC 2307 prescribes *posixAccount* as this object class, which is the default value for this token. Change this token to let Privileged Access Manager LDAP-enabled utilities operate against LDAP DITs with nonstandard schemas.

**Default:** Token not set (posixAccount).

- **ldap\_userdn**

Defines the distinguished name (DN) of the LDAP user that Privileged Access Manager LDAP-enabled utilities use for retrieving user data from the LDAP DIT. Based on RFC 2307, Privileged Access Manager expects to find the user data in the *uid* and *uidNumber* attributes of the *ou=People* level in the DIT. For security reasons, we recommend that this user (`ldap_userdn`) is given access to this data only.

If anonymous access to the DIT is permitted, you can keep this token empty. Otherwise, you set this token and run the `seldapcred` utility for Privileged Access Manager LDAP-enabled utilities to authenticate to the LDAP service. Only do this once, as `seldapcred` stores your encrypted credential in a file for reuse.

For example, set this token as follows:

```
ldap_userdn = uid=user1,ou=People,dc=myCompany,dc=com
```

**Default:** Token not set

- **ldap\_userinfo\_ladb**

Specifies whether to retrieve user information from the LDAP Directory Information Tree (DIT).

**Limits:** yes, no

**Default:** no

- **ldap\_verbose**

Specifies whether to enable detailed account of LDAP operations that are involved in sebuildla getting user data.

Use this setting when you set up LDAP data retrieval in sebuildla or when troubleshooting.

Valid values are **0**-disabled; a non-zero integer-enabled.

**Default:** 0

- **locale**

Determines the language for the Privileged Access Manager daemons and utilities. Privileged Access Manager can function in several languages.

Supported languages include: C, Japanese, Chinese-s, Chinese-t

For the complete list of languages, see `/etc/ca/localeX/calocmap.txt`; on Linux, see `/opt/CA/SharedComponents/cawin/locale/`.

**Default:** C

- **pam\_enabled**

Valid on SOLARIS, HP-UX, and LINUX only.

Specifies whether the local host enables use of PAM for authentication and password changes in the LDAP database.

To do that, it checks whether the PAM library can be dynamically loaded (the library must exist on your system).

Valid values are: 'no', 'yes'.

**Default:** yes

- **parent\_pmd**

Defines a comma-separated list of policy model databases (PMDBs) from which this computer accepts updates. The local Privileged Access Manager database rejects updates from any PMDB that is not specified in this list.

You can also specify a file path that contains a line-separated list of PMDBs.

Set this token to `"_NO_MASTER_"` for the local Privileged Access Manager database to accept updates from any PMDB.

If you do not set this token, the local Privileged Access Manager database does not accept updates from any PMDB.

Each PMDB is specified in the following format: `pmd_name@hostname`

For example:

```
parent_pmd = pmd1@host1,pmd2@host1,pmd3@host2
```

```
parent_pmd = /opt/CA/PAMSC/parent_pmdbs_file
```

**Default:** Token is not set (database does not accept updates from any PMDB).

**Note:** sepass does not support multiple destinations on the parent\_pmd token.

- **passwd\_pmd**

Specifies the PMDB to which sepass sends password updates.

If you do not set this token, it inherits the value of the parent\_pmd token.

The format is `pmd_name@hostname`.

The parent\_pmd and passwd\_pmd tokens can have the same value. If the values in the parent\_pmd and passwd\_pmd tokens are not the same, the passwd\_pmd database sends its updates to the parent\_pmd database for distribution.

Therefore, the parent\_pmd database must be a child (subscriber) of the passwd\_pmd database.

No default.

**Note:** sepass does not support multiple destinations on the passwd\_pmd token.

- **ReverseIpLookup**

Controls the way seagent identifies the connecting client.

The following values are valid:

**yes**-seagent looks up the IP address of the socket of the open client.

**no**-seagent uses the host name as received from the client; seagent does not resolve any host names. (The same effect can be achieved by disabling class `TERMINAL`.)

**Default:** yes

- **secondary\_pmd**

Specifies the PMDB used as the secondary target for password replacement for users who are not defined in the primary target (passwd\_pmd).

The format is *pmd\_name@hostname*.

No default.

- **SEOSPATH**

Specifies the directory in which Privileged Access Manager is installed.

You can install Privileged Access Manager in any directory, *if* it is not *on* an NFS-mounted file system.

**Default:** *ACInstallDir*

- **SyncUnixFilePerms**

Specifies whether Privileged Access Manager synchronizes its ACL permissions with the ACL and other permissions of the native UNIX system, if they exist.

The following values are valid:

**no**-Do not synchronize the UNIX file permissions with Privileged Access Manager ACLs.

**warn**-Do not synchronize ACL permissions, but issue a warning if the permissions in Privileged Access Manager and UNIX conflict.

**traditional**-Change rwx permissions for the group and the owner according to Privileged Access Manager ACLs, issue a warning in all other cases.

**acl**-Change native file-system ACLs according to Privileged Access Manager ACLs (on platforms that support ACLs).

**force**-Functions the same as traditional or acl (on platforms that support ACLs), but also forces mapping defaccess to "other" permissions.

**Note:** On HP-UX and Sun Solaris 2.5 (and above), support is provided for the file system ACLs. On other platforms and operating system versions, only traditional permissions mode of a file are supported.

**Default:** no

- **TRUEPATH**

Specifies the directory where Privileged Access Manager is physically located. The Privileged Access Manager directory may be a symbolic link to another physical location. This token points to the actual physical location where Privileged Access Manager is installed.

**Default:** *ACInstallDir*

- **use\_rpc\_protocol**

Determines whether the RPC portmapper is required. The presence of the RPC portmapper is required if you want to use the old (1.43) Privileged Access Manager protocol. The old protocol is required to support NIS+ password changes.

This token replaces the old\_protocol token.

The following values are valid:

**yes**-Use the RPC portmapper to assign the port.

**no**-Use the port that is specified by the ServicePort token.

**Default:** no

## SEOS\_syscall

In the [SEOS\_syscall] section, SEOS\_syscall kernel module uses the following tokens.

- **bypass\_NFS**

Determines whether to bypass NFS files from SEOS events.

Valid values:

**0**-Do not by pass NFS files

**1**-Bypass NFS files

**Default:** 0

- **bypass\_realpath**

Specifies whether to bypass the real file paths resolution for authorization.

If you enable this setting (1), Privileged Access Manager does not resolve file paths for authorization. This accelerates file events handling. However, generic rules are not enforced for file accesses that are made using links.

**Example:** A deny access rule for /realpath/files/\* is not considered if this setting is enabled and a user accesses a file in this directory from a link. Create a generic rule for the link too (/alternatepath/\*).

**Default:** 0 (disabled)

- **cache\_enabled**

Determines whether to use caching for full path resolution to determine access permissions for files.

Valid values:

**0**-No caching

**1**-Use caching

**Default:** 0

- **cache\_rate**

Determines the cache rate that used when the cache is enabled for full path resolution.

Bigger values mean better caching.

**Default:** 10000

- **cache\_realpath**

Specifies whether to cache the resolved full path.

**Values:** 0 (no caching), 1 (use caching)

**Default:** 0

- **call\_tripAccept\_from\_seload**

Determines whether to call tripAccept from the seload command after Privileged Access Manager starts. If tripAccept is called, defines a list of comma-separated TCP/IP ports that tripAccept should connect to, and wake up the listeners of the ports.

Valid values:

**1 to 64000** - Any TCP/IP port number

**0**-Do not call tripAccept from seload.

**Limits:** 0-64000

**Default:** 0

- **cdserver\_conn\_res**

Determines whether to treat T\_CONN\_RES streams messages as high priority messages in the fiwput routine on UnixWare.

Valid values:

**1**-handle T\_CONN\_RES streams messages as high priority messages in the fiwput routine.

**0**-handle T\_CONN\_RES streams messages as low priority messages in the fiwput routine.

**Default:** 0 (1 on UnixWare)

- **debug\_protect**

Determines whether to allow debugging of any program while Privileged Access Manager is running.

Valid values:

**0**-Debugging allowed

**1**-Debugging not allowed

**Default:** 1

- **DESCENDENT\_dependent**

Determines whether a descendent of a SEOS daemon can register a SEOS service.

Valid values:

**0**-Anyone can register a SEOS service

**1**-Only a descendant can register a SEOS service

**Default:** 0

- **dtrace\_coexistence**

Defines how Privileged Access Manager co-exists with dtrace. If dtrace is installed and set to monitor syscalls, it loads the systrace kernel module. This module interacts with Privileged Access Manager with undefined results and can cause system panic or syscall interception problems.

**Default:** 0 (dtrace is prevented from loading)

Valid values:

**0**-Privileged Access Manager prevents dtrace from loading the systrace kernel module.

**1**-Dtrace loads the Systrace kernel module. In this case you must ensure that your system loads the modules and Privileged Access Manager in the following order:

1. a. Load and start Privileged Access Manager (seload)
- b. Load systrace (modprobe systrace)
- c. dtrace system calls
- d. Unload systrace (rmmod systrace)
- e. Stop Privileged Access Manager (secons -sk)
- f. Unload Privileged Access Manager (SEOS\_load -u)

**WARNING**

Loading systrace and Privileged Access Manager in a different order can result in system panic or syscall interception problems.

- **exec\_read\_enabled**

Specifies whether the Privileged Access Manager kernel identifies script execution.

Valid values:

**0**-Privileged Access Manager kernel does not identify script execution.

**1**-Privileged Access Manager kernel identifies script execution.

**Default:** 0

- **file\_bypass**

Indicates whether Privileged Access Manager checks file access for files that are not defined in the database. By default Privileged Access Manager does not check files that are not defined in the database.

Valid values:

**-1**-Do not check all files

**0**-Check all files

**Default:** -1

- **file\_rdevice\_max**

Defines the maximum number of devices in the device protection table.

**Default:** 0-Privileged Access Manager does not protect system devices.

**Note:** We recommend that you specify a minimum of 20 system devices.

- **GAC\_root** Determines whether to use GAC caching for files when the user is root. By default GAC is not used when the user is root.

Valid values:

**0**-No caching for root user

**1**-Use caching for root

**Default:** 0

- **HPUX11\_SeOS\_Syscall\_number**

Determines the default syscall number to communicate with SEOS\_syscall on HP-UX.

Valid values include any unused syscall entry number in sysent.

**Default:** 254

- **kill\_signal\_mask**

Defines which signals to protect.

Valid values include a mask that ORs (includes) all the signals that we want SEOS events for.

**Default:** SIGKILL, SIGSTOP, or SIGTERM events

Actual value varies by platform:

- (HP-UX) 0x804100
- (Sun Solaris) 0x404100
- (IBM AIX and Digital DEC UNIX) 0x14100
- (Linux) 0x44100

- **LINUX\_SeOS\_Syscall\_number**

Determines the default syscall number to communicate with SEOS\_syscall on LINUX.

- **max\_generic\_file\_rules**

(Valid on AIX, HP, Linux, and Solaris only) Defines the maximum number of generic file rules allowed in the database.

**Note:** A large number may cause strange behaviors on different platforms. For assistance, contact CA Support at <http://ca.com/support>.

Valid values include any number greater than 511.

**Default:** 256

- **max\_regular\_file\_rules**

(Valid on AIX, HP, Linux, and Solaris only) Defines the maximum number of file rules allowed in the database.

**Note:** A large number may cause strange behaviors on different platforms. For assistance, contact CA Support at <http://ca.com/support>.

Valid values include any number greater than 4095.

**Default:** 4096

- **mount\_protect**

Determines whether to allow mount and unmount of directories used by Privileged Access Manager.

Valid values:

**0**-Allow mounting

**1**-Do not allow mounting

**Default:** 1

- **proc\_bypass**

Determines whether to check file access when a file belongs to a process file system (/proc).

Valid values:

**0**-Token is ignored

**1**-Bypass file access checks

**Default:** 1

- **SEOS\_network\_intercept\_type** (Valid on HP-UX 11.11, 11.23, 11.31, and Sun Solaris 8, 9, 10, 11)

Specifies the type of network interception to use.

**WARNING**

Configure SEOS\_use\_streams = yes. Do not modify the SEOS\_network\_intercept\_type token yourself. For assistance, contact Broadcom Support at <https://www.broadcom.com/support>.

Valid values:

**0**-TCP Hook

**1**-Streams

**2**-Network System Call

**Default:** 2

- **SEOS\_request\_timeout**  
Specifies the time to keep a request in the authorization queue.  
Valid values:  
**0** - Timeout is disabled  
**2 to 1000** - the timeout interval in seconds  
**Default:** 0  
**Note:** If the timeout is set to less than 2 seconds or more than 1000 seconds, Privileged Access Manager reverts to the default value (0). No timeout is applied.
- **SEOS\_streams\_attach**(Valid on HP-UX 11.11, 11.23, 11.31, and Sun Solaris 8, 9, 10, 11)  
Specifies whether Privileged Access Manager attaches the SEOS Streams to the open TCP streams during startup.If you change this setting, restart all daemons that already listen to the network for Privileged Access Manager to protect them.  
**Note:** To use SEOS\_streams\_attach, configure SEOS Streams as the network interception method.  
Valid values are yes and no.  
**Default:** yes
- **SEOS\_unload\_enabled**  
Determines whether the SEOS\_syscall kernel module can be unloaded.  
Valid values:  
**0**-Do not allow the unload  
**1**-Allow the unload  
**Default:** 1
- **SEOS\_use\_ioctl**  
Specifies the Privileged Access Manager kernel module communication method (ioctl or system call).You can use the ioctl communication method when all available system call numbers are in use by the operating system.  
  
**WARNING**  
Do not modify this token yourself. For assistance, contact Broadcom Support at <https://www.broadcom.com/support>.  
  
Valid Values:  
**0**-system call  
**1**-ioctl  
**Default:** 0
- **SEOS\_use\_streams**  
(Valid on HP-UX 11.11, 11.23, 11.31, and Sun Solaris 8, 9, 10, 11)  
Specifies whether to use streams subsystem for network interception.  
Valid values are yes and no.  
**Default:** no
- **silent\_admin**  
Defines the user IDs of the maintenance users. The activity of this user is permitted when security is down and silent\_deny is yes. To define the maintenance user, use the user numeric UNIX UID.  
**Default:** 0 (user ID of root)
- **silent\_deny**  
Determines whether to deny any event when security is down.  
Valid values:  
**yes**-Silent deny is enabled (maintenance mode)  
**no**-Silent deny is disabled  
**Default:** no
- **STAT\_intercept**  
Specifies whether to check file access when a STAT system call occurs.

Valid values:

**0**-Do not check file access

**1**-Check file access

If you specify 1 (check file access), Privileged Access Manager does not let users without read permissions perform operations that get information about a file. Such user attempts are recorded as "read" in the audit log. If you set this value to 0, any user without read access can get the file information.

**Default:** 0

- **STOP\_enabled**

Determines whether to use the STOP feature, which protects from stack overflow attacks.

Valid values:

**0**-Off

**1**-On

**Default:** 0

- **suid\_cache\_max**

Specifies the maximum number of entries in the setuid cache. The setuid cache is used for managing non-PAM ready login applications such as sftp.

**0**-The cache is disabled.

**Default:** 128

**Note:** Do not change this value unless directed by Broadcom staff. For assistance, contact Broadcom Support at <https://www.broadcom.com/support>.

- **synchronize\_fork**

Determines how fork synchronization is managed.

*Valid values on HP-UX platforms:*

**1**-Report forks from parent

**2**-Report forks from child

*Valid values on other platforms:*

**1**-Parent reports without synchronization

**2**-Parent reports with synchronization (not supported on Linux)

**Limits:** Any value lower than 1 is interpreted as 1. Any value greater than 1 is interpreted as 2.

**Default:** 1

**Note:** Do not modify this setting yourself because it may cause strange behaviors on different platforms. For assistance, contact Broadcom Support at <https://www.broadcom.com/support>.

- 

- **syscall\_monitor\_enabled**

Specifies whether Privileged Access Manager monitors processes that are executing Privileged Access Manager code. If you have this enabled (the default), you can use the secons -sc or secons -scl to view these processes.

Valid values:

**0**-inactive

**1**-active

**Default:** 1

- **threshold\_time**

Defines how long, in seconds, an intercepted system call can be blocked before it is considered risky. If a process is blocked for a period that is longer than this time, Privileged Access Manager reports that SEOS\_syscall module unload can fail.

**Note:** This value affects the unload readiness reports Privileged Access Manager provides. For more information, see the *Enterprise Administration Guide*.

**Default:** 60

- **trace\_enabled**

Determines whether to use the SEOS\_syscall circular trace buffer.

Valid values:

**0**-Do not use tracing

**1**-Use tracing

**Default:** 0

- **use\_tripAccept**

Determines whether to use the tripAccept utility when unloading SEOS\_syscall to wake up the blocked accept system calls. This avoids running SEOS\_syscall code after the module is unloaded.

Valid values are yes and no.

**Default:** yes

## seosd

In the [seosd] section, the tokens determine the behavior of the authorization daemon and the cache utility for performance improvement.

- **allow\_exec\_login** Recognizes the *exec login* shell script command as a login event.

**Values:** 0,1

**Default:** 0

- **autobypass\_level**

Specifies the level of automatic program bypass.

**Values:**

- disabled: auto-bypass is disabled
- info: Save information in the run-time table
- bypass: info + enable auto-bypass until next restart

**Default:** bypass

- **bypass\_filenames**

- Specifies a file that contains a list of file names to be exempted from seos events.

For example, `bypass_filenames = /opt/CA/PAMSC/bin/bypass_filenames`

**Default:** Token not set

- **bypass\_nfs\_port**

Specifies whether the port used by nfs (port 2049) are bypassed for CONNECT. The bypass exists to let NFS function correctly.

If you change the value of this token to *no*, there will be no bypass for this port. Make sure that you then provide the required Privileged Access Manager rules to replace this bypass. Following is an example of such rules (you *cannot* use them as is):

```
nr hostnet all mask (0.0.0.0) match(0.0.0.0)
```

```
nr TCP 2049 owner(nobody) defaccess(none)
```

```
authorize TCP 2049 hostnet(all) access(w) uid(root)
```

```
nr TCP nfsd owner(nobody) defaccess(none)
```

```
authorize TCP nfsd hostnet(all) access(w) uid(root)
```

### NOTE

If you set the value of this token to *no* but do not provide the correct Privileged Access Manager rules, NFS stops working.

**Default:** yes

- **bypass\_outgoing\_TCPIP**

Defines a comma-separated list of ports for which seos\_syscall will not pass outgoing connection events to seosd.

**Default:** Token not set

- **bypass\_suid\_for\_login**

Specifies the path of the login program for which the dummy SUID system calls should be ignored.

This is used in case of some login programs, such as samba, which generate a large number of dummy SUID system calls. These system calls may interfere with the correct recognition of the logging in user.

**Default:** none

- **bypass\_suid\_program**

Allows multiple su commands. On some platforms, the system's su binary works in a nonstandard way: When an su command to a non-root user is requested, it executes su to root prior to executing su to the requested user.

If Privileged Access Manager surrogate protection is set for the root user, it may prevent the successful execution of an su to non-root users as well.

To use the surrogate protection for the root user on such platforms and still to be able to su to non-root users without interruption, set the bypass\_suid\_program token to contain the real path for the system's su binary.

**Default:** none

- **bypass\_system\_files**

Determines whether the Privileged Access Manager authorization engine should bypass read access for the /etc/passwd and /etc/group system files.

Valid values are:

**yes**-bypasses read access to system files.

**no**-does not bypass read access to system files.

**Default:** yes

- **bypass\_TCPIP**

Allows you to add one or more ports separated by commas for which seos\_syscall will not pass events to seosd.

The syntax is bypass\_TCPIP=*port1[,port2,portx]*

**Default:** Token not set

- **bypass\_whois** Defines utilities that the Privileged Access Manager bypasses.

**Values:** Utilities in *ACInstallDir/PAMSC/bin* **Default:** none

- **bypass\_xdm\_ports**

Specifies whether the ports used by xdm (ports 6000-6010) are bypassed for CONNECT. The bypass exists to let xdm function correctly.

If you change the value of this token to *no*, there will be no bypass for these ports. Make sure that you then provide the required Privileged Access Manager rules to replace this bypass. Following is an example of such rules (you *cannot* use them as is):

```
nr hostnet all mask (0.0.0.0) match(0.0.0.0)

nr TCP X-Win owner(nobody) defaccess(none)

authorize TCP X_Win hostnet(all) access(r)

authorize TCP X_Win hostnet(all) access(w) uid(root)

authorize TCP X_Win hostnet(all) access(w) gid(mygroup)

nr TCP 6000 owner(nobody) defaccess(none)

authorize TCP 6000 hostnet(all) access(r)
```

```
authorize TCP 6000 hostnet(all) access(w) uid(root)
```

```
authorize TCP 6000 hostnet(all) access(w) gid(mygroup)
```

### NOTE

If you set the value of this token to *no* but do not provide the correct Privileged Access Manager rules, xdm stops working. If the value of this token to *yes* and an outgoing connection is made via ports 6000-6010, the class name in the corresponding audit record is **TERMINAL**.

**Default:** yes

- **cron\_program**

Improves the check for cron login in seosd.

Set the cron\_program token to contain the real path for the system's cron binary.

**Default:** none

- **core\_if\_watchdog\_signal**

Specifies whether to create a core file when the watchdog process sends signal.

**Values:** yes, no

**Default:** no

- **dbdir**

Specifies the location of the Privileged Access Manager database.

**Default:** *ACInstallDir/seosdb*

- **debug\_backup\_dir**

Specifies the location of the backup debug files.

**Default:** Privileged Access Manager product log directory

- **debug\_backup\_num**

Defines the number of backup debug files to save.

**Values:** A positive number

**Default:** 2

- **debug\_file** Specifies the location of the seagent debug messages file.

**Default:** *ACInstallDir/log/seagent\_debug*

- **debug\_level**

Defines the lowest level of debug messages to save. The level of the value set and all levels above are saved.

**Values:** Disabled (no messages are saved), Critical, Very High, High, Normal., Low

**Default:** Critical

- **debug\_size**

Defines the maximum size in MBs of the debug messages file.

**Values:** A positive number

**Default:** 256

- **debug\_zone**

Defines which seosd submodules (zones) to produce debug messages for.

**Values:** -1 (All zones), 1 (SKI), 2 (QP), 4 (RESOLV), 8 (SEOSD), 10 (AUXFALLBACK), 20 (AUTH)

**Default:** -1

- **device\_file**

Specifies whether to scan all devices in /dev.

When the value of this token is set to Yes and the tty is not found in the standard list, Privileged Access Manager scans all the devices located in /dev.

(qplib resolves the tty name from the standard devices.)

### NOTE

You can add devices to the list of the tty names.

**Default:** no

- **dns\_server**

Specifies the DNS server name used to change host resolving from the default server to another server. This token is usually used when the DNS caching option is enabled.

**Default:** none

- **domain\_names**

Specifies a list of domain names that seosd appends to short host names it receives for authorization purposes in order to create a fully qualified name, so that these names can be authorized in the relevant HOST, CONNECT, or TERMINAL classes.

To identify a full name, seosd tries to append domain names in the domain\_names list to the short name for authorization purposes.

seosd first looks for a relevant rule in its database, using the short name only. If it does not find a record that matches the short name, it appends each domain name specified in the domain\_names token, one by one, until it finds a match.

For example, suppose you assign domain\_names the following list:

domain\_names= market.com, journey.com, total.com

Here is how seosd handles the matching process when a request from a subscriber called *acme*-which was not defined as a rule in the database-comes in:

acme (not found)acme.market.com (not found)acme.journey.com (not found)acme.total.com (found)

seosd uses the first record that matches (acme.total.com in this example) for authorization purposes.

**Default:** As defined in /etc/resolv.conf

- **EnablePolicyCache**

Determines whether a run-time table should be used to store the database values required for authorization. The run-time table is loaded to the memory when seosd starts. This avoids connecting to the database and thus reduces the authorization time.

Valid values are yes and no.

**Default:** no

- **FileCache\_auths**

If caching is enabled, specifies the number of records in the authorization pool. The maximum number of authorization records that can be cached is 800.

**Default:** 80

- **FileCache\_CleanInt**

Specifies how often to erase the file cache (in minutes).

**Default:** 60

- **FileCache\_files**

If caching is enabled, specifies the number of records in the file pool. The maximum number of file records that can be cached is 200.

**Default:** 20

- **FileCache\_InitPrio**

Specifies the initial priority value of new records in the cache table.

**Default:** 10

- **FileCache\_PriorInt**

If caching is enabled, specifies the frequency of recalculating priorities in the cache table. Each time a new record is saved counts as one.

**Default:** 1

- **FileCache\_users**

If caching is enabled, specifies the number of records in the user pool. The maximum number of user records that can be cached is 500.

**Default:** 50

- **ftp\_data\_port** Specifies the port number that ftp service uses to transfer data.

**Note:** Verify that the ftp\_data\_port number is identical in both seos.ini and /etc/services files. **Default:** 20

- **ftp\_port** Specifies the port number that ftp service uses to communicate.

**Note:** Verify that the ftp\_port number is identical in both seos.ini and /etc/services files. **Default:** 21

- **get\_login\_terminal**  
Determines whether seosd attempts to find the peer address of the login program in an alternative way. This is useful for connections such as ssh.  
Valid values include yes and no.  
**Default:** yes
- **grace\_admin**  
Determines the number of the grace logins that are set when an administrator changes users' passwords.  
**Default:** Token not set (1)
- **GroupidResolution**  
Determines how Privileged Access Manager resolves GID numbers to group names.  
Valid values include the following:  
**system**-Privileged Access Manager uses a system call to translate gid numbers. This value can be used for stand-alone, DNS client, and DNS server stations. (See also the resolve\_timeout token in this table.)  
**cache**-gid numbers and group names are cached in seosd. This is the fastest and easiest way to do translations but the cache cannot be updated during runtime.  
**ladb**-Privileged Access Manager uses a lookaside database to translate gid numbers. The sebuildla utility must be run to recreate the lookaside database each time an update to the relevant transaction table takes place.  
For NIS, and NIS+ servers, you can use either cache or ladb.  
For Sun Solaris 2.5 and above and HP-UX 11.x, you can use either cache or ladb.  
For all stations, the value ladb is preferred.  
**Default:** Token not set (system)
- **HostResolution**  
Determines how Privileged Access Manager resolves IP addresses to host names.  
Valid values include the following:  
**system**-Privileged Access Manager uses a system call to translate IP addresses. This value can be used for stand-alone, NIS/NIS+ client, and DNS client stations. (See also the resolve\_timeout token in this table.)  
**cache**-Host names and their IP addresses are cached in seosd. This is the fastest and easiest way to do translations but the cache cannot be updated during runtime.  
**ladb**-Privileged Access Manager uses a lookaside database to translate IP addresses. The sebuildla utility must be run to recreate the lookaside database each time an update to the relevant transaction table takes place.  
For NIS, NIS+, and DNS servers, you can use either cache or ladb; the value ladb is preferred.  
**Default:** Token not set (system)
- **IsolatedDaemon**  
Determines whether seosd closes the file descriptors stdin, stdout, and stderr when they become a daemon.  
Valid values include the following:  
**yes**-seosd closes these file descriptors when they become a daemon.  
**no**-seosd does not close these file descriptors when they become a daemon.  
**Default:** no
- **kill\_ignore**  
Specifies whether seosd ignores (denies) the kill -9 command directed toward any one of the three main Privileged Access Manager daemons. Valid values include the following:  
**yes**-Ignores the kill command. This is the default value.  
**no**-The kill command terminates seosd.  
**Default:** yes
- **login\_parent\_check**  
Specifies whether the parent process should continue (once a child process has logged in) with the login sequence or abandon the sequence and inherit the login from the child.  
Valid values are 0 and 1.  
If it is 0, the parent continues with the login sequence.  
If it is 1, the parent abandons the login sequence and inherits the login from the child.

**Default:** Token not set (0)

- **lookaside\_allowdupuid**

Determines whether sebuildla will register duplicate UIDs

Valid values:

**yes**-register duplicate UIDs

**no**-in case of duplicate UIDs, register only one UID

**NOTE**

Duplicate UIDs may cause inconstancy On UNIX OS

**Default:** no

- **lookaside\_path**

Specifies the directory where the lookaside database is located. Create this directory before running the sebuildla utility.

**Note:** The lookaside database files are built and updated using the sebuildla utility.

**Default:** *ACInstallDir/ladb*

- **max\_loggedin\_users**

Defines the maximum number of logged in users.

**Note:** This value determines the size of one of the internal memory tables. The larger the table, the more memory it consumes.

**Limits:** 4096-20480

**Default:** 8192

- **MultiLoginPgm**

Defines the name and full path of a program that performs multiple logins. It is used to detect the correct login sequence for these special login applications.

MultiLoginPgm is the login application name with the full path.

**Default:** none

- **network\_cache\_timeout**

Specifies the time interval, in minutes, between network cache-table cleanings, if network cache is used. Use this token to set time limits for the stored accepted incoming TCP requests.

**NOTE**

For more information about using the network cache, see the *Endpoint Administration Guide for UNIX*.

**Default:** 10

- **nfs\_devices**

Specifies the name and path of the file that contains the NFS major device numbers. Specify the full file path.

Privileged Access Manager uses this file if it fails to get the program using device and inode number and also fails to get it using its name. The file contains the NFS defaults for major device numbers for every platform. This may vary from system to system. To find the numbers for your system, use a small program with the UNIX getmajor() function. Then, edit the nfsdevs.init file (or the file you named with this token) to contain the numbers you find.

**NOTE**

Whenever you mount and remount the NFS system, you should update your nfsdevs.init file. You can also use the first four digits of the device only. These numbers remain unchanged, even when you unmount and remount the system.

**Default:** *ACInstallDir/etc/nfsdevs.init*

- **protect\_bin**

Specifies whether seosd protects the Privileged Access Manager binary files. Specify one of the following values:

**yes**-seosd protects the Privileged Access Manager binary files unless rules that allow such access are defined.

**NOTE**

Do not specify yes when the \_default access for your FILE records is none because, unless all /opt/CA/PAMSC/bin files have FILE records, inaccessibility of files could make Privileged Access Manager unusable.

**no-seosd** does not protect the Privileged Access Manager binary files.

**Default:** no

- **resolve\_rebind**

Specifies if seosd re-establishes the connection to the NIS server after a time-out failure.

We strongly recommend that you do not change the default value.

**Default:** yes

- **resolve\_timeout**

Specifies the maximum number of seconds seosd tries to resolve IP to address, user ID to user name, group ID to group name, or service port number to service name.

The value takes effect in two cases:

When seosd is using system resolution. (See the HostResolution, ServiceResolution, UseridResolution, and GroupidResolution tokens.)

When the under \_NIS\_server token is set to no.

If the specified time expires without a resolution, seosd assumes that no resolution exists for the specified IP, ID, or port.

If value is set to 0, there is no time out.

**Default:** 5

- **rt\_priority**

Determines whether seosd has real-time priority.

Valid values are yes and no

When this token is set to yes, seosd will have real-time priority.

**Default:** yes

- **ServiceResolution**

Determines how Privileged Access Manager translates TCP port numbers to service names.

Valid values include the following:

**system**-Privileged Access Manager uses a system call to translate TCP port numbers. This value can be used for stand-alone, NIS/NIS+ client, DNS client, and DNS server stations. (See also the resolve\_timeout token in this table.)

**cache**-Service names and their TCP port numbers are cached in seosd. This is the fastest and easiest way to do translations but the cache cannot be updated during runtime.

**ladb**-Privileged Access Manager uses a lookaside database to translate TCP port numbers. The sebuildla utility must be run to recreate the lookaside database each time an update to the relevant transaction table takes place.

For NIS, and NIS+ servers, use either cache or ladb.

**Default:** system

- **sim\_login\_timeout**

Defines the timeout (in minutes) before Privileged Access Manager removes unused simulated login user entries from the Accessor Element Entry table (ACEE).

Privileged Access Manager performs a simulated login to create ACEE entries when it needs access to information that can be found in the ACEE.

**Default:** 60

- **special\_check**

Specifies whether to enable file path checking on kernel module loading. When enabled, Privileged Access Manager checks that the kernel module to be loaded matches the filepath property of the KMODULE record (for non-Linux systems), or matches the signature of the KMODULE record (for Linux systems).

**Default:** no

- **terminal\_default\_ignore**

Determines whether the defaccess value of the \_default TERMINAL and of the specific TERMINAL records are considered when authorizing administrative access.

Valid values are yes and no.

**yes**-Administrative access ignores the defaccess value of the \_default and of any specific TERMINAL records. In this case, administrative access will require an explicit authorization rule for a relevant specific TERMINAL record.

**no-** Administrative access considers the defaccess value of all relevant TERMINAL records whether it is `_default` or specific.

**Default:** yes

- **terminal\_search\_order**

Specifies whether seosd tries to check a TERMINAL defined by name before trying it by its IP address.

Valid values are:

**name** - TERMINALs will be checked by name before IP address.

**ip** - TERMINALs will be checked by IP address before name.

**NOTE**

TERMINAL class supports generic rules defined by wildcards (IP address or host name pattern match). Generic rules are *always* checked after specific (full-name) rules. For example, if you set this to *ip*, seosd looks for a TERMINAL resource in the following order: complete IP address match, complete host name match, IP address pattern match, host name pattern match.

**Default:** name

- **trace\_backup** Specifies whether to back up the trace messages file when it reaches the configured file size limit.

**Values:** yes, no

When set to yes, the `trace_backup` token saves a backup of the trace file, and creates a trace file.

**Default:** yes

- **trace\_file\_backup** Specifies the location of the trace messages backup file.

**Default:** *ACInstallDir/log/seosd.trace.bak*

- **trace\_file**

Specifies the name of the file to which the trace messages are sent, if trace messages are requested.

**Default:** *ACInstallDir/log/seosd.trace*

- **trace\_file\_size** Defines the maximum size of the trace messages file.

**Default:** 512 MB

- **trace\_file\_type**

Determines whether the trace file is written in binary or text format.

Valid values include the following:

**binary**-The trace file should be written in binary format. This option reduces the space occupied by this file.

**text**-The trace file should be written in text format.

The daemon seosd checks the value of this token and compares it to the contents of the trace file. If the token value does not match the format of the trace file, seosd saves the trace file under its name and adds the extension `.backup`.

**Default:** text

- **trace\_filter**

Specifies the name and path of the file that contains the filter data that is used to filter the trace messages.

**Default:** *ACInstallDir/data/language/etc/trcfilter.init*

- **trace\_space\_saver**

Specifies the amount of free space, in MB, to be left in the file system. When the amount of free space is less than this number, Privileged Access Manager disables the trace.

**NOTE**

Trace is never automatically enabled, even if more space becomes available at a later time.

**Default:** 512

- **trace\_to**

Specifies the destination of trace messages.

Valid values include the following:

**file**-Privileged Access Manager sends the trace messages to the file specified by the `trace_file` token. To disable tracing, use the `secons -t` command. For more information, see the `trace_file` token in this table.

**file,stop**-Privileged Access Manager generates trace messages during daemon initialization. Once the daemon is initialized, trace messages generation stops.

**none**-Privileged Access Manager does not issue trace messages. This is the normal setting after you install and implement Privileged Access Manager.

**NOTE**

If the token is set to **file** or **file,stop**, the Privileged Access Manager trace can be toggled with the **seosd** command with the **-t** option.

**Default:** file, stop

- **update\_dev\_trusted\_pgm** Specifies whether **seosd** updates the trusted program device number when the trusted program starts.  
**Values:** yes, no  
**Default:** yes
- **UpdSurrogLogin**  
Specifies whether Privileged Access Manager updates the user's last access time on a surrogate login.  
Valid values are:  
**1** - Privileged Access Manager updates the user's last access time on a surrogate login.  
**0** - Privileged Access Manager does *not* update the user's last access time on a surrogate login
- **Undef\_ForPacI**  
Determines whether **seosd** checks an undefined user when there is an asterisk (\*) in the accessor's name in a PACL.  
Valid values include the following:  
**1**-**seosd** will not include undefined users with an asterisk in their PACL.  
**0**-**seosd** will include undefined users with an asterisk in their PACL.  
**Default:** 0
- **under\_NIS\_server**  
Determines whether **seosd** uses internal name resolution instead of system name resolution.  
Valid values include the following:  
**yes**-**seosd** stores in memory or in a lookaside database (see the **use\_lookaside** token) all user, group, host, and port information during startup.  
This is required for NIS, NIS+, and DNS server machines, and for the following operating systems: Sun Solaris 2.5 and above, HP-UX 11.x, IBM AIX 4.3.x, and IRIX 6.5.

**WARNING**

Turning this token off could hang the machine if it is an NIS server or one of the previously-mentioned operating systems.

**no-seosd** uses system name resolution and the **resolve\_timeout** token takes effect.

**NOTE**

This token is automatically assigned a value during installation.

This token remains for purposes of backward compatibility only. If you have a new Privileged Access Manager installation or an installation of version 2 or higher, use the tokens **HostResolution**, **ServiceResolution**, **UseridResolution**, and **GroupidResolution** instead.

**Default:** Assigned during installation

- **use\_lookaside**  
Determines whether **seosd** stores the user, group, host, and port information in a lookaside database or in memory.

**NOTE**

This token is used in conjunction with the **under\_NIS\_server** token and has no relevance unless the **under\_NIS\_server** token is set to **yes**.

Valid values include the following:

**yes**-**seosd** uses the lookaside database for user, group, host, and service details. The lookaside database is built by the **sebuildla** utility and can be refreshed by it at any time.

The location of the lookaside database is set by the **lookaside\_path** token.

**no-seosd** caches all user, group, host, and service information during startup so that all translations can be done in memory. We recommend that seosd be restarted daily to refresh the cache.

This token remains for purposes of backward compatibility only. If you have a new Privileged Access Manager installation or an installation of version 2 or higher, use the tokens HostResolution, ServiceResolution, UseridResolution, and GroupidResolution instead.

**Default:** no

- **use\_mapped\_user\_name**

(Valid if both Privileged Access Manager and UNAB are installed) Specifies whether seosd uses the user enterprise name in audit records.

**Values:** yes, no

**Default:** no

- **use\_nfs\_devices**

Determines whether to use NFS devices. Valid values are yes or no.

**Default:** Yes

- **use\_standard\_functions**

Determines whether sebuildla in an NIS environment will retrieve users by calling the standard system function getpwent or by parsing the output of ypcat passwd and cat /etc/passwd commands.

Valid values are:

**yes**-use the standard system function getpwent

**no**-use parsing of the output of ypcat passwd and cat /etc/passwd commands.

**Default:** yes

- **use\_trusted\_script**

Specifies whether seosd will use the trusted script mechanism.

When the trusted script mechanism is used, programs called from within a shell script retain the name of the shell script in the internal Privileged Access Manager tables.

This means that if a script was used in a PACL, these programs will inherit that privilege. This also means that you cannot protect these programs via Privileged Access Manager.

A trusted script begins with #! on the first line.

When the trusted script mechanism is **not** used, these programs will be registered in the internal Privileged Access Manager tables under their own names.

**Default:** yes

- **use\_unab\_db**

(Valid if both Privileged Access Manager and UNAB are installed) Specifies whether seosd uses the UNAB database to resolve users and groups name if the current method is unable to do so. This token coincides with the tokens: use\_lookaside, UseridResolution, GroupidResolution.

**Values:** yes, no

**Default:** no

- **UseFileCache**

Specifies whether to use the cache tool for file records to improve performance.

**Default:** yes

- **UseNetworkCache**

Determines whether Privileged Access Manager caches accepted incoming TCP requests.

#### **NOTE**

For more information about using the network cache, see the *Endpoint Administration Guide for UNIX*.

Valid values are yes and no.

**Default:** no

- **UseridResolution**

Specifies how Privileged Access Manager translates UID numbers to user names.

Valid values include the following:

**system**-Privileged Access Manager uses a system call to translate uid numbers. This value can be used for stand-alone, NIS/NIS+ client, DNS client, and DNS server stations.

**cache**-User names and their uid numbers are cached in seosd. This is the fastest and easiest way to do translations but the cache cannot be updated during runtime.

**ladb**-Privileged Access Manager uses a lookaside database to translate uid numbers. The sebuildla utility must be run to recreate the lookaside database each time an update to the relevant transaction table takes place.

For NIS and NIS+ servers, Sun Solaris 2.5 and above, or HP-UX 11.x operating systems, you must use either cache or ladb.

**Default:** system

- **watchdog\_refresh**

Determines whether seosd refreshes the Watchdog to scan the privileged programs and secured files for each file handle.

Valid values include the following:

**yes**-seosd refreshes the Watchdog.

**no**-seosd does not refresh the Watchdog.

**Default:** no

## seosdb

In the [seosdb] section, the tokens manage database checking and rebuilding.

- **CheckAlways**

Determines whether the database should be checked for corruption at Privileged Access Manager initialization.

Valid values are yes and no.

**Default:** yes

- **CheckProgram**

Specifies the full path and parameters of an alternative command to be used instead of the internal code for checking the database. The command should return 0 if the database is valid or a nonzero number if it should be corrected.

**Default:** Token not set (do not run any program; same as using *dbmgr -u -fast*)

- **CreateNewClasses**

Specifies whether you can add new classes, created with the seclassadm utility, to a database.

Valid values are yes and no.

**Default:** yes

- **CreateNewProps**

Specifies whether to save data about the new properties in a file when the Privileged Access Manager sepropadm utility creates new database property.

Valid values are yes and no.

If it is yes, sepropadm saves the data about new properties in a file and when dbmgr -c utility later generates the new Privileged Access Manager database, dbmgr uses this file to add these properties to the database.

**Default:** yes

- **RebuildAlways**

Indicates whether the Privileged Access Manager database should always be rebuilt at Privileged Access Manager initialization.

Valid values are yes and no.

**Default:** no

- **RebuildProgram**

Specifies the full path and parameters of an alternative command to be used instead of the internal code for correcting the database.

**Default:** Token not set (do not run any program; same as using *dbmgr -u -build all*)

## seoswd (UNIX)

In the [seoswd] section, the tokens determine the behavior of the Watchdog.

**agent\_manager\_check\_enabled**

Specifies whether to protect the AgentManager daemon.

**Default:** no

**agent\_manager\_refresh\_interval**

Specifies the interval when the Watchdog checks if the Agent Manager daemon is running or not.

**Default:** 10 minutes

**BlockingInterval**

Specifies the interval, in seconds, that the Watchdog waits for a response from the main daemon. When elapsed, the Watchdog sends a signal to the main daemon.

**Default:** 60 seconds

**debug\_backup\_dir**

Defines the location of the backup debug messages files.

**Default:** Privileged Access Manager product log directory

**debug\_backup\_num**

Defines the number of debug backup files to save.

**Values:** A positive number

**Default:** 2

**debug\_file**

Defines the location of the file to which seoswd debug messages are written.

**Default:** /log/seoswd\_debug under the CM product directory

**debug\_level**

Defines the lowest level of debug messages to save. The level of the value set and all levels above are saved.

**Values:** Disabled (no messages are saved), Critical, Very High, High, Normal, Low

**Default:** Critical

**debug\_size**

Defines the maximum size in MBs of the debug messages file.

**Values:** A positive number

**Default:** 256

**IgnoreScanInterval**

Specifies whether to scan programs and files at specific intervals.

If the token value is no, then the Watchdog performs interval scanning. If the value is yes, then it does not scan at intervals.

**NOTE**

If you do not specify the scan times with the PgmTestTime or SecFileTestTime tokens, and this token is set to yes, then the Watchdog does not scan trusted programs or secured files respectively.

**Default:** no

**PgmRest**

Specifies the period, in seconds, after the last event and before checking programs again. The program rests to prevent system overload.

**Default:** 10 seconds

### **PgmTestInterval**

Specifies the time interval, in seconds, between the rescanning of trusted programs.

#### **NOTE**

If the value equals or is greater than one day (86400 seconds), then IgnoreScanInterval defaults to yes.

**Default:** 18000 seconds (five hours)

### **PgmTestStartTime**

Specifies the start time, in hh:mm format, of the first trusted program scan.

**Default:** If you do not set this token, the Watchdog performs the first scan shortly after startup.

### **PgmTestTime**

Specifies fixed scan times, in hh:mm format, for trusted programs. You can specify more than one scan time by separating them with spaces.

**Default:** If you do not specify scan times, and you set the IgnoreScanInterval token to yes, then the Watchdog does not scan trusted programs.

### **policyfetcher\_refresh\_interval**

Specifies the interval, in seconds, to verify that the policyfetcher daemon is running.

**Default:** 600

### **ProcHandlesCritical**

Specifies the process critical handle count. The Watchdog restarts the process when the critical handle count is exceeded.

**Valid Values:** 0 (disables token), 800 (minimum value)

**Default Value:** 1500

### **ProcHandlesHigh**

Specifies the high watermark for the process handle count. The Watchdog restarts the process during the restart hours when the defined handle count is exceeded.

**Valid Values:** 0 (disables token), 800 (minimum value)

#### **NOTE**

The token is disabled if the value is greater than ProcHandlesCritical value.

**Default Value:** 1000

### **ProcRestartHours**

Specifies the hours when the Watchdog restarts the high handle count process.

**Valid Values:** 0 - 23 (value in hours)

**Default Value:** 0 - 5

### **ProcVSizeCritical**

Specifies the process critical memory size in megabytes. The Watchdog restarts the process immediately when the specified limit is exceeded.

**Default Value:** 500 MB

### **ProcVSizeHigh**

Specifies the high watermark for process memory size. The Watchdog restarts during the restart hours.

**Default Value:** 300 (value in megabytes)

### **ProcVSizeInterval**

Specifies the interval, in seconds, between the process performance counters verification. The Watchdog checks the following processes:

SeOS Watchdog (seoswd)  
 SeOS Engine (seosd)  
 SeOS Agent (SeOSAgent)  
 SeOS Policy Model (sepmdd)  
 CA ControlMinder Agent Manager (AgentManager)  
 CA ControlMinder Report Agent (ReportAgent)  
 Default: 900 seconds

### **RefreshParams**

Specifies the time interval, in seconds, between successive reads by the Watchdog of the seos.ini tokens.

**Default:** 86400 (one day)

### **SecFileRest**

Specifies the period, in seconds, after the last event and before checking secured files again. To prevent system overload, the Watchdog rests.

#### **NOTE**

If you do not specify scan times, and you set the IgnoreScanInterval token to yes, then seoswd does not scan secured files.

**Default:** 10

### **SecFileTestInterval**

Specifies the time interval, in seconds, between the rescanning of secured files.

**Default:** 36000 (ten hours)

### **SecFileTestStartTime**

Specifies the start time, in hh:mm format, of the first scan of secured files.

**Default:** If no value is given, the Watchdog performs the first scan a short time after the Privileged Access Manager daemons start.

### **SecFileTestTime**

Specifies fixed scan times, in hh:mm format, for secured files. You can specify more than one scan time by separating them with spaces.

**Default:** N/A

### **SeosAYT**

(UNIX only) Specifies the time interval, in seconds, between the Watchdog checks of the daemon seosd ("Are you there?").

#### **WARNING**

Do not modify this token by yourself because an incorrect value can cause problems in the operation of Privileged Access Manager. For assistance, contact CA Support at <http://ca.com/support>.

**Default:** 60

**SignalMinInterval**

Specifies the interval, in seconds, between scans after a HUP signal triggers a one-time scan on demand, to protect the system against overload.

**NOTE**

Scan on demand is performed both on trusted programs and secured files.

**Default:** 60

**UnTrustMissing**

Determines whether the Watchdog attempts to untrust a program or file, even though it cannot find it. For example, if the file was deleted or the relevant NFS partition is not mounted.

**Values:** yes (Attempt to untrust the missing file), no (Do not attempt to untrust the missing file).

**Default:** yes

**unab\_check\_enabled**

Specifies whether to protect the authentication daemon.

**Values:** yes, no

**Default:** no

**unab\_refresh\_interval**

Specifies the interval, in seconds, to verify that the authentication daemon is running.

**Default:** 600

**UnTrustMissing**

Specifies whether the Watchdog must attempt to untrust a program or a file, even though it is not found. For example, a file is deleted or the relevant NFS partition is not mounted.

**Values:** yes (attempt to untrust the missing file), no (do not attempt to untrust the missing file)

**Default:** yes

**VerifyCtime**

Specifies whether Privileged Access Manager Watchdog checks the time of the last file status change of trusted programs and secure files.

**Valid Values:** yes, no.

**Default:** no

**WatchdogRequestsInterfaceName**

Specifies the pipe server name which communicates with the Watchdog.

**Default:** WatchdogRequests

**serevu**

In the [serevu] section, the tokens determine the attributes of the serevu utility.

- **config\_file**

Specifies the location of the serevu configuration file.

**Default:** *ACInstallDir/etc/serevu.cfg*

- **def\_diff\_time**

Specifies the time interval during which serevu scans the relevant system log for failed logins.

The value can be specified in seconds (that is, 300) or minutes (that is, 5m).

For example, if the token is set to 300, serevu searches for failed logins that occurred during the previous 300 seconds.

We recommend that this value be an even multiple of the value in the *def\_sleep\_time* token.

**Default:** 5m (5 minutes)

- **def\_disable\_time**

Specifies the time that a user account is disabled because of too many failed login attempts.

The value can be specified in seconds (that is, 300) or minutes (that is, 5m). You can also use the *FOREVER* value to disable user logins forever.

**WARNING**

Use the *FOREVER* value to disable user logins permanently.

**Default:** 6m (6 minutes)

- **def\_fail\_count**

Specifies the number of failed logins each user is entitled to, per period, in the token *def\_diff\_time*.

Users with at least this number of failed logins over the specified time period are disabled.

**NOTE**

We recommend that the number of failed logins always be the same as the value of allowed unsuccessful login attempts set on your system. For example, on Sun Solaris use the *RETRIES* token in the */etc/default/login* file to set the system value.

Default values are five for Solaris and three for HP-UX and AIX. See your operating system documentation for more details.

**Default:** 5

- **def\_sleep\_time**

Specifies the time between successive serevu checks.

The value can be specified in seconds (that is, 120) or minutes (that is, 2m).

**Default:** 2m (2 minutes)

- **save\_disable\_path**

Specifies the location of the disabled user accounts list so serevu can handle disabled users when it goes down.

**Default:** *ACInstallDir/log/serevu\_disable.users*

## sesu

In the [sesu] section, the tokens control logging on as a user other than yourself, without having to enter the password of the other user.

- **AlwaysTargetShell**

Determines whether to use the target shell (SysV style) or the invoker shell (BSD style). If yes, Privileged Access Manager uses the target user shell.

Valid values are yes and no.

**Default:** no

- **FilterEnv**

Specifies a list of environment variables that sesu does not pass to the shell when the target user is root. Separate variable names with spaces or tabs.

No default.

- **old\_sesu**

Determines whether the old or new sesu utility is used.

Valid values include the following:

**yes**-Use the old `sesu` utility as it was in previous versions.

**no**-The new `sesu` utility calls the native `su` program (as defined in the `SystemSu` token) to ensure consistency between `su` and `sesu`. If the `SystemSu` token is not valid, `sesu` reverts to the old mechanism.

**NOTE**

If this token is set to `no`, the tokens `Path`, `AlwaysTargetShell`, `sys_env_file`, and `FilterEnv` are ignored.

**Default:** yes

- **Path**

Specifies the value that `sesu` uses to set the `PATH` environment variable. If the token is not set, `sesu` does not set the `PATH` variable.

No default.

- **request\_target\_password**

Specifies whether to request the password of the target user when the `old_sesu` token is set to `no` and the user is executing `sesu` for a non-root user.

**Default:** yes

- **UseStrongAuthentication**

Specifies whether `sesu` requests the users to strongly authenticate themselves by providing a One Time Password.

**Note:** Define the authentication server in the `strong_auth_server` token of the `strong_auth` section.

**Valid values:** yes, no

**Default:** no

- **sys\_env\_file**

Specifies an ASCII file containing environment variable values for the `sesu` session. This token is relevant only when starting `sesu` with the `-` parameter (`sesu -`). The format for each line of the file is *variable = value*.

**Default:** None (except for IBM AIX where it is `/etc/environment`)

- **SystemSu**

Specifies the location of the `/bin/su` program. Update this token if you use a program in a location other than the default location. When `sesu` cannot find the authorization daemon, it executes the program specified in this token.

**NOTE**

On AIX, replace the system `su` binary with a symbolic link to the `sesu` wrapper instead of the `sesu` binary.

**Default:** `/bin/su`

- **UseInvokerPassword**

Determines whether `sesu` requires the invokers to specify their own passwords. If the token value is `no`, `sesu` does not require any password.

**Default:** no

## sesudo

In the `[sesudo]` section, the tokens determine the attributes of the `sesudo` utility.

- **echo\_command**

Determines whether `sesudo` displays the command before executing it. To echo the command, set the token value to `yes`.

**Default:** No

- **echo\_success**

Determines whether `sesudo` should print the successful message to the terminal when a successful `sesudo` command is run.

Valid values are `yes` and `no`.

**Default:** yes

## standalone1

In the [standalone] section, the tokens specify options for administrating using a standalone machine.

- **full\_login\_check**  
Specifies whether to consider administrating a site using standalone as a login.  
**Valid values:** 0 and 1. When this token is set to 1, it is considered as a login to the machine.  
**Default:** 0

## strong\_auth

In the [strong\_auth] section, the tokens define the strong authentication server.

**Note:** For more information about how to set up strong authentication, see the CA AuthMinder topic in the *Privileged Access Manager Integration* section.

- **strong\_auth\_server**  
Defines the URL of the strong authentication server used by the sepromote utility.  
**Example:** (for SSL connection) ssl://123.456.7.89:9742  
**Example:** (for non SSL connection) tcp://otp\_server.com:7222  
**Default:** none
- **organization\_name**  
Defines the organization where CA Strong Authentication searches users of strong authentication. Sepromote users can overwrite the value of this token from the command line.  
**Note:** For more information about this CA Strong Authentication parameter, see the Setting the Default Organization section in the *CA Strong Authentication Administration Guide*.  
**Default:** "defaultorg"

## tcp\_communication

In the [tcp\_communication] section, the token defines common TCP connection settings.

- **listening\_backlog**  
Defines the number of simultaneous new TCP connection requests that each listening block can establish.  
**Default:** 128

## The UNAB Conflicts File

The UNAB conflicts file is created after you attempt to migrate users and group to Active Directory. The file details the conflicts that were discovered by UNAB during the migration process. Review this file to resolve the conflicts that are reported in the file.

This file contains the following fields:

```
Solution Entity Type,Solution Entity Name,Solution Operation,Solution AD Mapped Name,Conflicts,UID,Home
Directory,GID,Member of,Members,GECOS
```

- **Solution Entity Type**  
Displays the type of solution entity to migrate.  
**Limits:** user, group
- **Solution Entity Name**  
Displays the name of the entity.
- **Solution Operation**  
Displays the entity migration status.

**Limits:** Keeplocal, Migrate, Map

- **Solution AD Mapped Name**  
Displays the Active Directory account name that the local account is mapped to.
- **Conflicts**  
Displays the conflicts that were found during the migration.
- **UID**  
Displays the user ID.
- **Home Directory**  
Displays the user home directory.
- **GID**  
Displays the group ID.
- **Member Of**  
Displays the groups that the user is a member of.
- **Members**  
Displays a list of users that are members in the group.
- **GECOS**  
Displays GECOS information.

## The uxauth.ini File

### Valid on UNIX

The uxauth.ini configuration file contains various tokens that control the functionality of UNAB. The UNAB configuration file is divided into sections that relate to different sets of tokens that control UNAB functionality:

Section	Description
ad	Contains Active Directory tokens with the parameters that you entered during installation
agent	Contains tokens that control the various UNAB parameters
global	Contains tokens that control UNAB general settings
libdefaults	Contains tokens that control Kerberos configuration settings
logmgr	Contains tokens that the UNAB logging utility uses
map	Contains tokens that specify Active Directory attribute names
message	Contains tokens that UNAB uses to define the message file
migrate	Contains tokens that UNAB uses during the migration process
nss_cache_update_post_job	Specifies the UNAB utility that was used to prepare an input file to drive post-updates of the UNAB nss.db database by the UNAB agent. Post-update utilities can be found in the UNAB libin subdirectory. Available options: postupdate-nss-gr Default value: none nss_cache_update_post_job = none
one way trust	Contains tokens that UNAB uses to support one way trust domains
pam	Contains tokens that control the UNAB PAM module
passwd	Contains tokens that UNAB uses to control password changes during the migration process
register	Contains tokens that control the UNAB registration functionality

## ad

The [ad] section contains Active Directory tokens with the parameters that you entered during installation.

- **ad\_domain**  
Defines the name of the Active Directory domain.  
  
**NOTE**  
Do not manually edit the value of this configuration setting. Use the uxconsole -register utility to set the value of this configuration setting.
- **ad\_gc\_port**  
Specifies the port that the Active Directory Global Catalog service uses.  
**Default:** 3268
- **ad\_site**  
Defines the name of the Active Directory site that contains the DCs that the UNIX host uses to communicate with Active Directory.  
Any values in the lookup\_dc\_list override the value of this configuration setting. The UNIX host does not communicate with any DC listed in the ignore\_dc\_list configuration setting.  
  
**NOTE**  
Do not manually edit the value of this configuration setting. Use the uxconsole -register utility to set the value of this configuration setting.  
  
**Default:** none
- **base\_dn**  
Defines the base\_dn of the Active Directory server. Privileged Access Manager automatically sets the value of this configuration setting.
- **cache\_cleanup\_interval**  
Specifies the cleanup interval, in hours to clean up the local users and group cache for users that are removed from partner domains with one-way trust with the registered domain. This parameter is ignored if the registration domain has no partners with one-way trust.  
**Value:** Any positive integer.  
**Default:** 24  
**Example:** cache\_cleanup\_interval = 24
- **cache\_cleanup\_startup\_time**  
Specifies the start time to clean up the local users and group cache for users that are removed from partner domains with one-way trust with the registered domain. This parameter is ignored if the registration domain has no partners with one-way trust.  
**Value:** Any integer from 0 through 23.  
**Default:** 3 (cleanup starts at 3am)  
**Example:** cache\_cleanup\_startup\_time = 3
- **computer\_container**  
Defines the location of the UNIX host in Active Directory.  
**Default:** cn=Computers
- **domain\_query\_order**  
Specifies the order in which UNAB queries Active Directory domains for users and groups.  
**Options:** none-no order specified; comma separated list of Active Directory domains  
**Default:** none
- **group\_container**  
Specifies the base entry to search for UNIX users in Active Directory.  
**Limits:** container name (cn=groups), ROOT for the complete Active Directory query.  
**Default:** ROOT
- **group\_custom\_filter**  
Specifies a custom search filter to apply during groups search in Active Directory.

**Example:** gidNumber=\*

**Default:** none

- **ignore\_dc\_list**  
Specifies the Active Directory domain controllers that are ignored for LDAP connection.  
**Options:** none, comma separated list of fully qualified host names  
**Default:** none
- **ignore\_domain\_list**  
Specifies the Active Directory domains that UNAB ignores when it queries users and groups.  
**Options:** none - query current and all trusted domains; all - do not query trusted domains; a comma separated list of domains to ignore.  
**Default:** none
- **ignore\_group\_container**  
Specifies the Active Directory group containers to ignore. Containers are defined by their Distinguished Names, comma separated.  
**Limits:** none, comma separated list of distinguished names  
**Default:** none
- **ignore\_user\_container**  
Specifies the Active Directory user containers to ignore. Containers are defined by their Distinguished Names, comma separated.  
**Limits:** none, comma separated list of distinguished names  
**Default:** none
- **ldap\_port**  
Defines the port the Active Directory LDAP service uses.  
**Default:** 389
- **lookup\_dc\_list**  
Specifies the Active Directory domain controllers that are used for LDAP connection. If you specify a list of domain controllers, UNAB uses the specified domain controllers only. If you do not specify the DCs to use, UNAB discovers the Active Directory site that is closest to the physical location of the endpoint and communicates with DCs in the discovered site.  
**Options:** none, comma separated list of fully qualified host names.  
**Default:** none
- **lookup\_domain\_list**  
Specifies the Active Directory domains that established a bi-directional trust with the domain that you registered UNAB.  
**Options:** none, UNAB automatically discovers the trusted domains, comma separated list of trusted domains  
**Default:** none
- **user\_container**  
Specifies the base entry to search for UNIX users in Active Directory.  
**Limits:** container name, ROOT for complete Active Directory query.  
**Default:** ROOT
- **user\_custom\_filter**  
Specifies a custom search filter to apply during users search in Active Directory.  
**Default:** none

## agent

Privileged Access Manager maintains agent settings it uses under the following key:

HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Agent

Agent key entries (and any subkeys) are for internal use only.

- **ShutdownWaitingTimeout**

Defines the timeout period, in milliseconds, the Privileged Access Manager Agent waits for its components to gracefully shut down. If Privileged Access Manager components do not shut down gracefully, the Agent shuts down forcefully.

**Note:** This registry entry is for internal use only.

**Default:** 60000

## global (uxauth.ini)

The [global] section contains the parameters that control the UNAB general settings.

- **activation**  
Specifies the host activation level.  
**Limits:** 0, 1, 2
  - 0 - not registered
  - 1 - registered (login permitted for user defined in local user store only)
  - 2 - activated (login is permitted for users who are defined in local user store or defined in either the .allow file or in the UNAB login policy)**Default:** 0
- **CASHCOMP**  
Specifies the path to the CA shared components install directory.  
**Default:** /opt/CA/SharedComponents
- **integration\_mode**  
Specifies the UNAB installation method.  
**Limits:** 1 - partial integration, 2 - full integration  
**Note:** Specify partial integration (1) if you want to maintain the UNIX user store.  
**Default:** 2
- **locale**  
Defines the language for the UNAB agent and utilities.  
**Example:** C (English), japanese, chinese-s, chinese-t  
**Default:** C
- **kerberos\_configuration**  
Specifies how Kerberos configuration is used when implementing a UNAB assisted Kerberos SSO.  
**Limits:**
  - internal Specifies that the configuration file and user credential caches are stored under /opt/CA/uxauth and opt/CA/uxauth/etc directories
  - external Specifies that the configuration file and user credential caches are stored in their native locations

**NOTE**  
This token is automatically configured during UNAB registration. Linux, HPUX, and Solaris store the user credentials in /tmp directory. AIX stores the user credentials in /var/krb5/security/creds directory

**Default:** internal
- **product\_path**  
Defines the name of the UNAB install directory.  
**Default:** /opt/CA/uxauth

## libdefaults

The [libdefaults] section contains tokens that control Kerberos configuration settings.

- **default\_realm**

Defines the default Kerberos realm for the UNAB endpoint. A value of *unregistered* specifies that UNAB does not use Kerberos.

**Default:** unregistered

- **dns\_lookup\_kdc**

Specifies that UNAB uses DNS SRV (service locator) records to look up the KDC (Key Distribution Centre) services location.

**Limits:** true, false

**Default:** true

- **dns\_lookup\_realm**

Specifies that UNAB uses DNS TXT records to look up domain to realm mappings.

**Limits:** true, false

**Default:** false

- **ticket\_lifetime**

Defines the ticket lifetime in seconds.

**Default:** 2400

## logmgr (uxauth.ini)

The [logmgr] section contains tokens that the UNAB logging utility uses.

- **audit\_back**

Defines the full path name of the audit log backup file.

**Default:** /opt/CA/uxauth/log/uxauth.audit.bak

- **audit\_group**

Specifies the name of the group that is permitted to read the audit log files.

**Limits:** none, *group\_name*

– None - No group access, only root can read the audit log files

– *group\_name* - Defines the name of the group that can read the audit log files

### NOTE

If you change the value of this token after UNAB creates the audit log file, you must use *selang* commands to set the file group ownership and the group permissions to read the log. Any files that are created after you set the value of this token have the permissions that you specify.

**Default:** none

- **audit\_log**

Defines the full path name of the audit log file.

**Default:** /opt/CA/uxauth/log/uxauth.audit

- **audit\_max\_files**

Defines the maximum number of audit log files to save for each of the specified backup modes. When the maximum number of backup audit log files is reached, UNAB deletes the oldest backup file when it creates the newest. A value of 0 specifies that UNAB keeps accumulating backup files.

**Default:** 0

- **audit\_size**

Defines the maximum size of the audit log file in KB.

**Note:** The minimum value that you can specify for this token is 50 KB.

**Default:** 1024

- **audit\_to\_syslog**

Specifies whether to log audit events to syslog file.

**Limits:** yes, no

**Default:** no

- **BackUp\_Date**

Specifies the interval for backing up the audit log files.

**Limits:** none, yes, daily, weekly, monthly

- none - performs the backup when the file reaches the size that is specified in the audit\_size token but does not timestamp the file.
- yes - Audit log file backup is performed when the audit file reaches the size that is specified in the audit\_size token
- daily - Audit log files backup is performed daily
- weekly - Audit log files backup is performed on a weekly basis
- monthly - Audit log files backup is performed on a monthly basis

**Note:** If you specify daily, weekly, or monthly for this token, UNAB creates a time stamp, backs up the audit log file when the current date surpasses the specified interval, and appends the time stamp to the name of the backup file. However, if the size of the audit log file reaches the size that is specified in the audit\_size token before the current date surpasses the specified interval, UNAB backs up the audit log. UNAB does not append the time stamp to the name of the backup file. If you specify yes for this token, the time stamp is always appended to the name of the backup file.

**Default:** none

- **error\_back**

Defines the full path name of the error log file backup copy.

**Default:** /opt/CA/uxauth/log/uxauth.error.bak

- **error\_group**

Specifies the name of the group that is permitted to read the error log files.

**Limits:** none, *group\_name*

- None - No group access, only root can read the error log files
- *group\_name* - Defines the name of the group that can read the error log files

**Note:** If you change the value of this token after UNAB creates the error log file, you must use `selang` commands to set the file group ownership and the group permissions to read the log. Any files that are created after you set the value of this token have the permissions that you specify.

**Default:** none

- **error\_log**

Defines the full path name of the error log file.

**Default:** /opt/CA/uxauth/log/uxauth.error

- **error\_size**

Specifies the maximum size of the error log file in KB.

**Note:** The minimum value that you can specify for this token is 50 KB.

**Default:** 50

## map

### Valid in Full Integration Mode

The [map] section contains tokens that UNAB uses to specify Active Directory attribute names.

- **group\_gid\_attr\_name**

Specifies the Active Directory attribute name that indicates the UNIX group ID.

**Default:** gidNimber

- **group\_member\_attr\_name**

Specifies the Active Directory attribute name that lists members of a group.

**Limits:** member, memberUid

**Note:** Use value memberUid only when user\_name\_attr\_name = msSFU30Name.

**Default:** member

- **user\_gecos\_attr\_name**

Specifies the Active Directory attribute name that indicates the UNIX user gecos.

**Default:** gecoss

- **user\_gid\_attr\_name**  
Specifies the Active Directory attribute name that indicates the UNIX group ID.  
**Default:** gidNumber
- **user\_homedir\_attr\_name**  
Specifies the Active Directory attribute name that indicates the UNIX user home directory.  
**Default:** unixHomeDirectory
- **user\_loginshell\_attr\_name**  
Specifies the Active Directory attribute name that indicates the UNIX user login shell.  
**Default:** loginShell
- **user\_name\_attr\_name**  
Specifies the Active Directory attribute name for the UNIX user name.  
**Default:** sAMAccountName
- **user\_uid\_attr\_name**  
Specifies the Active Directory attribute name that indicates the UNIX user ID.  
**Default:** uidNumber

## message (uxauth.ini)

The [message] section contains tokens UNAB uses to define the message file.

- **filename**  
Defines the full path name of the message file.  
**Default:** /opt/CA/uxauth/data/uxauth.msg

## migrate

The [migrate] section contains tokens that UNAB uses during the migration process.

- **conflicts\_file**  
Defines the full path name of the migration conflicts file.  
**Default:** /opt/CA/uxauth/log/migrate.conflicts
- **create\_ad\_groups**  
Specifies whether to create new Active Directory groups during migration if no identical groups were found in Active Directory.  
**Limits:** yes, no  
**Default:** yes
- **disable\_mapped\_user**  
Specifies whether to disable the UNIX password of partially migrated (mapped) users.  
**Limits:** yes, no  
**Default:** yes
- **ignore\_gecos\_conflict**  
Defines whether to ignore gecoss user attribute-related conflicts that UNAB finds during the migration process.  
**Limits:** yes, no  
**Default:** yes
- **is\_gid\_migration\_a\_prerequisite**  
Specifies whether the migration of the user's primary group is a prerequisite to migrate the user.  
**Limits:** yes, no  
**Default:** no
- **journal**  
Defines the full path name of the migration journal file.

**Default:** /opt/CA/uxauth/log/migrate.journal

- **minimal\_gid**  
Defines the minimal group ID that will be migrated to Active Directory during the migration process. Groups with a lesser GID are not migrated.  
**Default:** 101
- **minimal\_uid**  
Defines the minimal user ID that will be migrated to Active Directory during the migration process. Users with a lesser UID are not migrated.  
**Default:** 101
- **remove\_migrated\_user**  
Specifies whether to remove the local user account after migration.  
**Limits:** yes, no  
**Default:** yes
- **try\_to\_map\_on\_conflict**  
Specifies whether to map conflicting accounts if the full migration process fails.  
**Limits:** yes, no  
**Default:** yes

## passwd (uxauth.ini)

The [passwd] section contains tokens that UNAB uses to control password changes during the migration process.

- **YpGrpCmd**  
Defines the command to generate the NIS group map.  
**Default:** make group
- **YpMakeDir**  
Defines the makefile directory that is used when creating NIS maps.  
**Default:** /var/yp
- **YpPassCmd**  
Defines the command to generate the NIS password map.  
**Default:** make passwd
- **YpServerGroup**  
Defines the full pathname of the group file on the NIS server.  
**Default:** /etc/group
- **YpServerPasswd**  
Defines the full pathname of the password file on the NIS server.  
**Default:** /etc/passwd
- **YpServerSecure**  
Defines the full pathname to the password file of the operating system.  
**Default (AIX):** /etc/security/passwd  
**Default (HP-UX):** /.secure/etc/passwd  
**Default (Solaris):** /etc/shadow  
**Default (all other OS):** /etc/shadow

## one\_way\_trust

The [one\_way\_trust] section contains tokens that UNAB uses to manage one-way trust domains.

### NOTE

For each domain UNAB maintains a separate entry in this section.

- **domains**

Specifies the Active Directory domains that have a one-way trust relationship with the UNAB registration domain.

**Options:** a comma separated list of domains, none

**Default:** none

### Example: One-way trust domain entry

The following example shows how UNAB maintains a one-way trust domain details:

```
[domain.company.com]
ep_name=Computer
ep_type=Windows Agentless
account_name=Administrator
account_container=Accounts
```

In this example, you have established a one-way trust with the domain (domain.company.com) and specified the endpoint type (Windows Agentless), domain user account that is used to retrieve users and groups details from the domain (Administrator) and the account container in Active Directory domain (Accounts).

#### NOTE

You do not have to specify an administrator account. The user account must have permissions to read users and groups attributes only.

## pam

The [pam] section contains tokens that UNAB uses to interact with the PAM module.

- **debug\_mode\_for\_user**  
Defines whether the PAM module can print messages to the user screen during login.  
**Options:** yes, no  
**Default:** yes
- **home\_directory\_permission**  
Specifies the default file permissions that are assigned to the user home directory.  
**Values:** 0-7  
**Default:** 700  
**Example:** 700 indicates that each user has read, write, and execute permissions to their home directories only.
- **pam\_ad\_password\_only**  
Defines the PAM module behavior when the mapped user logs in with a local password.  
**Options:** yes, no  
**Default:** yes
- **pam\_delete\_user\_ccache**  
Defines whether the pam\_uxauth module deletes the Active Directory user credentials cache upon login completion.  
**Values:** Yes (Delete the AD user credentials after login), no (The credentials cache is not changed)  
**Default:** No
- **pam\_exit\_on\_deny**  
Defines the PAM module behavior if the login was denied due to enterprise or local policy settings or Active Directory account state.  
**Options:** yes (The PAM module closes the sequence and prevents other PAM modules from authenticating the user), no (The PAM module does not close and enables other PAM modules to authenticate the user. The no value allows the login server to retry the PAM sequence call)  
**Default:** yes
- **pam\_receive\_timeout**  
Specifies the time, in seconds, that the PAM module waits for the UNAB agent (uxauthd) to respond.  
**Limits:** any positive integer.

**Default:** 10

- **user\_minimal\_uid**

Defines the minimal UID for the local storage to authenticate in the Active Directory.

**Values:** any positive number.

**Default:** 101

## register

The [register] section contains tokens that control UNAB registration functionality.

- **start\_uxauthd**

Specifies whether to run the uxactivate utility at the end of the installation process.

**Limits:** yes, no

**Default:** yes

- **verbose**

Defines the verbose level to use during the installation process.

**Default:** 0

## trcfilter.init

### Valid on UNIX

The Privileged Access Manager daemon also uses the trcfilter.init initialization file.

This optional file contains entries that specify filter masks for filtering out Privileged Access Manager trace messages. Each line of the file contains a regular expression. When a message is sent to the trace file, seosd checks whether the message matches one of the entries in the trcfilter.init file. It writes the trace message to the file only if it does not match any of the expressions specified in the trcfilter.init file.

For example, the following trcfilter.init file causes all messages that begin with INFO or WATCHDOG to be discarded. They are not written to the trace file.

```
WATCHDOG*
```

```
INFO*
```

### NOTE

This file does not filter audit records generated by user traces. To filter these audit records, edit the audit.cfg file.

## Utilities

### acuxchkey Utility: Change Encryption Key Settings

Use the acuxchkey utility to change encryption key and Message Queue settings. This command has the following format:

```
acuxchkey -t -pwd password
```

- **-t**

Specifies the Message Queue change option.

- **-pwd *password***

Defines the Message Queue password.

### Example: Change Message Queue Password

This command saves the changed Message Queue encrypted password in the database. The password is "secret", and must be in clear text and enclosed in double quotes:

```
acuxchkey -t -pwd "secret"
```

### Example: Change Distribution Server Communication Settings

This example shows you how to change the Distribution Server settings to work with SSL:

```
env config
editres CONFIG accommon.ini section (communication) token (Distribution_Server) value ("ssl://DS_host:61616")
```

## ChangeEncryptionMethod Utility: Change Encryption Method

### Valid on UNIX

The ChangeEncryptionMethod utility changes the encryption methods.

#### NOTE

This utility is supplied as a script file and is located in the lbin directory.

When you run this utility, you can select one of the following encryption methods:

- DEFAULT
- AES (128bit, 192bit, or 256bit)
- DES
- TRIPLEDES
- SCRAMBLE

If you do not specify an encryption method, the utility prompts you for it. The utility searches for existing Policy Models in the system. The utility then decrypts them by running "sepm -de pmd\_name", and changes the encryption method by linking libcrypt to the new shared library: libaes128, libaes192, libaes256, libdes, libtripledes, or libscramble.

#### NOTE

To run this utility, Privileged Access Manager must be running. To change the encryption method, the script asks you whether it can temporarily shut down Privileged Access Manager.

#### WARNING

Verify that you use identical encryption methods on the Privileged Access Manager Enterprise Management server and on the Privileged Access Manager endpoints. All password history is lost if you select to change the encryption method of existing endpoints.

This command has the following format:

```
ChangeEncryptionMethod.sh [DES|TRIPLEDES|SCRAMBLE|AES128|AES192|AES256]
```

## dbmgr Utility

The dbmgr utility lets you create, manage, and maintain the Privileged Access Manager database files.

#### NOTE

This utility replaces the following utilities from previous versions: dbdump, rdbdump, dbutil, secreddb, sedb2scr, and semigrate.

**Important!** Use this utility only with the guidance of support personnel during problem resolution. For assistance, contact CA Support at <http://ca.com/support>.

To run the dbmgr utility, you must have the ADMIN, AUDITOR, or SERVER attribute.

The utility handles several tasks and has the associated following functions:

Task	Function
Create a database	dbmgr -create
Display database information	dbmgr -dump
Create a script that defines a database	dbmgr -export
Copy database data to a flat file	dbmgr -migrate
Manage an existing database	dbmgr -util
Backup a database	dbmgr -backup
Restore a database	dbmgr -restore

### dbmgr -create Function: Create a Database

The dbmgr -create function generates a new empty database. Use this function only at installation time, or when you want to create a database or PMDB. Privileged Access Manager creates the database in the current directory.

#### NOTE

If you want to add user-defined classes to the new database, first run the seclassadm utility after creating the new database.

This command has the following format:

```
dbmgr {-create|-c} {-c[q]|-h} [-d] [-f filename] \
[-n] [-o] [-t terminalNames] \
[-u userName [,userName...]] [-ux userName [,userName...]] \
[-v] [-w] [-k] [-n pathName]
```

- **-create|-c**  
Executes the database creation function of the dbmgr utility.
- **-c**  
Prompts you for whether you want to create a new database.
- **-cq**  
Creates a new database without prompting you first.
- **-h**  
Displays the help for this function.
- **-d**  
Prints database layout documentation. The output contains a full description of the structure and property formats used in the database.
- **-f filename**  
Defines a file to direct output to, instead of the standard output device.
- **-k**  
Specifies to run the coexistence utility when the database creation completes.
- **-n pathName**  
(UNIX Only). Defines the full pathname of the Privileged Access Manager database to back up.  
When you are creating a new database, a basic class scheme is generated. When you are adding new classes to the database using the seclassadm utility, the class information is stored in a file in the database directory. To back up a specific database with its class scheme (such as a policy model database), specify its location with the -n option. The user-defined class information is taken from that location. If you do not specify the -n option, the class information file

is searched for in the local directory where the database is to be created. If it is not found there, the file is taken from the active Privileged Access Manager security database directory.

- **-t *terminalName***  
Defines a comma-separated list of terminals, from which the superusers can manage the local database, to create in the database.
- **-u *userName* [*userName...*]**  
Defines a comma-separated list of users to create in the database. These users are defined as Privileged Access Manager security administrators.  
If the -t option is specified, these users are authorized to manage the local database from the defined terminals.  
See also the -ux parameter.
- **-xu *userName* [*userName...*]**  
Defines a comma-separated list of enterprise users to be defined as Privileged Access Manager security administrators.  
If the -t option is specified, these users are authorized to manage the local database from the defined terminals.  
If no users are created dbmgr -create creates a user in the database that corresponds to *root* on UNIX, or Administrator on Windows, with the ADMIN, AUDITOR, and IGN\_HOL attributes.
- **-v**  
Disables the progress messages.

#### NOTE

The -v and -d options cannot be used together.

#### Example: Create a new database on Windows

If at the system prompt `c:\temp>`, enter the following command:

```
dbmgr -c -c -u user1 -t myterminal.company.com
```

When you confirm that you want to create the database, the utility creates a new database in the `c:\temp` directory. It creates the user *user1* in the database, who has the ADMIN, AUDITOR, and IGN\_HOL attributes, and can administer the database from the terminal *myterminal.company.com*.

#### Example: Create a new database on UNIX

If at the `\tmp\db` directory, enter the following command:

```
dbmgr -c -cq -d -f dbLayout
```

The utility creates a new database in the `\tmp\db` directory. It also creates a file (*dbLayout*) that contains the database layout documentation. By default, it creates the user *root* in the database, and assigns it the ADMIN, AUDITOR, and IGN\_HOL attributes.

#### dbmgr -dump Function: Display Database Information

The `dbmgr -dump` function reports on the records in the database. Use this function to perform the following operations:

- Display information for records of a specified class
- Display information for a single record of a specified class
- Display information for all records of a class, except a specified one
- Generate lists of classes and property definitions
- Generate a list of groups that a user belongs to
- Generate a list of records of a particular class

This function assumes that the Privileged Access Manager daemons are not running; you must invoke it from the directory where the database resides. If you use the -r switch, Privileged Access Manager daemons must be running, and you

must have the ADMIN, AUDITOR, or SERVER attribute. To execute this function, you must also have READ and WRITE permission on the database files.

This command has the following format:

```
dbmgr {-dump|-d} [-h] [-r] [-f fileName] \
[c] [fc] [g user] [l class] [p class] [fp class] \
[d class [props|@fileName] \
[dn class [props|@fileName] \
[e classrecord [props|@fileName] \
[en classrecord [props|@fileName] \
[o classrecord [props|@fileName] \
[on classrecord [props|@fileName]
```

- **-dump|-d**  
Executes the database dump function of the dbmgr utility.
- **-f *fileName***  
Directs output to the specified file, instead of the standard output device.
- **-h**  
Displays the help for this function.
- **-r**  
Displays information about the database currently being used by the authorization daemon.  
If you omit this option, dbmgr displays information about the database in the current directory.
- **c**  
Lists the names of all classes defined in the database.
- **d *class* [*props*|@*fileName*]**  
Displays the values of selected properties for all records of a class. The *class* parameter specifies the class. The *props* parameter defines a space-separated list of properties whose values you want to display.  
To read the property list from a file, specify the full pathname of a file, preceded by an at sign (@). Each property listed in the file must appear on a separate line.  
If you do not specify any properties, the values of all the properties are listed.
- **dn *class* [*props*|@*fileName*]**  
Same as the *d* option, only properties with unknown values are not displayed.
- **e *class record* [*props*|@*fileName*]**  
Displays the values of selected properties for all records of a class *except* for a single, specified record. The *class* parameter specifies the class. The *record* parameter specifies the name of the record to omit from the list. The *props* parameter defines a space-separated list of properties whose values you want to display.  
To read the property list from a file, specify the full pathname of a file, preceded by an at sign (@). Each property listed in the file must appear on a separate line.  
If you do not specify any properties, the values of all the properties are listed.
- **en *class record* [*props*|@*fileName*]**  
Same as the *e* option, only properties with unknown values are not displayed.
- **fc**  
Lists all class information for all classes in the database.
- **fp *class***  
Lists all property information on properties of the specified class.
- **g *user***  
Lists the groups that the specified user is a member of.
- **l *class***  
Lists all the records in the specified class.
- **o *class record property* / on *class record property***

Displays the values of selected properties for a single record of a class. The *class* parameter specifies the class. The *record* parameter specifies the record. The *props* parameter defines a space-separated list of properties whose values you want to display.

To read the property list from a file, specify the full pathname of a file, preceded by an at sign (@). Each property listed in the file must appear on a separate line.

If you do not specify any properties, the values of all the properties are listed.

- *o class record property / on class record property*  
Same as the *o* option, only properties with unknown values are not displayed.
- *p class*  
Lists the names of the properties of the specified class.

#### NOTE

You can only specify one other option apart from *-r* and *-f*.

## dbmgr -export Function: Create Script that Defines a Database

The *dbmgr -export* function replicates a database on other stations. It generates a script that consists of the *selang* commands required to define an existing database.

#### NOTE

You cannot copy database files from one architecture to another when using native commands (such as *cp* or *tar* on UNIX or *copy* on Windows), if the files do not use the same byte order. For example, you cannot copy a database from a Sparc-based machine to an Intel based machine, because each uses a different byte order.

#### WARNING

Review the script before you execute it.

This command has the following format:

```
dbmgr {-export|-e} {-l|-r} [-c className] [-f fileName]
```

- **-export|-e**  
Executes the database export function of the *dbmgr* utility.
- **-h**  
Displays the help for this function.
- **-l**  
Exports the database in the current directory.

#### NOTE

This option assumes the Privileged Access Manager daemons are not running. If the daemons are running, then it assumes you are operating on a different database from the one being used by the daemons.

- **-r**  
Exports the database currently being used by Privileged Access Manager. You must have the *ADMIN* or *SERVER* attribute, and the Privileged Access Manager daemons must be running.
- **-c className**  
Defines a space-separated list of classes which you want to export from the database.
- **-f fileName**  
Directs output to the specified file, instead of the standard output device. You can then create a new database from the file, by instructing *selang* to read the commands from the file.

## dbmgr -migrate Function to Copy Data to a Flat File

The dbmgr -migrate function copies data from user and program records in an existing database to a flat file (binary format). The function can also copy the data from the flat file into a new database. The database from which the data is imported must be version 1.21 or later.

When you copy a flat file into a new database, use the same version of this function that you used to create the flat file. If you have more than one version, we strongly recommend that you use the most recent version.

**Note:** For better security, delete the old database, the script that is used to build the new database, and the flat file created by this function after copying the data from the old database into the new database.

### WARNING

Always create a backup of the database before using this function.

This command has the following format:

```
dbmgr {migrate|-m} {-r|-w|-h} [-s] filename \

[-v versionNumber] [-f fileName]
```

- **-migrate|-m**  
Executes the database migration function of the dbmgr utility.
- **filename**  
Defines the flat file that you want to copy data from or into.
- **-f filename**  
Directs output to the specified file, instead of the standard output device.
- **-h**  
Displays the help for this function.
- **-r**  
Reads the database in the current directory and copies certain data into the flat file *filename*.
- **-s**  
Reads the information from the database using the Privileged Access Manager server rather than reading the database directly. This option is only valid with the -r switch.  
You must have administrator privileges and R (read) and W (write) access to the terminal to use this option.  
If you do not specify this option, the function reads from or writes to the database in the current directory.
- **-v versionNumber**  
Reads a flat file that was created by a previous version. This option is only valid for -w command. Enter this option after the file name and supply the version number.
- **-w**  
Reads the flat file *filename* and copies the data into the database in the current directory.

### Example: Copy data from an existing database to a new database

The following steps illustrate how to copy data from an existing database into a new database. The old database is assumed to be in the directory /tmp/old\_db. The new database is assumed to be in the directory *ACInstallDir*/seosdb (where *ACInstallDir* is the directory in which you installed Privileged Access Manager).

**Note:** This procedure is written using UNIX pathnames but can be followed on Windows by modifying these pathnames as appropriate.

#### Follow these steps:

1. Log in as a superuser.

2. If the product daemons are running, shut them down with the following command:

```
secons -s
```

3. Create a backup of the old database by copying it to a different location or to a backup medium.
4. Copy the database into /tmp/old\_db, then create a script that duplicates the old database by running the dbmgr utility on the old database:

```
cd /tmp/old_db

/opt/CA/PAMSC/bin/dbmgr -export -l -f lang_script
```

5. Create a database:

```
cd /opt/CA/PAMSC/seosdb

/opt/CA/PAMSC/bin/dbmgr -c -cq
```

6. Execute the script that is generated in the previous step and create the database:

```
cd /opt/CA/PAMSC/seosdb

/opt/CA/PAMSC/bin/selang -l /tmp/old_db/lang_script
```

7. Execute the dbmgr utility to create a flat file containing data from the old database:

```
cd /tmp/old_db

/opt/CA/PAMSC/bin/dbmgr -migrate -r flat_file
```

8. Load the data from the flat file into the new database:

```
cd /opt/CA/PAMSC/seosdb

/opt/CA/PAMSC/bin/dbmgr -migrate -w /tmp/old_db/flat_file
```

## dbmgr -util Function: Manage Existing Database

The dbmgr -util function performs management and maintenance operations on a database. It assumes Privileged Access Manager is not currently running. Invoke it from the directory where the database resides.

The -util option is used to manage and manipulate the local database specified by the parameter *filename*. Database files have the extension .dat and must be DBIO files. Database index files (files with the extension .001) cannot be used with the -util option.

This command has the following format:

```
dbmgr {-util|-u} [-h] \
[-all filename] \
```

```

[-build filename] \
[-check] \
[-close] \
[-dump filename] \
[-dup srcdst] \
[-fast] \
[-free filename] \
[-index filename] \
[-key filename] \
[-load dbascii] \
[-scan filename] \
[-scana filename] \
[-stat filename] \
[-verify] \
[-f fileName]

```

- **-util-u**  
Executes the database management and maintenance functions of the dbmgr utility.
- **-all *filename***  
Performs all index checks; same as specifying the *-index* and *-free* options.
- **-build *filename***  
Builds indexes of a DBIO based on data records.
- **-check**  
(UNIX only). Performs a fast sanity and consistency check on all index entries for all database files.
- **-close**  
Closes the database if it is open.
- **-dump *filename***  
Dumps the data file as ASCII on the standard output device.
- **-dup *src dst***  
Duplicates the DBIO file based on the file header.
- **-f *fileName***  
Directs output to the specified file, instead of the standard output device.
- **-fast**  
Performs a fast sanity check on all index entries for all the database files.
- **-free *filename***  
Checks for a free index.
- **-index *filename***  
Checks the consistency of the index.
- **-key *filename***  
Sequentially scans an index file.
- **-load *db* ascii**  
Loads an ASCII file and converts it into a DBIO file.
- **-scan *filename***  
Scans the database sequentially.
- **-scana *filename***  
Scans the database sequentially, including deleted records.
- **-stat *filename***  
Lists the header information of the database file.
- **-verify**  
(UNIX only). Verifies that certain predefined objects exist in the database; for example, SEOS, ADMIN, and UACC for all classes.

## dbmgr -backup Function: Back Up a Database

The dbmgr -backup function creates an online backup of the Privileged Access Manager database in the specified directory. This function is available whether the Privileged Access Manager daemons are running or not.

This command has the following format:

```
dbmgr {-backup|-b} backup_directory
```

- **-backup|-b**  
Executes the database backup function of the dbmgr utility.
- *backup\_directory*  
Defines the backup directory. This directory cannot be located on a remote machine; if the directory does not exist, the function creates it.

## dbmgr -restore Function: Restore a Database

### Valid on UNIX

The dbmgr -restore function performs an online restore of the Privileged Access Manager database in the specified directory. This function is available whether the Privileged Access Manager daemons are running or not.

This command has the following format:

```
dbmgr {-restore|-r} restore_directory
```

- **-restore|-r**  
Executes the database restore function of the dbmgr utility.
- *restore\_directory*  
Defines the directory where the database you want to restore resides.

## DictImport Utility: Import the Dictionary File

The DictImport utility prepares and imports dictionary files into the Privileged Access Manager database. After you install Privileged Access Manager, import the dictionary file into the product database and then activate it. You can then set password protection.

The DictImport utility sets the use\_dbdict password rule to *db* and activates the DICTIONARY class and PASSWORD class.

### NOTE

The centralized dictionary is disabled if the PASSWORD class is not active.

This command has the following format:

```
DictImport [-h] [-o selangFilename] [-f dictionaryFilename]
```

### NOTE

This utility is supplied as a script file and is located in the lbin directory.

- **-f dictionaryFilename**  
Generates selang commands that import all the dictionary words from the specified file. If you omit this option, the dictionary file is defined from values in the configuration settings.
- **-h**  
Displays the help for this utility.
- **-o selangFilename**  
Writes selang commands to the specified file. If you omit this option, selang commands are written to the standard output device.

## dmsmgr Utility

The dmsmgr utility lets you manage the advanced policy management infrastructure. Infrastructure components include Privileged Access Manager endpoints, Deployment Map Server (DMS), and Distribution Host (DH).

The utility handles several tasks and has the associated following functions:

Task	Function
Create a DMS or a DH	dmsmgr -create
Remove a DMS or a DH	dmsmgr -remove
Remove obsolete nodes from the DMS database	dmsmgr -cleanup
Configure advanced policy management	dmsmgr -config
Restore a DMS or a DH	dmsmgr -restore
Synchronize a DMS or an HD	dmsmgr -sync

### dmsmgr -create Function: Create a DMS or a DH

The dmsmgr -create function creates a Deployment Map Server (DMS) or a Distribution Host (DH) on a computer where Privileged Access Manager is installed.

#### NOTE

You can also create a DMS or a DH during installation.

#### NOTE

The user running the utility is always granted administration rights for the created DMS or DH.

This command has the following format:

```
dmsmgr -create -auto [-osgroups] [-admin user [,user...]] [-xadmin user [,user...]] \
[-desktop hosts]
dmsmgr -create -dms name \
[-admin user [,user...]] [-xadmin user [,user...]] \
[-desktop hosts] [-subscriber dh-names]
dmsmgr -create -dh name \
[-admin user [,user...]] [-xadmin user [,user...]] \
[-desktop hosts]
```

- **-admin *user* [,user...]]**  
(Optional) Defines internal users as administrators of the created DMS or DH.
- **-auto**  
Creates a DMS and a DH with default names (DMS\_\_, DH\_\_, and DH\_\_WRITER).  
Use this option to create a DMS and a DH and the required associations between them.
- **-osgroups**  
(Optional) Specifies to create predefined host groups when you create a DMS.
- **-desktop *hosts***  
(Optional) Defines a comma-separated list of computers that have TERMINAL access rights to the computer with the created DMS or DH.

#### NOTE

Whether specified or not, the terminal running the utility is always granted administration rights for the created DMS or DH.

- **-dh *name***

Creates a DH with the *name* specified on the local host.

#### NOTE

If you use this option to create a DH, Privileged Access Manager tells you to synchronize the DMS and DH even if the DH is already subscribed and no policies were previously sent. This message is a reminder of the steps you need to take and may not be indicative of the actual situation. If you completed all required steps, you can safely ignore it.

- **-dms *name***  
Creates a DMS with the *name* specified on the local host.
- **-subscriber *dh\_names***  
(Optional) Defines a comma-separated list of DH PMDBs that the created DMS will policy updates to. Specify each DH in the following format: *DH\_name@hostname*.
- **-xadmin *user* [,*user*...]**  
(Optional) Defines enterprise users as administrators of the created DMS or DH.

### dmsmgr -remove Function: Remove a DMS or a DH

The dmsmgr -remove function removes a DMS or a DH on a computer where Privileged Access Manager is installed.

This command has the following format:

```
dmsmgr -remove {-dms|dh} name
dmsmgr -remove -auto
```

- **-auto**  
Removes the default DMS and DH from the local host.  
These are the DMS and DH databases created by default during installation or when you use dmsmgr -create -auto.
- **-dh *name***  
Removes the specified *name* DH from the local host.
- **-dms *name***  
Removes the specified *name* DMS from the local host.

### dmsmgr -cleanup Function: Remove Obsolete Nodes

The dmsmgr -cleanup function removes obsolete nodes from the DMS or DH database. These are HNODE objects that represent Privileged Access Manager nodes that have been unavailable for a specified amount of time.

#### NOTE

As a routine maintenance procedure, clean the DMS and DH from these obsolete nodes.

This command has the following formats:

```
dmsmgr -cleanup {-hnode|-deployment} -days number {-dms|-dh} name
dmsmgr -cleanup -policy name -vcount number {-dms|dh} name
```

- **-hnode**  
Removes HNODE objects that represent Privileged Access Manager nodes that have been unavailable for more than *number* days.
- **-deployment**  
Removes the DEPLOYMENT objects that are older than *number* days.
- **-policy *name***  
Removes the POLICY objects (policy versions) that belong to the specified policy and are older than *number* versions.
- **-dh *name***

- Defines the name of the DH you want to remove the obsolete nodes from.
- **-dms *name***  
Defines the name of the DMS you want to remove the obsolete nodes from.
- **-vcount**  
Defines the number of versions to keep.

## dmsmgr -config Function: Configure Advanced Policy Management

The dmsmgr -config function configures advanced policy management.

This command has the following format:

```
dmsmgr -config[-] [host_name] {-endpoint|-dhname names|-drname names}
dmsmgr -config -osgroups [-dms name]
```

- **-config[-]**  
Configures or removes the configuration of advanced policy management.
- **-dhname *names***  
Configures the endpoint to work with the comma-separated list of Distribution Hosts.
- **-dms *name***  
Defines the name of the DMS on which the automatic host groups are created.
- **-drname *names***  
Configures the endpoint to work with the comma-separated list of disaster recovery Distribution Hosts.
- **-endpoint**  
Configures the endpoint for advanced policy management.
- ***host\_name***  
Performs the configuration on *host\_name*. If no host is specified, performs the configuration on the local computer.
- **-osgroups**  
Adds automatic host groups to the DMS.  
**Note:** For more information about automatic host groups, see the *Enterprise Administration Guide*.

## dmsmgr -restore Function Restore a DMS or DH

The dmsmgr -restore function restores a DMS or a DH from backup files. You can restore a DMS or DH when Privileged Access Manager is running or stopped, over an existing DMS, or into a new directory.

This command has the following format:

```
dmsmgr -restore -dms name -source path\
[-replica name] [-subscriber dhname[,dhname...]] \
[-admin user[,user...]] [-xadmin user[,user...]]
dmsmgr -restore -dh name -source path\
[-admin user[,user...]] \
[-xadmin user[,user...]] [-desktop host[,host...]]
```

- **-admin *user[,user...]***  
(UNIX) Defines internal users as administrators of the restored DMS or DH.
- **-desktop *host[, host...]***  
(Optional) Defines a list of computers that have TERMINAL access rights to the computer with the restored DH.

### NOTE

Whether specified or not, the terminal running the utility is always granted administration rights for the restored DH.

- **-dh *name***

Defines the name of the DH that is restored on the local host.

- **-dms *name***  
Defines the name of the DMS that is restored on the local host.
- **-replica *name***  
(Optional) Defines the name of the disaster recovery DMS. Use this parameter if you have set up Privileged Access Manager in a disaster recovery deployment and restore a production DMS. Specify the disaster recovery DMS name in the following format: *DMS\_name@hostname*.
- **-source *path***  
Defines the directory that contains the backup files to restore.
- **-subscriber *dh\_name*[, *dh\_name*...]**  
(Optional) Defines a comma-separated list of DHs that the restored DMS sends policy updates to. Specify each DH in the following format: *DH\_name@hostname*.
- **-xadmin *user*[,*user*...]**  
(UNIX) Defines enterprise users as administrators of the restored DMS or DH.

## **dmsmgr -sync Function Synchronize a DMS or a DH**

The dmsmgr -sync function synchronizes between the DMS and the DH to create a mirror image of the DMS on the DH. You can execute the synchronization process from the Enterprise Management Server or from a dedicated Distribution Server.

This command has the following format:

```
dmsmgr -sync -dhname <dhname> [-dms<dms-name>]
```

```
dmsmgr -sync self [-dh<dhname>]
```

- **-dms<dms-name>**  
Synchronizes the DMS with the DH.

### **NOTE**

Run the command from the DMS computer.

- **-dh<dhname>**  
Synchronizes the DH with the DMS.

### **NOTE**

Run the command from the DH computer.

- **-dhname<name>**  
Specifies a comma separated list of Distribution Hosts.
- **self**  
Specifies to synchronize the DH with the DMS.

### **NOTE**

Run the command from the Distribution Server.

## **eACoexist Utility Detect and Register Coexisting Trusted Programs**

### **Valid on Windows**

The eACoexist utility detects any coexisting programs in the local system (for example, CA Anti-Virus). If the detected program is trusted, Privileged Access Manager registers the program using a SPECIALPGM rule. A special program rule defines the types of access for that program and makes sure that Privileged Access Manager bypasses it when granting access.

This command has the following format:

eACoexist [plug-in-path]

- *plug-in-path*  
(Optional) Defines the path to the folder that contains the coexistence plug-ins you want the coexistence program to use.  
If you do not define a path, the program uses the default path where the coexistence plug-ins are stored (*ACInstallDir\Coexistence*).

## The Coexistence Utility

The coexistence utility (eACoexist) that Privileged Access Manager supplies, lets you resolve potential conflicts with other programs on the local computer.

When the coexistence utility runs, it performs the following actions:

1. Checks that *one* of the following conditions apply:
  - a. Privileged Access Manager is not running.
  - b. You have the ADMIN attribute.
 If neither conditions apply, the utility exits.
2. Locates the response.ini file, as follows:
  - When the utility runs during installation, it uses the path *media\_drive:\Coexistence\\_architecture*
  - If Privileged Access Manager is installed on the computer, it uses the following registry key value:  
`HKLM\SOFTWARE\ComputerAssociates\AccessControl\AccessControl\SeOSD\ResponseFile`
 If the file does not exist the utility exits.
3. Locates the coexistence plug-ins directory, as follows:
  - If you run the utility and pass a parameter from the command line, it uses this parameter as the path of the plug-in.
  - When the utility runs during installation, it uses the path *media\_drive:\Coexistence\\_architecture*
  - If you run the utility with no parameters, it concatenates the string "Coexistence" to the following registry key value:  
`HKLM\SOFTWARE\ComputerAssociates\AccessControl\AccessControl\SeOSPath`
 If the directory does not exist, or there are no coexistence plug-ins in the directory, the utility exits.
4. Executes the discovery process.  
To do this, it enumerates the executables in the coexistence plug-ins directory and executes them one by one, as follows:
  - a. Stores the result of the plug-in execution in %windir%\EACDiscovery.ini

### NOTE

The utility automatically deletes this file on successful completion of the plug-in discovery process.

- b. Checks that the output file EACDiscovery.ini exists.  
If the file does not exist, the utility continues to execute the next plug-in.
- c. For each product section in EACDiscovery.ini, concatenates the section (product) name and version value and checks whether the response file contains the matching section.

### NOTE

The response.ini file contains a section for each coexisting program. If a section name appears with a version number, for example, eTrust Audit-1.5, the utility performs the action only for the specified version.

- d. If a matching section exists in the response file, executes the action that is set by the value of the Act-Utility-0 in that section, as follows:
  - Issues a warning that the discovered product is not compatible with Privileged Access Manager.
  - Stops the discovered services of the product.

The utility retrieves the discovered services of the product from the EACDiscovery.ini file.

- Same as bullet 2, but during Privileged Access Manager installation.
- Starts the services if the discovered product.

The utility retrieves the services of the discovered product from the EACDiscovery.ini file.

- Creates trusted program rules (SPECIALPGM) for the processes of the discovered product and starts Privileged Access Manager.

The utility retrieves the processes of the discovered product from the EACDiscovery.ini file. It also retrieves the respective program type (pgmtype) from this file. It then creates a temporary script file (*ACInstallDir\Data\discoveryscp*) that it executes when Privileged Access Manager starts.

- Same as bullet 2, but during Privileged Access Manager uninstall.

#### NOTE

Each section can contain more than one action. For example, you can have Act-Utility-0, Act-Utility-1, and Act-Utility-2 that are executed in that order.

### Policy Manager Plug-In

The coexistence utility runs the Policy Manager plug-in to scan the computer for Policy Manager registry keys and executables before the Privileged Access Manager installation begins, as follows:

- Queries the following registry key for existence:

`HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\App Paths\SeAM.Exe`

If the registry key exists, the plug-in:

- Reads the value of the Path entry
- Returns the following executable pathname:

`FilePathFromRegistry\Bin\SeAM.exe`

- Issues a compatibility warning during Privileged Access Manager installation

This is the default action as defined in the response file. The Policy Manager plug-in does not add a trusted program (SPECIALPGM) rule by default.

#### NOTE

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on). Also, the Policy Manager application is no longer provided with Privileged Access Manager.

### BrightStor Plug-In

The coexistence utility runs the BrightStor plug-in to scan the computer for CA BrightStor registry keys and executables at the end of a Privileged Access Manager installation and whenever the utility runs, as follows:

1. Queries the following registry keys for existence:

`HKLM\SOFTWARE\ComputerAssociates\BrightStor ARCserve Backup\UniversalClientAgent\Common`

`HKLM\SOFTWARE\ComputerAssociates\Cheetah\UniversalClientAgent\Common`

`HKLM\SOFTWARE\ComputerAssociates\BrightStor Enterprise Backup\UniversalClientAgent\Common`

When the first registry key exists, the plug-in:

- Reads the value of the Path entry
- Returns the following executable pathname:

`FilePathFromRegistry\UnivAgent.exe`

- Creates a SPECIALPGM resource of type DCM

This is the default action as defined in the response file.

2. If the plug-in cannot find any of the registry keys in Step 1, it queries the following registry keys for existence:

`HKLM\SOFTWARE\ComputerAssociates\BrightStor ARCserve Backup\Base\Path`

`HKLM\SOFTWARE\ComputerAssociates\Cheetah\Base\Path`

HKLM\SOFTWARE\ComputerAssociates\BrightStor Enterprise Backup\Base\Path

When the first registry key exists, the plug-in:

- Reads the value of the HOME entry
- Returns the following executable pathname:  
`FilePathFromRegistry\carunjob.exe`
- Creates a SPECIALPGM resource of type DCM  
 This is the default action as defined in the response file.

3. If the plug-in also cannot find any of the registry keys in Step 2, it queries the following registry key for existence:

HKLM\SOFTWARE\ComputerAssociates\ARCserveIT\Base\Path

If the registry key exists, the plug-in:

- Reads the value of the HOME entry
- Returns the following executable pathname:  
`FilePathFromRegistry\ASRunJob.exe`
- Creates a SPECIALPGM resource of type DCM  
 This is the default action as defined in the response file.

4. Queries the following registry keys for existence:

HKLM\SOFTWARE\ComputerAssociates\CA\_BAOF\CurrentVersion

HKLM\SOFTWARE\ComputerAssociates\BrightStor Backup Agent for Open Files\CurrentVersion

When the first registry key exists, the plug-in:

- Reads the value of the ServicePath entry
- Creates a SPECIALPGM resource of type DCM for *ServicePathFromRegistry*  
 This is the default action as defined in the response file.

#### NOTE

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

### Dr. Watson Plug-In

The coexistence utility runs the Dr. Watson plug-in to scan the computer for Dr. Watson executables at the end of a Privileged Access Manager installation and whenever the utility runs, as follows:

- Queries the following pathname for existence:

`%windir%\system32\drwtsn32.exe`

If the file exists, the plug-in creates a SPECIALPGM resource of type DCM.

This is the default action as defined in the response file.

#### NOTE

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

### eTrust AV Plug-In

The coexistence utility runs the eTrust AV plug-in to scan the computer for CA Antivirus registry keys and executables at the end of a Privileged Access Manager installation and whenever the utility runs, as follows:

1. Reads the following registry key entry values:

HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\App Paths\InocIT.Exe\Path

HKLM\SOFTWARE\ComputerAssociates\eTrustITM\CurrentVersion\Path\Home

If one of the entries returns a value, the plug-in creates the following SPECIALPGM resources of type DCM:

- *FilePathFromRegistry\InoRT.exe*
- *FilePathFromRegistry\InoTask.exe*
- *FilePathFromRegistry\InocIT.exe*
- *FilePathFromRegistry\ShellScn.exe*

This is the default action as defined in the response file.

2. Reads the following registry key entry value:

```
HKLM\SOFTWARE\ComputerAssociates\ScanEngine\Path\Engine
```

If the entry returns a value, the plug-in creates the following SPECIALPGM resource of type DCM:

```
FilePathFromRegistry\InoCmd32.exe
```

#### NOTE

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

### Scout Plug-In

The coexistence utility runs the Scout plug-in to scan the computer for SurfControl Web Filter for Windows registry keys and executables at the end of a Privileged Access Manager installation and whenever the utility runs, as follows:

- Queries the following registry key for existence:

```
HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\App Paths\Scscout.Exe
```

If the registry key exists, the plug-in:

- Reads the value of the Path entry
- Returns the following executable pathname:

```
FilePathFromRegistry\scoutsvc.exe
```

- Creates a SPECIALPGM resource of type DCM

This is the default action as defined in the response file.

#### NOTE

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

### Windows Plug-In

The coexistence utility runs the Windows plug-in to scan the computer for Windows services and registry keys at the end of a Privileged Access Manager installation and whenever the utility runs, as follows:

1. Extracts the directory path of the executable of the service "WinMgmt" (*ServicePath*)
2. Creates the following SPECIALPGM resource of type REGISTRY:

```
ServicePath
```

This is the default action as defined in the response file.

3. Creates the following SPECIALPGM resource of type PBF:

```
%windir%\System32\cidaemon.exe
```

This is the default action as defined in the response file.

#### NOTE

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

## eTrust Audit Plug-In

The coexistence utility runs the eTrust Audit plug-in to scan the computer for eTrust Audit Version 1.5 registry keys and files before the Privileged Access Manager installation begins, as follows:

1. Queries the following registry key for existence:

```
HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\App Paths\acdistagn.exe
If successful it extracts the "Path" value designated %PathFromRegistry%.
```

If the registry key exists, the plug-in:

- Reads the value of the Path entry
- Returns the following executable pathnames:

```
FilePathFromRegistry\bin\acactmgr.exe
FilePathFromRegistry\bin\SeLogRcd.exe
FilePathFromRegistry\bin\acdistagn.exe
FilePathFromRegistry\acdistsrv.exe
FilePathFromRegistry\acfwrecd.exe
FilePathFromRegistry\acrecorderd.exe
FilePathFromRegistry\aclogrd.exe
FilePathFromRegistry\portmap.exe
FilePathFromRegistry\SeLogRec.exe
FilePathFromRegistry\SeLogRd.exe
FilePathFromRegistry\snmprec.exe
```

This is the default action as defined in the response file. The eTrust Audit plug-in does not add a trusted program (SPECIALPGM) rule by default.

2. Stops the following services:

- "eAudit Action Manager"
- "eAudit Distribution Agent"
- "eAudit Log Router"
- "eAudit Recorder"
- "eAudit Redirector"
- "eAudit Portmap"

If a more recent version of eTrust Audit is installed, it stops the following services:

- "eTrust Audit Action Manager"
- "eTrust Audit Collector"
- "eTrust Audit Distribution Agent"
- "eTrust Audit Distribution Server"
- "eTrust Audit FW-1 Recorder"
- "eTrust Audit Generic Recorder"
- "eTrust Audit Log Router"
- "eTrust Audit Portmap"
- "eTrust Audit Recorder"
- "eTrust Audit Redirector"
- "eTrust Audit SNMP Recorder"

3. When the Privileged Access Manager installation completes, it restarts these same services.

The coexistence utility also runs the eTrust Audit plug-in to:

- Stop the eTrust Audit services when you uninstall Privileged Access Manager
- Start the eTrust Audit services after the Privileged Access Manager uninstall completes

**NOTE**

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

**eTrust Audit80 Plug-In**

The coexistence utility runs the eTrust Audit80 plug-in to scan the computer for eTrust Audit r8 registry keys and files at the end of a Privileged Access Manager installation and whenever the utility runs, as follows:

- Queries the following registry key for existence:

```
HKLM\SOFTWARE\ComputerAssociates\eTrust Audit\Paths
```

If successful it extracts the "Path" value designated %PathFromRegistry%.

If the registry key exists, the plug-in:

- Reads the value of the RootPath entry
- Creates the following SPECIALPGM resources of type DCM:

```
FilePathFromRegistry\bin\acactmgr.exe
FilePathFromRegistry\bin\SeLogRcd.exe
FilePathFromRegistry\bin\acdistsagn.exe
FilePathFromRegistry\acdistsrv.exe
FilePathFromRegistry\acfwrecd.exe
FilePathFromRegistry\acrecorderd.exe
FilePathFromRegistry\aclogrd.exe
FilePathFromRegistry\portmap.exe
FilePathFromRegistry\SeLogRec.exe
FilePathFromRegistry\SeLogRd.exe
FilePathFromRegistry\snmprec.exe
```

This is the default action as defined in the response file.

**NOTE**

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

**F-Secure Antivirus Plug-In**

The coexistence utility runs the F-Secure Antivirus plug-in to scan the computer for F-Secure Anti-Virus registry keys and files, as follows:

- Before the Privileged Access Manager installation begins the plug-in stops the F-Secure Anti-Virus services.
- When the Privileged Access Manager installation completes, the plug-in queries the following registry key for existence:

```
HKLM\SOFTWARE\Data Fellows\F-Secure\Anti-Virus
```

If successful it extracts the "Path" value designated %PathFromRegistry%.

If the registry key exists, the plug-in:

- Reads the value of the Path entry
- Creates the following SPECIALPGM resources of type DCM:

```
FilePathFromRegistry\fssm32.exe
FilePathFromRegistry\fsgk32st.exe
```

This is the default action as defined in the response file. The eTrust Audit plug-in does not add a trusted program (SPECIALPGM) rule by default.

- Whenever the coexistence utility runs, the plug-in:
  - a. Stops the F-Secure Anti-Virus services

- b. Creates the same SPECIALPGM resources it creates when the Privileged Access Manager installation completes (as described earlier in this topic)
- c. Restarts the F-Secure Anti-Virus services

**NOTE**

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

**McAfee VirusScan Plug-In**

The coexistence utility runs the McAfee VirusScan plug-in to scan the computer for the McAfee VirusScan service at the end of a Privileged Access Manager installation and whenever the utility runs, as follows:

1. Extracts the directory path of the executable of the service "McShield" (*ServicePath*)
2. Creates the following SPECIALPGM resource of type DCM:

```
ServicePath
```

This is the default action as defined in the response file.

**NOTE**

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

**Windows Modules Installer Plug-In**

The coexistence utility runs the Windows Modules Installer plug-in to scan the computer for the Windows Modules Install service at the end of a Privileged Access Manager installation and whenever the utility runs, as follows:

1. Extracts the directory path of the executable of the service "TrusterInstaller" (*ServicePath*)
2. Creates the following SPECIALPGM resource of type PBF:

```
ServicePath
```

This is the default action as defined in the response file.

**NOTE**

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

**Services and Controller Plug-In**

The coexistence utility runs the Services and Controller plug-in to scan the computer for the Windows services management executable at the end of a Privileged Access Manager installation and whenever the utility runs, as follows:

1. Checks if the operating system version is Windows Vista or later  
If the OS is of an earlier Windows version, the plug-in terminates.
2. Creates the following SPECIALPGM resource of type KILL:

```
%windir%\system32\services.exe
```

This is the default action as defined in the response file.

**NOTE**

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

## Resource Hosting Subsystem Plug-In

The Privileged Access Manager installation process runs the Resource Hosting Subsystem plug-in during installation, and the coexistence utility runs the Resource Hosting Subsystem when a customer executes the utility. The Resource Hosting Subsystem plug-in scans the computer for the Cluster Service Element, as follows:

1. Checks if the operating system is Windows Server 2008 or later.  
If the OS is of an earlier Windows version, the plug-in terminates.
2. Checks if the Cluster Service Element is installed on the computer.  
If the Cluster Service Element is not installed, the plug-in terminates.
3. Creates the following SPECIALPGM resource of type PBF:

```
system_drive:\Windows\Cluster\rhs.exe
```

### NOTE

The response file determines the default action that the coexistence utility performs at prescribed stages (what to do before Privileged Access Manager installation, after installation, and so on).

## response.ini Configure the Coexistence Utility

### Valid on Windows

The response file instructs the coexistence utility (eACoexist) what actions to perform when it runs. The response file contains a predefined set of actions for every plug-in that the coexistence utility runs. You can edit the response file to change the default plug-in actions.

### NOTE

The response file pathname is specified in the ResponseFile configuration setting of the SeOSD section. This file is *ACInstallDi\Data\response.ini* by default.

### NOTE

This file has the following format:

```
[Section Name]
Act-Stage-#=Action
...
```

- **Section Name**  
Defines the name of a section that matches a coexistence plug-in.  
The coexistence utility runs the plug-in according to the actions that are defined in this section.
- **Act-Stage-#=Action#**  
Defines the action that you want the plug-in to perform at the prescribed stage.
  - **Stage**  
Specifies the prescribed stage in which you want the plug-in to perform the action, as follows:
    - a. **BeginInstall** The plug-in performs the specified action before Privileged Access Manager starts installing.
    - b. **EndInstall** The plug-in performs the specified action after the Privileged Access Manager installation completes.
    - c. **Utility** The plug-in performs the specified action when you execute the coexistence utility.
    - d. **BeginUninstall** The plug-in performs the specified action before Privileged Access Manager starts the uninstall.
    - e. **EndUninstall** The plug-in performs the specified action after the Privileged Access Manager uninstall completes.
  - **#**  
Specifies the order in which the plug-in executes actions in this stage.
  - **Action**  
Specifies a number that defines the action the plug-in should take, as follows:
    - a. Warn that Privileged Access Manager is not compatible with discovered products.
    - b. Stop services during Privileged Access Manager installation.

- c. Stop services.
- d. Start services.
- e. Create SPECIALPGM rules.
- f. Stop services during Privileged Access Manager uninstall.

### Example: Dr. Watson Plug-in Actions

This example displays the default action the Dr. Watson coexistence plug-in performs by default when discovering the Dr. Watson program on the computer.

```
[DrWatson]
Act-EndInstall-0=5
Act-Utility-0=5
```

This section specifies that when the plug-in runs after a Privileged Access Manager installation completes, it should create SPECIALPGM rules for the program. It also specifies that it should do the same when you execute the utility.

## eACSigUpdate Utility Replace STOP Signature File

### Valid on Windows

The eACSigUpdate utility replaces the local stack overflow protection (STOP) signature file with a file you updated on another computer.

#### NOTE

The eACSigUpdate utility automatically runs when Privileged Access Manager starts, and then at a regular interval, if a signature file broker or a parent Policy Model is defined.

This command has the following format:

```
eACSigUpdate hostname target_file
```

- *hostname*  
Defines the name of the host computer that has the updated the STOP signature file you want to copy to this computer

#### NOTE

For the command to work, you must have administration privileges on the remote host.

- *target\_file*  
Defines the full path and name of the new signature file. This is the location and name of the signature that is retrieved from the specified host.

## eACSyncLockout Utility Synchronize Account Lockout

### Valid on Windows

The eACSyncLockout utility synchronizes an account's lockout with the Privileged Access Manager database. (That is, upon account lockout, the corresponding user's record in the Privileged Access Manager database is suspended.) This utility is effective only when password synchronization is on *and* the user running the utility has the ADMIN property.

This command has the following format:

```
eACSyncLockout -start [-u username] [-p password]
eACSyncLockout -stop|-remove|-debug
```

- *-p password*  
Defines the user password for the service to be installed and started. If -p is not specified, the utility assumes the user has no password.
- **-remove**

Causes the service to be stopped and uninstalled. (In the next boot of the machine, the service does not appear in the Service Control Manager.)

- **-start**  
Causes the service to be installed and started. If -u is not specified, the utility installs and starts the service in the current user's context.
- **-stop**  
Stops the service.
- **-u *user***  
Defines the user context for installing and starting the service.

## issec Utility Display CA Privileged Access Manager Server Control Daemon Status

### Valid on UNIX

The issec utility displays the status of Privileged Access Manager security daemons. If you do not specify any options, the following information appears:

- The Privileged Access Manager version and installation directory
- The status of the Privileged Access Manager kernel extension
- The status of three major daemons: seosd, agent, and watchdog
- The status of daemons: serevu, selogrd, selogrcd, eacws, ReportAgent, policyfetcher, KBLAudMgr
- The status of the PMDB daemon and its name
- The status of the daemons that have been specified in the [daemons] section of seos.ini

This command has the following format:

```
issec [-b] [-k] [-h]
```

- **-b**  
Displays the status and pid of major daemons (seosd, agent, and watchdog).
- **-k**  
Checks if Privileged Access Manager kernel extension is loaded.
- **-h**  
Displays the help for this utility.

## ldap2seos Script Extract Users from LDAP for Adding into CA Privileged Access Manager Server Control

### Valid on UNIX

The ldap2seos utility extracts users from an LDAP database at the server host and adds them to the Privileged Access Manager database.

#### **WARNING**

Privileged Access Manager lets you use LDAP users directly without importing them if the LDAP user store is used by the operating system, that is, it is an enterprise user store. Consider using this functionality of Privileged Access Manager instead of the ldap2seos utility.

The ldap2seos utility extracts information from an LDAP server about the defined users. The extracted information is automatically used to execute selang commands to add the users to the database. The generated commands are also printed to the standard output and saved automatically to the file named /tmp/ldap2seos.tcl.log.

This utility requires access to a TCL shell environment. The ldap2seos script assumes that the TCL shell path is /usr/local/bin/tclsh. If the TCL shell is placed elsewhere, change the first line in the script.

For the utility to work correctly, Privileged Access Manager must be running. The utility updates the database, so a user with the ADMIN privilege must run it. This user must also be authorized in the LDAP database settings to make the search query.

This script has the following format:

```
ldap2seos [options]
```

- **-accfld *account-field***  
Specifies the LDAP field name containing the user ID for Privileged Access Manager.  
If the UNIX user ID is in the LDAP userid field, this option is unnecessary.  
If the UNIX user ID is assigned to an LDAP field other than the userid field, specify the LDAP field as *account-field* and the LDAP userid field is ignored.

#### NOTE

If the script cannot find the userid, users are not uploaded to the Privileged Access Manager database.

- **-b *base-entry***  
Specifies the base entry, in the LDAP database, from which the users are taken. The entry must be valid inside the LDAP database. If the base entry is omitted, LDAP uses the default base entry to provide the users.
- **-d *dn***  
Specifies an entry name to be used with the **-w** switch to authenticate to LDAP as another user; mostly needed to log into LDAP as admin user.
- **-f *filename***  
Specifies a file to which data that are retrieved from the LDAP server can be temporarily stored.
- **-h**  
Displays help for this utility. The screen contains a listing and explanation of ldap2seos usage and options.
- **-h *ldap-host***  
Specifies the name of the host where the LDAP database is located. The default is the local host.
- **-l *ldap-dir***  
Specifies the directory containing the line command utilities that are assumed to be in the bin subdirectory. The default is /usr/local/ldap.
- **-p *port***  
Specifies the port LDAP uses for connections. The default is port 389.
- **-u**  
Identical to **-h**, displays help. The screen contains a listing and explanation of ldap2seos usage and options.
- **-w *bindpasswd***  
Specifies the user password. To be used with the **-d** option where authentication is required to access the LDAP database.

#### Example: Extract User Information

The following command extracts information about users from the LDAP database at host myhost.mysite.com and tries to add them to the Privileged Access Manager database.

```
ldap2seos -h myhost.mysite.com
```

## seos2ldap Script Export CA Privileged Access Manager Server Control Users to LDAP

seos2ldap exports Privileged Access Manager users from the database to an LDAP database at a server host. It extracts appropriate information about users from the Privileged Access Manager database. It then transmits the information to the LDAP database of the selected server. The extracted information is used to generate an LDIF file. Specified users are added to the LDAP database. The responses are saved automatically to the file named /tmp/seos2ldap.tcl.log.

This utility requires access to a TCL shell environment. ldap2seos assumes that the TCL shell path is /usr/local/bin/tclsh. If the TCL shell is placed elsewhere, change the first line in the script.

For the utility to work correctly, Privileged Access Manager must be running. The utility reads from the database, so the user who runs it must have the ADMIN privilege. This user must also be authorized in the LDAP database settings to make changes.

The entry schema, if you elect to use one, for the LDAP database should look like the schema for the Netscape server. If you have changed the Netscape schema, or are using another type of LDAP server, you might need to edit the `seos2ldap` sample script accordingly.

If a Privileged Access Manager database user already appears in the LDAP database, the user is not added. An error message is produced but the export process continues.

This script has the following format:

```
seos2ldap [options]
```

- **-b *base-entry***  
Specifies the base entry, in the LDAP database, that stores user information. The entry must be valid inside the LDAP database. If the base entry is omitted, LDAP prompts the user to provide it.
- **-d *dn***  
Specifies an entry name to be used with the **-w** switch to authenticate to LDAP as another user. This option is required to log into LDAP as an admin user.
- **-f *filename***  
Specifies a file to which data that are retrieved from the LDAP server can be temporarily stored.
- **-h**  
Displays a help for the utility. The screen contains a listing and explanation of `ldap2seos` usage and options.
- **-h *ldap-host***  
Specifies the name of the host where the LDAP database is located. The default is the local host.
- **-l *ldap-dir***  
Specifies the directory containing the line command utilities that are assumed to be in the `bin` subdirectory. The default is `/usr/local/ldap`.
- **-noprompt**  
Cancels base entry prompt. If you did not use the **-b *base-entry*** flag to specify the base LDAP entry, by default `seos2ldap` prompts for a base entry. This flag suppresses the prompt.
- **-p *port***  
Defines the port LDAP uses for connections. The default is port 389.
- **-u**  
Identical to **-h**, displays help. The screen contains a listing and explanation of `ldap2seos` usage and options.
- **-w *bindpasswd***  
Defines the user password. Use this with the **-d** option where authentication is required to access the LDAP database.

### Example: Export User Information

The following command extracts information about users from the Privileged Access Manager database and creates an LDIF file named `SeOS_user_dump`. The command adds records to the LDAP database at host `myhost.mysite.com`. You can edit the LDIF file later and can update LDAP manually.

```
seos2ldap -h myhost.mysite.com
```

## ntimport Utility Import Windows Users and Groups

### Valid on Windows

The `ntimport` utility extracts Windows users and groups from the Windows operating system database for import into a local database. The utility creates the Windows commands necessary to add users and groups to the local Privileged Access Manager database.

**WARNING**

Privileged Access Manager lets use Windows users and groups directly, without needing to import them into the database. Consider using this functionality of Privileged Access Manager instead of the `ntimport` utility, which was developed before Privileged Access Manager could use Windows users and groups directly.

The generated commands are displayed to the standard output. Use the option `-f` if you want to create a file to use as input to the `selang` utility.

This command has the following format:

```
ntimport {-a|{[-u] [-g] [-c]}} [-d] [-U] \
[-D] [-f filename] [-o owner] [-p pmdb] \
[-pa pmdb] [-r remote-host] [-v]
```

- **-a**  
Performs all actions of the `-c`, `-g`, and `-u` switches.
- **-c**  
Generates the `selang` commands that are required to join users to their default groups.
- **-d**  
Imports users and groups with their domain as prefix.
- **-D**  
Retrieves user and group information from the first available domain controller.
- **-f filename**  
Redirects the output to the specified file.
- **-g**  
Generates `selang` commands that are required to import groups from Windows to the local database.
- **-o owner**  
Sets ownership rules for each imported record. Use this flag, to prevent *Administrator* from automatically becoming the owner of all the records. *Owner* is the name of the user or group to be assigned ownership of all records defined by `ntimport`.
- **-p pmdb**  
Generates commands for importing user and groups into the AC environment of the `pmdb`.
- **-pa pmdb**  
Generates commands for importing user and groups into the AC and native environments of the `pmdb`.
- **-pn pmdb**  
Generates commands for importing user and groups into native environment of the `pmdb`.
- **-r remote-host**  
Retrieves user and group information from the specified `remote-host`.
- **-u**  
Generates the `selang` commands that are required to import users from the Windows database to the local database. Names longer than 40 characters are truncated.
- **-U**  
Generates the `selang` commands that are required to import surrogate rules for users.
- **-v**  
Provides the user with progress information. Use this flag to verify the progress of the program when there are many users or groups.

## policydeploy Utility Manage Enterprise Policy Deployment

The `policydeploy` utility manages multiple-rule policies (advanced policy management). The utility stores policy versions on DMS nodes, assigns policies to hosts and host groups, and unassigns these policies. You can also directly deploy or undeploy a stored policy or upgrade deployed policies to the latest version.

The utility handles several tasks and has the following functions:

Task	Function
Assign or unassign a policy	<code>policydeploy -assign</code>
Delete a policy	<code>policydeploy -delete</code>
Deploy a policy	<code>policydeploy -deploy</code>
Undeploy a policy	<code>policydeploy -undeploy</code>
Re-execute a deployment task	<code>policydeploy -fix</code>
View deployment scripts	<code>policydeploy -getrules</code>
Join or remove a host to a host group	<code>policydeploy -join</code>
Migrate a PMD to advanced policy management	<code>policydeploy -migrate</code>
Reset policy deployment	<code>policydeploy -reset</code>
Restore all policies	<code>policydeploy -restore</code>
Store a policy	<code>policydeploy -store</code>
Upgrade a policy version	<code>policydeploy -upgrade</code>
Downgrade a policy version	<code>policydeploy -downgrade</code>

## policydeploy -assign Function Assign or Unassign a Policy

This function assigns or unassigns the specified policy to one or more hosts or host groups.

This function has the following format:

```
policydeploy -assign[-] name -hnode|-ghnode list [-dms list]
```

- **-assign *name***  
Assigns the specified policy to one or more hosts or host groups.
- **-assign- *name***  
Unassigns the specified policy from one or more hosts or host groups.
- **-dms *list***  
(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.  
If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following `selang` command after you create a new DMS using `dmsmgr`:

```
so dms+(new_dms_name)
```

### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

- **-ghnode *list***  
Defines a comma-separated list of host groups (GHNODE objects) that you want to assign the policy to.
- **-hnode *list***

Defines a comma-separated list of hosts (HNODE objects) that you want to assign the policy to.

### Example: Assign an IIS 5 Protection Policy

The following example shows you how to assign a policy for securing Internet Information Services (IIS) 5 web servers. We will review the policy and the latest (fourth) version of policy IIS5 and then assign the policy to a host group called IIS5Servers. Policy IIS5 is stored on the crDMS@cr\_host.company.com DMS node.

1. Connect to the DMS using selang:

```
hosts crDMS@cr_host.company.com
```

You can now query our DMS via selang.

2. If you're not sure what is the latest finalized version of the policy, issue the following selang command to find all versions of the policy:

```
sr GPOLICY IIS5
```

The selang window lists the properties of the IIS5 policy, including the Final Policy, which is the latest version of the policy that you can assign (finalized).

3. Issue the following selang command to view the policy deployment and undeployment scripts:

```
sr RULESET IIS5#04
```

The selang window displays the IIS5#04 RULESET object, including the deployment and undeployment rules that relate to the fourth version of the IIS5 policy.

4. In a command prompt window, run the policydeploy utility:

```
policydeploy -assign IIS5 -ghnode IIS5Servers
```

This assigns the IIS5 policy to all hosts in the IIS5Servers logical host group, and in turn deploys the fourth version of the IIS5 policy on these hosts.

### Example: Unassign an IIS 5 Protection Policy

The following example shows you how to unassign an assigned IIS 5 policy from the web servers that we assigned it to in the previous example.

In a command prompt window, run the policydeploy utility:

```
policydeploy -assign- IIS5 -ghnode IIS5Servers
```

This unassigns the IIS5 policy from all hosts in the IIS5Servers logical host group, and in turn undeploys the version of the IIS5 policy that is deployed on these hosts.

### policydeploy -delete Function Delete a Policy

This function deletes the specified policy or policy version.

#### NOTE

Before you delete a policy, remove any policy dependencies. Before you delete a policy or policy version, undeploy or unassign the policy or policy version from all hosts and host groups.

You cannot delete a policy or policy version if:

- It is a prerequisite for another policy.
- It is assigned to a host or host group.
- It is deployed on a host or host group.
- It has a status of Undeployed with failures.
- It has a status on the DMS.

This function has the following format:

```
policydeploy -delete name[#xx] [-dms list]
```

- **-delete *name* [#xx]**  
Deletes the specified policy or policy version.
- **-dms *list***  
(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.  
If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following `selang` command after you create a new DMS using `dmsmgr`:

```
so dms+ (new_dms_name)
```

#### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

### Example: Delete an Unassigned IIS 5 Protection Policy

The following example shows you how to delete an unassigned IIS 5 policy from the DMS. In this example, policy IIS5 is not assigned to any hosts or host groups and is stored on the `crDMS@cr_host.company.com` DMS node.

To delete the IIS 5 protection policy, open a command prompt window and run the `policydeploy` utility:

```
policydeploy -delete IIS5
```

Policy IIS5 is deleted from the `crDMS@cr_host.company.com` DMS node.

### Example: Delete an IIS 5 Protection Policy Version

The following example shows you how to delete the unassigned policy version IIS5#05 from the DMS. In this example, policy version IIS5#05 is not assigned to any hosts or host groups and is stored on the `crDMS@cr_host.company.com` DMS node.

To delete the IIS 5 protection policy version, open a command prompt window and run the `policydeploy` utility:

```
policydeploy -delete IIS5#05
```

Policy version IIS5#05 is deleted from the `crDMS@cr_host.company.com` DMS node.

## policydeploy -deploy Function Deploy or Undeploy a Policy

This function deploys and undeploys policies on the specified endpoints, without assigning policies to a host or unassigning policies from a host.

This function has the following format:

```
policydeploy { -deploy name[#xx] | -undeploy name[#xx] } {-nodelist hnode_list | -root dbs} [-dms list]
```

- **-deploy *name* [#xx]**  
Prompts you for whether you want to directly deploy the specified stored policy version (without assigning the policy to the host) on defined endpoints. To deploy the latest stored version of the policy, omit the policy version number.
- **-dms *list***  
(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.

If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following `selang` command after you create a new DMS using `dmsmgr`:

```
so dms+(new_dms_name)
```

#### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

- **-nodelist *hnode\_list***  
Defines a comma-separated list of hosts (HNODE objects) that you want to perform the operation for.
- **-root *dbs***  
Defines a comma-separated list of databases where the policy should be deployed or undeployed.

#### NOTE

If the root database is a Policy Model parent, the policy is deployed or undeployed throughout its subscribing databases. If the root database is a Privileged Access Manager endpoint, the policy is deployed or undeployed on the specified database only. This option is for backward compatibility with r8 SP1 databases and PMDBs.

- **-undeploy *name*[#*xx*]**  
Prompts you for whether you want to directly undeploy the specified policy version *name*#*xx* (without unassigning the policy) from defined endpoints.  
To undeploy the latest stored version of the policy, omit the policy version number.

## policydeploy -fix Function Re-execute Deployment Task

This function fixes the specified deployment task or package and redeploys the task or package.

This function has the following format:

```
policydeploy -fix {-task list | -package list} [-dms list]
```

- **-dms *list***  
(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.  
If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following `selang` command after you create a new DMS using `dmsmgr`:

```
so dms+(new_dms_name)
```

#### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

- **-fix**

#### NOTE

Fixes and redeploys the specified deployment task or package.

- **-package *list***  
Defines a comma-separated list of deployment packages (GDEPLOYMENT).
- **-task *list***

Defines a comma-separated list of deployment tasks.

## policydeploy -getrules Function View Deployment Scripts

This function lets you view the selang deployment and undeployment scripts for the specified policy version.

```
policydeploy -getrules name[#xx] -ds file1 -uds file2 [-dms list]
```

- **-dms *list***  
(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.  
If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following selang command after you create a new DMS using dmsmgr:

```
so dms+(new_dms_name)
```

### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

- **-ds *file1***  
Specifies the path name of the file containing the deployment rules. These are the commands necessary to construct the policy. When you use the -getrules option, the utility creates this file.

### WARNING

Policy deployment does not support commands that set user passwords. Do not include such commands in your deployment script file. Native selang commands are supported but do not appear in deviation reports.

- **-getrules *name[#xx]***  
Retrieves the selang deployment and undeployment scripts for the specified policy version. If you do not specify a policy version, the command applies to the latest policy version.
- **-uds *file2***  
Defines the path name of the file containing the rules required to undeploy the policy. These are the commands necessary to undeploy the policy. When you use the -getrules option, the utility creates this file.  
When Privileged Access Manager undeploys a policy, if there is no policy undeployment script stored, Privileged Access Manager calculates the commands required to remove the policy.

## Example: View the Deployment Scripts Associated with an IIS 5 Protection Policy

The following example shows you how to view the selang scripts associated with deploying and undeploying a policy for securing Internet Information Services (IIS) 5 web servers. The name of the policy is myPolicy.

To view the selang scripts, run the following command:

```
policydeploy -getrules myPolicy -ds c:\folder\deployRules.txt -uds undeployRules.txt
```

## policydeploy -join Function Join or Remove a Host to a Host Group

This function joins a host to a host group or removes a host from a host group.

This function has the following format:

```
policydeploy -join[-] hnode_name -ghnode name [-dms list]
```

- **-dms *list***

(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.

If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following `selang` command after you create a new DMS using `dmsmgr`:

```
so dms+(new_dms_name)
```

#### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

- `-ghnode name`  
Defines the name of the host group for the operation you want to perform.
- `-join hnode_name`

#### NOTE

Adds the specified host to the host group.

- `-join- hnode_name`

#### NOTE

Removes the specified host from the host group.

## policydeploy -migrate Function Migrate a PMD to Advanced Policy Management

This function migrates a PMD to the advanced policy management environment. When you migrate a PMD to advanced policy management, you create policies from the rules in the PMD, create a host group and hosts in the DMS, and assign the policies to the host group.

This function has the following format:

```
policydeploy -migrate pmdName@hostName [-dms name] [-policydir directory] \
[-exportfilter "class, class..."] [-hgcreate] [-pcreate name] [-addpmdfilter]\
[-unsubs] [-delete] [-auto]
```

- `pmdName@hostName`  
Defines the name of the PMD to migrate.
- `-dms name`  
(Optional) Defines the name of the DMS that the rules in the PMD will be migrated to. If you do not specify the DMS name, the DMS name is retrieved from the Privileged Access Manager database on the local host.

#### NOTE

If you do not specify a DMS name and there is more than one DMS name specified in the Privileged Access Manager database on the local host, the rules in the PMD are migrated to all specified DMSs.

- `-policydir directory`  
(Optional) Defines the directory in which the policy file is stored. If you do not specify a directory, the policy file is stored in your current working directory.  
The name of the policy file is `pmdName_hostName_policy`.
- `-exportfilter "class, class..."`  
(Optional) Specifies the Privileged Access Manager classes to export from the PMD database. If you do not specify any classes, all classes in the PMD database are exported.  
The following points apply to the `-exportfilter` parameter:

If you export rules that modify resources in a particular class, and the class has a corresponding resource group, Privileged Access Manager also exports the rules that modify resources in that resource group.

If you export rules that modify resources in a particular resource group, Privileged Access Manager also exports the rules that modify the member resource of the resource group.

If you export rules that modify resources in a particular class and that class has a PACL, Privileged Access Manager also exports the rules that modify resources in the PROGRAM class.

If you export rules that modify resources in a particular class and that class has a CALACL, Privileged Access Manager also exports the rules that modify resources in the CALENDAR class.

If you export rules that modify resources in a particular class, and one of the resources in that class is a member of a CONTAINER resource group, Privileged Access Manager exports the rules that modify resources in the CONTAINER class and the rules that modify the resources that are members of each CONTAINER resource group.

- **-hgcreate**  
(Optional) Creates a host group (GHNODE object) on the DMS that corresponds to *pmdName*, creates hosts (HNODE objects) on the DMS that correspond to endpoint subscribers of *pmdName*, and joins the hosts to the host group.
- **-pcreate *name***  
(Optional) Creates a POLICY object on the DMS that contains the rules in the policy file that was exported from *pmdName*, and assigns the POLICY object to the host group on the DMS that corresponds to *pmdName*. If you specify *name*, the created POLICY object is named *name\_POLICY#01*; if you do not specify *name*, the created POLICY object is named *pmdName\_POLICY#01*.
- **-addpmdfilter**  
(Optional) Applies a filter file to *pmdName*. The filter file is named filter.flt and is located in the same directory as *pmdName*.

#### NOTE

You use the filter file to create a password PMD. The filter file lets only user password commands be sent to the subscribers of *pmdName*.

- **-unsubs**  
(Optional) Unsubscribes endpoint subscribers from *pmdName*.
- **-delete**  
(Optional) Deletes *pmdName* after the policydeploy -migrate function has finished executing.
- **-auto**  
(Optional) Specifies to execute both the -hgcreate and -pcreate options. This option does the following:
  - Exports the rules in *pmdName*
  - Creates a host group (GHNODE object) on the DMS that corresponds to *pmdName*
  - Creates hosts (HNODE objects) on the DMS that correspond to endpoint subscribers of *pmdName*
  - Joins the hosts to the host group
  - Creates a POLICY object on the DMS that contains the rules in the policy file that was exported from *pmdName*
  - Assigns the POLICY object to the host group on the DMS that corresponds to *pmdName*

#### Example: Migrate Rules and Create a Host Group

This example migrates the rules from Master PMD on host A to DMS\_\_ on host B, saves the policy file to the C:\Data\policies\_MasterPMD\_hostA directory, creates a host group named MasterPMD on DMS\_\_, creates hosts on DMS\_\_ that correspond to the endpoint subscribers of Master PMD, and joins the hosts to the MasterPMD host group:

```
policydeploy -migrate MasterPMD@hostA -dms DMS__@hostB -policydir "C:\Data\policies_MasterPMD_hostA" -hgcreate
```

## policydeploy -reset Function Reset Policy Deployment

This function resets policy deployment on the endpoint. Privileged Access Manager undeploys all the effective policies on the endpoint, deletes all advanced policy management properties, and resets host status.

This function has the following format:

```
policydeploy -reset hnode_name [-dms list]
```

- **-dms *list***  
(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.  
If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following selang command after you create a new DMS using dmsmgr:

```
so dms+(new_dms_name)
```

### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

- **-reset *hnode\_name***  
Resets policy deployment on the specified endpoint.

## policydeploy -restore Function Restore All Policies

This function undeploys any policies on the specified host, then restores (directly redeploys) all the policies that should be deployed (assigned or directly deployed) on the host by resending all the deployment tasks to the host for execution.

This function has the following format:

```
policydeploy -restore hnode_name [-dms list]
```

- **-dms *list***  
(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.  
If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following selang command after you create a new DMS using dmsmgr:

```
so dms+(new_dms_name)
```

### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

- **-restore *hnode\_name***

### NOTE

Restores (directly redeploys) all the policies that should be deployed on the specified host.

## policydeploy -store Function Store a Policy

This function stores the specified policy on the DMS nodes specified by the command or in the local Privileged Access Manager database. Unless you use the `-silent` option, you need to confirm this action at the prompt.

If no previous version of the specified policy is stored on the DMS, version 1 of the policy is created (*name#01*). If a previous version of this policy exists, a new version of the policy is created (*name#last\_version+1*). The policy version you store is automatically finalized. When you need to update a policy, you must store a new version of the policy that contains the required modified policy deployment and undeployment rules.

This function has the following format:

```
policydeploy -store name -ds file1 [-uds file2] [-dms list] [-desc description] [-prereq list] [-silent]
```

- **-desc *description***  
(Optional) Defines the business description for the policy.
- **-dms *list***  
(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.  
If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following `selang` command after you create a new DMS using `dmsmgr`:

```
so dms+(new_dms_name)
```

### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

- **-ds *file1***  
Specifies the path name of the file containing the deployment rules. These are the commands necessary to construct the policy. When you use the `-getrules` option, the utility creates this file.

### WARNING

Policy deployment does not support commands that set user passwords. Do not include such commands in your deployment script file. Native `selang` commands are supported but do not appear in deviation reports.

- **-prereq *list***  
(Optional) Defines a comma-separated list of policies that must be deployed before you can deploy this policy.

### WARNING

If a prerequisite policy is not deployed when you try to deploy a dependent policy, the deployment task's status is changed to *Pending Prerequisite* and the deployment resumes when all prerequisite policies are deployed. Similarly, if you try to undeploy a policy that is a prerequisite to another deployed policy, the deployment task's status is changed to *Pending Dependents* and the deployment resumes when all dependent policies are undeployed.

- **-silent**  
(Optional) Suppress the confirmation prompt for the requested action.
- **-store *name***  
Stores the specified policy on the specified DMS nodes or in the local Privileged Access Manager database.  
**Note:** Policy names cannot include the `#` (hash) character which is reserved for denoting policy version numbers and is added automatically.
- **-uds *file2***  
Defines the path name of the file containing the rules required to undeploy the policy. These are the commands necessary to undeploy the policy. When you use the `-getrules` option, the utility creates this file.

When Privileged Access Manager undeploys a policy, if there is no policy undeployment script stored, Privileged Access Manager calculates the commands required to remove the policy.

### Example: Store an IIS 5 Protection Policy

The following example shows you how to store a policy for securing Internet Information Services (IIS) 5 web servers. This is the first time we store this policy on the DMS.

#### NOTE

The selang commands in this example are for resources on a Windows operating system but the same procedure also applies on UNIX.

1. Save a file named IIS5.selang with the following IIS script:

```
# IIS5 deployment script
eu inet_pers owner(nobody)
er FILE c:\InetPub\wwwroot\* defaccess(none) owner(nobody)
authorize FILE c:\InetPub\wwwroot\* uid(inet_pers) access(all)
er FILE c:\InetPub\wwwroot\scripts defaccess(none) owner(nobody)
er FILE *.asp defaccess(none) owner(nobody)
authorize FILE *.asp uid(inet_pers) via(pgm(inetinfo.exe)) access(read, execute)
```

These are the commands necessary to deploy an IIS 5 protection policy.

2. Save a file named IIS5\_rm.selang with the following script:

```
# IIS5 undeployment script
ru inet_pers
rr FILE c:\InetPub\wwwroot\*
rr FILE c:\InetPub\wwwroot\scripts
rr FILE *.asp
```

These are the commands necessary to undeploy the IIS 5 protection policy we created in Step 1.

3. Open a command prompt window and run the policydeploy utility:

```
policydeploy -store IIS5 -ds IIS5.selang -uds IIS5_rm.selang -desc "IIS5 web server security policy" -
silent
```

This stores on the DMS the policy IIS5 (GPOLICY object) and the first version of the policy (IIS5#01 POLICY object) with the scripts defined in IIS5.selang and IIS5\_rm.selang.

## policydeploy -upgrade Function Upgrade or Downgrade a Policy Version

This function upgrades a policy to its latest finalized version on the defined hosts, or downgrades a policy to a specified policy version on the defined hosts.

This function has the following format:

```
policydeploy {-upgrade name | -downgrade name#xx} [-nodelist hnode_list|-ghnode name] [-list] [-dms name]
```

- **-dms list**

(Optional) Specifies a comma-separated list of DMS nodes to use. When you deploy or undeploy a policy, these are the DMS nodes to which the action is reported. When you store a policy, these are the DMS nodes where the policy is stored.

If you do not specify DMS nodes with this option, the utility uses the list of DMS nodes specified in the local Privileged Access Manager database. To specify a list of DMS nodes in the database, you need to issue the following selang command after you create a new DMS using dmsmgr:

```
so dms+(new_dms_name)
```

#### NOTE

You need to issue the same command if you did not specify the DMS node during installation, or if you want to replace or add the registered DMS on the endpoint. However, when you specify to create an advanced

policy management server during installation, the DMS is added to the database and you do not need to manually run the above command.

- **-downgrade *name#xx***  
Downgrades a policy to the specified policy version on the defined hosts.
- **-ghnode *name***  
Defines the name of the host group for the operation you want to perform.
- **-list**  
(Optional) Lists the hosts that have a version of the specified policy deployed, that is not the version specified. If you use **-upgrade** the implicitly specified version is the latest available.
- **-odelist *hnode\_list***  
Defines a comma-separated list of hosts (HNODE objects) that you want to perform the operation for.
- **-upgrade *name***  
Upgrades the specified policy to its latest finalized version on the defined hosts.

### Example: Upgrade an IIS 5 Protection Policy

The following example shows you how to upgrade a policy. We will first review the deployment to see which hosts do not have the latest version of this policy deployed.

1. In a command prompt window, run the policydeploy utility:

```
policydeploy -upgrade IIS5 -list
```

This lists the hosts that have an older version of the IIS5 policy deployed.

2. Upgrade all of these hosts to the latest version of the policy:

```
policydeploy -upgrade IIS5
```

### Example: Downgrade an IIS 5 Protection Policy

The following example shows you how to downgrade a policy. We will first review the deployment to see which hosts have a deployed policy that has earlier versions.

1. In a command prompt window, run the policydeploy utility:

```
policydeploy -downgrade IIS5#3 -list
```

This lists the hosts that have a version of the IIS5 policy deployed that is later than version 3.

2. Downgrade all of these hosts to the third version of the policy:

```
policydeploy -downgrade IIS5#3
```

## ReportAgent Utility Send Report Snapshots and Audit Events

The ReportAgent sends report snapshots and audit events to the Distribution Server for inclusion in Privileged Access Manager, UNIX Authentication Broker, and Audit Log reports.

Configure an endpoint for reporting before you run the ReportAgent. When you configure an endpoint for reporting, you specify the Distribution Server with which the ReportAgent communicates and the schedule at which it runs. After you configure an endpoint for reporting, the ReportAgent runs as a daemon or service and sends snapshots at the scheduled times. However, to send report snapshots or audit events to the Distribution Server immediately, run the ReportAgent on demand.

**Note:** For more information about how to configure an endpoint for reporting, see the *Implementation Guide*. You can also use the `report_agent.sh` script to configure, start, and stop the ReportAgent on UNIX computers.

On UNIX computers, you run the ReportAgent utility from the `ACSharedDir/bin` directory, where `ACSharedDir` is the default directory `/opt/CA/PAMSCShared`. You may also need to set the library path environment variable.

This command has the following syntax:

```
ReportAgent -debug {0 | 1 | 2} -task {0 | 1 | 2 | 3 | 4} [-now]
```

```
ReportAgent -report snapshot
```

- **-debug {0 | 1 | 2}**  
Specifies to run the ReportAgent in debug mode. The ReportAgent service or daemon must be stopped to use this option.  
**Limits:** 0Prints debug information to the console.  
1Prints debug information to the log file.  
2Does not print debug information (no output).
- **-task {0 | 1 | 2 | 3 | 4}**  
Specifies the information that the ReportAgent sends to the Distribution Server.  
**Limits:** 0Sends a snapshot of the Privileged Access Manager database and any local PMDBs to the queue/snapshots queue on the Distribution Server.  
1Sends endpoint audit events to the queue/audit queue on the Distribution Server.  
2(UNIX) Sends a snapshot of the UNIX Authentication Broker database to the ac\_endpoint\_to\_server queue on the Distribution Server.  
3(UNIX) Sends UNIX Authentication Broker audit events to the queue/audit queue on the Distribution Server.  
4(UNIX) Sends keyboard logger audit events to the queue/audit queue on the Distribution Server.
- **-now**  
Run the ReportAgent immediately.  
If you do not specify this option, the ReportAgent runs at the next scheduled time.
- **-report snapshot**  
Send a snapshot of the Privileged Access Manager database and any local PMDBs to the queue/snapshots queue on the Distribution Server immediately. The ReportAgent service or daemon must be running to use this option.

#### Example: View ReportAgent Debug Information

The following example sets the library path environment variable on a Linux computer, then specifies the following actions:

- To run the ReportAgent in debug mode immediately
- To print debug information to the console
- To send audit events to the Distribution Server

```
LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:/opt/CA/PAMSCShared/lib
```

```
export LD_LIBRARY_PATH
```

```
cd /opt/CA/PAMSCShared/bin
```

```
./ReportAgent -debug 0 -task 1 -now
```

## ReportAgent Log Files

The following table lists the log files to which the ReportAgent writes debug information when you run the ReportAgent -debug 1 command. In this table, *ACSharedDir* is the default directory /opt/CA/PAMSCShared and *ACInstallDir* is the directory in which you installed Privileged Access Manager:

ReportAgent Option	UNIX Log File	Windows Log File
-task 0	<i>ACSharedDir</i> /log/ac2xml.log	<i>ACInstallDir</i> \log\ac2xml.log
-task 1	<i>ACSharedDir</i> /log/ac2elm.log	<i>ACInstallDir</i> \log\ac2elm.log
-task 2	<i>ACSharedDir</i> /log/unab2xml.log	-
-task 3	<i>ACSharedDir</i> /log/unab2elm.log	-
-task 4	<i>ACSharedDir</i> /log/kbl2elm.log	-

## report\_agent.sh Script Configure the Report Agent

### Valid on UNIX

The report\_agent.sh script lets you configure the Report Agent daemon after installation. Use the report\_agent.sh script if you need to change the Report Agent configuration settings you set when you installed Privileged Access Manager.

The report\_agent.sh script is located in *ACSharedDir*/lbin. By default, this directory is /opt/CA/PAMSCShared/lbin.

This command has the following format:

```
report_agent.sh start
```

```
report_agent.sh stop
```

```
report_agent.sh config -server##hostname [-proto {ssl|tcp}] [-port port_number] [-rqueue queue_name] \
```

```
[-schedule <time@day[,day2,...]>] [-audit] [-bak] [-silent]
```

- **config**  
Specifies that the remaining parameters configure the Report Agent daemon.
- **start**  
Starts the Report Agent.
- **stop**  
Stops the Report Agent.
- **-server *hostname***  
Defines the name of the Distribution Server host. Combined with the input from the -port option, the script constructs the Distribution Server URL and sets the report\_server configuration setting in the ReportAgent section.
- **-audit**  
Specifies whether you want to send endpoint audit data to the Distribution Server. This sets the reportagent\_enabled configuration setting in the ReportAgent section.
- **-bak**  
Specifies to keep timestamped backups of audit files. This sets the logmgr section configuration setting Backup\_Date to yes and audit\_max\_files to 50.
- **-port *port\_number***

Defines the port number to use for communication with the Distribution Server. Combined with the input from the `-server` option, the script constructs the Distribution Server URL and sets the `report_server` configuration setting in the ReportAgent section.

- **-proto**  
Specifies the connection protocol (TCP or SSL). This sets the `use_ssl` configuration setting in the ReportAgent section
- **-rqueue *queue\_name***  
Defines the name of the queue to which the Report Agent sends snapshots of the local database and any PMDBs. This sets the `send_queue` configuration setting in the ReportAgent section.
- **-schedule *<time@day[,day2,...]>***  
Defines when to generate reports and when to send the reports to the Distribution Server.
- **-silent**  
Specifies not to ask for confirmation.

### Example: Configure the Report Agent

This example sets the Report Agent to send database snapshots to a Distribution Server on `rscomp.com` using port 61616 over SSL and a queue named `queue/snapshots`. It also enables sending audit data to the Distribution Server and sets backup settings for the audit log file:

```
report_agent.sh config -server rscomp.com -proto ssl -port 61616 -rqueue queue/
snapshots -audit
```

Once you configure Report Agent, you should update the `+reportagent` user with a correct password (shared secret) that the Distribution Server expects. To do this, enter the following:

```
eu +reportagent epassword(Shared_Secret) nonnative
```

## seaudit Utility Display Audit Log Records

The `seaudit` utility displays the records in the Privileged Access Manager audit log file. To execute the `seaudit` utility on Windows, you must have the `AUDITOR` attribute and must belong to the `audir_group` in `seos.ini`. When displaying audit records that include passwords, `seaudit` protects the password identity by substituting a series of asterisks (`***`) in place of the password text.

### NOTE

You can use the string matching in the command switches and options. Some UNIX shells automatically expand mask arguments; therefore, when invoking `seaudit` from such a shell, prevent the masks from being handled by the shell by typing a backslash (`\`) before an asterisk or question mark.

### NOTE

The `seaudit` utility displays trace records by user name, not by user ID.

This command has the following format:

```
seaudit switch [options]
```

- **switch**  
Defines the mode of operation for the utility. Can be *one* of the following options:
  - **-a | -all**  
Displays all records except the user trace records sent to the audit log by the tracing facility.

**NOTE**

The connected TCP records, which are available for UNIX, are also not displayed. Specify the `-c` option to display these records.

- **-, | -help**  
Displays the help for this utility.
- **{-i | -inet} *host service***  
Displays the INET audit records of the TCP requests received from the specified hosts for the specified services. Both *host* and *service* are masks that identify the set of hosts and services that seaudit searches for. On UNIX, to list the TCP records with the network ID (port number) to which connection was made, add the `-c` flag. For example:  
  

```
seaudit -i -c myhost telnet
```
- **{-l | -login} *user1, user2, ... terminal***  
Displays the LOGIN records for the comma-separated specified users, on the specified terminal. Both *user* and *terminal* are masks. On UNIX, this also lists records that are created by serevu when it enables and disables users, and records that are created by the authorization daemon when an invalid password is entered.
- **{-r | -resource} *class resource user1, user2, ...***  
Displays the general resources audit of the specified class on the specified resource for the specified comma-separated users.
  - a. *class* is a mask that identifies the class to which the accessed resource belongs.
  - b. *resource* is a mask that identifies the names of the resources that were accessed.
  - c. *user* is a mask of the name of the user who accessed the resource.
- **-s | -start**  
Displays the Privileged Access Manager startup and shutdown messages.
- **-St | -Stat *message\_number***  
(UNIX only). Displays a description of the watchdog message number.
- **-t | -table**  
Displays the table of log codes.
- **-tr**  
Displays trace records of all the users whose activities are being traced.  
**Note:** Trace records display the login session ID column by default. If you do not want to display this column, use the `-format` option.
- **-trr *resource***  
Displays the trace records of the specified resource.
- **-tru {*uid1|user1*}, {*uid1|user2*}, ...**  
Displays the trace records of the users with the specified numeric uids or user names.
- **-u *command class record user***  
Displays database update audit records:
  - a. *command* is a mask identifying the set of selang commands to search for.
  - b. *class* is a mask identifying the classes to search for.
  - c. *record* is a mask identifying the records to search for.
  - d. *user* is a mask identifying the users who executed the commands.
- **-w**  
Displays the watchdog audit records.

**NOTE**

The user trace does not record an event when a user deletes an internally protected file.

- **options**

Defines optional modifiers that change the way that the utility displays its information. Can be one or more of the following options:

- **-c**

(UNIX only). Displays the *connected* INET records. These records are generated for session ID tracking, which list the port number of successful TCP connections.

For example, a user (user1) opens a Telnet session from comp1 to comp2, both with Privileged Access Manager installed. Privileged Access Manager on comp2 can be configured (logconnected configuration setting) to send the acknowledgement to comp1 with the credentials of the user who logged in through the Telnet session (this may be a user other than user1). When comp1 receives this acknowledgement, it creates a TCP-CONNECTED record (a session establishment record) that can then be displayed using the -c option.

- **-detail**

Displays detailed information about each record.

- **-delim *delimiter***

Defines the delimiter to use before the first field and between the remaining fields. For example, the following command makes fields appear in quotation marks that are separated by a comma:

```
seaudit -a -delim \,
```

- **-delim2 *delimiter***

Same as the -delim option, except that the delimiter does not appear before the first field.

- **-delim3 *delimiter***

Same as the -delim option, except that it includes a delimiter between day, month, and year.

- **-delim4 *delimiter***

Same as the -delim2 option.

- **-ed *date***

Specifies the end date. Records that are logged after this date are *not* displayed.

You can specify the *date* in one of two ways:

- Using the format *dd-mm-yyyy*.
- Using the string *today* to set the date as today.

You can also use the string *today* followed by - (minus) and a number. This defines the date as the specified number of days before today. For example, *today-3* means that the date is three days ago.

- **-et *time***

Specifies the end time. Records that are logged after this time are *not* displayed.

You can specify *time* in one of two ways:

- Using the 24-hour format *hh:mm*
- Using the string *now* to set the time as now.

You can also use the string *now* followed by - (minus) and a number. This defines the time as the specified number of minutes before now. For example, *now-60* means that the time is sixty minutes (one hour) ago. To delineate a time frame within a particular day, use this option with -sd, -ed or both.

**Note:** The *now* string is valid for the present day's time. For example, if the present time is 130 am, you specify *now-89*. If you specify *now-90*, then no records appear.

- **-f | -failure**

Specifies *not* to display access failures.

- **{-fn | -file} *fileName***

Specifies the name of the audit log file to be searched.

- **-format *release***

Specifies that the output format looks like it did for the Privileged Access Manager *release*.

*release* Defines the release number. The valid values are:

- a. **80sp1** The output in r8 SP1 did not include the effective UID column that exists in newer releases.
- b. **12** The output in r12.0 did not include the ability to display password change records. For trace records, the output in r12.0 also did not include the login session ID information.

- **-g | -grant**  
Specifies *not* to display successful (granted) accesses.
- **-gn | -grantnotify**  
Specifies *not* to display successful (granted) accesses, except for notify records.
- **-kbl -a -sid *sid* {-rp | -pr | -cmd | -exe | -disp}**  
(UNIX only) Specifies to display the content of the keyboard logging audit file (kbl.audit).
  - **-a**  
Displays all recorded sessions in the audit file.
  - **-sid *sid***  
Specifies the keyboard logging session ID.
  - **-rp**  
Replays the entire keyboard logging session.
  - **-pr**  
Displays the entire keyboard logging session, excluding control characters.
  - **-cmd**  
(UNIX Only) Displays the commands that the user entered during the command line logging session.
  - **-exe**  
Displays the EXECARGS details of commands that the user executed in the shell.
  - **-disp**  
Specifies to display the recorded session time.

#### NOTE

You can run the command in the following shells: bash, tcsh, csh, ksh, jsh, rsh, ash, zsh

- **-logout**  
(UNIX only) Specifies *not* to display logout records.
- **-millennium**  
(UNIX only) Specifies that years be displayed with four digits instead of two.
- **-n | -netaddr**  
Specifies that the internet addresses should be displayed instead of host names in TCP/IP records.
- **-notify**  
Specifies *not* to display NOTIFY audit records.
- **{-o | -origin} *host***  
Specifies that only records originating from the specified host be displayed.  
This option is only applicable when browsing records from a consolidated audit file that is created by the selogrcd log-routing collection daemon.
- **-pwa**  
(UNIX only) Specifies *not* to display password attempt records.
- **-sd *date***  
Specifies the start date. Records that logged prior to this date are *not* displayed.  
You can specify the *date* in one of two ways:
  - Using the format *dd-mm-yyyy*.
  - Using the string *today* to set the date as today.
 You can also use the string *today* followed by - (minus) and a number. This defines the date as the specified number of days before today. For example, *today-3* means that the date is three days ago.
- **sessionid**  
Specifies to show a column that contains user login session ID information. This column is hidden by default.

**NOTE**

This option is valid only for endpoints with r12.0 SP1 and above.

- **-st *time***

Specifies the start time. Records that logged before this time are *not* displayed.

You can specify *time* in one of two ways:

- Using the 24-hour format *hh:mm*
- Using the string *now* to set the time as now.

You can also use the string *now* followed by - (minus) and a number. This defines the time as the specified number of minutes before now. For example, *now-60* means that the time is sixty minutes (one hour) ago. To delineate a time frame within a particular day, use this option with *-sd*, *-ed* or both.

**Note:** The *now* string is valid for the present day's time. For example, if the present time is 130 am, you specify *now-89*. If you specify *now-90*, then no records appear.

- **-v | -servnum**

Specifies that port numbers are displayed instead of service names.

- **-warn**

Specifies *not* to display warning records.

**Examples**

- To list all audit records since 3 January 2004, use the following command:

```
seaudit -a -sd 04-Jan-2004
```

- To list the failed logins of the user root from any terminal on 3 January 2004, use the following command:

```
seaudit -sd 04-Jan-2004 -ed 04-Jan-2004 -l root * -g
```

- To list all accesses of user John to every resource of class FILE, use the following *command*:

```
seaudit -r FILE "*" John
```

- To list all audit records that were logged between 17:00 (the first day) and 08:00 (the following day), for all dates, use the following command:

```
seaudit -a -st 17:00 -et 08:00
```

- To list all audit records that were logged between 08:00 and 17:00, use the following command:

```
seaudit -a -st 08:00 -et 17:00
```

- To list all warning records for logins and resource accesses for a single user, use the following command:

```
seaudit -login * * -resource * * * -grant -failure -logout -pwa
```

- To list all login records for two users, use the following command:

```
seaudit -login "user1, user2"
```

- To list all audit records from yesterday, use the following command:

```
seaudit -a -sd today-1 -ed today-1
```

- To list all the audit records in the kbl.audit log file, use the following command:

```
seaudit -kbl
```

- To display all the recorded sessions in the audit file, use the following command:

```
seaudit -kbl -a
```

- To display the keyboard logger audit log file, use the following command:

```
seaudit -kbl -a -sid 22764
```

- To replay a user session, use the following command:

```
seaudit -kbl -sid 22316 -rp
```

- To display all the commands that a user enters in a session, use the following command:

```
seaudit -kbl -sid 22316 -cmd
```

- To list all audit records that trace the activity of a single user with UID 244 attempting to access files, use the following command:

```
seaudit -tru 244 -trr FILE
```

- To list all audit records that trace the activity of two users, use the following command:

```
seaudit -tru "user1, 244"
```

- To list all audit records logged from 5 minutes ago, use the following command:

```
# date

## sebuildla Utility Create a Lookaside Database

### Valid on UNIX

The `sebuildla` utility creates a lookaside database for use by the Privileged Access Manager daemon, `seosd`. The `seosd` daemon uses the database to translate UNIX UIDs to user names, GIDs to group names, host IP addresses to host names, and service ports to port names. The database contains only the number to name translation. `sebuildla` also lets you add information from the LDAP Directory Information Tree (DIT) to the user lookaside database.

#### WARNING

To set up `sebuildla` and the required LDAP configuration settings, you must be familiar with LDAP and must be able to execute the `ldapsearch` command. We recommend that you read the man pages for `ldap(1)`, `ldapsearch(1)`, and the information about setting up in the documentation for your LDAP client. Also, before you use `sebuildla` to build the lookaside databases, specify the full path of the lookaside database, in the `lookaside_path` configuration setting.

The first time that you build the lookaside database, use the following command:

```
sebuildla -a
```

This creates *all* of its components. Single files of the database can be updated later by using the relevant switches.

If you installed Privileged Access Manager on a NIS, NIS+, or DNS server, place calls to the `sebuildla` utility in the related makefiles.

#### NOTE

By default, the lookaside database files (`groupdb.la`, `hostdb.la`, `servdb.la`, and `userdb.la`) are protected against all user access other than access with the `sebuildla` program.

The `sebuildla` utility scans the resolution mechanisms in the system, such as `/etc` files and NIS, to build the lookaside databases.

- `sebuildla` reads `/etc/resolv.conf` to get the domain name used.

#### NOTE

For Privileged Access Manager to resolve host names to fully qualified names, the `resolv.conf` file must have either the domain or search configuration option defined. For more information about the `resolv.conf` file, see the man pages for this file.

- `sebuildla` uses the system resolution option to create the lookaside database. (This is usually the net caching daemon.)
- Privileged Access Manager uses the `/etc/nsswitch.conf` file (for the net caching daemon or any other system resolution option) to decide where to retrieve data from.

For example, if the `/etc/nsswitch.conf` file contains the following line for hosts, information is retrieved from the local machine's files first (`/etc/hosts`); it then retrieves information from the DNS and then the NIS:

```
hosts:      files dns nis
```

If the file contains the following line instead, information is retrieved only from your local machine's files. The look aside database contains only the hosts that are in `/etc/hosts`:

hosts:            files

## NOTE

If a host has a fully qualified name, sebuildla uses it.

Variations in machine configuration may cause instances where sebuildla does not list all the names of a local environment. In this case, you can use sebuildla to load all the required entries from a list file. To do this, create a list file with each object name on a separate line. The utility reads this list file and ensures that all the objects in the list file are added to the relevant lookaside database if necessary. sebuildla ignores duplicate objects.

The following table lists the files sebuildla uses to build each lookaside database.

Objects in	Are added to the
<i>ACInstallDir</i> /ladb/userlist	users lookaside database
<i>ACInstallDir</i> /ladb/grouplist	groups lookaside database
<i>ACInstallDir</i> /ladb/hostlist	hosts lookaside database
<i>ACInstallDir</i> /ladb/servlist	services lookaside database

In the format of the files in the *ACInstallDir*/ladb directory:

- sebuildla ignores empty lines or lines that begin with an exclamation point (!), number sign (#), or a semicolon (;).
- Other lines represent entries that sebuildla must add to the appropriate lookaside database, if the entry can be resolved.
- The user, group, host, or service name must start in the first position of the line.

You can use dbmgr -dump -r 1 HOST > /opt/CA/PAMSC/ladb/hostlist to create the list files. For example, to create a list of the hosts that are defined in class HOST in the local database, enter:

```
dbmgr -dump -r 1 HOST > /opt/CA/PAMSC/ladb/hostlist
```

The -l switch makes a single request from DNS for a list of all hosts in the default domain, instead of querying the DNS server for the FQDN of each host entry as it is obtained. The fast load option is effectual only if DNS is installed. Only host names in the default domain are made fully qualified. Fully qualified names are left as such. Host names that are scanned from the system mechanism that are not fully qualified, and are not found in the default domain, are left unqualified. Host names that are loaded from the hostlist file that are not fully qualified are discarded.

This command has the following format:

```
sebuildla switch [options]
```

- **switch**  
Specifies the mode of operation for the utility. Can be *one* of the following:
  - **-a**  
Creates *all* the lookaside database files.
  - **-e**  
Creates a hosts lookaside database file excluding the DNS.
  - **-g**  
Creates a groups lookaside database file.
  - **-h**

Creates a hosts lookaside database file with the DNS.

– **-help**

Displays the help for this utility.

– **-n**

Collects information from an LDAP Directory Information Tree (DIT) and appends it to the users lookaside database it creates from the primary user data source (-u switch). You can only use this switch with the -u switch or the -a switch so it is most useful when the LDAP DIT provides more user data and is not used as the system's naming service.

Before you use this switch, follow these steps:

- a. Set the following seos.ini file tokens for Privileged Access Manager to find the LDAP service: ldap\_base, ldap\_hostname, and ldap\_userdn
- b. Run the seldapcred utility to store the encrypted LDAP password.
- c. (Optional) Set the ldap\_port and ldap\_timeout tokens for your environment.  
The time it takes to retrieve information from the LDAP service depends on how fast the LDAP service is, and how much user data is stored in the DIT. You can adjust the ldap\_timeout token in the [seos] section of the seos.ini file to account for these aspects.
- d. (Optional) If you are using a non-standard schema, set the ldap\_uid\_attr, ldap\_uidNumber\_attr, and ldap\_user\_class tokens.

– **-s**

Creates a services lookaside database file.

– **-u**

Creates a users lookaside database file.

**NOTE**

You can specify the -n switch with the -u switch to add user data that is collected from an LDAP service.

– **-G**

Lists the contents of the groups lookaside database files.

– **-H [IPv4 | IPv6]**

Lists the contents of the hosts lookaside database files.

– **-S**

Lists the contents of the services lookaside database files.

– **-U**

Lists the contents of the users lookaside database files.

• *options*

Specifies optional modifiers that change the way that the utility displays its information. Can be one or more of the following:

– **-l**

Loads the lookaside database using only the list file. This excludes the resolution mechanism of the system.

– **-f**

Fast loads the lookaside database (hosts only) when using the -h switch.

## sechkey Utility

Use the sechkey utility to manage Privileged Access Manager encryption and so protect your Privileged Access Manager management communications. You must have the ADMIN attribute to use sechkey.

You can use it to set an encryption key for symmetric encryption, or you can use it for SSL (PKI) encryption.

If you are using symmetric keys, we recommend that you change the key from the default. If you are using SSL, we recommend that you change the default certificate and associated private key from the default.

Whichever encryption method you use, change the keys on all computers at your site after you have installed or upgraded Privileged Access Manager. This prevents unauthorized users from accessing the system.

The utility handles the following tasks:

- [Change a symmetric encryption key](#)
- [Change the symmetric encryption method](#)
- [Configure X.509 certificates](#)

## sechkey Utility Change a Symmetric Encryption Key

The sechkey utility changes the Privileged Access Manager symmetric encryption key for Privileged Access Manager programs.

You can run sechkey in interactive or non-interactive mode. When you run sechkey in interactive mode, sechkey prompts you to enter the old and new encryption keys.

You must stop Privileged Access Manager before you use sechkey to change a symmetric encryption key. You must have the ADMIN attribute to use sechkey.

### WARNING

To avoid communication problems, use the same encryption key on all computers that run Privileged Access Manager components.

This utility has the following format in interactive mode:

```
sechkey
```

This utility has the following format in non-interactive mode:

```
sechkey {oldkey | -d} {newkey | -d} [-s registry_path]
```

sechkey has some additional switches that are only valid on UNIX computers. This utility has the following format for UNIX computers:

```
sechkey {oldkey | -d} {newkey | -d | -n} [-nopmd | -r hostname]
```

```
sechkey -k newkey
```

```
sechkey -c
```

- **-c**  
(UNIX) Clears the selogrd encryption key. The default key is saved in the key file.  
**Note:** The saved key itself is encrypted with the default encryption method.
- **-d**  
Specifies the default Privileged Access Manager key.
- **-k**  
(UNIX) Specifies the selogrd encryption key that you want to change to. The encryption key is saved in a new file or updated in the old one.
- **-n**  
(UNIX) Lists the programs that are using the current key, without changing to a different key.
- *newkey*  
Specifies the new encryption key.
- **-nopmd**  
(UNIX) Changes the key without updating the Policy Model update file with the new key.
- *oldkey*  
Specifies the (current) encryption key that you want to change.
- **-r hostname**  
(UNIX) Specifies the name of the remote computer whose encryption key you want to change.

To use this option, Privileged Access Manager must be running on both the local and remote computers. This parameter does not actually change the key; rather, it saves information so that the next time you start Privileged Access Manager on the remote computer (using `seload -c`), the key is changed.

- **-s *registry\_path***  
(Windows) Specifies the registry root path where the encryption key for Privileged Access Manager programs is stored. This switch is only valid for third-party programs that use the Privileged Access Manager SDK.

### Example: Check If a UNIX Computer Uses the Default Encryption Key

The following command checks if a UNIX computer uses the default Privileged Access Manager encryption key:

```
sechkey -d -n
```

### sechkey Utility Change the Symmetric Encryption Method

The `sechkey` utility changes the symmetric encryption method for Privileged Access Manager programs. When you change the symmetric encryption method, `sechkey` decrypts each encrypted password in the Privileged Access Manager database then encrypts each password with the new encryption method.

#### NOTE

If Privileged Access Manager is operating in FIPS-only mode, you cannot change the symmetric encryption method. Privileged Access Manager operates in FIPS-only mode when the value of the `fips_only` configuration token in the `crypto` section is 1. This restriction prevents you from changing the encryption method to a non-FIPS compliant method.

You must stop Privileged Access Manager before you use `sechkey` to change the symmetric encryption method. You must have the ADMIN attribute to use `sechkey`.

#### WARNING

To avoid communication problems, use the same encryption method on all computers that run Privileged Access Manager components.

This utility has the following format:

```
sechkey -m -sym {aes128 | aes192 | aes256 | des | tripledes | default} [-s registry_path]
```

- **-m**  
Specifies to change the encryption method.
- **-s *registry\_path***  
(Windows) Specifies the registry root path where the encryption key for Privileged Access Manager programs is stored. This switch is only valid for third-party programs that use the Privileged Access Manager SDK.
- **-sym**  
Specifies the new encryption method to use.
  - **aes128**  
Specifies to use the following encryption method:  
(Windows): `aes128enc.dll`  
(UNIX): `libaes128.so`
  - **aes192**  
Specifies to use the following encryption method:  
(Windows): `aes192enc.dll`  
(UNIX): `libaes192.so`
  - **aes256**  
Specifies to use the following encryption method:  
(Windows): `aes256enc.dll`  
(UNIX): `libaes256.so`
  - **des**

Specifies to use the following encryption method:

(Windows): desenc.dll

(UNIX): libdes.so

– **tripleDES**

Specifies to use the following encryption method:

(Windows): tripledesenc.dll

(UNIX): libtripleDES.so

– **default**

Specifies to use the following proprietary Privileged Access Manager encryption method:

(Windows): defenc.dll

(UNIX): libscramble.so

### Example: Change the Symmetric Encryption Method to AES256

The following command changes the symmetric encryption method to AES256:

```
sechkey -m -sym aes256
```

### sechkey Utility Configure X.509 Certificates

The sechkey utility configures the root and server certificates that Privileged Access Manager uses to authenticate communication between components.

You can use the sechkey utility to perform the following tasks:

- Configure Privileged Access Manager to use third-party root and server certificates, including OU password-protected certificates
- Create a server certificate from a third-party root certificate
- Save the password of a password-protected certificate on the computer

Stop Privileged Access Manager before you use sechkey to configure X.509 certificates. You must have the ADMIN attribute to use sechkey.

#### NOTE

If Privileged Access Manager is operating in FIPS-only mode, you cannot use password-protected certificates. Privileged Access Manager operates in FIPS-only mode when the value of the `fips_only` configuration token in the `crypto` section is 1. This restriction prevents you from encrypting passwords within the certificate with a non-FIPS compliant method.

This command has the following format to create an X.509 root or server certificate:

```
sechkey -e {-ca|-sub [-priv privfilepath]} [-in infilepath] [-out outfilepath] [-capwd password] [-subpwd password]
```

This command has the following format to use OU password-protected server certificates:

```
sechkey -g {-subpwd password | -verify}
```

- **-ca**

Specifies that sechkey creates a self-signed certificate that is used as a CA (root) certificate.

sechkey stores the certificate and private key in the PEM file that is defined by the `ca_certificate` configuration setting in the `crypto` section.

- **-capwd password**

Specifies the password for the private key of the root certificate that sechkey uses to generate a server (subject) certificate.

- **-e**  
Specifies that sechkey creates an X.509 certificate.
- **-g**  
Specifies that Privileged Access Manager uses third-party server certificates. Save the third-party server certificate in the location that is specified in the `subject_certificate` configuration setting in the `crypto` section. you can also edit the value of the `subject_certificate` configuration setting in the `crypto` section to specify the full path to the third-party server certificate.

#### NOTE

If you install the server certificate in a new directory, write Privileged Access Manager FILE rules to protect the new directory.

- **-in *infilepath***  
Specifies the input file that contains the certificate information. If `-in` is not specified, sechkey reads the information from the standard input.  
sechkey requires the following information to create a certificate:
  - Serial Number
  - Subject
  - Not Before (First valid day for certificate)
  - Not After (Last valid day for certificate)
 sechkey can use the following information, but the information is not mandatory:
  - Email
  - URI (often named URL)
  - DNS name
  - IP Address
- **-out *outfilepath***  
Specifies the output file to put the certificate information. The output file is a copy of the input information. If `-out` is not specified, sechkey does not duplicate the input information.
- **-priv *privfilepath***  
Specifies the file that holds the private key that is associated with the certificate. This option is only valid when used with the `-sub` option.
- **-sub**  
Specifies that sechkey creates a server (subject) certificate.  
sechkey stores the certificate and private key in the PEM file that is defined by the `subject_certificate` configuration setting in the `crypto` section.  
If `-priv` is not specified, the `private_key` configuration setting in the `crypto` section defines the file that holds the private key that is associated with the certificate.  
If you create a password-protected server certificate, sechkey does not encrypt the certificate. If you create a server certificate that is not password-protected, sechkey encrypts the certificate using AES256 and the Privileged Access Manager encryption key.
- **-subpwd *password***  
Specifies the password for the private key of the server (subject) certificate. sechkey stores the password in the `crypto.dat` file in the `ACInstallDir/Data/crypto` directory, where `ACInstallDir` is the directory in which you installed Privileged Access Manager. The `crypto.dat` file is hidden, encrypted, read-only, and protected by Privileged Access Manager. Privileged Access Manager is stopped, only the superuser can access the password.
- **-verify**  
Verifies that Privileged Access Manager can use the stored password to open the password-protected server key.

**Example: Create a Server Certificate from an OU Password-Protected Third-Party Root Certificate**

The following command creates a server certificate from an OU password-protected third-party root certificate, using the following values:

- The path to the input file that contains the certificate information is C:\Program Files\CA\PAMSC\data\crypto\sub\_cert\_info
- The path to the private key for the root certificate is C:\Program Files\CA\PAMSC\data\crypto\ca.key
- The password for the private key for the root certificate is P@ssw0rd

```
sechkey -e -sub -in "C:\Program Files\CA\PAMSC\data\crypto\sub_cert_info" -priv "C:\Program Files\CA\PAMSC\data\crypto\ca.key" -capwd P@ssw0rd
```

### Example: Input File

The following is an example of an input file that contains certificate information with IPv4 addresses:

```
SERIAL: 00-15-58-C3-5E-4B

SUBJECT: CN=192.168.0.1

NOTBEFORE: "12/31/08"

NOTAFTER: "12/31/09"

E-MAIL: john.smith@example.com

URI: http://www.example.com

DNS: 168.192.0.100

IP: 168.192.0.1
```

For IPv6, the DNS and IP addresses are shown below:

```
...
DNS: fd6d:8d64:af0c:1:0:242:22:233
IP: ssl://[fd6d:8d64:af0c:1:0:242:22:233]:61616
```

## seclassadm Utility Administer CA Privileged Access Manager Server Control Classes

The seclassadm utility manages Privileged Access Manager classes. The utility adds new user-defined classes to the local database. Invoke it from the directory in which the database resides (or use the -p option), while Privileged Access Manager is *not* running.

### NOTE

Running seclassadm creates a file in the seosdb directory with the new class information. When you create a new database with dbmgr -c, user-defined classes are created in the new database if the CreateNewClasses configuration setting is set to yes (the default).

This command has the following format:

```
seclassadm -add className [-a access] [{-|+}c] [-d access] \
```

```
[-f] [-g] [-o] [-p db_pathname] [-t]
seclassadm -del className
seclassadm -upd className {-|+}c [-p db_pathname]
```

- **-add *class-name***  
Adds a new resource class to an existing database, where *class-name* is the name of the new class. Privileged Access Manager reserves class names that are in uppercase characters. When adding a class, use at least one lowercase character. Class names can be up to 79 characters long. After creating a class, enable the class by using the selang setoptions command.
- **-del *class-name***  
Deletes the specified resource class from the database.
- **-upd *class-name***  
Updates the specified resource class in the database.
- **-a *access***  
Specifies the access modes for the class. The string *access* represents the allowed accesses. A single character code that is listed in any order represents each access mode. The string must not contain any blank or other non-alphabetic characters. Valid access modes are:

Abbreviation	Description
C	control
D	delete
E	create
F	filesan
M	chmod
O	chown
R	read
S	security
T	utime
U	update
V	rename
W	write
X	execute

- **-d *access***  
Specifies the default access mode for the class. This is the access mode that Privileged Access Manager assigns to a user when you execute the authorize command without specifying an access authority. This implicit access that is used by the authorize command is *not* the same as the default access assigned to a resource. The possible accesses modes are listed in the -a option.
- **-f**  
Specifies that Privileged Access Manager accepts a new class name, even if the name contains all uppercase letters.

**NOTE**

By default, the seclassadm utility does not let you create a class name that is all uppercase. Privileged Access Manager uppercase names are reserved for the predefined Privileged Access Manager classes.

- **-g**  
Specifies that the new class is a resource that groups members of an existing class. The relationship between the existing class and the new group class is the same as the relationship between any class and its group class in the

database (for example, `TERMINAL` and `GTERMINAL`). A resource that groups members of an existing class must begin with the uppercase letter `G`. That is, it has the same name as the existing class, but begins with the prefix `G`.

- **-o**  
Creates a `_default` record for the new class and sets its default access.
- **-p *db\_pathname***  
Specifies the full pathname of the local database.  
By default, the utility works on the database in the current directory. Use this option to define a different directory where the database resides.

### Examples: Add a new class to the database

The following examples demonstrate how you can use the `seclassadm` utility to add a class to the database:

- To add a resource class by the name *dbfield*, use the following command:  

```
seclassadm -add dbfield
```
- To add a resource class by the name *report* with only `READ` access, use the following command:  

```
seclassadm -add report -d R -a R
```
- To add a resource class by the name *batch\_jobs* with `READ`, `WRITE`, and `MODIFY` permissions and `READ` access as the default when not specified, use the following command:  

```
seclassadm -add batch_jobs -d R -a RWM
```
- To add a new class whose objects are groups of resources in the class `DEPTA`, with access `execute` and implicit access `execute`, use the following command:  

```
seclassadm -add DEPTA -d X -a X -g -f
```

## secompas Utility Compare Passwords

### Valid on UNIX

The `secompas` utility compares passwords in the Privileged Access Manager database with the passwords in the UNIX password file.

For each user in the Privileged Access Manager database, the utility outputs one line that contains the user name and a message indicating whether the user is not defined in UNIX, whether the user has no password in Privileged Access Manager, or whether the passwords match. The utility also displays the total number of users it compared and the number of users whose passwords do not match. It only adds to this total when the password exists in both environments and it is not the same. If a user is not defined in an environment, or the password is missing from an environment, `secompas` does not add to the counter of unmatched passwords.

To compare passwords, the `secompas` utility uses the `/etc/passwd` file, the shadow password files, and NIS/NIS+ password maps.

### NOTE

You must have the `ADMIN` attribute to use this utility.

This command has the following format:

```
secompas [-db] [-ok] [-ux]
```

- **-db**  
Specifies not to display users that do not have a password in the Privileged Access Manager database.
- **-h**  
Displays the help for this utility.
- **-ok**  
Specifies not to display users that have the same password in the Privileged Access Manager database and UNIX (password match).
- **-ux**

Specifies not to display users that do not exist in UNIX.

### Example: Utility output

This example shows sample output from the utility:

```
Checking root           : No password in Access Control database.
Checking tst_001       : Undefined in UNIX.
Checking tst_002       : No password in UNIX password file
Checking tst_003       : *** PASSWORDS DO NOT MATCH. ***
Checking tst_004       : *** NO MATCH - UNIX DISABLED ***
Checking tst_005       : OK
```

Total of 6 users found in database.

2 unmatched password(s) found. (1 UNIX DISABLED).

The following explains each line in the preceding output:

```
Checking root           : No password in Access Control database.
```

Either the user *root* is not defined in the Privileged Access Manager database or the user is defined in the database but does not have a password in it.

```
Checking tst_001       : Undefined in UNIX.
```

The user *tst\_001* is defined in the Privileged Access Manager database but not in UNIX.

```
Checking tst_002       : No password in UNIX password file
```

The user *tst\_002* is defined in UNIX but does not have a password.

```
Checking tst_003       : *** PASSWORDS DO NOT MATCH. ***
```

The Privileged Access Manager password does not match the UNIX password of the user *tst\_003*.

```
Checking tst_004       : *** NO MATCH - UNIX DISABLED ***
```

The *tst\_004* user account was disabled in the UNIX environment. *secompas* identifies a disabled user account by the asterisk (\*) in front of the password in the */etc/passwd* file.

```
Checking tst_005       : OK
```

The Privileged Access Manager password matches the UNIX password of the user *tst\_005*.

## secons Utility

The *secons* utility is the Privileged Access Manager security console. It lets you perform the following tasks:

- On UNIX:

- Display run-time statistics on Unix
- [Manage concurrent login options](#)
- Manage Privileged Access Manager tracing
- [Manage Enabled Kernel](#)
- [Manage resource caching](#)
- [Manage CA Privileged Access Manager Server Control shutdown](#)
- [Reload configuration settings](#)
- [Remove XUSER objects](#)
- [Display kernel tables](#)
- [Clean, enable, or disable kernel cache tables](#)
- On Windows:
  - [Control instrumentation run-time settings](#)
  - [Display run-time statistics on Windows](#)
  - [Display ACEE Records](#)
  - [Manage concurrent login options](#)
  - Manage Privileged Access Manager tracing
  - [Refresh IP addresses for network resources](#)
  - [Remove XUSER objects](#)
  - [Resolve recycled accounts](#)
  - [Shut down CA Privileged Access Manager Server Control](#)
  - [Display your user name and security credentials](#)

The secons utility is available to both security administrators and other users. However, only some options are available for users who do not have the ADMIN attribute. These options are:

-m (trace management), -d-, -d+, -ds (login management), and -whoami (user's credentials).

## secons Utility Manage CA Privileged Access Manager Server Control Shutdown on UNIX

### Valid on UNIX

The secons utility shuts down Privileged Access Manager and the associated daemons. You can also use this utility to find out which processes are still executing Privileged Access Manager code.

Only users who are defined as ADMIN or OPERATOR can shut down Privileged Access Manager. To shut down Privileged Access Manager on remote computers, you must be defined as ADMIN or OPERATOR on those remote computers.

This command has the following format:

```
secons [-s [hosts | ghosts]] \
      [-S [{selogrd | selogrcd | serevu}]] \
      [-sc] [-scl] [-sk]
```

- **-s [hosts | ghosts]**  
Shuts down the Privileged Access Manager daemons on the defined, space-separated, list of remote hosts. If you do not specify any hosts, Privileged Access Manager shuts down on the local host.

You can define a group of hosts by entering the name of a *ghost* record. If you use this option from a remote terminal, the utility requests password verification. You also need admin privileges on both the remote and local computers, and write permission to the local computer on the remote host database.

- **-S [{selogrd | selogrcd | serevu}]**

If you do not define a daemon, terminates the Privileged Access Manager daemons and attempts to terminate active daemons selogrd, selogrcd, and serevu. If the selogrd, selogrcd, or serevu tokens in the [daemons] section of seos.ini file are set to *yes*, termination request is sent to the running Privileged Access Manager main daemon or a termination signal is sent to the specified daemon if the product is already down.

If you define a daemon, secons does not terminate the Privileged Access Manager daemons. If the appropriate token in the [daemons] section of seos.ini file is set to *yes*, it sends the termination request to the running Privileged Access Manager main daemon or it sends the termination signal to that daemon if Privileged Access Manager is down.

- **-sc[l]**

Displays processes that are still executing Privileged Access Manager code.

You cannot unload Privileged Access Manager if an application, which is loaded on top of Privileged Access Manager, has an open system call (syscall) that is hooked by Privileged Access Manager. Once you know which processes are still executing Privileged Access Manager code, you can shut down these processes and can unload the Privileged Access Manager kernel module. You can then use UNIX exits to automatically shut down these processes before unloading the kernel and then restart them after the kernel unloaded.

The *-sc* output displays as a two-column table with the system call number in the first column, and the process identifier in the second column.

The *-sc/* option also displays parent process ID (PPID), UID, time, and program name information for the processes that are still executing Privileged Access Manager code. The time information lets you find out how long the process has Privileged Access Manager hooked. If the time is relatively short, the hook is likely to be a temporary one.

You can also run this while Privileged Access Manager is running to help you predict what causes unload issues in advance. However, sometimes, such as the *accept* command, Privileged Access Manager code removes the hook during unload. This means that some of the active hooks you see while Privileged Access Manager is running may not actually affect unloading.

**Note:** By default, Privileged Access Manager monitors system calls that it intercepts. Set the *syscall\_monitor* token in the seos.ini file to 0 (disabled) if you do *not* want Privileged Access Manager to monitor system calls.

- **-sk**

Shuts down all Privileged Access Manager daemons and prepares the Privileged Access Manager kernel extension to be unloaded.

### Example: Shut Down Privileged Access Manager

- To shut down the Privileged Access Manager daemon, enter:

```
secons -s
```

- To shut down the Privileged Access Manager daemon on remote hosts HOST1 and HOST2, enter:

```
secons -s HOST1 HOST2
```

### Example: Display Information for Processes that are Still Executing Privileged Access Manager Code

- To display basic information about processes that are still executing Privileged Access Manager code:

```
secons -sc
```

The output that you receive looks similar to the following:

```
CA PAMSC secons vX.X.X.xxx - Console utility
```

```
Copyright (c) YYYY CA. All rights reserved.
```

```
Active system calls:
```

```
syscall      5 - PID: 27477
```

- To display more information about processes that are still executing Privileged Access Manager code:

```
secons -scl
```

The output you receive looks similar to the following:

```
CA PAMSC secons vX.X.X.xxx - Console utility
```

```
Copyright (c) YYYY CA. All rights reserved.
```

```
Active system calls:
```

```
-Syscall 102 - PID: 2105 PPID: 1 UID: 0 TIME: 4d-4h PROGRAM NAME: /usr/sbin/vsftpd
```

```
Syscall 5 - PID: 24269 PPID: 4289 UID: 0 TIME: 2d-21h PROGRAM NAME: /bin/bash
```

A dash (-) at the beginning of the output line means that Privileged Access Manager assesses that this hook is not likely to cause you issues when unloading. When you use this command, Privileged Access Manager also adds lines to the audit log that records whether the unloading Privileged Access Manager is likely to succeed. For example, the following audit record is created when you run `secons -scl` and there is at least one blocking system call that is likely to prevent Privileged Access Manager from unloading:

```
10 Nov YYYY 05:47:22 F CHECK      root      Scan      339 0 SEOS_syscall      unload
```

## secons Utility Manage CA Privileged Access Manager Server Control Tracing

The `secons` utility manages Privileged Access Manager tracing. Tracing lets you monitor operating system events. Privileged Access Manager can accumulate a file of messages reporting operating system events that you can then display.

This command has the following format:

```
secons [-t+] [-t-] [-tt] [-ts] [-tc] [-tv [size] [-file fileName]]
secons -m message
secons -send heartbeat
secons -pupm trace {enable | disable | clear}
```

- **-m *message***  
Adds a text message to the trace file.
- **-t+**  
Enables tracing, which causes the Privileged Access Manager engine (`seosd`) to dump messages that specify its operations and actions to the trace file.
- **-t-**  
Disables tracing, which stops the Privileged Access Manager engine `seosd` from dumping messages to the trace file.
- **-tc**  
Clears the trace file, removing all records from it.

**NOTE**

You can use this option whether seosd is running.

- **-ts**  
Displays the current tracing status.
- **-tt**  
Toggles the tracing status.
- **-tv [size] [-file fileName]**  
Displays a real-time trace output. The utility displays the last *size* KB (by default, 2 KB) of the trace file and keeps the session open so that any new trace messages added to the file are displayed. This is similar to the UNIX tail -f command.  
Use Ctrl+C to stop this operation.  
**Note:** You can use this option whether seosd is running. Use the full\_year configuration setting to select whether you want to display the year in four digits (the default, yes) or two digits.
  - *size*  
Specifies the size, in kilobytes, of the portion of the file you want to display, starting from the end. Specify 0 to show the entire trace file. If you do not specify this option, secons uses the default, 2 KB.
  - *-file fileName*  
Reads *fileName* instead of *ACInstallDir/log/seosd.trace*.
- **-send heartbeat**  
Sends a heartbeat to the Privileged Access Manager Server immediately.
- **-pupm trace {enable | disable | clear}**  
**Valid for the Shared Account Management Agent**  
Specifies tracing options on the Shared Account Management Agent during runtime. You do not need to restart Privileged Access Manager to modify the trace options.  
**Limits:** enable, enables tracing; disable, disables tracing; clear, clears the trace file.

**WARNING**

The trace options that you specify apply to the current session only. After Privileged Access Manager restarts the trace option is set according to the OperationMode token in the PUPMAgent section.

## secons Utility Manage Concurrent Login Options

The secons utility manages concurrent login options. You can configure Privileged Access Manager to prevent a user from logging in more than once. This prevents intruders from logging into the accounts of users who are already logged in.

This command has the following format:

```
secons [-d+] [-d-] [-ds] [-l+] [-l-] [-ls] \
      [-u+ userName] [-u- userName] [-us userName]
```

- **-d+**  
Enables concurrent logins for the user running the command.
- **-d-**  
Disables concurrent logins for the user running the command. Using this command kills any concurrent logins of the user to the local computer.

**NOTE**

You can also place this command in the .login or .cshrc file of a user to disable concurrent logins.

- **-ds**  
Displays the concurrent logins setting for the user running the command.
- **-l+**  
Enables concurrent logins system-wide.

**NOTE**

By default, Privileged Access Manager enables login, but in cases where the system is shut down for maintenance, you can disable login for a specific period.

- **-l-**  
Disables concurrent logins system-wide.
- **-ls**  
Displays system-wide login status.
- **-u+ *userName***  
Enables concurrent logins for the defined user.
- **-u-*userName***  
Disables concurrent logins for the defined user.
- **-us *userName***  
Displays the concurrent logins setting for the defined user.

## secons Utility Manage Resource Caching on UNIX

### Valid on UNIX

The secons utility manages resource caching (file cache) on UNIX. The cache, a runtime table, "remembers" the previous answer to an authorization request (permit or deny) for resources in the FILE class. When an identical authorization is requested, the request is answered with the last response that was stored in the cache memory tables.

This command has the following format:

```
secons [-C+] [-C-] [-CA value] [-CC interval] [-CD] \
[-CF value] [-CI init_value] [-CP interval] -CU value]
```

- **-C+**  
Enables caching of file authorization.
- **-C-**  
Disables caching of file authorization.
- **-CA *value***  
Specifies the maximum number of authorization records in a table.  
**Default:** 80  
**Limits:** A number between 1 and 800
- **-CC *interval***  
Specifies the cache clean interval in minutes.  
**Default:** 60  
**Limits:** A number greater than 0
- **-CD**  
Displays the cache table to the standard output.
- **-CF *value***  
Specifies the maximum number of file records in a table.  
**Default:** 20  
**Limits:** A number between 1 and 200
- **-CI *init\_value***  
Specifies the initial priority value for a new record in the cache table.  
**Default:** 10
- **-CP *interval***

Specifies the cache priority computing interval.

**Default:** 1 (one record)

**Limits:** A number between 1 and 10

- **-CU value**

Specifies the maximum number of user records in a table.

**Default:** 50

**Limits:** A number between 1 and 500

### Example: Change cache settings

The following example shows you how you can change settings of the cache so that the maximum number of file, user, and authorization records in the cache are 60:

```
secons -CF 60 -CU 60 -CA 60
```

### Example: Display the cache table

The following example shows the output of the secons -CD command:

```
=====
FILE CACHE (configuration, statistics, and dispatcher data)
=====
sizes(bytes)      tables:          | max records:      | intervals
cache  head      files    users    auth | files users auths | clean prio
-----
40244   44        5600    4200    30400 | 20   50   80   | 60  1
=====
table |statistics          | priority  |min | rec | average      |pri |init
name  | hits misses (ok) | maxim  minim|ind | used | usage  life |fact|prio
-----
files |   5   1  83% |   0     0 | 0 | 1 |         |    | 
users |   5   1  83% |  10     2 | 0 | 1 | 0       | 0  | 1 | 10
auths |   4   2  66% |   2     | 0 | 2 |         |    | 
=====
FILE TABLE
=====
No  type    pid priority user                                file name
-----
0   EXPL    372      0   0                                /etc/shadow
=====
USER TABLE
=====
No  user name    prio  life  used  UID  EUID  RUID  auth prev(file)next
-----
0   root        2     2    7    0    0    0    0    50( 0) 50
=====
AUTHORIZATION RESULT TABLE (R - Result: 'P'-permit, 'D'-deny ...)
=====
No  R ACEE acc  Log stage prv(usr)nxt time          terminal  program
-----
0   P   6  read  0  00036 80( 0) 1   07:48:25          /usr/bin/login
=====
```

The following explains the preceding output:

The output consists of five parts:

- The cache configuration. It contains the following fields:
  - Size of the cache (in bytes)
  - Size of the cache header (in bytes)
  - Size of the file table (in bytes)
  - Size of the user table (in bytes)
  - Size of the results table (in bytes)
  - The maximum number of file records
  - The maximum number of user records
  - The maximum number of result records
  - Statistic: hits in the table
- The table of file records. It contains the following fields:
  - Sequential number of the record
  - Type of the file (EXPLICIT, IMPLICIT)
  - Process ID number
  - Priority of the record, is sum of its users priorities
  - Appropriate user record number in the table of users
  - Name of the file
- The table of users. It contains the following fields:
  - Sequential number of the record
  - User name
  - Priority of the record
  - Record lifetime counter
  - Record usage counter
  - User ID; user effective ID; really used by security ID
  - Appropriate authorization record number in the table of authorization
  - Previous user record number in the chain of users
  - Appropriate file record number
  - Next user record in the chain of users
- The table of authorization results. It contains the following fields:
  - Terminal
  - Stage
  - Granted stage
  - Result - authorization result (P or D)
  - ACEE number
  - Access type
  - Logging options flag value
  - The stage number the decision was made
  - Previous authorization record number in the chain of records
- Appropriate user record number
  - Next authorization record number in the chain of records
  - Statistic: the number of missed records in the table
  - Authorization class
  - Program name (with the via parameter)
  - Notification string
  - Update time (GMT)
- Dispatcher Data. It contains the following fields:

- Statistic: number of missed records in the table
- Statistic: number of hits in the table
- Maximum priority in a table
- Minimum priority in a table
- Number of entries with minimum priority
- Number of used records
- Average usage (only for users table)
- Average life (only for users table)
- Priority calculation factor (only for users table)
- Initial value of the record priority (only for users table)

## secons Utility Shut Down Privileged Access Manager Server Control on Windows

### Valid on Windows

The secons utility shuts down the Privileged Access Manager engine and all other Privileged Access Manager services on the local station or on one or more remote stations.

Only users defined as ADMIN or OPERATOR can shut down Privileged Access Manager. To shut down Privileged Access Manager on remote computers, you must be defined as ADMIN or OPERATOR on those remote computers.

This command has the following format:

```
secons -s [hosts | ghosts]
```

**-s** [*hosts* | *ghosts*]

Shuts down the Privileged Access Manager services on the defined, space-separated, remote hosts. If you do not specify any hosts, Privileged Access Manager shuts down on the local host.

You can define a group of hosts by entering the name of a ghost record. If you use this option from a remote terminal, the utility requests password verification. You also need admin privileges on both the remote and local computers, and write permission to the local computer on the remote host database.

## secons -dbclean Remove XUSER Objects from the CA Privileged Access Manager Server Control Database

The secons utility removes XUSER objects that were not resolved to their native security identifiers (SID) from the Privileged Access Manager database. Use the secons -dbclean command to remove XUSER objects that no longer exist in the native environment.

This command has the following format:

```
secons -dbclean <osuser>
```

- **-dbclean**  
Specify to remove all XUSER objects that were not resolved from the Privileged Access Manager database.
- **<osuser>**  
Specifies the native user account name.

## secons -acee Function Display ACEE Records on Windows

### Valid on Windows

The `secons` utility lets you monitor the Accessor Element Entry (ACEE) table that caches accessors in the authorization engine. The ACEE stores information about the following users:

- **Logged in user** A user that has logged in to the operating system. Specific ACEE attributes for this type of user are:
  - Login session ID
  - Login session type
- **Management user** A user that has logged in to a Privileged Access Manager management application (using an LCA connection). For example, `selang`.
- **Authorization API user** A user that was referenced in `SEOSROUTE_*` API.
- **SPECIALPGM Logical user** A user that is being referenced at least in one SPECIALPGM record. A specific ACEE attribute for this type of user is:
  - ACEE association with SPECIALPGM records
- **Built in user** A user that is built in Privileged Access Manager. For example, `_undefined`.

#### NOTE

Only a Privileged Access Manager administrator can use this command.

This command has the following format:

```
secons -acee [handle | all | list]
```

- **all**  
Displays all ACEE records.
- **handle**  
Defines the ACEE handle you want to display.
- **list**  
Displays a summary list of all ACEE records, without the full details.

#### Examples: Display ACEE Records

- This example displays a list of handles in the ACEE:

```
secons -acee list
```

The `secons` output looks like this:

```
ACEE handle '0' represents 'Logged on User': NT AUTHORITY\ANONYMOUS LOGON (OS User)
ACEE handle '1' represents 'Logged on User': NT AUTHORITY\NETWORK SERVICE (OS User)
ACEE handle '2' represents 'Logged on User': COMPl-SRV-X86\John
ACEE handle '3' represents 'Logged on User': NT AUTHORITY\LOCAL SERVICE (OS User)
ACEE handle '4' represents 'Logged on User': NT AUTHORITY\SYSTEM (OS User)
ACEE handle '5' represents 'Management User': COMPl-SRV-X86\John
ACEE handle '6' represents 'SPECIALPGM Logical User': logicaluser
```

- This example displays handle 6 in the ACEE:

```
secons -acee 6
```

The `secons` output looks like this:

```
ACEE handle '6' represents 'SPECIALPGM Logical User': logicaluser
ACEE was created at: Wed Feb 20 17:35:52 2008
ACEE was last accessed at: Wed Feb 20 17:35:52 2008
ACEE user role is: Regular
ACEE audit mode is: Failure, Login Success, Login Failure; Originated from User definition
ACEE user is a member of 0 'CA ControlMinder' groups
ACEE user is associated with 1 SPECIALPGM records
  1. C:\WINDOWS\system32\calc.exe
```

## secons -checkSID Function Resolve Recycled Accounts on Windows

### Valid on Windows

The secons utility compares the security identifier (SID) of each enterprise account (XUSER and XGROUP resource) with the native Windows account SID, and creates a backup of recycled accounts. As the Privileged Access Manager authorization is based on SID, where the SID of a Privileged Access Manager accessor resource differs from the native account SID (a recycled account), the utility creates a new account (with the same name as the old account) and backs up the obsolete resource using the following naming convention: *SID (accountName)*

#### NOTE

For more information on recycled enterprise store accounts, see the *Endpoint Administration Guide for Windows*.

This command has the following format:

```
secons -checkSID {-groups | -users} [accountName [,accountName...]]
```

- **-groups**  
Specifies that secons should examine enterprise group records.
- **-users**  
Specifies that secons should examine enterprise user records.
- **accountName**  
Specifies the name of a user or group that secons should search for. If *accountName* is omitted, secons looks for all groups or users.

## secons -i Function Display Run-time Statistics on Windows

### Valid on Windows

The secons utility displays Privileged Access Manager run-time statistics and internal counters. Use this statistical system behavior information to learn the following:

- How many events were triggered for each interception type.
- How effective each kernel cache is, by comparing the number of cached events against the number of fully authorized events.

**Note:** It is normal for the audit queue to increase in periods of increased activity. However, the queue size should decrease once the load is normal again.

This command has the following format:

```
secons -i [-reset]
```

- **-i**  
Displays runtime statistics as formatted text.
- **-reset**  
(Optional) Resets the run-time counters to zero.

### Example: Display run-time data

The following describes the information that is not self-explanatory in the output of the secons -i command:

- **Database run-time data**  
Displays the number of classes, objects, and properties in the Privileged Access Manager database, the ID of the last created class, object, and property, and the number of property values.

Use this information to evaluate the size of the database. The more objects and properties you use, the bigger the database is.

- **Kernel run-time data**

Displays for each of the kernel caches (file, registry, and surrogate) their creation time, size, and efficiency. Efficiency is the number of audit events out of the total number of events. The remaining interception events follow the authorization process.

Use this information to evaluate the need for, and efficiency of, each kernel cache.

- **Kernel audit information**

Displays the current kernel audit queue size and the maximum size it reached and when.

Use this information to evaluate the audit queue behavior. You should make sure that the audit queue does not exceed the maximum allocated queue size, which is set in the FsiDrv\MaxAuditRecordLimit Privileged Access Manager registry entry. When this limit is reached, Privileged Access Manager generates audit events more slowly so that the queue can be resolved.

- **User mode enforcement run-time data**

Displays information for intercepted file, registry, logon, kill, and Windows service events in Full Enforcement mode. You can find out about the number of events being authorized by the authorization engine and the maximum and average time an authorization process took to complete for each class.

Use this information to troubleshoot problems in a live production system. It provides you with some valuable initial data without needing to shut down Privileged Access Manager.

- **User mode audit run-time data**

Displays information for audit events (cached intercepted event).

Use this information to monitor user mode audit queue behavior. If the maximum audit queue increases consistently, make sure that Privileged Access Manager can write to the audit log file. Privileged Access Manager may not be able to write to the file if the system has run out of disk space, or it does not have native access permissions to file.

**Note:** It is normal for the audit queue to increase in periods of increased activity. However, the queue size should decrease once the load is normal again.

## secons -i Function Display Run-time Statistics on UNIX

### Valid on UNIX

The secons utility displays Privileged Access Manager run-time statistics about system behavior including:

Network connection requests.

- Current service levels for FILE protection rules
- The size of the audit and error log queues
- The size of cached tables
- The size of the database
- The number of records in each part of the database

This command has the following format:

```
secons -i
```

- **-i**  
Displays runtime statistics as formatted text.

### Example: Display run-time data

The following example shows the output of the secons -i command:

## Runtime Statistics:

-----

## INet statistics:

Requests denied : 0  
Requests granted : 17  
Errors found : 0

## Queues size:

Audit log: 0  
Error log: 0

## Cached tables info:

ACEE handles : 11  
Protected clients : 0  
Trusted programs : 77  
Untrusted programs: 3

## Database info: (Record count &amp; first free ID)

Classes : 235 ( CID 0x00f0 )  
Properties : 4829 ( PID 0x1346 )  
Objects : 842 ( OID 0x0000035a )  
PropVals : 4109 ( N/A )

## CA PAMSC memory utilization statistics:

-----

CA PAMSC security daemon (seosd, pid=4265 Total=13MB Res=8MB)

CA PAMSC agent daemon (seagent, pid=4268 Total=10MB Res=3MB)

CA PAMSC watchdog daemon (seoswd, pid=4276 Total=6MB Res=3MB)

CA PAMSC policyfetcher daemon (policyfetcher, pid=4331 Total=11MB Res=1MB)

CA PAMSC AgentManager daemon (AgentManager, pid=4561 Total=22MB Res=3MB)

Kernel load statistic:

```
Queue: ----- FILE: SEOS current queue depth : 0 SEOS max queue depth : 1 SEOS current queue rate
msec SEOS max queue rate : 0 req/
msec SURROGATE: SEOS current queue depth : 0 SEOS max queue depth : 1 SEOS current queue rate
msec SEOS max queue rate : 0 req/
msec Total: SEOS current queue depth : 0 SEOS max queue depth : 2 SEOS current queue rate : 0
msec SEOS max queue rate : 20 req/
msec Syscalls: ----- FILE: Active SEOS handlers : 0 syscs SEOS hanlers calling rate : 0.0866
msec(406 handlers within 4684 msecs) Average processing time : 0.014742 msecs (407 handlers wi
msec(363 handlers within 8368826 msecs) Average processing time : 0.126374 msecs (364 handlers
```

-----

The following code explains each line in the preceding output:

INet statistics:

```
Requests denied : 0
Requests granted : 17
Errors found : 0
```

Displays statistics of network access authorization that is performed by Privileged Access Manager. These lines summarize the number of denials, grants, and errors during the authorization of network requests.

Queues size:

```
Audit log: 0
Error log: 0
```

The product creates logging with file locking and so it is possible that certain events are held in memory and written to log files after a while. If these values exceed 10, then an error could be interfering with the product logging facility.

Cached tables info:

```
ACEE handles : 11
Protected clients : 0
Trusted programs : 77
```

Untrusted programs: 3

Displays information about the size of cached tables Privileged Access Manager uses:

- Accessor Element Entry (*ACEE*) is a table containing logged-in processes.
- *Protected clients* list the number of cached clients. Usually, this value is 0.
- *Trusted Programs* lists the number of entries in class PROGRAM that are cached in memory. Typically, all programs should be cached as trusted.
- *Untrusted Programs* displays the number of programs that were found to be untrusted.

Database info: (Record count & first free ID)

```
Classes      :    235 ( CID      0x00f0 )
Properties   :   4829 ( PID      0x1346 )
Objects      :    842 ( OID 0x0000035a )
PropVals     :   4109 ( N/A )
```

General information regarding the size of the database and the number of records in each part of the database.

Displays information about the size of the memory the following daemons use: seosd, seagent, seoswd, policyfetcher, and AgentManager:

CA PAMSC memory utilization statistics:

-----

CA PAMSC security daemon (seosd, pid=4265 Total=13MB Res=8MB)

CA PAMSC agent daemon (seagent, pid=4268 Total=10MB Res=3MB)

CA PAMSC watchdog daemon (seoswd, pid=4276 Total=6MB Res=3MB)

CA PAMSC policyfetcher daemon (policyfetcher, pid=4331 Total=11MB Res=1MB)

CA PAMSC AgentManager daemon (AgentManager, pid=4561 Total=22MB Res=3MB)

The Privileged Access Manager Watchdog daemon monitors the memory use of the daemons based on the interval that is defined in the ProcVSizeInterval token. If a process exceeds the specified watermark in the ProcVSizeHigh token, the Watchdog restarts the process within the time frame that is defined in the ProcRestartHours token. If a process exceeds the memory size that is specified in the ProcVSizeCritical token, the Watchdog daemon immediately restarts the process.

## secsn -kt Function Display Kernel Tables on UNIX

Valid on UNIX

The secons utility displays the kernel tables.

This command has the following format:

```
secons -kt tableNumber
```

- **-kt**  
Displays the specified kernel table.
- **tableNumber**  
Specifies the kernel table to display. *tableNumber* must be one of the following values:
  - **1**  
Specifies to display the SpecPgm kernel table.
  - **2**  
Specifies to display the TrustPg kernel table.
  - **3**  
Specifies to display the LoginPg kernel table.
  - **4**  
Specifies to display the DBfiles kernel table.
  - **5**  
Specifies to display the FRegExp kernel table.
  - **6**  
Specifies to display the DCMfile kernel table.
  - **7**  
Specifies to display the AC pids kernel table.
  - **8**  
Specifies to display the InoCach kernel table.  
**Note:** Not valid on Linux.
  - **9**  
Specifies to display the F cache kernel table.
  - **10**  
Specifies to display the NetwDCM kernel table.
  - **11**  
Specifies to display the MntDirs kernel table.
  - **12**  
Specifies to display the F inode kernel table.
  - **13**  
Specifies to display the STOPexp kernel table.  
**Note:** You cannot display this kernel table if STOP is not enabled.
  - **15**  
Specifies to display the Family kernel table.
  - **16**  
Specifies to display the DbgProt kernel table.
  - **17**  
Specifies to display the TCPport kernel table.
  - **18**  
Specifies to display the TCPoutp kernel table.
  - **19**  
Specifies to display the ProcSrv kernel table.
  - – **20**

- Specifies to display the ACEE kernel table.
- **21**  
Specifies to display the Status kernel table.  
**Note:** This option shows the status of all kernel tables.
- **22**  
Specifies to display the StreamSockets kernel table.  
**Note:** This option is for HP-UX and Solaris only when SEOS STREAMS module is enabled.
- **23** Specifies to display the KBLshell kernel table.
- **24** Specifies to display the KBLcmdlog kernel table.
- **25** Specifies to display the Devices kernel table.
- **26** Specifies to display the Auto bypassed programs kernel table.
- **27** Specifies to display the User cache kernel table.
- **all** Specifies to display all tables.

### Example: Display the DBfiles Kernel Table

**Note:** The following is an example of the output when you display the DBfiles kernel table:

```
secons -kt 4

DBfiles

file      ID  i-node  device  program name
-----
1    29  280391  356515  /opt/CA/PAMSC/seosdb/seos_ids.dat

### Kernel Tables

Kernel tables list frequently-accessed information to help improve Privileged Access Manager performance. Kernel tables improve performance because Privileged Access Manager does not need to check the database to permit, deny, or resolve events that are listed in the kernel tables.

Privileged Access Manager includes the following types of kernel tables:

- **Cache tables** List the results of previous resource access requests, resolved inode numbers, and accepted incoming TCP requests.
- **Protected resource tables** List resources for which, when access is requested, Privileged Access Manager always sends an authorization request to the Privileged Access Manager engine.
- **Bypass tables** List resources for which, when access is requested, Privileged Access Manager permits access without sending an authorization request to the Privileged Access Manager engine.
- **Process table** Lists information about all the processes running in the system.

The following table provides information about each kernel table:

Table Name	Type	Lists	Column Names	Configuration Setting
SpecPgm	Protected resource	All objects in the SPECIALPGM class	flags; user; oid; i-node; device; program	SPECIALPGM class records
TrustPg	Protected resource	All objects in the PROGRAM class	flags; i-node; device; program	PROGRAM class records

LoginPg	Protected resource	All objects in the LOGINAPPL class	flags; i-node; device; program name	LOGINAPPL class records
DBfiles	Protected resource	All objects in the FILE class	file ID; i-node; device; program	FILE class records <b>Note:</b> The maximum number of records in this table is defined by max_regular_file_rules in the SEOS_syscall section of the seos.ini file
FRegExp	Protected resource	Generic file access rules that are defined in the FILE class	fid; expression	Defined by a generic rule in a FILE class record <b>Note:</b> The maximum number of records in this table is defined by max_general_file_rules in the SEOS_syscall section of the seos.ini file
DCMfile	Bypass	Do-not-call-me files that you define using GAC	fid; user; type; access	GAC.init file
ACpids	Bypass	Process IDs for the Privileged Access Manager daemons	pid; service; contractID	-
InoCach	Cache	Cached inodes	i-node; device; priority; entry	cache_enabled in the SEOS_syscall section of the seos.ini file
F cache	Cache	Cached file access authorization results	file ID; access; acee; answer; phash; prio	-
NetwDCM	Cache	Cached accepted incoming TCP connections	peer; port; local port; flag; prio	UseNetworkCache in the seosd section of the seos.ini file
MntDirs	Protected resource	Directories that Privileged Access Manager protects from mounting	dir ID; i-node; device; mount point	-
F inode	Protected resource	Inode and device number of objects in the FILE class	file ID; i-node; device; links	-
STOPbyp	Bypass	Objects in the PROGRAM class for which Privileged Access Manager does not provide STOP protection	i-node; device; program	If STOP is enabled, objects in this table have a SPECIALPGM record with the property pgmtype(STOP)
STOPexp	Bypass	Regular expressions that define objects in the PROGRAM class for which Privileged Access Manager does not provide STOP protection	priority; n-chars; expression	If STOP is enabled, objects in this table are defined by a generic rule in a SPECIALPGM record with the property pgmtype(STOP)
Family	Bypass	Privileged Access Manager daemons	service; pid; contractID	-

DbgProt	Protected resource	Privileged Access Manager binaries that Privileged Access Manager protects from debugging	pid; access; name in proc	-
TCPport	Bypass	Ports for which seos_syscall will not pass events to seosd	TCP port	bypass_TCPIP in the seosd section of the seos.ini file
TCPoutp	Bypass	Ports for which seos_syscall will not pass outgoing connection events to seosd	TCP port	bypass_outgoing_TCPIP in the seosd section of the seos.ini file
ProcServ	Process	Lists information about all the processes running in the system	#n; pid; ppid; acee; flags; uid; euid; zone; arg0; ACuser <b>Note:</b> There are many more internal columns in this table that are not displayed by the secons utility	-

### Kernel Table Column Names

The following list explains the kernel table column names:

- **#n**  
Entry number in the kernel table.
- **access**  
Defines the type of access that Privileged Access Manager permits, or the type of access that a user requested. The value is a sum of access types:  
**1-read2-write4-chown8-chmod16-rename32-unlink64-utimes128-chattr256-link512-chdir1024-create**
- **acee**  
Defines the ACEE of the user making the access request.
- **ACuser**  
Defines the Privileged Access Manager user name of the user.
- **answer**  
Defines the response (permit or deny) that Privileged Access Manager made to the access request. Valid values include:  
**0deny**  
**1permit**
- **arg0**  
Defines the program name, as defined in argument number 0 when the program executes.
- **contractID**  
(Solaris 10 only) Defines the contract process ID.
- **device**  
Defines the logical disk that the file resides on.
- **dir ID**  
Defines the directory ID.
- **entry**  
Defines the string value of the inode.
- **euid**

Defines the effective user ID.

- **expression**  
Defines the expression (text pattern used for string matching) that specifies the resources to which the entry applies.
- **fid or file ID**  
Defines the file ID that Privileged Access Manager uses to identify the file.
- **flags**  
Defines the bit mask flag for the entry.
- **i-node**  
Defines the inode number.
- **links**  
Defines the number of hard links of the file.
- **local port**  
Defines the port on the local host that accepts the incoming TCP connection.
- **mount point**  
Defines the location in the directory to protect from mounting.
- **n-chars**  
Defines the number of characters in the expression.
- **name in proc**  
Defines the process name in the /proc file system.  
**Note:** In the /proc file system, each process is represented as a file, and the file name is the process number.
- **oid**  
Defines the object ID.
- **peer**  
Defines the peer host address.
- **phash**  
Defines the hash value of a path string.
- **pid**  
Defines the process ID.
- **port**  
Defines the port from which the incoming TCP connection originated.
- **ppid**  
Defines the parent process ID.
- **prio or priority**  
Defines the priority of the entry in the kernel table. When the kernel table is full, the entry with the lowest priority is removed when Privileged Access Manager writes a new entry to the kernel table.
- **program or program name**  
Defines the name of the program.
- **service**  
Defines the name of the Privileged Access Manager service (daemon).
- **TCP port**  
Defines the TCP port to which the entry applies.
- **type**  
Defines the protected file type.
- **uid or user**  
Defines the user ID.
- **zone**  
(Solaris 10 only) Defines the zone ID.  
**Note:** The value of this column is always 0 for a non-Solaris 10 computer.

## Cache Tables

There are three types of kernel cache tables:

- **F cache** The file cache table caches the results of previous authorization requests. When an identical authorization request is made, Privileged Access Manager answers the request with the last response that is stored in the file cache table.

### NOTE

The file cache tables is cleaned every 30 minutes and whenever a record changes in the following classes: CALENDAR, CONTAINER, FILE, GFILE, GROUP, HOLIDAY, PROGRAM, SECLABEL, SECLEVEL, SHIFT, and USER.

- **InoCach** The inode cache table caches resolved inode numbers. When Privileged Access Manager needs to resolve an inode number to a file name, it checks the InoCach table before it checks the file system.
- **NetwDCM** The network cache table stores accepted, incoming TCP requests. When Privileged Access Manager receives an incoming TCP request that is identical to a request in the network cache, Privileged Access Manager automatically permits the request.

You can use the `secons` utility to display, clean, enable, and disable kernel cache tables.

## Protected Resource Tables

When Privileged Access Manager intercepts an authorization request, it checks if the resource to which access is requested is listed in the protected resource tables in the kernel.

If the resource is listed in the protected resource tables, Privileged Access Manager always sends an authorization request to the Privileged Access Manager engine. If the resource is not listed in the protected resource table, Privileged Access Manager may not send an authorization request to the engine but instead resolve the access request in the kernel.

## Bypass Tables

When Privileged Access Manager intercepts an authorization request, it checks if the resource to which access is requested is listed in the bypass tables in the kernel.

If the resource is listed in the bypass tables Privileged Access Manager permits the access request. If the resource is not listed in the bypass tables Privileged Access Manager passes the request to the Privileged Access Manager authorization engine for further access checks.

## secons -krc Function Clean, Enable, or Disable Kernel Cache Tables on UNIX

### Valid on UNIX

The `secons` utility cleans, enables, or disables the kernel cache tables.

This command has the following format:

```
secons -krc optionNumber
```

- **-krc**  
Specifies to clean, enable, or disable a kernel cache table.
- **optionNumber**  
Specifies the action to perform. *optionNumber* must be one of the following:
  - **1**  
Cleans the F cache table.
  - **2**

- Enables the F cache table.
- **3**  
Disables the F cache table.
- **4**  
Cleans the NetwDCM table.
- **5**  
Enables the NetwDCM table.
- **6**  
Disables the NetwDCM table.
- **7**  
Cleans the F inode table.

**NOTE**

Not valid on Linux.

- **8**  
Enables the F inode table.

**NOTE**

Not valid on Linux.

- **9**  
Disables the F inode table.

**NOTE**

Not valid on Linux.

**Example: Clean the F cache Table****NOTE**

The following example cleans the F cache table:

```
secons -krc 1
```

**secons -refIP Function Refresh IP Addresses for Network Resources****Valid on Windows**

The secons utility refreshes the IP addresses of database network resources. For the refresh to work on a particular host, the DNS must have already been refreshed on that host. Use the following Windows command to refresh the DNS manually:

```
ipconfig /flushdns
```

This command has the following format:

```
secons -refIP [hosts]
```

- **-refIP [hosts]**  
(Windows only) Defines a space-separated list of hosts on which Privileged Access Manager will refresh IP addresses for network resources. If no hosts are listed, local network resources are refreshed.  
This option lets you update Privileged Access Manager resources with the current IP address and is particularly useful in a DHCP environment where IP addresses are assigned dynamically.

**secons -rl Function Reload Configuration Settings and KBL on UNIX****Valid on UNIX**

The secons utility reloads the seos.ini file for seosd and the KBL (Keyboard Logger). This lets you update your configuration settings without having to shut down Privileged Access Manager.

This command has the following format:

```
secons -rl
```

- **-rl**  
(UNIX only) Reloads the seos.ini configuration file and updates settings without shutting down Privileged Access Manager.

## secons -v Function Control Instrumentation Run-time Settings on Windows

### Valid on Windows

The secons utility controls Privileged Access Manager instrumentation run-time settings. You can use the utility to load an external DLL library into an active process and modify the run-time tracing configuration of Privileged Access Manager instrumentation plug-ins. You must have the ADMIN or OPERATOR attribute to execute this command.

This command has the following format to load a DLL library:

```
secons -v target load "dll_name"
```

This command has the following format to enable or disable the trace on a Privileged Access Manager instrumentation plug-in:

```
secons -v target trace plugin_name {trace:enable|trace:disable}:{file:"tracefile_path"|debug}
```

### NOTE

Privileged Access Manager does not start the trace until the trace is correctly configured.

This command has the following format to configure the trace on a Privileged Access Manager instrumentation plug-in:

```
secons -v target trace plugin_name trace:option:{sources:{1 | 4} | filtering:value | filecyclic:{0 | 1} | filelimit:value }
```

- **debug**  
Specifies that the command enables or disables tracing to the debug output channel.
- **file:"tracefile\_path"**  
Defines the full path to the file that Privileged Access Manager writes the trace to.

### NOTE

If you specify the trace:disable parameter, Privileged Access Manager ignores any value that you specify for the file:"tracefile\_path" parameter.

- **filecyclic:{0 | 1}**  
Specifies if cyclic file tracing is enabled. If you enable cyclic file tracing, when the size of the trace file reaches the specified maximum size, Privileged Access Manager returns to the start of the trace file and continues writing the trace.  
This parameter has the following values:  
**0**-Disable cyclic file tracing  
**1**-Enable cyclic file tracing
- **filelimit:value**  
Defines the maximum size, in bytes, of the trace file. A value of 0 means the trace file has no maximum size.
- **filtering:value**  
Defines the bitwise filter mask that filters the trace for the specified instrumentation plug-in. Privileged Access Manager does not write filtered events to the trace file.

**NOTE**

To specify no filtering, that is, to specify that Privileged Access Manager writes all events to the trace, use the following value: 0xFFFFFFFF. All other values for this parameter depend on the plug-in that you specify.

- **load "*dll\_name*"**  
Specifies to load the specified DLL into the target process. The DLL operating environment and the target process operating environment must be identical. For example, if you specify a 32-bit process as the target process, the DLL must also be 32-bit.

**WARNING**

The DLL must be located in the *ACInstallDir\bin* folder.

- **sources:{1 | 4}**  
Specifies where Privileged Access Manager outputs the trace.  
This parameter has the following values:  
**1**-Output to file  
**4**-Output to debug API trace
- **target**  
Defines the target process or processes. This parameter has one of the following values:
  - **all\_32bit**  
Specifies to send the command to all 32-bit processes running on the computer.
  - **all\_64bit**  
Specifies to send the command to all 64-bit processes running on the computer.
  - **PID**  
Defines the process ID of the target process. The target process must be running on the computer.
  - **process\_name**  
Defines a mask that identifies the names of the target process. The target process must be running on the computer. For example, if you specify cmd.exe for this parameter and there are three instances of cmd.exe running on the computer, Privileged Access Manager applies the command to all three processes.
- **trace *plugin\_name***  
Specifies to modify the run-time tracing configuration for the Privileged Access Manager instrumentation plug-in named *module\_name*, for example, cainstrm or stopplg.

**NOTE**

You must specify the DLL name of the plug-in. If you upgrade an instrumentation plug-in and the name of the DLL for the plug-in changes, you must specify the name of the new DLL in the command. For example, if you upgrade the cainstrm plug-in and the name of the upgraded DLL for the plug-in is cainstrm2.dll, you must specify cainstrm2 as *plugin\_name*.

- **trace:disable**  
Specifies to enable the trace on the target plug-in.
- **trace:enable**  
Specifies to disable the trace on the target plug-in.

**NOTE**

This parameter changes the status of the trace enabled flag in run time. Privileged Access Manager does not begin the trace until the trace is correctly configured.

- **trace:option**  
Specifies to configure the trace on the target plug-in.

**Example: Enable Tracing to the Debug Output Channel**

The following command changes the status of the trace enabled flag in run time for all files in the stopplg plug-in that are in 32-bit processes running on the computer. Privileged Access Manager does not begin the trace until the trace is correctly configured:

```
secons -v all_32bit trace stopplg trace:enable:debug
```

### Example: Apply a Trace Filtering Mask to a Plug-in

The following command applies a trace filtering mask to all files in the cainstrm plug-in that are in the process with PID 362:

```
secons -v 362 trace "cainstrm trace:option:filtering:4294967295"
```

### secons -whoami Function Display Your User Name and Security Credentials

#### Valid on Windows

The secons utility displays the user name as it is known to the Privileged Access Manager authorization engine. This is the information that it stores in the Accessor Element Entry (ACEE) table. The ACEE stores information about the following users:

- **Logged in user**A user that has logged in to the operating system. Specific ACEE attributes for this type of user are:
  - Login session ID
  - Login session type
- **Management user**A user that has logged in to a Privileged Access Manager management application (using an LCA connection). For example, selang.
- **Authorization API user**A user that was referenced in SEOSROUTE\_\* API.
- **SPECIALPGM Logical user**A user that is being references at least in one SPECIALPGM record. A specific ACEE attribute for this type of user is:
  - ACEE association with SPECIALPGM records
- **Built in user**A user that is built in Privileged Access Manager. For example, *\_undefined*.

This command has the following format:

```
secons -whoami
```

### Example: Display Your User Name and Security Credentials

This example displays your own user name and security credentials as they are known to the Privileged Access Manager authorization engine:

```
secons -whoami
```

The secons output looks like this:

```
ACEE handle '2' represents 'Logged on User': COMP1-SRV-X86\John
```

```
ACEE was created at: Wed Feb 20 17:34:47 2008
```

```
ACEE was last accessed at: Wed Feb 20 17:36:49 2008
```

```
ACEE user role is: Auditor, Administrator
```

```
ACEE audit mode is: Failure, Login Success, Login Failure; Originated from User definition
```

```
ACEE user is a member of 0 'CA PAMSC' groups
```

ACEE's Logon session ID is: 0:68737

ACEE's Logon session type is: Interactive

## secons Manage Enabled Kernel

This command has the following format:

```
secons [-dk] [-ek] [-ik]
```

- **-dk**  
Disable kernel extension

### WARNING

Use this parameter only when instructed to do so by CA Support.

- **-ek** <kernel extension name>  
Enable kernel extension
- **-ik**  
List kernel extensions

## secons -raf Function Reloads the audit.cfg file and KBL

### Valid on UNIX

The secons utility reloads the audit.cfg file for seosd and KBL (Keyboard Logger), and also reloads the auditrouteft.cfg file for ReportAgent.

This command has the following format:

```
secons -raf
```

- **-raf**  
(UNIX only) Reloads the the audit.cfg file for seosd and KBL (Keyboard Logger), and also reloads the auditrouteft.cfg file for ReportAgent. It updates the configuration settings without shutting down Privileged Access Manager.

## secrepsw Utility Create Policy Model and Shadow Files

### Valid on UNIX

The secrepsw utility creates a password record for every user in the /etc/passwd file. This is necessary for administering users defined by PMDBs operating over a UNIX environment. The utility can also create and remove shadow files.

### NOTE

This utility is located in the lbin directory and only root can use it. You must change the shadow token in the pmd.ini file to yes before you use this utility.

This command has the following format:

```
secrepsw [-h] [-c] [-r PolicyModel] [-s PolicyModel]
```

- **-c**

Creates a new Policy Model password file from the /etc/passwd and /etc/shadow files on the local computer.

- **-h**  
Displays the help for this utility.
- **-r *PolicyModel***  
Transfers user names and passwords from the Policy Model's shadow file back to the original Policy Model password file (passwd).
- **-s *PolicyModel***  
Transfers user names and passwords from the Policy Model password file (passwd) to the Policy Model's shadow file.

## sedbpchk Utility Back Up the Database

### Valid on UNIX

The sedbpchk utility creates a backup copy of the database. It copies the runtime database to a temporary location, performs various database integrity checks on the temporary database, and, if the database passes the checks, copies the temporary database into a backup location.

If the database does not pass the integrity tests, sedbpchk tries to determine whether any updates were applied to the database while the copy was being made. If there were updates, the conclusion that the database is corrupted may not be accurate.

If there were no updates while the database was being copied, the conclusion that the database is corrupted is probably true. In that case, a mail message is sent to the system administrator, who can then use the backup directory to override the corrupted runtime database.

### NOTE

This script is *not* foolproof. It may conclude that a database is corrupted when it is not. However, the conclusion that a database is okay is always accurate.

You must have root and ADMIN privileges to run this script. Before using sedbpchk, we recommend that you review the script, located in *ACInstallDir/bin* as sedbpchk.sh, to confirm that the values of the following fields match the needs of your site.

- **MAIL\_TO**  
Specifies the name of the user who is sent the notification that the database is corrupt.
- **RETRIES**  
Specifies the number of times the utility checks the database when it suspects that the database is corrupted before sending the notification.
- **ACInstallDir**  
Specifies the location of the Privileged Access Manager installation directory.
- **SE\_BINDIR**  
Specifies the location of the Privileged Access Manager binary files directory.
- **SE\_DB\_DIR**  
Specifies the location of the Privileged Access Manager runtime database directory.
- **SE\_BCKDIR**  
Specifies the location of the backup database directory.
- **SE\_TMPDIR**  
Specifies the location of the temporary database directory.

### NOTE

This utility is supplied as a script file; you need to specify the .sh extension to run it.

This command has the following format:

```
sedbpchk
```

## seerrlog Utility Display Error Log Records

### Valid on UNIX

The seerrlog utility displays the records in the Privileged Access Manager error log. You must either have permission to read the error log file, or be a member of the group that can read the error log files (the group defined in the configuration setting `error_group`).

This command has the following format:

```
seerrlog [-h] [-s date] [-e date] [-d] [-f filename]
```

- **-s date**  
Specifies the start date for the list. Lists records written on and after the defined date.  
**Limits:** Date should be in the format dd-mm-yyyy.
- **-e date**  
Specifies the end date for the list. Lists records written up to and including the defined date.  
**Limits:** Date should be in the format dd-mm-yyyy.
- **-d**  
Specifies *not* to print the detailed information of failures.
- **-h**  
Displays the help for this utility.
- **-f filename**  
Specifies the error log file to read.  
By default, seerrlog reads the `ACInstallDir/log/seos.error` file. You cannot define this file in the database, and only Privileged Access Manager can write to the file.

### Examples

- To list all error records written since 3 January 2006, specify:  

```
seerrlog -s 03-Jan-2006
```
- To list all error records written between 3 January 2006 and 1 January 2007, specify:  

```
seerrlog -s 03-Jan-2006 -e 01-Jan-2007
```

## segrace Utility Display User Login Information

The segrace command line utility displays the number of grace logins left for a user, the number of days remaining until the user's existing password expires, or the date and time the user last logged on, and from which terminal.

### NOTE

For more information about the grace login property of a user, see the *Endpoint Administration Guide* for your OS.

Before segrace can work, the system administrator must activate Privileged Access Manager password checking by entering the selang command:

```
setoptions class+(PASSWORD)
```

Subsequently, every time a user's password is changed, the new password is checked against the password quality rule set in the database.

## segrace Utility Display User Login Settings on UNIX

### Valid on UNIX

The `segrace` utility displays login settings for a user. We recommend that you run the `segrace` command every time a user logs in. To do so, add the command to `/etc/profile` and `/etc/csh.login` (or `/etc/.login` for Solaris).

To permit `segrace` to count grace logins, you must use the `sepass` utility to change passwords. If users have no grace logins left, `segrace` invokes the `sepass` utility, which requests that the users replace their passwords. Your site may decide which command to execute instead of the `sepass` utility by specifying another utility in the `sepass_command` token in the `segrace` section of the `seos.ini` file.

This command has the following format:

```
segrace [-h] [-d days] [-l] [-p] [userName]
```

- **-d *days***  
Displays the number of days that remain until the user's current password expires. The number appears only if the number of days you specify in the *days* parameter is greater than, or equal to, the interval value in the Privileged Access Manager option. If you omit the *days* parameter, `segrace` uses a default of seven days. This option works only if the user's password was changed using `sepass`.
- **-h**  
Displays the help for this utility.
- **-l**  
Displays the date and time the user last logged in, and from which terminal.
- **-p**  
Prompts for a new password when a user's password has expired.
- ***userName***  
If you specify a user name, and the requester has the ADMIN attribute, `segrace` displays the required login information for the specified user.  
If you do not specify a user name, `segrace` displays the login details for the current user.

## segrace Utility Display User Login Settings on Windows

### Valid on Windows

The `segrace` utility displays login settings for a user. This utility can be executed from a remote machine, as a standalone module.

#### NOTE

If you invoke `segrace` without any parameters, and no grace logins are found for a user, `segrace` does not display anything.

This command has the following format:

```
segrace [-h] [-d days] [-l] [-p] [-s host] [userName]
```

- **-d *days***  
Sets the warning *days* parameter to be different from the default one configured in the server.
- **-h**  
Displays the help for this utility.
- **-l**  
Displays the date and time the user last logged in, and from which terminal.
- **-p**  
Prompts for a password warning if the password is about to be expired in the *warning days* period and/or if the user has a grace count.
- **-s *host***  
Specifies the remote server name where the Privileged Access Manager database will be used.
- ***userName***

If you specify a user name, and have the ADMIN attribute, segrace displays the required data for the specified user.  
If you do not specify a user name, segrace displays the login details for the current user.

## SegraceW Utility Check Password Expiry on Windows

### Valid on Windows

This Windows GUI grace utility checks whether the user's password has expired and/or the user has a grace login count. If it has, SegraceW displays a window in which the user can replace the password.

SegraceW can be executed as a standalone module in a non-Privileged Access Manager environment. This enables you to apply this utility on any workstation in a domain.

SegraceW tries to connect first to the primary domain controller (in an NT 4.0 environment). SegraceW looks for backup domain controllers only if the attempted connection fails. In a Windows 2000 or later environment, SegraceW tries to connect to the first domain controller it finds.

#### NOTE

If a remote host is specified explicitly in the SegraceW execution options, then SegraceW connects only to the remote host.

The SegraceW utility is designed to be called from login batch files located at Domain Controller's NETLOGON share.

The SegraceW utility checks whether the user password has expired and/or the user has a grace login count.

#### NOTE

For segraceW implementation in a domain environment, you must install MS VC++ 2005 Redistributable to the member server. The installation must be equivalent to the Privileged Access Manager installation on the remote server.

If the grace login count attribute of the user exists, then:

- If the number of remaining grace logins for the user is zero, SegraceW forces the user to change the password.
- If the number of remaining grace logins for the user is positive, SegraceW advises the user to change the password.

If the user does not have a grace login count, SegraceW checks password expiration status.

- If the password is about to be expired in a time frame larger than the value of the *warning days* parameter configured at the server side, SegraceW does nothing.
- If the password is about to expire in a time frame equal or less than the value of the *warning days* parameter configured at the server side, SegraceW advises the user to change the password.
- If the password has been expired, SegraceW forces the user to change the password.

When changing the password, SegraceW displays a change password message that asks the user to provide the old password, the new password, and confirm the new password.

After passing confirmation check, the password is updated in the domain controller's SAM database.

This command has the following format:

```
segracew [d] [-s host]
```

- **d**  
Sets the *warning days* parameter to be different from the default configured in the server.
- **-s host**  
Connects to the specified remote or local host to retrieve information.

#### NOTE

Before you can connect to a remote host, copy the encryption library from the remote host to the local host and rename it to defence.dll.

## seini Utility Manage Configuration Files

### Contents

#### Valid on UNIX

The `seini` utility manages Privileged Access Manager database and initialization files for any host. For any host, the `seini` utility can do the following:

- Display the path of the Privileged Access Manager database
- Display the path of an initialization (.ini) file
- Display the contents of a token from an initialization file
- Set the value of a specific token in a specific section of an initialization file
- Delete a specific token from a specific section of an initialization file

The `seini` utility also displays all tokens in any of the other .ini files. The name of the initialization file must always end in the suffix `.ini`. You can work on an .ini file from any remote host as long as you have `WRITE` and `ADMIN` privileges.

If you do not specify any switch, `seini` displays the paths of the database and the `seos.ini` file.

#### NOTE

The `seini` utility can only update the `seos.ini` file when `seosd` is *not* running, or when a rule in the database specifically permits it.

`seini` can perform an intelligent token and section search, by including certain tokens in the `seos.ini` file. This feature checks for spelling errors by comparing each token or section with the one you specified until it finds an exact or partial match (within a 25% error margin). If it finds the relevant token or section, `seini` performs the specified operation; otherwise it displays an error message.

#### NOTE

The intelligent search feature works only on the host where you invoke the `seini` utility.

This command has the following format:

```
seini [-d] [host]
seini [-i] [host]
seini [-H host] \
{[-f [host.]section.token [ini_file]] | \
[-r [host.]section.token [ini_file]] | \
[-s [host.]section.tokenvalue [ini_file]] | \
[-sn [host.]section.tokenvalue [ini_file]] }
```

- **-d [host]**  
Displays the path of the database on the remote host. If you do not specify a host, `seini` displays the path of the local host.
- **-f [host.]section.token [ini\_file]**  
Displays the value of the token in the section of the specified initialization file on a specified host. If `seini` cannot find the specified section or token, an empty line appears. You must separate the host, section, and token names with a period (.). If you do not specify the *ini\_file*, Privileged Access Manager searches the `seos.ini` file for the section and token. To display information about the local machine, omit the *host* parameter.
- **-g section**  
Displays a list of tokens in the defined section.
- **-h**  
Displays the help for this utility.
- **-H [host]**  
Specifies the remote host to be used with the `-f`, `-r`, `-s`, and `-sn` flags.
- **-i [host]**

Displays the pathname of the initialization file seos.ini. If you do not specify a host, seini displays the pathname on the local host.

- **-r [host.]section.token [ini\_file]**  
Deletes the token from the section of the initialization file in the specified host. If you do not specify the *ini\_file*, Privileged Access Manager deletes the token from the seos.ini file.  
To delete information on the local machine, specify the section and token names only.
- **-s [host.]section.token value [ini\_file]**  
Sets the value of the token in the section of the initialization file in the specified host. If you do not specify the *ini\_file* parameter, Privileged Access Manager sets the value in the seos.ini file. If the section or token does not exist, and you specified a remote host, Privileged Access Manager creates that section or token.  
To create a section or token on the local machine, use the -sn switch.
- **-sn [host.]section.token newValue [ini\_file]**  
Sets the value of the token in the section of the initialization file in the specified host. If you do not specify the *ini\_file* parameter, Privileged Access Manager sets the value in the seos.ini file. If the section or token does not exist, and you specified the local host, Privileged Access Manager creates that section or token.  
To create a section or token on a remote machine, use the -s switch.

### Examples: Using seini

- To find out where the seos.ini initialization file is located on the local computer, use the following command:  

```
seini -i
```
- To find out the value of the *trace* configuration setting in the [seosd] section, use the following command:  

```
seini -f seosd.trace_file
```
- To set the value of the *trace\_to* configuration setting in the [seosd] section, use the following command:  

```
seini -s seosd.trace_to file
```

The command output should look like this:

```
The token seosd.trace_to now set to file (was file,stop)
```

### selang Utility Run the Privileged Access Manager Command Line

The selang utility invokes a command shell that provides access to the Privileged Access Manager database and the native environment. The database is updated dynamically by issuing selang commands from within the command shell.

#### NOTE

The result of the command's execution is sent to the standard output unless you include the -o option.

This command has the following format on UNIX:

```
selang [{-c command|-f file}] [{-d path|-p pmdb}] [-o file] [-r file] [-s] \
[-u userpass]
selang [-l] [-o file] [-r file] [-s] [-u userpass]
```

This command has the following format on Windows:

```
selang [{-c command|-f file}] [{-d path|-p pmdb}] [-o file] [-r file] [-s] [-v]
selang [-l] [-o file] [-r file] [-s] [-v]
```

- **-c command**  
Specifies the selang command to execute. After selang executes the command, it exits.  
If *command* contains any spaces, enclose the entire string in quotation marks. For example:  

```
selang -c "showusr rosa"
```
- **-d path**  
Specifies that selang commands update the database in the defined path.  
**Note:** You can only specify a local database.
- **-f file**  
Specifies that selang commands are read from the defined file rather than from the terminal's standard input.

As `selang` executes the commands in the input file, the line number of command being executed appears on the screen. The `selang` prompt does not appear on the screen. After `selang` executes the commands in *file*, it exits.

- **-h**  
Displays the help for this utility.
- **-l**  
Specifies that `selang` updates the default local database, usually `ACInstallDir/seosdb` (where `ACInstallDir` is the directory where you installed Privileged Access Manager).  
You do not need to specify this option with `-d` or `-p`.

**NOTE**

This option replaces `selang`. It is only valid when `seosd` is not running, and only an Privileged Access Manager administrator with sufficient native privileges to update the database files can execute it.

- **-o file**  
Specifies that `selang` output is written in the specified file. Each time you invoke `selang`, it creates a new, empty file. If you specify the name of an existing file, `selang` writes over the information currently in the file.
- **-p pmdb**  
Specifies that `selang` commands update the database of the defined PMDB, which must be in the local station (this is the database in the PMDB subdirectory). Changes to the database are not propagated to subscribers.

**NOTE**

This option is not valid if either `sepmdd` or `seosd` is running on the specified PMDB and is not the same as using the *hosts command*.

**WARNING**

Do not make changes that require propagation in this mode. If you use native mode when making updates, Privileged Access Manager updates only the native host files (as defined in the Privileged Access Manager configuration options).

- **-r file**  
Specifies that `selang` reads the commands from the defined file. The file should consist of commands in normal `selang` syntax, separated by semicolons or line breaks. After executing the commands in *file*, `selang` prompts the user for input.  
If you do not define a file for this option, `selang` uses the `.selangrc` file in your home directory.
- **-s**  
Specifies that `selang` opens in silent mode, without displaying the copyright message.
- **-u user pass**  
(UNIX only) Specifies a username and password for running `selang`.  
To use this option, you must set the `check_password` token in the `seos.ini` file to `yes`; this causes Privileged Access Manager to prompt you with Enter your password when you run `selang -u`. You have three attempts to login.  
The token `no_check_password_users` in the `[lang]` section of the `seos.ini` file contains a list of users that bypass the password checking during a login to `selang`.

**NOTE**

If the `check_password` token is set to `no` (the default), `selang` does not require any passwords.

- **-v**  
(Windows only) Writes command line to output.

Usage notes:

- If `-h` is used, all other options are ignored.
- You cannot use the `-c` option with the `-f` option.
- You cannot use the `-d` option with the `-p` option.
- If you specify `-d` or `-p`, you do not need to specify `-l`.

## seldapcred Utility Encrypt and Store a Credential

### Valid on UNIX

The seldapcred utility encrypts and stores a credential you provide. This credential is used by LDAP-enabled Privileged Access Manager utilities (such as sebuildla) for retrieving data from an LDAP Directory Information Tree (DIT). Together with the value of the ldap\_userdn token in the [seos] section of the seos.ini file, it lets the utility authenticate to the LDAP service. For a simple authentication, the credential is a password corresponding to the ldap\_userdn value. For SASL authentication, the credential has different semantics.

The seldapcred utility writes the encrypted credential to *ACInstallDir/etc/ldapcred.dat*

This command has the following format:

```
seldapcred [-h] [-w [credential]]
```

- **-h**  
Displays the help for this utility.
- **-w [credential]**  
Specifies the credential you want seldapcred to encrypt and store. If you do not provide input to the seldapcred utility, it prompts you to enter this value. By using the interactive mode in this way, you prevent exposing the credential to other users.

## seload Utility Load and Start CA Privileged Access Manager Server Control

### Valid on UNIX

The seload utility loads the Privileged Access Manager extension to the UNIX kernel and starts the Privileged Access Manager daemons. The seload utility loads Privileged Access Manager daemons locally and remotely. It also determines whether the Privileged Access Manager extension to the UNIX kernel is loaded on the specified host. If seosd is not running, seload starts the daemon on the specified host. If you omit the -r switch and parameter, the seosd daemon runs on the local host.

You can instruct seload to load one of the following daemons on the remote host: seosd, selogrd, selogrcd, or serevu. This process depends on the tokens.

Use seload if Privileged Access Manager is placed in the boot sequence of the server station.

### NOTE

- When Privileged Access Manager is installed, sample initialization files for every operating system supported by Privileged Access Manager are placed in the *ACInstallDir/samples/system.init* directory. Use these files if Privileged Access Manager is to be started as part of the system initialization.
- The seload utility requires that the executable se\_loadtest be located in *ACInstallDir/sbin* (where *ACInstallDir* is the installation directory). This program determines whether the Privileged Access Manager extension to the UNIX kernel is loaded.
- When working remotely, the seload utility requires the following:
  - The executable rseload is located in Privileged Access Manager dir/sbin. This program runs on the remote host and activates seload.
  - The file /etc/services contains seosload service. You should add this file during Privileged Access Manager installation.
  - The file /etc/inetd.conf contains the rseload program. You can add this program during Privileged Access Manager installation.

This command has the following format:

```
seload [-c] [-nopmd] [-r host [daemon]]
```

- **-c**  
Changes the encryption key that was set using the `sechkey -r` command.
- **-nopmd**  
If you specify the `-c` switch with the `-nopmd` switch, `seload` does not update the Policy Model update file with the new key.
- **-r *host [daemon]***  
Loads the `seosd` daemons, and any other daemon specified in the `[daemons]` section of the `seos.ini` file.  
If you specify a *daemon*, `seload` starts only that daemon; it ignores the `seos.ini` token. You must supply with the daemon's full path.  
The `seos.ini` token in the `[daemons]` section is used only if you specify a value. It has no default value. If you do specify a value, `seload` substitutes the value in the token for the standard values of the specified utility or program. For example, if you specify the value `selogrd=yes`, `seload` automatically starts the `selogrd` daemon after it starts the `seosd` daemon.

## selogmix Utility Split and Merge Audit Log Files

### Valid on UNIX

The `selogmix` utility splits and merges Privileged Access Manager audit log files.

This command has the following format:

```
selogmix {-s|-m} [-fn fileName] [-l fileName1fileName2] \
[-c weight1:weight2] [-t days] [-d] [-i]
```

- **-c *weight1:weight2***  
Specifies the correlation of file sizes for splitting files where *weight1* indicates the relative weight of the first file and *weight2* indicates the relative weight of the second file. If you omit this option, `selogmix` uses a one-to-one correlation.
- **-d**  
Specifies to run `selogmix` in debug mode. In this mode, `selogmix` displays all settings.
- **-fn *fileName***  
Specifies the name of the audit log file to be split or the resulting file of a merge. If you omit this option, `selogmix` uses the file name specified by the `audit_log` token in the `[logmgr]` section of the `seos.ini` file.
- **-h**  
Displays the help for this utility.
- **-i**  
Specifies to run `selogmix` in interactive mode. In this mode, `selogmix` prompts you for confirmation before overwriting existing files; otherwise, it overwrites without confirmation.
- **-l *fileName1 fileName2***  
Specifies the files used in the merge or split operation.  
You must specify both file names for this option. For merging, specify the two file names you want to merge; for splitting, specify the two destination files. If you omit this option, `selogmix` uses the file name specified by the `audit_log` token in the `seos.ini` file and suffixes 1 and 2 to the file name.
- **-m**  
Merges two audit log files.
- **-s**  
Splits a specified audit log file.
- **-t *days***  
Specifies a number of days. You can only use this option for splitting files. Specify how many days from the end of logging to put into a separate file. If you omit this option, `selogmix` separates one last logging day.

### Examples

- To split the standard log file into two files of equal size, use the following command:

```
selogmix -s
```

The original audit file is named *ACInstallDir/log/seos.audit*

The new split files are named *ACInstallDir/log/seos.audit1* and *ACInstallDir/log/seos.audit2*.

- To separate records for the last two days from the log file, use the following command:

```
selogmix -s -t 2
```

- To split a log file into two files with a defined correlation in size, use the following command:

```
selogmix -s -c 1:2
```

- To merge two specified files into one named file, use the following command:

```
selogmix -m -l seos.audit1 seos.audit2 -fn seos.audit.merge
```

## semsgtool Utility Maintain the Message File

The semsgtool utility lets you:

- Show a single message from the Privileged Access Manager message file
- List an entire section of messages
- Dump the entire file into ASCII files, one ASCII file for each section
- Build a new message file
- Change message to a new one
- List messages, including substring
- Validate the message file

You can only specify one command each time you execute semsgtool.

The default location of the message file is *ACInstallDir/data/seos.msg*

### NOTE

The Privileged Access Manager message file is comprised of sections and message numbers. Each section holds messages for different Privileged Access Manager modules or sub-modules.

This command has the following format:

```
semsgtool {-build|-b} asciiSourceFileOutputMessageFile
semsgtool {-change|-c} [messageFile] {0xerror-code|section#msg#}new-message
semsgtool {-dump|-d} messageFile
semsgtool {-list|-l} [messageFile] sectionNumber
semsgtool {-number|-n} [messageFile] subString
semsgtool {-show|-s} [messageFile] [0xerror-code|section#msg#]
semsgtool {-validate|-v} [messageFile]
```

- **-build|-b**  
Creates a new Privileged Access Manager message file from an ASCII source file.
- **-number|-n**  
Lists messages in the message file that include a defined string.
- **-change|-c**  
Creates a new message file, named *messageFile.new*, where the specified message has the defined modified string.
- **-dump|-d**  
Dumps the message file into several files, one file for each section of the message file. This creates ASCII source files that later can be used to create new Privileged Access Manager message files.
- **-h**  
Displays the help for this utility.
- **-list|-l**

Lists all the messages in a given section in the message file.

- **-show|-s**  
Shows the message associated with a specific message code.
- **-validate|-v**  
(Windows only). Validates the message file by checking for duplicate messages and messages that exceed the allocated boundaries.
- **0xerror-code**  
Defines the hex number of the error code for the message that you want to display or change.
- **asciiSourceFile**  
Defines the source file in ASCII format from which semsgtool builds a new message file.
- **messageFile**  
Defines the name of the message file. If you omit this option, semsgtool uses the message file as specified in the configuration settings.
- **OutputMessageFile**  
Defines the name of a new message file to build.
- **section# msg#**  
Defines the section number and message number of the error code for the message that you want to display or change.
- **sectionNumber**  
Defines the section number of the section you want to list all the messages for.

### Example

- To list the message associated with the error code 0x205, enter the following command:  

```
semsgtool -s seos.msg 0x205
```
- To list the messages in section 512, enter the following command:  

```
semsgtool -l seos.msg 512
```
- To create a modified Privileged Access Manager message file, follow these steps:
  - a. Create a new message file with a modified message:  

```
semsgtool -c 0x2501 "This is the new message"
```

  
A new message file, seos.msg.new, is created with the modified message.
  - b. Copy the new file over the Privileged Access Manager message file:  

```
copy seos.msg.new seos.msg
```

  
Copies the new message file with the modified message on top of the old seos.msg file.
- To show the message associated with the error code 0x0205, enter the following command:  

```
semsgtool -s 0x205
```

## senable Utility Enable a Disabled User Account

### Valid on UNIX

The senable utility enables the login of a user that was disabled for any reason, at any location at which the user was disabled, including PMDBs. For example, the serevu daemon might disable a user, or the user's suspend date or expire date arrived.

After the senable utility enables the user account, it calls the sepass utility, which prompts for a new user password. To restore the most recent password, use the -n option.

The senable utility enables an undefined user account by deleting that account from the local /etc/passwd file.

To execute senable remotely, specify your local terminal needs in a rule that grants it WRITE permission for accessing the remote station. Otherwise, you cannot perform Privileged Access Manager administration there.

**NOTE**

For more information about remote administration restrictions, see the section [Endpoint Administration for UNIX](#).

This command has the following format:

```
senable [-host hostname] userNames [-n]
```

- **-host *hostname***  
Selects the host with the account to change from disabled to enabled.  
You must have ADMIN or PWMANAGER attributes on two hosts to use the -host option:
  - The host with the account to be changed from disabled to enabled.
  - The host where you enter the senable command.
- **-h**  
Displays the help for this utility.
- **-n**  
Runs the command noninteractively. If you use this option, senable does not call sepass, and restores the most recently used password.
- ***userNames***  
Defines a space-separated list of user names for accounts being changed from disabled to enabled.

## senone Utility Execute a Command as an Unauthorized User

### Valid on UNIX

The senone utility executes a command issued by a highly authorized user as an unauthorized user process.

**NOTE**

Only highly authorized users who are testing untrusted programs should use this utility.

When you invoke the senone utility, it deletes the process credentials from the authorization daemon. senone then executes a shell with the credentials of a user who is not defined to Privileged Access Manager. From this point on, any program invoked from within this shell is executed with the credentials of the non-Privileged Access Manager user. Because senone does not change the invoker's user ID, the user's UNIX privileges remain unchanged.

**WARNING**

We recommend that users who are logged in as root not run untrusted programs. Even when running untrusted programs with senone, unexpected problems can occur.

If you invoke senone without specifying a command, it executes the user's shell as defined in /etc/passwd.

This command has the following format:

```
senone [command]
```

- **-h**  
Displays the help for this utility.
- ***command***  
Specifies the command you want senone to execute as an unauthorized user.

## SEOS\_load Utility Load the CA Privileged Access Manager Server Control Interception Module

### Valid on UNIX

The SEOS\_load utility controls the dynamic Privileged Access Manager kernel module (SEOS\_syscall). The interception module must be loaded before running any Privileged Access Manager utility.

**NOTE**

You can use UNIX exits to automatically run programs before and after loading and unloading the kernel.

On streams supported platforms, this utility loads the Privileged Access Manager module to streams depending on the SEOS\_use\_streams token in the [SEOS\_syscall] section of the seos.ini file. If the token is set to yes, the module is pushed into streams.

This command has the following format:

```
SEOS_load [-i|-k|-s|-u]
```

- **-i**  
(For HP-UX and Sun Solaris platforms only.) Displays information about the Privileged Access Manager kernel extension.
- **-k**  
(For HP-UX and Sun Solaris platforms only.) Loads the Privileged Access Manager module into the kernel without pushing into streams.
- **-s**  
(For HP-UX and Sun Solaris platforms only.) Inserts the Privileged Access Manager kernel module into streams. This option ignores the SEOS\_use\_streams token in the SEOS\_syscall section of the seos.ini file.
- **-u**  
Unloads the Privileged Access Manager kernel extension from the kernel and then removes the module from streams.

#### NOTE

You cannot unload Privileged Access Manager if an application, which is loaded on top of Privileged Access Manager, has an open system call (syscall) that is hooked by Privileged Access Manager. Use *secons -sc* or *secons -sc/* to find these processes. You can then shut down these processes and unload the Privileged Access Manager kernel module, or use UNIX exits to automatically shut down these processes before unloading the kernel and then restart them after the kernel unloaded.

## sepass Utility Set or Replace a Password

### Valid on UNIX

The sepass utility sets a new password or replaces an existing password in the local host, in a Policy Model, or in the NIS or NIS+ server, as applicable.

The sepass utility changes the user password. Additionally, privileged users can use sepass to change the passwords of other users. When changing your own password, sepass prompts you for your old password.

#### NOTE

If seosd is not running, sepass runs a default password program. The DefaultPasswdCmd token in the passwd section of the seos.ini file specifies the default password program. Passwords are stored and transferred over the network in an encrypted format.

This command has the following format:

```
sepass [-d] [-l] [-p] [-s policy_model@hostname] \  
[-g number] [-x] [userName]
```

- **-d**  
Displays all the information it has regarding the password update, such as on which stations the update succeeded and if you did not activate setoptions class+(PASSWORD), that the password's quality was not checked. This switch is useful when debugging.
- **-g *number***  
Defines the number of grace logins for *userName*.
- **-h**  
Displays the help for this utility.
- **-l**

Replaces the password only on the local station; that is, in the local password file (usually `/etc/passwd`), security files, and the local database.

In the NIS/NIS+ environments, users are not usually defined in the `/etc/passwd` file of the client; therefore, the password on the client station is not updated.

In NIS/NIS+ server stations, the password is updated locally and propagated by NIS/NIS+.

This switch and the `-p` and `-s` switches are mutually exclusive.

- **-p**  
Changes the password only on the remote station and on the PMDB at the host specified in the switch. This switch and the `-l` and `-s` switches are mutually exclusive.
- **-s *policy\_model@hostname***  
Replaces the password on the local station and on the PMDB at the host specified in the switch. This switch and the `-l` and `-p` switches are mutually exclusive.
- **-x**  
Replaces the password as if changed by the user *username*. This switch updates the time and date of the last change in the database. Grace logins are terminated.

#### NOTE

To let you change the root password as if changed by root, you have to set the `RootPwAsOwn` appropriately. For more information about `seos.ini` tokens, see the *Reference Guide*.

- ***username***  
(Optional) Specifies the name of the user whose password `sepass` changes. If you omit this option, your own password is set.

## Examples

The following examples illustrate how you can use `sepass` in a variety of situations:

- To change your own password on the local host, enter the command:

```
sepass -l
```

#### NOTE

If no PMDB is defined at the site, you can omit the `-l` switch. If a PMDB is in use at the site, omitting the `-l` switch changes your password on all subscriber databases of the PMDB. In an NIS/NIS+ client, this switch *does not* change the password; in an NIS/NIS+ server, the password is changed and then propagated.

- To change the password of any user other than your own, on the local host only, enter the command:

```
sepass -l username
```

*username* must exist in the `/etc/passwd` file, the appropriate UNIX security files, and the database.

In an NIS/NIS+ client, `sepass` does not change the password. In an NIS/NIS+ server, the password is changed and then propagated.

- To change the password of a user on several stations at a site where NIS is not in use, follow these steps:
  - a. Create a PMDB.

#### NOTE

For more information about creating PMDBs, see the *Endpoint Administration Guide for UNIX*.

- b. Add all the users whose details must be distributed to the subscriber computers, to both the UNIX and the Privileged Access Manager environments of the PMDB.
- c. Subscribe all the stations to receive the updated passwords to the PMDB.
- d. On every subscriber, set the tokens in the `[seos]` section of the `seos.ini` file to the names of your PMDB. For example:

```
passwd_pmd = PMD1@morocco
```

```
parent_pmd = PMD1@casablanca
```

Enter the command:  
`sepass username` When `sepass` completes execution, the user's password is changed on all the subscriber databases.

## AM SC sepmd Utility

The sepmd utility is the Policy Model management utility, enabling you to perform the following tasks:

- Administer subscribers and the update file
- Administer Dual Control
- Manage the Policy Model log file
- Manage the PMDB
- Back up the PMDB
- Restore the PMDB

### NOTE

Run the sepmd utility on the host where the Policy Model resides.

Use the table of contents to access the topics in this section.

## sepmd Utility Administer Subscribers and the Update File

The sepmd utility creates, removes, and assigns subscribers.

This command has the following format:

```
sepmd {-C|-de|-l|-L|-p|-R} pmd
sepmd {-n|-r|-u} <pmd> <subscriber>
sepmd -s <pmd> <subscriber> <offset>
sepmd -sm pmdmf_subscribermf_typedmf_sysidmf_adminoffset
sepmd -smq pmd <-predefined> <ACMQ queue> [-destination <destination>]
sepmd -t pmd {auto|offset}
```

- **-C**  
This parameter displays all commands and their offsets in the update file. The offset indicates the location of the update inside the file, which you might want to specify when you subscribe another database or PMDB.
- **-de**  
(UNIX only) Decrypts the information in the encrypted updates.dat file. Data encryption for this file occurs when you set the UseEncryption PMDB configuration setting to yes.
- **-l**  
Lists the subscribers of the Policy Model.
- **-L**  
Lists the Policy Model and its status, including number of errors, availability, offset, synchronization mode, and the next command to be propagated. The update file contains all updates that must be, or have been, propagated by the Policy Model. The offset indicates the location of the next update that must be sent to a subscriber. Both initial and latest offsets also appear.
- **-n**  
Creates a new subscriber and then updates it retroactively to the Policy Model. For general rules that apply for updating a subscriber, see the description for the -s option.

### NOTE

This option sends the contents of the entire PMDB—including the LOGINAPPL (UNIX only) and SPECIALPGM objects—to the new subscriber. You might want to filter out these objects if the subscriber's objects differ from those of the parent.

The -n option does not replace the Policy Model database definitions on the target subscriber database definition, rather it is added to the existing Policy Model. If the target database contains additional resources or attributes, the new Policy Model does not remove them after subscription is complete.

A subscriber added with `-n` is marked as *sync*, indicating that it is now in synchronization mode and receives all of the PMDB rules. When the subscriber has received all the rules, it is released from synchronization mode and becomes a regular subscriber. The `-n` option might take some time to process. If there are multiple or contradictory updates, the last one is used.

### **WARNING**

When you subscribe a Privileged Access Manager endpoint or a PMDB to another PMDB using `sepmdb -n`, the new parent PMDB should not contain any policies (POLICY object names) that already exist in the new subscriber. Undeploy each existing policy from the subscriber and then delete the POLICY object and linked RULESET object from the subscriber before you subscribe it to the new parent PMDB.

On UNIX, if the `send_unix_env` token in the `seos.ini` file is set to yes, the `-n` option also sends the contents of Policy Model password and group files. We recommended that you view the database, by using `dbmgr -export -l`, to ascertain the commands being forwarded.

- **-p**  
Lists the resident Policy Models and their status.
- **-r**  
Removes the subscriber from the list of unavailable subscribers maintained by `sepmdd`, making the subscriber available for immediate updates. Normally, if a subscriber is down and cannot receive updates from the Policy Model, `sepmdd` tries to send updates to that subscriber only after a certain period of time. However, if you specify this option, `sepmdd` skips the waiting period and tries to send updates to the subscriber immediately.
- **-R**  
Update all subscribers with their real offset.
- **-s**  
Subscribes another database or PMDB to the Policy Model. When you subscribe a host to a Policy Model, the host must be up, and Privileged Access Manager must be running on that host. Additionally, the PMDB must be the parent PMDB of the subscribed host. You establish this relationship with the `parent_pmd` subscriber configuration setting, which must contain the name of the PMDB to which the host is being subscribed.  
When you subscribe a Policy Model to another Policy Model,
  - the token `parent_pmd` in the `pmd.ini` file of the subscribed Policy Model must contain the name of the Policy Model to which it is subscribing (its parent Policy Model).
  - Privileged Access Manager must be running on the host in which the subscribed policy resides.
 A PMDB should have only one parent. If you decide to establish a Policy Model with more than one parent give the `parent_pmd` token the name of a file containing a list of the parent Policy Models. However, establishing more than one parent is not recommended because you risk inundating your database with unreliable instructions from multiple sources.
- **-sm**  
Assigns a mainframe subscriber to the Policy Model.
- **-smq**  
Subscribes a pre-defined message queue subscriber to a policy model.
  - **<ACMQ queue>**  
Specifies the following pre-defined Message Queue queues:
    - a. ServerToServer
    - b. ServerToServerBroadcast
    - c. ServerToEndpointBroadcast
    - d. EndpointToServer
    - e. ServeryoEndpoint
  - **-destination**  
Specifies the destination of the Privileged Access Manager component that receives messages from the subscriber.
- **-t**  
Truncates the update file by deleting entries from it.

**NOTE**

On UNIX, if the `force_auto_truncate` PMDB configuration setting is set to no, `sepmc -t` does not truncate the update file. If the token is set to yes, the command truncates the update file even if there are no subscribers to the Policy Model.

- If you are using *offset* (manual cutting), you can find the offset by running `sepmc` with the `-L` option.

**NOTE**

Use the true offset from the `-L` parameter to truncate the file, and not an offset derived by subtracting from the start offset.

- If you are using *auto*, `sepmc` calculates the offset of the first unpropagated entry and deletes all the entries before it. Using *auto* saves the step of running the utility with the `-L` parameter.

If a subscriber received fewer than all updates before the specified offset, `sepmc` displays an error message and does not truncate the file. If you want to truncate the file anyway, do the following:

- Unsubscribe the host that was not updated
- Truncate the file
- Resubscribe the host to the Policy Model

If you do this, the subscriber fails to receive one or more updates from the Policy Model. The subscriber's offset changes to the last offset of the updates file.

- **-u**  
Removes a subscriber from the Policy Model subscription list.
- **auto**  
Instructs `sepmc` to calculate the offset of the first unpropagated entry and to delete all the entries before it.
- **offset**  
Used with the `-s` or `-sm` options, specifies the point within the update file from where the newly added subscriber starts receiving updates.  
Used with the `-t` option, specifies the distance from the beginning of the update file to the position of a particular subscriber.  
Use the `-C` option to see the valid update offsets. If you specify an offset that is in the middle of an update, the offset is moved forward to the beginning of the next update. If you specify an invalid offset (smaller than the first offset or larger than the last), an error message appears.
- **pmd**  
Specifies the name of the Policy Model.
- **-predefined**  
Specifies to use pre-defined message queue subscribers
- **subscriber**  
Specifies the subscriber station or the host of the subscriber PMDB.

## sepmc Utility Administer Dual Control

### Valid on UNIX

The `sepmc` utility manages Dual Control transactions. The `sepmc` utility gives a unique ID number to each transaction when it is created.

**NOTE**

For more information about Dual Control, see the *Endpoint Administration Guide for UNIX*.

When you use Dual Control, the name of the PMDB must be *maker* and the `is_maker_checker` configuration setting must have the value yes for both the PMDB and Privileged Access Manager.

This command has the following format:

```
sepmc -m {1|1a|1o}
```

```
sepmdd -m {d|r} <transactionId>
sepmdd -m p <transactionId> <code>
```

- **-m d**  
Deletes the transaction. A transaction is one or more commands that must be approved before they are implemented on the PMDB. Only the user who created the transaction can delete it.
- **-m l**  
Lists the unprocessed transactions (awaiting the Checker) of the user who invoked the command. Each transaction is listed with its ID number, the name of its Maker (the user who created the transaction-in this case the same user who invoked the command), and its description, if any.
- **-m la**  
Lists all the unprocessed transactions of all the Makers. Each transaction is listed with its ID number, the name of its Maker, and its description, if any.
- **-m lo**  
Lists the unprocessed transactions (awaiting the checker) of all the Makers *except* the transactions of the user who invoked the command.
- **-m p**  
Processes a transaction. When the Checker (any admin user *except* the Maker who created the transaction) enters an ID number, all the commands in the specified transaction appear in a list.  
This option does not work in the following circumstances:
  - If one or more of the commands in the transaction pertain to the user who invoked the command.
  - If the transaction is locked by a different Checker
  - If the transaction was created by the user who invoked the command-Makers cannot act as Checkers for their own transactions.
  - If the specified transaction ID does not exist.
  - If the user who invokes the command does not have the authority to be a Checker.
- **-m r**  
Retrieves or locks a transaction.
  - If you are the user who created the transaction (the Maker) this parameter retrieves a specific, unprocessed transaction. After you retrieve the transaction, you can direct it to an appropriate file and use the ASCII editor of your choice (vi, emacs, and so on) to update the transaction.
  - If you are a user who is *not* the Maker (Checker) this parameter locks the transaction before processing. You cannot change a locked transaction.
- **transactionID**  
Specifies the unique identifying number that sepmdd gives to the transaction when it is created
- **code**  
Specifies a numeric code that tells the Checker what to do when processing the transaction:
  - **0**  
Rejects the transaction, in which case all the commands in the transaction are deleted and no changes are implemented in the PMDB
  - **1**  
Authorizes the transaction, in which case the commands are immediately implemented in the PMDB
  - **2**  
Unlocks the transaction so that it can be processed later, or by a different Checker.

## sepmdd Utility Back Up the PMDB

The sepmdd utility lets you back up the Policy Model database.

This command has the following format:

```
sepmdb {-bl|-ul} pmd
sepmdb -bd <pmd> <destination>
sepmdb -bh <pmd> <destination> <backup_host>
```

- **-bd**  
Backs up *pmd* to the directory *destination*.
- **-bh**  
Backs up *pmd* to the directory *destination* for Policy Models in a hierarchy. The backup modifies the PMDB subscribers so that the subscription still works when the backup is moved to the *backup\_host* host.
- **-bl**  
Locks the *pmd* so that it does not propagate commands to subscribers.  
Use this command if the Policy Model has subscribers and you want to ensure that updates are not accepted while the backup is in process.
- **-ul**  
Unlocks a locked *pmd*
- **backup\_host**  
Defines the name of the host where you intend to move the backup host to
- **destination**  
Defines the name of the directory where you want the PMDB files to be backed up to
- **pmd**  
Defines the Policy Model database, which is located where specified by the `_pmd_directory_` configuration setting.

### Example: Back Up a PMDB

The following command backs up a PMDB named myPMDB to the /tmp/my\_pmdb directory:

```
sepmdb -bd pmdb /tmp/my_pmdb
```

You can now manage the PMDB as required:

```
selang -d /tmp/my_pmdb
```

### Example: Back Up a PMDB with Subscribers

The following commands show you how to back up a PMDB that has subscribers and then move the PMDB to a different host:

1. Lock the PMDB:

```
sepmdb -bl mainPMDB
```

Privileged Access Manager locks the PMDB so that it does not send or receive updates.

2. Back up the PMDB:

```
sepmdb -bh mainPMDB /tmp/my_pmdb host63
```

Privileged Access Manager backs up the PMDB to the /tmp/my\_pmdb

On UNIX, Privileged Access Manager updates subscribers.dat with the backup host name you specified.

On Windows, Privileged Access Manager creates a *pmd.reg* file, which is a dump of the *pmd* registry settings with the Parent\_Pmd configuration setting value changed to match the new host you specified.

3. Unlock the PMDB:

```
sepmdb -ul mainPMDB
```

Privileged Access Manager unlocks the PMDB.

4. Transfer the PMDB backup to its new host.

#### NOTE

The new host must have the same OS and Privileged Access Manager version as the current computer.

5. (Windows only) Import the mainPMDB.reg file into the registry on the new host.

You can now continue to use the PMDB as you typically would.

## sepmdd Utility Manage the Policy Model Log File

The sepmdd utility manages the Policy Model log file. The Policy Model log file provides a detailed audit trail of Policy Model data base activities. For example:

```
Wed Nov 4 10:08:02 2003 pmdb1:Processing list request for missouri.yourco.com
Wed Nov 4 10:08:02 2003 pmdb1:Processing list request for oregon.yourco.com
Wed Nov 4 10:09:14 2003 pmdb1:Empty request
Wed Nov 4 10:09:15 2003 pmdb1:Processing shutdown request
Wed Nov 4 10:09:15 2003 pmdb1>Delete filters
Wed Nov 4 10:10:04 2003 pmdb1:Opened error logs
Wed Nov 4 10:10:04 2003 pmdb1:Try to load filters
Wed Nov 4 10:10:04 2003 pmdb1:Filters file : nis_filter.dat
```

Running sepmdd for the first time automatically creates the Policy Model log file.

On UNIX, use the pmd\_log\_level PMDB configuration setting to control the PMDB logs:

- **0** - Do not log any entries
- **1** - List only error messages
- **2** - List error and informational messages (default value)

### NOTE

A warning message in the log file tells you whether you have exceeded file size limitations. Use configuration settings to increase the size of the log file. Privileged Access Manager does not rename (rotate) the pmd\_log file automatically.

This command has the following format:

```
sepmdd {-sl|-kl|-dl|-cl} pmd
```

- **-cl**  
Clears the contents of the Policy Model log file
- **-dl**  
Displays the Policy Model log file
- **-kl**  
Makes the Policy Model log file unavailable
- **-sl**  
Makes the Policy Model log file available
- **pmd**  
Specifies the name of the Policy Model

## sepmdd Utility Manage the PMDB

The sepmdd utility stops and starts Policy Models. On UNIX, it also reloads configuration settings that affect the Policy Model.

### NOTE

In Windows, unlike UNIX, sepmdd does not stop or start the Policy Model service. Instead, it activates and deactivates the Policy Model.

You must have ADMIN authority in the Policy Model to use sepmdd for starting or querying the Policy Model.

This command has the following format:

```
sepmdd {-c|-e|-k|-S} pmd
sepmdd -tm seconds
```

- **-c**  
Clears the Policy Model error log
- **-e**  
Displays the Policy Model error log
- **-k**  
On UNIX, this shuts down the Policy Model daemon safely. On Windows, it deactivates the Policy Model service.

**NOTE**

Do not use the kill command on UNIX to shut down the Policy Model daemon.

- **-ri**  
On UNIX, it reloads the Policy Model and Privileged Access Manager configuration files (pmd.ini and seos.ini respectively) while sepmd is running. You can only use this option at intervals of one minute or more. This option checks configuration changes in the following tokens: parent\_pmd, \_retry\_timeout\_, \_min\_retries\_, and \_shutoff\_time\_.  
On Windows, it reloads Policy Model information from the registry to the hosts. Use this switch if you changed data and want to be sure that it is sent to the host PMDBs.
- **-S**  
On UNIX, starts the Policy Model daemon. On Windows, it activates the Policy Model service.  
Use this option to start the daemon when you do not have any other commands to execute.
- **-tm seconds**  
(Windows only) Sets an initial timeout interval (in seconds) for the executed request.
- **pmd**  
Specifies the name of the Policy Model

## sepmd Utility Restore the PMDB

The sepmd restores a PMDB on a local host. The backup files that you use to restore the PMDB must be from a host running the same platform, operating system, and version of Privileged Access Manager as the restoration host. Privileged Access Manager must be running on the restoration host.

**NOTE**

If you back up and restore the PMDB on different terminals, the PMDB does not automatically update the terminal resource in the restored PMDB database. Add the new terminal resource to the restored PMDB. To add the new terminal resource, stop the restored PMDB, run the *selang -p pmdb* command, then start the restored PMDB.

This command has the following format:

```
sepmd -restore pmd [-source path] [-admins user[,user...]] \
[-xadmins user[,user...]] [-parent_pmd name[,name...]]
```

- **-restore**  
Restores the PMDB on the localhost
- **-admins user[,user...]**  
(UNIX) Defines internal users as administrators of the restored PMDB.
- **-parent\_pmd name[,name...]**  
(Optional) Defines the name of the restored PMDB parent PMDBs. Specify the parent PMDB name in the format *pmdb@host*.
- **pmd**  
Defines the name of the PMDB to restore
- **-source(path)**

(Optional) Defines the directory where the backup files are located. The path is required as a full path. If you do not specify the source directory, the PMDB is restored from the files in the default location. The default location is defined in the `_pmd_backup_directory_` token.

**NOTE**

**Default:** (UNIX) `ACInstallDir/data/policies_backup/pmdNameDefault`: (Windows) `ACInstallDir\data\policies_backup\pmdName`

- **-xadmins *user[,user...]***  
(UNIX) Defines enterprise users as administrators of the restored PMDB.

## sepmdbadm Utility Create PMDB Definitions

### Valid on UNIX

The `sepmdbadm` utility creates the definitions to run a PMDB. The `sepmdbadm` utility is a script consisting of Privileged Access Manager and the required UNIX commands to define a PMDB, to define the relationship of the PMDB to PMDBs above and below it, and to define its subscriber stations. By default, the user root is defined as the administrator and auditor of the PMDB. Run the `sepmdbadm` utility locally. You can run it through a remote shell. When you use `sepmdbadm` to create a PMDB, point subscribers to the PMDB and synchronize the UIDs and GIDs.

You can run this utility in interactive or non-interactive modes:

- In non-interactive mode, you enter arguments in the command line. The utility builds the PMDB and its hierarchy according to the values it receives.
- In interactive mode, you do not enter arguments in the command line. The `sepmdbadm` utility asks the user if the desired mode is interactive. If the user answers y, then the utility proceeds to ask the user for option values.

When creating a PMDB with `sepmdbadm`, you identify the stations that are the subscribers of the Policy Model. Update the `parent_pmd` token in each subscriber `seos.ini` file with the name of the PMDB to which you have subscribed the station. If you do not do this, the subscribers do not accept updates from the PMDB.

By subscribing several stations to the same PMDB, and by subscribing one PMDB station to another, you can create a hierarchy of PMDBs.

This command has the following format:

```
sepmdbadm options
```

- **--admin *name***  
Defines the Privileged Access Manager administrator of the PMDB
- **--auditor *name***  
Defines the Privileged Access Manager auditor of the PMDB
- **-c | --clean *pmdbName***  
Removes the specified Policy Model. This option shuts down the Policy Model daemon, removes the file protections from the database, and deletes the Policy Model directory with all its contents.  
You cannot use this option with the `--noconfirm` option.
- **--desktop *hostname***  
Specifies a station from which the administrators can administer PMDBs on the local host. If you do not specify any stations, the administrators can only administer the PMDBs from the local host.
- **--group\_fname *fileName***  
Defines the location of the groups file under NIS
- **-h | --help**  
Displays the help screen
- **-i | --interactive**  
Runs `sepmdbadm` in interactive mode
- **-l**

Specifies to run sepmdadm in local mode, meaning that you can create a PMDB when Privileged Access Manager is not running.

#### NOTE

Unless you specify this option you must have Privileged Access Manager running to use sepmdadm.

- **--nis | --NIS**  
Performs NIS setup on the Policy Model. Use this option if the PMDB is installed on a NIS server.
- **--noconfirm**  
Specifies that the user is not asked to confirm answers. This option is useful when invoking sepmdadm from within a shell script in non-interactive mode.
- **--parentpmd *pmdbName***  
Specifies the name of the parent PMDB to which this PMDB is subscribed. If you use this parameter with the -subsconfig parameter, sepmdadm updates the parent\_pmd token in the seos.ini file. If you use this parameter without the --subsconfig parameter, sepmdadm updates the parent\_pmd token in the pmd.ini file.

#### NOTE

If you want to define multiple parent Policy Models, you must to use quotation marks. For example, to create a Policy Model and define its parent, use the following command:

```
sepmdadm --pmdname subs2 --admin abc123 --admin root --auditors abc123 --desktop pcp36949 \
--parentpmd "aa@pcp36949,bb@pcp36949"
```

- **--passwd\_fname *fileName***  
Defines the location of the passwd file under NIS
- **--passwdpmd *pmdbName***  
Specifies the PMDB to which sepass sends password updates. This option updates the passwd\_pmd token in the [seos] section of the seos.ini file.

#### NOTE

You can use this parameter only when you also use the --subsconfig switch.

When creating a multi-level Policy Model, set this parameter to the PMDB at the top of the pyramid, so that password changes can be propagated to all levels in the PMDB system.

- **--pmdname *pmdbName***  
Specifies the name of the PMDB to be created
- **--pwmanager *name***  
Specifies the Privileged Access Manager password manager of the PMDB
- **--seosdir *directory***  
Specifies the directory in which Privileged Access Manager is installed. Use this option only if Privileged Access Manager is not installed in the default directory.
- **--subsconfig**  
Specifies that the local station is a subscriber. When using this parameter, you must specify the parameters --parentpmd *pmdbName* and --passwdpmd *pmdbName* to update the relevant tokens in the seos.ini file.

#### NOTE

The parameters should follow the -subsconfig option when configuring a subscriber.

- **--subscriber *name***  
Specifies subscribers of this PMDB. They can be PMDBs or stations
- **--xadmin *name***  
Defines the enterprise user administrator of the PMDB
- **--xauditor *name***  
Defines the enterprise user auditor of the PMDB
- **--xpwmanager *name***  
Specifies the enterprise user password manager of the PMDB

### Example: Create a PMDB using the command line

Suppose that you have a station named bigcentral, where you want to maintain a PMDB for other stations to subscribe to. To create the PMDB at bigcentral, run sepmdadm there. This utility is located in the directory *ACInstallDir/bin*.

To create a PMDB on bigcentral named pmdb1 with workstat1 and workstat2 as subscribers and enterprise users adm1 and adm2 as administrators, run the following command from bigcentral:

```
sepmdadm --pmdname pmdb1 --subscriber workstat1 --subscriber workstat2 \
--xadmin adm1 --xadmin adm2
```

### Example: Pointing subscriber stations to the PMDB

To establish a station as a subscriber to a PMDB, it is not sufficient to specify the subscriber name at the PMDB station. Perform a procedure at the subscriber station also.

To subscribe the local station to a PMDB using the command line, use the parameters --parentpmd and --passwdpmd, in addition to the parameter --subsconfig.

For example, to subscribe the local station to the PMDB named pmdb2 on HOST2 and to the password PMDB named master1 on HOST1, enter the following command:

```
sepmdadm --subsconfig --parentpmd pmdb2@HOST2 --passwdpmd master1@HOST1
```

## sepropadm Utility Administer Database Properties

The sepropadm utility adds, updates, and deletes properties in the database. Invoke this utility from the directory in which the database resides, and while Privileged Access Manager is *not* running. The sepropadm utility can add only one property at a time.

### WARNING

This utility is for Privileged Access Manager technical support personnel use only. Use sepropadm only with a description file that was certified by Privileged Access Manager technical support personnel.

This command has the following format:

```
sepropadm file
```

- **file**

Specifies a description file that is supplied by Privileged Access Manager support personnel. The description file uses the following format:

- There must be one line that begins with the hash symbol (#); it must precede the description lines.
- Lines that begin with semicolon(;) are comments and are not processed.
- The description line to add a new double link OID must conform to the following format:

```
CLASS=%s    PROPERTY=%s    TYPE=%d    SIZE=%d    FLAGS=%x
```

- The description line to add a new property must conform to the following format:

```
CLASS=%s    PROPERTY=%s    TYPE=%d    SIZE=%d    FLAGS=%x    LINK2CLASS=%s
```

- The description line to delete a property must conform to the following format:

```
CLASS=%s    PROPERTY=%s
```

- The description line to change a property must conform to the following format:

```
CLASS=%s    PROPERTY=%s    TYPE=%d    SIZE=%d    FLAGS=%x    REPLACE=YES
```

### Example: A description file for sepropadm

The following is a sample description file.

```
; Sample Patch File for the CA PAMSC database
```

```
; Copyright YYYY CA International, Inc.
```

```
; -----
```

```
; DO NOT USE THIS FILE UNLESS YOU KNOW HOW TO!
```

```
# seclassadm database add property patch utility ; Format is : CLASS=PROGRAM PROPERTY=MD5 TYPE
```

## sepromote Utility Enforce Strong Authentication

Privileged Access Manager integrates with Advanced Authentication to provide a strong authentication option for privileged and other native users of the operating system.

The Privileged Access Manager system administrator restricts interactive sessions coming from a terminal by adding users to a group. To get write permission to files, users in this group must authenticate themselves using CA ArcotID OTP (one-time passwords).

After authentication, Privileged Access Manager does not apply the rules that are created for the native user (root), but it applies rules to users according to their internal identities. Privileged Access Manager differentiates non-restricted, restricted, and promoted users, and applies specific rules to them.

- When a user *name* from the `interactive_restricted` group logs in interactively, Privileged Access Manager identifies him as "`restricted_name`".

#### Examples:

- When root logs in interactively, Privileged Access Manager applies the rules for the user "`restricted_root`" (if specified) or otherwise "`_default`" restricted rules.
- When root logs in non-interactively, Privileged Access Manager applies the rules for the root user.
- When a user from the `interactive_restricted` group promotes himself with an enterprise name, Privileged Access Manager identifies him as "*name2*".

#### Example:

- When root promotes as "*name2*", Privileged Access Manager applies the rules for the user "*name2*".

This command has the following format:

```
sepromote [-h] [-u username] [-o orgname] [otp] [-v]
```

- **-h**  
Displays help and exits.
- **-u *username***  
Defines the name of the user in the `interactive_restricted` group who is requesting strong authentication.

**Default:** If not supplied as argument, the tool prompts for the user name.

- **otp**  
Defines the one-time password that the user in the interactive\_restricted group has generated.  
**Default:** If not supplied as argument, the tool prompts for the password.
- **-o orgname**  
Defines the organization where Advanced Authentication searches users of strong authentication.  
**Default:** Value of the organization\_name token in [strong\\_auth](#).
- **-v**  
Activates verbose mode.

## sepurgdb Utility Purge Database References to Undefined Records

### Valid on UNIX

The sepurgdb utility searches the entire database for references to undefined records, and then deletes those references from the database, reducing the size of the database.

#### WARNING

For safety purposes, back up the database, and then invoke the utility while the Privileged Access Manager daemons are *not* running.

When a record is deleted, references to it in lists such as ACLs or group membership lists are left as is, to reduce processing time. This does not cause any problems, because Privileged Access Manager assigns a previously unused, unique ID to each new record. Use this utility to free up some disk space.

Run sepurgdb as root and invoke the utility from the directory containing the database files. The database management system uses pre-allocated disk space. The size of the database file typically does not change significantly after purging. When the size of the database is increased later, the file size might not change due to the pre-allocation.

This command has the following format:

```
sepurgdb FilePath [Username]
```

- **FilePath**  
Specifies the base name for the utility log files. The sepurgdb utility creates two log files:
  - **FilePath.err**  
Contains a log of errors encountered
  - **FilePath.log**  
Contains a log of actions taken

#### NOTE

You can merge the two logs and direct them to the standard output by specifying a minus sign (-) for *FilePath*.

- **Username**  
(Optional) Specifies the name of the user that sepurgdb uses to replace deleted owners (users that no longer exist) of the group connection for the USER record.

#### NOTE

The user that you define must exist in the database, otherwise the utility ignores this option.

## sereport Utility Reports Configuration

The sereport utility provides HTML reports, accessible from a web browser, of database and Policy Model information. sereport operates on the current database that is used by the authorization engine.

You can set sereport options for the utility:

- On UNIX, sereport uses a configuration file that you specify using the -f option.  
By default, this setting is *ACInstallDir/etc/sereport.cfg*
- On Windows, sereport uses the registry, which you can configure. The registry settings for sereport are defined under the following key:

HKEY\_LOCAL\_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\Report

The reports that you can generate, their description and corresponding configuration file settings or registry keys are shown in following table.

Report Number	Title and Description	Section\Subkey	Tokens\Entries
1	Administrative Privileges Display specified administrative privileges of users.	admin_report	Hostname Objects_Pattern User_Mode
2	Login Limitation Display login limitations of users.	disablelogins_report	Hostname Objects_Pattern Properties User_Mode
3	Dormant Accounts Display inactive accounts by date (days). If an account does not have any login information, the create time is used to calculate dormant days.	dormant_report	Hostname Objects_Pattern Dormant_account User_Mode
4	Last Login Display last login date of users.	login_report	Hostname Objects_Pattern User_Mode
5	Password Change Display list of users whose passwords must be changed within the specified number of days.	passwd_report	Days_to_change Hostname Objects_Pattern User_Mode
6	Warning Mode Display resources with objects in warning mode.	warning_report	Class_Name Hostname Objects_Pattern
7	Untrusted Programs Display programs in untrusted mode.	untrust_report	Hostname Objects_Pattern
8	Users Privilege Access Rights Show access privileges of users to specified resources.	accessor_report	Accessor Class_Name Hostname Objects_Pattern
9	Compare users/groups in databases. Display users and groups that are defined in some but not all, databases.	grp_usr_compare	Hostname Objects_Pattern

10	Compare Protected Resources Display whether resources are defined in the specified databases.	res_compare	Class_Name Hostname Objects_Pattern
11	Compare Access Rights Display the differences in resource restrictions between a Policy Model and a subscriber database.	acc_compare	Class_Name Hostname Objects_Pattern
12	Compare Users Information Display differences in user definitions between a Policy Model and a subscriber database.	usr_compare	Hostname Objects_Pattern Properties
13	Compare PMDB and Subscriber Display the rules (as defined by the Class_Name and Object_pattern tokens) that exist on the PMDB, but do not exist on the subscriber database. Note: If all the rules on the PMDB exist on the subscriber database, then the databases are reported as IDENTICAL.	pmdb_compare	Class_Name Hostname Objects_Pattern

- **Accessor**  
Specifies the pattern (mask) for accessor selection. Use \* to select all accessors
- **Class\_Name**  
Specifies a list of classes
- **Days\_to\_change**  
Specifies the number of days that are left until the user is requested to change passwords
- **Dormant\_account**  
Specifies the period that the account is considered dormant
- **Hostname**  
Specifies a list of hosts from which the data is retrieved
- **Objects\_pattern**  
Specifies the pattern (mask) for object selection. Use \* to select all objects.
- **Properties**  
Specifies attributes that are associated with the objects
- **Report\_place**  
(UNIX only) Specifies the full path location where the report is printed.

**NOTE**

On Windows, you define the location of the output using the -f option of the command.

- **User\_Mode**  
Specifies a comma-separated list of user modes

You can also find the following configuration settings in the colors section\key:

- **title**  
Specifies the color of the report title
- **class\_title**

Specifies color of the report class\_title

- **background**  
(UNIX only) Specifies the color of the title report background. The background and logo must be written in full path.
- **logo**  
Creates the logo. The background and logo must be written in full path.

## sereport Utility Create HTML Reports on UNIX

### Valid on UNIX

The sereport utility creates HTML reports, accessible from a web browser, of database and Policy Model information. sereport operates on the current database that is used by the authorization engine.

To use sereport, you need READ privileges in all queried databases.

#### NOTE

The default configuration file is *ACInstallDir/etc/sereport.cfg*

This command has the following format:

```
sereport [-f|-file pathname] -r|-report number [-host hostnames]
```

- **-f | -file *pathname***  
(Optional) Specifies the full path of the configuration file. If you do not specify a file, sereport uses the default file *ACInstallDir/etc/sereport.cfg*
- **-host *hostnames***  
(Optional) Specifies the names of one or more hosts you want to report on. If you do not specify a host, sereport takes the host from the config file.
- **-r | report *number***  
Specifies the report number to create

## sereport Utility Create HTML Reports on Windows

### Valid on Windows

The sereport utility creates HTML reports, accessible from a web browser, of database and Policy Model information. sereport operates on the current database used by the authorization engine.

To use sereport, you need READ privileges in all queried databases.

This command has the following format:

```
sereport -f|-file pathname-r|-report number [-host hostnames]
```

- **-f | -file *pathname***  
Specifies the full pathname of the output file (the report).

#### NOTE

The content of the specified file is structured in HTML format so you should specify the *.html* extension for automatic file association.

- **-host *hostnames***  
(Optional) Specifies the names of one or more hosts you want to report on. If you do not specify a host, sereport uses *localhost*.
- **-r | report *number***  
Specifies the report number to create.

## seretrust Utility Generate Commands to Retruster Programs and Secure Files

The seretrust utility generates the selang commands that are required to retrust programs and secure files that are defined in the database. The seretrust utility reports the status of the SECFILE and PROGRAM resources that are defined as trusted but have changed. seretrust also checks whether programs have been changed but have not yet been caught by the Watchdog. (This means that in the Privileged Access Manager database, these programs are still marked as trusted.) These programs are added to seretrust output with a note stating that the program content or timestamp has been changed, and to retrust the program.

### NOTE

On UNIX, programs with setuid and setgid bits are stored in the database with full descriptions, including inode values. If you restore the system from backups, the programs occupy different inodes. Privileged Access Manager detects the mismatch between the inodes and marks all the trusted programs as untrusted. The seretrust utility locates the trusted programs that are defined in the database and updates their inode values, so that when you invoke Privileged Access Manager, the trusted programs remain trusted.

If you do not specify any switches, only untrusted programs and untrusted secured files are processed.

This command has the following format:

```
seretrust [-a] [-l|-m|-p|-s] path
```

- **-a**  
Processes all trusted and untrusted objects.
- **-h**  
Displays the help for this utility
- **-l**  
Extracts information about the programs and files from the database in the current directory.  
If you omit this option, seretrust processes the database that Privileged Access Manager uses.
- **-m**  
Calculates the signatures for all kernel modules. If the signature property of a kernel module record is not valid, seretrust updates it with the correct signature, which ensures that the kernel module is trusted. Signatures are used only for Linux kernel modules.
- **-p**  
Processes records in the PROGRAM class only
- **-s**  
Processes records in the SECFILE class only
- *path*  
Specifies the base path for searching programs and secure files to retrust.  
The utility processes the specified directory and all subdirectories.

### Example: Retruster untrusted programs and secure files

This example shows you how you can use the seretrust utility to retrust programs and secure files.

### NOTE

This example shows you a sample command output on UNIX, but the utility works the same on Windows.

To retrust programs and secure files, follow these steps:

1. As the Privileged Access Manager database administrator, enter the following seretrust command:

```
seretrust > retrust_script
```

The utility processes both trusted programs and secured files because you did not specify any options. It also uses the root path because you did not specify any base path.

seretrust displays the following information about the screen:

```
Retrusting PROGRAMs & SECFILEs, Base path = /
Total of 0 entries retrusted. (Class=SECFILE)
```

Total of 16 entities retrusted. (class=PROGRAM)

The following code is the content of a script file `seretrust` can create:

```
chres PROGRAM ("/usr/bin/chgrp") trust
chres PROGRAM ("/usr/bin/chie") trust
chres PROGRAM ("/usr/bin/crontab") trust
chres PROGRAM ("/usr/bin/cu") trust
chres PROGRAM ("/usr/bin/ecs") trust
chres PROGRAM ("/usr/bin/newgrp") trust
chres PROGRAM ("/usr/bin/rmqudev") trust
chres PROGRAM ("/usr/bin/rsh") trust
chres PROGRAM ("/usr/bin/sysck") trust
chres PROGRAM ("/usr/bin/uuname") trust
chres PROGRAM ("/usr/lib/methods/showled") trust
chres PROGRAM ("/usr/lib/mh/post") trust
chres PROGRAM ("/usr/lib/mh/slocal") trust
chres PROGRAM ("/usr/lpp/X11/bin/xlock") trust
chres PROGRAM ("/usr/lpp/X11/bin/xterm") trust
chres PROGRAM ("/usr/sbin/chvprt") trust
```

2. Run the `selang` script file `seretrust` created to retrust the programs and files:

```
selang -f retrust_script
```

## serevu Utility Handle Unsuccessful Login Attempts

### Valid on UNIX

The `serevu` utility handles users who have had a specified number of failed login attempts during a specified period. Depending on your specifications, it can disable, report, or ignore the user. By default, it disables the user in the UNIX environment of the local station. If no such user exists locally, `serevu` checks the NIS information to find the user.

If you set a value in the `passwd_pmd` configuration setting, Privileged Access Manager updates the appropriate PMDB, which then propagates the update to its subscribers. If you did not set a value in the `passwd_pmd` token, Privileged Access Manager uses the value in the `parent_pmd` configuration setting, which then propagates the update to its subscribers.

**Note:** If you want `serevu` to send commands to the PMD (which, you can configure in `serevu.cfg`) and `root` is not defined on the PMD with the `ADMIN` attribute or with terminal access, you should define the following on the PMD and all of its subscribers:

```
eu _serevu logical
authorize admin USER uid(_serevu) access(a)
# The following line can be executed on the master PMD only
authorize terminal localTerminalName uid(_serevu) access(a)
```

### NOTE

For the `serevu` utility to work properly, the user `root` must have write access to the file `/etc/passwd`. If you define a remote computer in the `serevu` configuration file (`serevu.cfg`), you must also give login authorization to the remote computer. For example:

```
eu _serevu admin logical
authorize terminal localTerminalName uid(_serevu) access(a)
er specialpgm $ACDIR/bin/serevu seosuid(_serevu) unixuid(root)
```

This command has the following format:

```
serevu {daemon|nodeamon} [-f nn] \
```

```
[ -d {nn[s|m|h|d|w]|FOREVER} ] \
[ {-s|-t} nn[s|m|h|d|w] ]
```

- **daemon**  
Runs the utility as a daemon. This is the default value.
- **nodaemon**  
Runs the utility as a regular process.
- **-d**  
Specifies the amount of time for which the user's login is disabled. By default, this value is in seconds.

**NOTE**

The amount of time a user account is disabled cannot be less than the amount of time between each serevu scan. The amount of time a user account is disabled should be a multiple of the time between each serevu scan.

- **-f**  
Specifies the number of failed logins. The serevu utility disables the accounts of users who reach this number of failed logins over the specified period.

**NOTE**

We recommend that the number of failed logins, which can also be defined by the value of the *def\_fail\_count* configuration setting, always be the same as the value of allowed unsuccessful login attempts set on your system. (On Solaris, for example, the system values for this are set in */etc/default/login* by the RETRIES token.) See your operating system documentation for more details.

- **-h**  
Displays the help for this utility.
- **-s**  
Specifies the time period, starting from *now* and going backwards, within which serevu scans for failed logins.  
**Default:** 300 seconds (configuration setting).
- **-t**  
Specifies the time period that should elapse between successive serevu checks.  
**Default:** 120 seconds (configuration setting).
- **FOREVER**  
Used with the -d option, specifies the time as unlimited. If you use this parameter, user logins will be disabled forever.
- **nn[s|m|h|d|w]**  
Used with the -d, -s, and -t options, specifies the time for the option.
  - **s**  
nn in seconds (the default).
  - **m**  
nn in minutes.
  - **h**  
nn in hours.
  - **d**  
nn in days.
  - **w**  
nn in weeks.

## sesu Utility Substitute User

The sesu utility lets you temporarily act as another user. This utility is the Privileged Access Manager version of the UNIX su command. However, the sesu utility provides a user substitution command that does not require you to provide the password of the substituted user. The authorization process is based on the Privileged Access Manager access rules as defined in class SURROGATE and, optionally, on the password of the user executing the command.

The `sesu` utility uses the tokens in the `sesu` section of the `seos.ini` file. It also uses the following special files:

- `/etc/passwd`
- `/etc/group`
- `/etc/shells`

To protect against inadvertent use, `sesu` is marked in the file system so that no one can run it. The security administrator must mark the program as executable and `setuid` to root before you can use it.

### WARNING

Before you use the `sesu` utility, define all users to the Privileged Access Manager database and set `sesu` prerequisites. This prevents you from opening up the entire system to users who are not defined to Privileged Access Manager.

The `sesu` utility optionally supports strong authentication and can prompt the user for a one-time password. Activate strong authentication in the `sesu` and `strong_auth` sections of the `seos.ini` file.

**Note:** For more information about strong authentication and the `sepromote` utility, see [sepromote Utility Enforce Strong Authentication](#).

Usage notes:

- If the Privileged Access Manager authorization server is not found, the utility executes the system standard `su` command.
- If the `sesu.old_sesu` configuration token is set to `no`, the utility executes the system standard `su` command.
- If `/etc/shells` exists, and it does not specify the current shell, `sesu` does not permit substitution to root.

This utility has the following format:

```
sesu [-] [username] [-l] [-n] [-s shell] [-c command]
```

- **-**  
Sets the environment to that of the target user.
- **NOTE**  
On Linux, this is the same as using the `-l` option.
- **-c *command***  
Executes the specified command then exits  
Enclose commands containing spaces in quotes.
- **-h**  
Displays the help for this utility
- **-l**  
(Linux only) Specifies that the shell it opens is a login shell
- **-n**  
Specifies not to prompt the user for password

### WARNING

When used, the utility runs as the root account and performs a LOGIN event.

### NOTE

If the security authorization server is not found, the utility uses `/bin/su`.

- **-s *shell***  
(Linux only) Specifies a shell to open instead of the shell from the user `passwd` entry  
The shell must be listed in the `/etc/shells` file.
- ***username***  
Changes the ID associated with the session to the ID of the specified target user *username*  
If you do not specify a *username*, `sesu` default to root.

## Examples

- The following command changes the UID to root. The environment remains that of the user who executed the command.

```
sesu
```

- The following command changes the UID to root. The utility changes the environment to root environment.

```
sesu -
```

- The following command surrogates to the user John.

```
sesu John
```

- The following command surrogates to the user Carol and executes the specified command, `ls -la`, from the `/home/carol` directory.

```
sesu - Carol -c "ls -la /home/carol"
```

- The following command surrogates to the user Angelo, uses a bash shell, and opens it as a login shell.

```
sesu Angelo -l -s /bin/bash
```

### NOTE

This code is valid on Linux only.

## sesudo Utility

The `sesudo` utility executes commands for one user with the permissions of another user. This lets regular users perform actions that require administrator authority.

The rules governing user authority to perform commands in this way are defined as access rules in the SUDO class. A record in the SUDO class contains a command script, and can specify both users who are permitted to run the script with `sesudo` and users who are forbidden to.

## sesudo Utility Execute a Command as Another User on UNIX

### Valid on UNIX

The `sesudo` utility executes commands for one user with the permissions of another user. The `sesudo` utility borrows the permissions of another user (the *target* user) to perform one or more commands. This allows regular users to perform actions such as the `mount` command, which require superuser authority.

The rules governing user authority to perform commands in this way are defined as access rules in the SUDO class. A record in the SUDO class contains a command script, and can specify both users who are permitted to run the script with `sesudo` and users who are forbidden to.

Each time `sesudo` runs, it returns one of the following values.

- **-2**  
Target user is not found, or command interrupted
- **-1**  
Password error
- **0**  
Execution successful
- **10**  
Problem with usage of parameters
- **11**  
syscall is not loaded
- **20**

- Target user error
- **22**  
syscall is loaded but the daemon is not running
- **30**  
Authorization error

This command has the following format:

```
sesudo {-h|-list|record [params]}
```

- **-h**  
Displays the help screen
- **-list**  
Lists sesudo commands that you can execute. These are the SUDO records defined in the Privileged Access Manager database that you are authorized to execute.
- **record**  
Specifies the name of the SUDO class record the security administrator gave to the command you want to execute using the sesudo utility
- **params**  
(Optional) Specifies the parameters that you want to send to the command you are executing

## sesudo Utility Execute a Command as Another User on Windows

### Valid on Windows

The sesudo utility executes commands for one user with the permissions of another user. The sesudo utility borrows the permissions of another user (the *target* user) to perform one or more commands. The utility allows regular users to perform actions such as the mount command, which requires superuser authority.

The rules governing user authority to perform commands in this way are defined as access rules in the SUDO class. A record in the SUDO class contains a command script, and can specify both users who are permitted to run the script with sesudo and forbidden users.

**Note:** The user executing the program that is invoked by sesudo cannot be changed from Privileged Access Manager for Windows.

This command has the following format:

```
sesudo {-h|-list|-do record [params]}
```

- **-h**  
Displays the online help screen
- **-list**  
Lists sesudo commands that you can execute. Lists the SUDO records that are defined in the product database that you are authorized to execute.
- **-do record [params]**  
Specifies that sesudo executes a command as another user
  - **record**  
Specifies the name of the SUDO class record the security administrator gave to the command that you want to execute using the sesudo utility
  - **params**  
(Optional) Specifies the parameters that you want to send to the command that you are executing

## seuidpgm Utility - Extract Trusted Programs

### Valid on UNIX

The seuidpgm utility extracts all the programs whose Set-User-ID bit or Set-Group-ID bits are on. seuidpgm traverses a file system and creates the selang commands for adding these programs to the PROGRAM class.

seuidpgm creates the commands in the selang command language and writes them to the standard output. You can use a pipeline to the selang utility, or redirect the output to a file. We recommended that you redirect the output to a file, because then you can edit the output to remove unwanted programs or add additional programs. Use this procedure to search for undesirable setuid programs in your system.

#### NOTE

We recommended that you run the UxImport utility to define users and groups before running the seuidpgm utility. However, if you have not run UxImport, you can use seuidpgm with the -g and -u options to define users and groups.

seuidpgm descends through the paths specified at the command line to all subdirectories of the starting path. Multiple start paths are allowed.

You can specify any number of options. When specifying more than one option, separate the options with spaces.

If a program is a setuid program and has write access, seuidpgm treats the program like all other setuid programs, but also sends a warning to standard error.

#### NOTE

For more information about how to control PROGRAM class records, see [Endpoint Administration Guide for UNIX](#).

This command has the following format:

```
seuidpgm optionstartDir ... [-x excludeDir]
```

- **-d**  
Automatically creates entries for setuid and setgid programs in the PROGRAM class, with defaccess set to execute, instead of analyzing the file permissions in UNIX to determine the permitted file access. In some cases, one setuid or setgid program executes another one. If you do not include this option, the program trying to execute the setuid or setgid program is *not* able to execute it.  
We recommend that you use this option.
- **-f**  
Creates rules for both the FILE and PROGRAM classes.
- **-g**  
Creates GROUP records for setgid programs.

#### NOTE

Use this option *only* if you have *not* run UxImport.

- **-l**  
Creates a single permit for programs which have *hard* or *symbolic* links.  
If you want to scan your file system from some directories only (not from the root directory) and to include the -l option, use multiple starting paths on the command line; otherwise the -l option might be inefficient.
- **-n**  
Does not traverse NFS at all.  
We recommend that you use this option.
- **-o**  
Writes the file names to the standard output but does not create selang commands.
- **-p**

Enables setuid programs from NFS directories, but only when the mount table allows setuid from that mounted file system.

- **-q**  
Runs the utility in Quiet-Mode; error messages are not sent to standard error.
- **-s**  
Creates entries for setuid/setgid programs in class SECFILE, instead of creating entries for the PROGRAM class.
- **-u**  
Creates USER records for setuid programs.

#### NOTE

Use this option *only* if you have *not* run UxImport.

- **-x *excludeDir***  
Excludes a directory from the tree. The specified directory is not searched for setuid and setgid programs. This option must be the last option specified in the command line. *Path* is the full path of the directory to be excluded. To exclude more than one directory, repeat the -x option for each directory.
- ***startDir***  
Specifies a space-separated list of top directories to search for trusted programs.

### Examples

- The following command prints selang commands to add all programs with set-user-id or set-group-id turned on, defaccess execute, checking for duplicate names or the same inode, in quiet mode, and without passing through NFS. The program scans from the /usr directory and its subdirectories, the /var directory and its subdirectories, and the /etc directory and its subdirectories. Output is directed to the file seprogs.seos in your home directory.

```
seuidpgm -dlqn /usr /var /etc > ~/seprogs.seos
```

The output looks similar to the following code:

```
## *****
```

```
## seuidpgm List Sun Feb 9 14:24:16 1997
```

```
# Start Path= /usr
```

```
# *****
```

```
nr PROGRAM /usr/lpp/bos/inst_root/lpp/inu_LOCK defaccess(EXEC) nr PROGRAM /usr/lpp/X11/bin/xlock
defaccess(EXEC) nr PROGRAM /usr/bin/setenv defaccess(EXEC) nr PROGRAM /usr/bin/shell defaccess(EXEC) nr
PROGRAM /usr/bin/su defaccess(EXEC) nr PROGRAM /usr/bin/sysck defaccess(EXEC) nr PROGRAM /usr/bin/tcbck
defaccess(EXEC) nr PROGRAM /usr/bin/usrck defaccess(EXEC) nr PROGRAM /usr/bin/vmstat defaccess(EXEC)
```

- The following command scans the root directory and all its subdirectories, except the /home directory:

```
seuidpgm -qln / -x /home
```

## seversion Utility Display CA Privileged Access Manager Server Control Program Module Version Information

### Valid on UNIX

The seversion utility displays information regarding the version of a Privileged Access Manager module. You can display the following data:

- The global and minor version numbers
- The date and time that the module was compiled
- The station that the module was compiled on
- SHA signatures

This command has the following format:

```
seversion [-a|-l|-g|-h|-m|-s|-s256|-s384|-s512|-5] module
```

- **-a**  
Displays the requested information in table format
- **-g**  
Displays only the global version number, without titles
- **-h**  
Displays the help for this utility
- **-l**  
Displays included library information
- **-m**  
Displays only the minor version number, without titles
- **-s**  
Displays the SHA1 signature, without titles
- **-5**  
Displays the MD5 signature, omitting titles.  
This option works only while not in FIPS-only mode.
- **-s256**  
Displays the SHA256 signature, without titles
- **-s384**  
Displays the SHA384 signature, without titles
- **-s512**  
Displays the SHA512 signature, without titles
- *module*  
Specifies the file name of the module whose version number you want to display

### Example

To display version information for the `sesudo` utility, enter the following command:

```
seversion /opt/CA/PAMSC/bin/seosd
```

A message similar to the following appears on the screen while not in FIPS mode:

```
CA ControlMinder seversion vX.X.X.xxx - Display module's version

Copyright (c) YYYY CA. All rights reserved.

Running under:  Linux

File name: /opt/CA/PAMSC/bin/seosd

Version   : major.minor.sp.build

Created   : MMMDDYYYYhh:mm:ss

OS info   : i86PC

SHA1      : 10068CC6A70195B84AF896682CCBA1A4B7B43CD1
```

MD5: : 1F9BD56CA523A33FFBC47551ECE093E5

## sewhoami Utility Display Your PAM SC Server Control User name and Security Credentials on UNIX

### Valid on UNIX

The sewhoami utility displays the user name as it is known to the Privileged Access Manager authorization daemon. sewhoami is similar to the whoami utility provided by UNIX systems, but it produces different and often more useful information:

- If the user executes an su command and then executes the UNIX whoami utility, it displays the user name according to the user ID acquired after executing the su command.
- If the user executes an su command and then executes the Privileged Access Manager sewhoami utility, it displays the original login ID of the user; it also displays authorization information.

This command has the following format:

```
sewhoami [-a|-d]
```

- **-a**  
Displays the user credentials; that is, the contents of the user ACEE

#### NOTE

For more information about the ACEE, see the *Endpoint Administration Guide for UNIX*.

- **-d**  
Displays the ACEE handle that is associated with the user and the handle name in the database

### Example: Display Your Privileged Access Manager User Name and Security Credentials on UNIX

This example displays your own user name and security credentials as they are known to the Privileged Access Manager authorization daemon:

```
sewhoami -a
```

If you are a root user, the sewhoami output might look like the following example:

```
root
ACEE Contents
User's Name : root
ACEE's Handle : 52
Group Connections Table:
Group Name Connection Mode
=====
admRegular
bin Regular
daemon Regular
disk Regular
root Regular
seosaudt Regular
sys Regular
wheelRegular
Categories : <None>
Profile Group : <None>
Security Label : <None>
User's Audit Mode : Failure LoginSuccess LoginFailure
```

```

User's Security Level : 0
Source Terminal : <Unknown>
Process Count for ACEE : 19
User's Mode : Admin Auditor
ACEE's Creation Time : Tue Mar 17 14:53:07 2009

```

If you are a user who is named test, not a root user, then the sewhoami output might look like the following example:

```

test
ACEE Contents
  User's Name : test
  ACEE's Handle : 65
  Group Connections Table:
  Group Name Connection Mode
  =====
  seosaudt Regular
  users Regular
Categories : <None>
Profile Group: secadmin
Security Label : <None>
User's Audit Mode : Failure LoginSuccess LoginFailure
User's Security Level : 0
Source Terminal : localhost.localdomain
Process Count for ACEE : 2
User's Mode : Admin Auditor
ACEE's Creation Time : Wed Mar 18 15:34:53 2009

```

## uninstall\_AC Utility Remove CA Privileged Access Manager Server Control from the Current Computer

### Valid on UNIX

The `uninstall_AC` utility removes all or part of Privileged Access Manager from the station on which you execute the command. The default (`-all`) removes the entire product from the station.

#### NOTE

Unload the Privileged Access Manager kernel extension before uninstalling.

This command has the following syntax:

```
uninstall_AC [-all | -admin] [-f] [-force] [-h] [-ignore_dep] [-d path] [-fn file]
```

- **-admin**

Removes only administration tools such as Security Administrator and seauditx from the station

#### NOTE

The *admin* package is no longer included with Privileged Access Manager. This option is used for removing older versions of Privileged Access Manager.

- **-all**

Removes the entire product from the station

- **-d path**

Defines the directory where Privileged Access Manager is installed

**NOTE**

If Privileged Access Manager is installed in the default directory (/opt/CA/PAMSC), you do not need to specify this option.

- **-f**  
Removes Privileged Access Manager in silent mode
- **-fn *file***  
Executes the specified file after the uninstall completes
- **-force**  
Forces uninstall to proceed even if the kernel extension unload process fails
- **-h**  
Displays the help for this utility
- **-ignore\_dep**  
Specifies that the uninstallation procedure does not verify dependency with other products

**Example: Completely remove Privileged Access Manager from a computer**

To remove Privileged Access Manager from this computer completely, if it was installed in the default directory, enter the command:

```
uninstall_AC
```

**uxauthd.sh Script Administer UNIX Authentication Broker Agent**

Use the uxauthd.sh script to administer the UNIX Authentication Broker agent. We recommend that you use the uxauthd.sh script to administer the UNIX Authentication Broker agent. This helps ensure that the environment is configured correctly.

The uxauthd.sh script is located in the following directory, by default: /opt/CA/uxauthd/sbin.

This command has the following format:

```
uxauthd.sh {start | stop | restart | status | debug level}
```

- **start**  
Starts the UNIX Authentication Broker agent
- **stop**  
Stops the UNIX Authentication Broker agent
- **restart**  
Restarts the UNIX Authentication Broker agent
- **status**  
Displays the status of the UNIX Authentication Broker agent. The status states are:
  - uxauthd running
  - uxauthd not running
- **debug *level***  
Specifies to start the UNIX Authentication Broker agent in debug level  
**Range:** 1-3

**NOTE**

Using uxauthd.sh to start or stop the UNIX Authentication Broker agent affects the status of the Report Agent.

## uxauth\_selinux.sh Enable SELinux Support

The `uxauth_selinux.sh` script deploys a SELinux policy that enables UNIX Authentication Broker to work in SELinux environment. The script enables support for the following utilities: `ssh`, `rlogin`, `ftp`, `sftp`, and `passwd`.

You can install the SELinux UNIX Authentication Broker policy using the extensive or the general installations. Extensive installation adds permissions for the SELinux security context type `usr_t`. General installation does not add permissions for the `user_t` type and hence UNIX Authentication Broker cannot support offline users login and user login reports.

The `uxauth_selinux.sh` script is located in the *UNIX Authentication Broker lbin* directory, by default: `/opt/CA/uxauthd/lbin`. The `uxauth` installation package can be customized to run the script during UNIX Authentication Broker installation where SELinux policy is installed in general mode. You can also run the script after installation from the default location.

### NOTE

Installing an extensive policy automatically uninstalls previously installed general policy.

This command has the following format:

```
uxauth_selinux.sh {-i [-e] | -r | -h}
```

- **-i**  
Installs the policy in the SELinux environment
- **-e**  
Specifies to invoke the extensive installation option that adds permissions for the `usr_t` type
- **-r**  
Removes the policy from the SELinux environment
- **-h**  
Displays the help

## uxconsole Utility Manage UNIX Authentication Broker Endpoints

The `uxconsole` utility lets you manage your UNIX Authentication Broker endpoints. Use the `uxconsole` utility to complete the following tasks:

- Display information about the UNIX Authentication Broker installation
- Register the UNIX Authentication Broker endpoint in Active Directory
- Manage and migrate users and groups.

The utility handles several tasks and has the following functions:

Task	Function
Register UNIX computers in Active Directory	<a href="#">uxconsole -register</a>
Deregister UNIX computers in Active Directory	<code>uxconsole -deregister</code>
Set verbosity level	<a href="#">uxconsole -debug</a>
Activate login for Active Directory users	<code>uxconsole -activate</code>
Deactivate login for Active Directory users	<code>uxconsole -deactivate</code>
Manage users mapping	<a href="#">uxconsole -map</a>
Migrate users and groups to Active Directory	<a href="#">uxconsole -migrate</a>
Manage users and groups	<a href="#">uxconsole -manage</a>
Display endpoint status	<a href="#">uxconsole -status</a>
Perform Kerberos operations	<a href="#">uxconsole -krb</a>
Perform LDAP queries in Active Directory	<a href="#">uxconsole -ldap</a>

Display UNAB NSS cache data	<a href="#">uxconsole -db -dump</a>
Delete Active Directory Users and Groups	<a href="#">uxconsole -db -del</a>
Verify Active Directory user accounts	<a href="#">uxconsole -verify</a>
Takes a snapshot (static mode) of the current AD topology (Domains, DCs, DNS, and so on) and saves in the Kerberos configuration section of the uxauth.ini file. To switch back to the default mode (dynamic mode), re-register (deregister and register again) UNAB. You can also manually update the Kerberos configuration section in the <a href="#">uxauth.ini</a> file.	<a href="#">uxconsole -freeze</a>

## uxconsole -map Manage Users Mapping

### Valid on UNIX

Use the map command to NIS or local user accounts to Active Directory user accounts.

#### NOTE

When you use the -map option, the uxconsole utility does not connect to Active Directory to identity conflicts in user account details.

This command has the following formats:

```
uxconsole -map [-add] [-scope {l|n|a}] { -all | <unix_name> [ <ad_name>] | -input <file> } [-d <domain> ] [-force] [-v]
uxconsole -map -local { <unix_name> | -input <file> } [-force] [-v]
uxconsole -map -del { <unix_name> | -input <file> } [-force] [-v]
uxconsole -map -show [<filter>] [-scope {l|n|a}] [-v]
uxconsole -map -h
```

- **-add**  
Add users mapping
- **-scope {l|n|a}**  
Specifies the mapping scope:
  - lmap the local user accounts only
  - nmap NIS/NIS+ user accounts only
  - amap local and NIS/NIS+ user accounts
- **-all**  
Specifies to map all NIS and or local user accounts with identical user names
- **<unix name>**  
Specifies to map a single UNIX user account, either NIS or local account

#### NOTE

You can also use this parameter to delete mapped NIS or local user accounts.

- **-ad <ad name>**  
Specifies the Active Directory name of the local user account
- **-input <file>**  
Specifies an input file containing mapping requests. Create the map file in a CSV format with the following fields and parameters:  

```
<unix_name>,[<ad_name>],[<domain>]
```
- **<unix\_name>**  
Specifies the UNIX user account name
- **[<ad\_name>]**

Specifies the Active Directory user account. *ad\_name* is an optional parameter. If you do not specify the Active Directory user account, the account is mapped to an AD account with the same UNIX user account name.

- **[<domain>]**  
Specifies the domain name of the Active Directory account. *domain* is an optional parameter
- **-d <domain>**  
Defines the Active Directory domain name that contains the user account

**NOTE**

You can specify the full user credentials using the following format: *<name>@<domain>*. If the domain name is not specified, then the domain is mapped to the registration domain.

- **-force**  
Specifies to force user mapping and overwrite existing mapping or migration status or delete user mapping

**NOTE**

By default, uxconsole does not delete partially migrated user accounts.

- **-local**  
Specifies to set the user account as a local exception

**NOTE**

If you specify a user as local exception, UNIX Authentication Broker does not manage the user account, although an identical user account may exist in the Active Directory.

- **-del**  
Specifies to delete local or NIS user mapping
- **-show**  
Specifies to display users mapping details

**<filter>**

Defines the wildcard that returns a subset of users

- **-v**  
Specifies to activate verbosity
- **-h**  
Displays the help

## uxconsole -manage Manage Users and Groups

### Valid on UNIX

Use this command to list or information for local or enterprise users and groups.

This command has the following formats:

```
uxconsole -manage {-find | -show [-detail]} {-user <filter> | -group <filter>}
```

```
uxconsole -manage -show -policy
```

- **-find**  
Specifies to display a list of local and enterprise users or groups
- **-show**  
Specifies to show the details of a specific user or group, a subset of users and groups, or to show policies
- **-detail**  
Specifies to display the user settings in detail
- **-user *filter***

Defines the wildcard that returns a subset of users

- **-group *filter***  
Defines the wildcard that returns a subset of groups
- **-policy**  
Specifies to display the enterprise login policy

### Example: Display User Status

The following example shows you the output for a local UNIX user (local1) who is mapped to an Active Directory user with a different name (ent1). The Active Directory user has UNIX attributes enabled, so can log in to the UNIX Authentication Broker endpoint:

```
uxconsole> ./uxconsole -manage -show -detail -user ent1
```

```
CA PAMSC UNAB uxconsole v12.52.0.160 - console utility
```

```
Copyright (c) YYYY CA. All rights reserved.
```

```
USER 'ent1' information
```

```
-----
```

```
Type                : Local User
```

```
Login Name          : local1
```

```
Mapped to           : ent1@example.com
```

```
Enterprise Account   : Enabled
```

```
Local Account        : Enabled
```

```
Login               : Allowed
```

```
Login Reason         : User exists locally
```

```
Uid                  : 300
```

```
Gid                   : 101
```

```
Shell                 : /bin/bash
```

```
Home Directory        : /home/local1
```

```

```

```
Type                : Enterprise User
```

```

Login Name           : ent1
Principal Name       : ent1@example.com
Enterprise Account    : Enabled
Login                : Allowed
Login Reason          : According to internal default
Uid                  : 10133
Gid                   : 13870
Shell                 : /bin/sh
Home Directory        : /home/ent1

```

## uxconsole -migrate Migrate UNIX Users and Groups to Active Directory

### Valid on UNIX

Using the migrate command migrates users and groups from the UNIX host into Active Directory. The migration process attempts to migrate local users and groups into Active Directory and disable the local accounts.

This command has the following format:

```

uxconsole -migrate [-scope {l|n|a}] {-mode {p|f}}[-input file] [-emulate] [-d domain] [-a name [-w pass]] [-
users] [-groups] [-cgc container] [-new] [-v level] [-h]
uxconsole -migrate [-show {-user filter|-group filter}]

```

- **-migrate**  
Defines the UNIX users migration option.
- **-scope {l | n | a}**  
Specifies the migration scope:
  - l migrate only local users and groups.
  - n migrate NIS users and groups from NIS/NIS+ server.
  - a migrate local and NIS/NIS+ users and groups.**Default:** l
- **-mode {p | f}**  
Specifies the migration mode.  
**Options:** partial, full  
**Default:** f
- **-input file**  
Defines the full path of the accounts map file.

### NOTE

Use the mapping file to resolve conflicts in user accounts that were discovered during the migration process. Create the map file in a CSV format with the following fields and parameters:

```
type <USER|GROUP>, UNIX name <username>, requested action <KEEPLocal|MIGRATE|MAP>, AD name <AD mapped name>
```

**Example:** USER,uxuser, MAP,aduser.

**WARNING**

You cannot specify the GROUP type to use the MAP action. You can use the MAP option to map user accounts only.

- **-emulate**

Specifies that the migration process runs in emulation mode.

**NOTE**

Running the uxconsole -migrate command in emulation mode does not migrate users to Active Directory. In emulation mode the uxconsole creates a journal file that reports on possible conflicts in users and groups IDs. Use the emulation mode to resolve conflicts between UNIX and Active Directory users and groups IDs.

- **-d *domain***

Defines the name of the domain to migrate users and groups to.

**NOTE**

Running the -migrate -d command without supplying the administrator credentials does not enable UNIX Authentication Broker to migrate users and groups to Active Directory.

- **-a *name***

Specifies the Active Directory administrator used to register, create, and update users properties in Active Directory.

**Note:** Running the -migrate command without supplying the administrator credentials does not enable UNIX Authentication Broker to append UNIX attributes nor to add accounts or groups to Active Directory. You cannot resolve conflicts that were discovered during migration without supplying the Active Directory administrator credentials.

- **-w *passwd***

Specifies the Active Directory administrator's account password.

- **-users**

(Optional) Specifies that only users are migrated to Active Directory.

**NOTE**

If not specified, all the users are migrated to Active Directory.

- **-groups**

(Optional) Specifies that only groups are migrated to Active Directory.

**NOTE**

If not specified, all the groups are migrated to Active Directory.

- **-cgc *container***

Specifies the name of the Active Directory container where new groups are created.

- **-new**

Specifies to migrate only new users and groups that were not previously migrated.

- **-v *level***

Specifies the verbose level.

**Range:** 1-5

- **-h**

Displays the help.

- **-show**

Displays users and groups migration information.

**NOTE**

If specified, users and groups are not migrated.

- **-user *filter***

Displays only those users that match the filter criteria.

- **-group *filter***

Displays only those groups that match the filter criteria.

## uxconsole -register Register UNIX Computers in Active Directory

### Valid on UNIX

Use the *uxconsole* command to register a UNIX host in Active Directory. A privileged account (not necessarily administrator account) user can register a UNIX host in Active Directory. To let the Active Directory users log in to the UNIX host, activate the UNIX Authentication Broker.

You can run the command multiple times on the same computer.

Example: Run the command to repair the UNIX Authentication Broker host registration with Active Directory when the keytab file is deleted.

The *uxconsole* command has the following format:

```
uxconsole -register -a name [-w pass] [-d domain] [-t site] [-v level] [-n] [-o container] [-s server] [-p #]
  [-sso] [-i #] [-h] [-k]
uxconsole -register -owt -d domain -a name [-w pass] [-v level]
uxconsole -register -owt -pupm -d domain -a name -epname name [-eptype type] [-container name] [-v level]
uxconsole -deregister -owt -d domain [-a name] [-v level]
uxconsole -deregister -a name [-w pass] [-d domain] [-v level] [-o container] [-s server] [-p #]
```

- **-register**  
Specifies that Active Directory registers UNIX Authentication Broker.
- **-deregister**  
Specifies that Active Directory deregisters UNIX Authentication Broker.
- **-a name**  
Specifies a user with privileges to register computers in Active Directory.  
**Default:** administrator
- **-epname**  
Specifies an endpoint where the privileged account originates.
- **-eptype**  
Specifies the endpoint type. If not otherwise specified, the endpoint type is Windows Agentless.
- **-w pass**  
Specifies the password of a user with privileges to register computers in Active Directory.
- **-d**  
Defines the domain name that the Active Directory is part of.
- **-h**  
Displays the program help.
- **-n**  
Specifies that the uxauthd agent runs after the registration process completes.
- **-o container**  
Specifies the Active Directory container name where you register the UNIX computer. The Active Directory container must exist before you register the UNIX computer.
- **-container**  
Specifies the name of the container where you register the privileged account.
- **-owt**  
Specifies a position-dependent argument that requests the proxy user key management. Register the UNIX Authentication Broker endpoint before using this option.
- **-p #**  
Specifies the Active Directory listening port number.
- **-pupm**  
Specifies to use Shared Account Management integration.
- **-s server**

Specifies the Active Directory Server name.

- **-sso**  
Specifies that the uxconsole manages Kerberos files for Single Sign On (SSO)
- **-t site**  
Defines the Active Directory site that contains Domain Controllers (DCs). The UNIX Authentication Broker uses DCs to communicate with the Active Directory. The UNIX authentication broker writes the site name to the `ad_site` configuration setting in the `ad` section of the `uxauth.ini` file. We recommend that you do not specify this option. If you do not specify this option, the utility automatically selects the best Active Directory site to use.

#### NOTE

The values in the `ignore_dc_list` and `lookup_dc_list` configuration settings affect how UNIX Authentication Broker implements Active Directory site support.

- **-v level**  
Defines the verbose level to use during the installation process.
- **-i #** Specifies the Key Distribution Server (KDC) configuration mode. **Limits:** 0 - Use host name for the registered domain KDC in Kerberos configuration  
1 - Use IP address instead of hostnames for KDC in Kerberos configuration  
2 - Use DNS-only KDC lookup  
**Default:** 0
- **-k** Specifies to skip the key version when the Active Directory fails to increase the key version on the Kerberos token.

### Example: Register a UNIX Host in Active Directory

The example shows how to register a UNIX computer in Active Directory by providing the following information:

- User name (-a administrator)
- Password (-w admin)
- Set the verbosity level (-v 3)
- Specify that the UNIX Authentication Broker agent does not run at the end of the installation (-n)
- Define the name of the container in Active Directory (-o OU=COMPUTERS), where the computer object representing the endpoint locates. The container must exist before you register the UNIX computer in Active Directory:

```
./uxconsole -register -a administrator -w admin -v 3 -n -o OU=COMPUTERS
```

For assistance while registering the UNIX host on Active Directory, refer to the following topics:

- [uxconsole -krb Perform Kerberos Operations](#)
- [uxconsole -ldap Perform LDAP queries in Active Directory](#)

### uxconsole -status Display UNIX Authentication Broker Status

#### Valid on UNIX

Use this command to display the status of UNIX Authentication Broker on the endpoint. Using the `-detail` argument displays all the available information about the status of UNIX Authentication Broker.

This command has the following format:

```
uxconsole -status [-detail]
```

- **-status**  
Specifies to display the UNIX Authentication Broker status.
- **-detail**

Specifies to display the UNIX Authentication Broker status in detail.

**Example: Display the UNIX Authentication Broker Status in Detail.**

The following example shows you the output that you receive when you run the `uxconsole - status -detail` command.

```
#./uxconsole -status -detail

CA PAMSC uxconsole v12.52.0.160 - console utility

Copyright (c) YYYY CA. All rights reserved.

Registration domain - example.com

DCs                - computer1, computer2

User search base    - DC=unixauth,DC=example,DC=com

User search filters

    Include         - CN=Users; OU=Test

    Exclude         - OU=WrongOU

Group search base    - CN=Users,DC=example,DC=com

Group search filters

    Exclude         - OU=Computers

Trusted domain      - DC=unab,DC=example,DC=com

DCs                - winserver

User search base     - DC=unabdom,dc=example,dc=com

User search filters

    Include         - CN=users

Group search base     - DC=unab,DC=example,DC=com

UNAB mode - full integration

UNAB status - activated

Agent status - running, pid = 6178
```

---

```
SELinux status          - permissive

SELinux UNAB policy     - uxauth_ex  (version: 1.0)

CA AC server host       - ssl://acserver.example.com:7243

CA AC server status     - connected (updated: Wed Jun 27 18:11:36 YYYY)

Time sync- enabled (NTP server: 192.168.1.10.0 or fd6d:8d64:af0c:1:0:242:22:233)

Enterprise policy - login@computer.com (updated: Wed Jun 27 18:11:36 YYYY)

Enterprise policy - loginHG@GHNODE#01 (updated: Wed Jun 27 18:11:36 YYYY)

Local policy - enabled

Default login access - deny

AD Unix users - 16 (updated: Wed Jun 27 18:11:36 YYYY)

AD Unix groups - 8 (updated: Wed Jun 27 18:11:36 YYYY)

AD Windows groups - 19 (updated: Wed Jun 27 18:11:36 YYYY)

Migration - not migrated

CA PAMSC - installed

  Include AD users and groups in AC ladb : yes

  Display AD names in AC Audit : no

  Support AD non-Unix groups in AC: yes

  PAM authentication in AC utilities : yes
```

In this example, the output displays the following information:

- The Active Directory domain name - example.com
- The DCs with which the endpoint communicates - computer1, computer2
- The user and group search base filters
- The trusted domain - unab.example.com
- UNAB mode - full integration
- UNAB status - activated
- UNAB agent (uxauthd) status - running, pid = 6178
- The SELinux installation status - permissive
- The deployed SELinux UNAB policy - uxauth\_ex (version: 1.0)
- The CA AC server host name or IP address
- The CA AC server connection status
- Whether time synchronization was activated - enabled
- The NTP server IP address - 192.168.1.100 (IPv4) or fd6d:8d64:af0c:1:0:242:22:233 (IPv6)
- The name of deployed enterprise login policies - login@computer.com, loginHG@GHNODE#01
- When the enterprise login policies were last updated
- Whether local login policy is activated - enabled
- Whether the default login policy is enabled - deny
- The number of UNIX users in Active Directory - 16 and the time that they were last updated
- The number of UNIX groups in Active Directory - 8 and the time that they were last updated
- The number of Windows groups in Active Directory - 19
- The time that the UNIX users and groups and Windows groups were last updated
- The migration status of the users - not migrated
- Whether Privileged Access Manager is installed on this endpoint - installed
- Whether to include information regarding Active Directory users and groups in the Privileged Access Manager ladb - yes
- Whether to display Active Directory users and groups names in Privileged Access Manager audit records - yes
- Whether Privileged Access Manager supports non-UNIX Active Directory groups - yes
- Whether to support PAM authentication in Privileged Access Manager utilities - yes

## uxconsole -krb Perform Kerberos Operations

### Valid on UNIX

Use this command to perform Kerberos operations from the UNIX Authentication Broker endpoint. For example, creating tickets. You do not need to install Kerberos on the endpoint to perform Kerberos operations.

This command has the following format:

```
uxconsole -krb [-init | -list | -passwd | -vno | -destroy | -resolve]
```

- **-init**  
Specifies to obtain and cache a ticket.
- **-list**  
Displays the content of a credentials cache or keytab.
- **-passwd**  
Specifies that an Active Directory user can modify password directly in the Active Directory on the end point using Kerberos protocol. To change the password, UNAB need not run on the endpoint. The passwd command also allows

a user with sufficient Active Directory privileges to reset password of another user. That is, a user performs an administrative change without the need to do it on Windows.

```
uxconsole -krb -passwd [-i kcf] [-h] [principal]
```

```
uxconsole -krb -passwd -a admin [-i kcf] principal
```

- **-i kcf**  
Specifies that the Kerberos configuration is used from a file named "kcf".
- **-h**  
Specifies the help screen.
- **-a**  
Specifies that an admin authenticates to the Active Directory as admin and changes the password for a principal.  
**Note:** An account admin must have appropriate privileges in the Active Directory.
- **principal**  
Specifies the principal that is known to the Active Directory. A principal name is required when the user is not located in the registration domain.
- **-vno**  
Displays the key version number for Kerberos principals.
- **-destroy**  
Specifies to destroy the credentials cache.
- **-resolve**  
Specifies to resolve a host name or IP address.

#### Example: Obtain a Ticket Granting Ticket (TGT) using UNIX Authentication Broker keytab

The following example shows how you obtain a TGT using UNIX Authentication Broker keytab:

```
./uxconsole -krb -init -k
```

#### Example: List the content of the credentials cache

The following example shows how you list the content of the credentials cache:

```
./uxconsole -krb -list
```

#### Example: List the content of the keytab with encryption data

The following example shows how to display the content of the keytab including available encryption information:

```
./uxconsole -krb -list -keytab
```

### uxconsole -ldap Perform LDAP queries in Active Directory

#### Valid on UNIX

Use this command to perform LDAP queries on Active Directory from a UNIX Authentication Broker endpoint that does not have LDAP installed. Use this command instead of the ldapsearch utility. You can use this command to troubleshoot UNIX Authentication Broker installation. For example, you can query Active Directory for the container to use.

**WARNING**

Verify that you have a Ticket Granting Ticket (TGT) before you use this command. You can obtain a TGT using the command: `uxconsole -krb`.

**NOTE**

The LDAP filter must comply with "RFC 2254".

This command has the following format:

```
uxconsole -ldap -search -delete [-d DC] [-p port] [-b base] [-s scope] [filter [attributes]]
```

- **-search**  
Specifies the search option
- **-delete**Deletes a user from the Active Directory.
- **-d *DC***  
Specifies the Domain Controller to query
- **-p *port***  
Specifies the LDAP port to use
- **-b *base***  
Specifies the search base
- **-s *scope***  
Specifies the search scope  
**Default:** sub
- **filter [*attributes*]**  
Specifies the filter and attributes to use

**NOTE**

If you do not specify a filter, the '(objectClass=\*)' is used. If you do not specify any attributes, the select all option ('\*') is used.

**Example: Display a DSE**

The following examples shows how you display a DSE:

```
./uxconsole -ldap -search '(&(objectClass=user) (objectCategory=user) )'
```

**uxconsole -dbdump Display UNAB NSS cache data****Valid on UNIX**

Use this command to display users and groups information from the UNIX Authentication Broker NSS database. You can use this command to view information about users and groups that are defined in Active Directory.

This command has the following format:

```
uxconsole -db -dump [-a] table [item]
```

- **-a**  
Displays extension fields.
- **table [*item*]**  
Displays the content of the specified table and items.

**NOTE**

If you do not specify the table name, this command displays all the supported tables. The supported tables are: pw (table with user attributes); gr (table with group attributes)

**Example: Display all Active Directory users stored in cache**

The following example shows how to display all Active Directory users who are stored in the endpoint cache:

```
./uxconsole -db -dump pw
```

#### **Example: Display all Active Directory groups stored in cache**

The following example shows how to display all Active Directory groups that are stored in the endpoint cache:

```
./uxconsole -db -dump gr
```

### **uxconsole -db -del Delete Active Directory Users and Groups**

#### **Valid on UNIX**

Use this command to delete users and groups from the Active Directory.

This command has the following format:

```
uxconsole -db -del table item
```

- **table** [*item*]  
Deletes the content of the specified table and items.

#### **NOTE**

If you do not specify the table name, this command displays all the supported tables. The supported tables are: pw (table with user attributes); gr (table with group attributes)

#### **Example: Delete all Active Directory users stored in cache**

The following example shows how to delete all Active Directory users who are stored in the endpoint cache:

```
./uxconsole -db -del pw
```

#### **Example: Delete all Active Directory groups stored in cache**

The following example shows how to delete all Active Directory groups that are stored in the endpoint cache:

```
./uxconsole -db -del gr
```

### **uxconsole -debug Set Verbosity Level for Modules**

#### **Valid on UNIX**

Use this command to set the verbosity level per module. UNIX Authentication Broker also sends PAM and NSS debug information to log files.

This command has the following format:

```
uxconsole -debug -m mod [-v level]
```

- **-m** *mod*  
Specifies the module to set the verbosity level  
**Options:** nss, pam, agent, all
- **-v** *level*  
Specifies the verbosity level.  
**Limits:** 0-5

UNIX Authentication Broker writes the debug information to the following files:

```
UNABInstallDir/log/debug/pam_debug
UNABInstallDir/log/debug/pam_debug.back
```

```
UNABInstallDir/log/debug/nss_debug
UNABInstallDir/log/debug/nss_debug.back
```

**NOTE**

If you set the verbosity level to more than 0 while the agent is not running, you receive a message indicating that the UNIX Authentication Broker PAM module was activated. UNIX Authentication Broker sends the debug information to the syslog only.

**uxconsole -verify Verify Active Directory User Account UNIX Attributes****Valid on UNIX**

Use this command to verify that an Active Directory user account is ready for use by UNIX Authentication Broker. This command locates the user account and verifies that the UNIX attributes (login shell, home directory, UID and GID) are consistent with the values as they exist in the UNIX Authentication Broker user cache database.

**NOTE**

This command does not verify the user password.

This command has the following format:

```
uxconsole -verify -user <user_name>[<user_name1>][<user_name2>...]
```

- **-user**  
Specifies to verify the user account UNIX attributes in Active Directory
- **<user\_name>**  
Specifies the Active Directory user account.

**Example: Verify Active Directory user account UNIX attributes**

The following example shows how to verify Active Directory user account UNIX attributes:

```
./uxconsole -verify -user Joe
```

In this example, you use the -verify command to verify the user account Joe UNIX attributes. UNIX Authentication Broker does the following:

- Checks the /etc/shells file to verify that the login shell specified is supported
- Verifies that the user name length consists with the limitations as imposed by the operating system
- Verifies that the home directory is specified
- Verifies that the UID is specified
- Verifies that the GID is specified

**How uxconsole Discovers an Active Directory Site**

When you register a UNIX Authentication Broker endpoint with Active Directory, by default the uxconsole utility discovers the closest Active Directory site and communicates only with domain controllers (DCs) in this site.

The following process describes how uxconsole discovers the closest Active Directory site:

1. The UNIX Authentication Broker endpoint queries the DNS for SRV (service) records in the following format:  
\_ldap.\_tcp.dc.\_msdcs.*domainName*  
The DNS returns the records for DCs in the domain.
2. The endpoint accesses Active Directory by binding and authenticating to a DC returned in the previous query.

**NOTE**

The endpoint can bind to any of the returned DCs.

3. The endpoint uses an LDAP query to search Active Directory for the site in which the endpoint resides. The query uses the following filters:
  - Base Dnno value
  - ScopeBase
  - AttributeNetlogon
  - DnsDomainFully-qualified domain name
  - ntver6.00
 For example, Filter on (&(DnsDomain=example.company.com)(ntver=6.00))  
 The DC returns the name of the site in which the endpoint resides.  
**Note:** The DC uses the endpoint IP address to determine the site in which the endpoint resides.
4. The endpoint queries the DNS for SRV records in the following format:  
`_ldap._tcp.Local/SiteName._sites.dc._msdcs.domainName.`  
 The DNS returns the records for DCs in the site in which the endpoint resides. The endpoint communicates only with DCs in this site.

## UxImport Utility Extract Information from the UNIX Operating System

### Valid on UNIX

The uximport utility extracts information from the UNIX operating system about the defined users, groups, terminals, hosts, and TCP services. The utility extracts information from NIS, if it is installed, and the system is configured accordingly. It also provides DNS support. You should use uximport as part of the installation procedure.

uximport automatically processed the extracted information to generate selang commands that you can use to add users and groups to the Privileged Access Manager database. The generated commands are printed to the standard output. Use redirection to a file, or pipeline to the selang utility.

This command has the following format:

```
UxImport switches [options]
```

- **-a**  
Generates the selang commands that are required to import users, groups, and hosts, and to join users to their default groups.
- **-c**  
Generates the selang commands that are required to join users to their default groups.

### NOTE

If you also import groups with the -g switch, Privileged Access Manager generates the commands that join users to the groups to which they are explicitly linked.

- **-g**  
Generates the selang commands that are required to import groups from UNIX and NIS to the Privileged Access Manager database.
- **-h**  
Generates the selang commands that are required to import hosts from UNIX, NIS, and DNS to the Privileged Access Manager database. uximport extracts host information from the file /etc/hosts and from NIS, and builds HOST resources. For each host entry in the file /etc/hosts or extracted from NIS, the appropriate newres command is built. Permission to receive any TCP service is assigned to that host.  
In addition, DNS is supported with the -d option. In some machines, information from the file /etc/hosts and NIS is ignored if the specified DNS daemon is running. In Solaris, the information that is gathered depends on the configuration of the system in the file /etc/nsswitch.conf.
- **-t**  
Generates the selang commands that are required to import terminal rules from UNIX and NIS to the Privileged Access Manager database.

uximport extracts host information from the file `/etc/hosts` and from NIS, and builds `TERMINAL` resources. For each entry in the file `/etc/hosts` or extracted from NIS, the appropriate newres `TERMINAL` command is built and permission to log in from the terminal is granted.

In addition, DNS is supported with the `-d` option. In some machines information from the file `/etc/hosts` and NIS is ignored if the specified DNS daemon is running. In Solaris, the information that is gathered depends on the configuration of the system in the file `/etc/nsswitch.conf`.

- **-T**  
Generates the `selang` commands that are required to import TCP services from UNIX and NIS to the Privileged Access Manager database. The names are set according to GECOS in UNIX. The names are truncated to 40 characters if they are longer.
- **-u**  
Generates the `selang` commands that are required to import users from UNIX and NIS to the Privileged Access Manager database. The actual user names are set according to GECOS in UNIX. The names are truncated to 40 characters if they are longer.

#### *options*

- **-d**  
Specifies the use of DNS for generating the list of hosts and terminals to import. Must be accompanied by the `-h` or `-t` switch.
- **-f**  
Skips search for multiple occurrences of the same name. By not using the standard `uximport` processes, this option handles the importing of many users and groups speedily, and saves memory. The `-f` option does not apply to hosts; you should combine them with one or more of the following switches: `-u`, `-g`, or `-a`. Also, use one of these switches when including the `-c` switch with the `-f` option.  
Join and surrogate rules are printed with create records.
- **-G**  
Creates `SURROGATE` class rules for groups. `uximport` adds a record to the `SURROGATE` class for each group it defines, therefore making `SURROGATE` requests protected resources. It also adds rules so that root can surrogate to each of the groups.
- **-gr *n***  
Specifies the number of grace logins for all users, forcing users to change their passwords after *n* logins. This ensures that the `PASSWD_L_C` property in the `USER` record is updated.
- **-o *owner***  
Sets ownership rules for each record. We recommended that you use this option to prevent root from automatically becoming the owner of all the records. *Owner* is the name of the user or group to be assigned ownership of all records that are defined by `uximport`.  
**Note:** You must specify this option as a separate argument followed by *owner*.
- **-pr *groupname***  
Assigns a profile group to users. If you specify this option, Privileged Access Manager uses that group when building the profile of a user. Otherwise, it uses the primary UNIX group.
- **-r**  
Specifies to continue scanning after a failure.
- **-s**  
Creates `SURROGATE` class rules for users and groups. The `uximport` function adds a `SURROGATE` record for every group it defines, thereby making `SURROGATE` requests to the group into protected resources.
- **-U**  
Creates `SURROGATE` class rules for users. `uximport` adds a record to the `SURROGATE` class for each user it defines, therefore making `SURROGATE` requests into protected resources. It also adds rules so that root can surrogate to each of the users.
- **-v**

Displays the status of the program (verbose mode). We recommended that you use this option if your site has many users, groups, or hosts, so that you can verify the progress of the program.

### Example

The following command extracts all information of users, groups, and hosts from the UNIX and NIS databases. It then creates the selang commands that add those records to the database. uximport then creates SURROGATE class records and provides progress indication. Output is directed to the file uxinfo.seos in your home directory.

```
UxImport -a -s -v > ~/uxinfo.seos
```

## uxpatcher Utility

The uxpatcher utility applies a patch to Privileged Access Manager. Use it to apply a patch immediately, or to schedule the application of the patch to occur at the next restart of the product. You can run the utility at any time.

When you schedule uxpatcher to run at the next restart of the product, the seload command checks a staging area for patches. If it detects a patch, it applies the patch before starting the product.

The seload command checks seos.ini for a new token. If the new token is set, then it checks for scheduled patches. The default behavior is not to check for patches, simply to start.

Set the token:

**seini -s seload.allow\_updates 1**

Turn off the token (default):

**seini -s seload.allow\_updates 0**

This command has the following format:

```
uxpatcher -s -x -c <patcher.ini> -r
```

- **-s**  
The patch is deployed to a staging area within the directory structure of the product. For example, if the product path is /opt/CA/PAMSC, then a directory for staging is created in /opt/CA/PAMSC/.pending\_patch. Once the product restarts, seload checks to determine whether it is supposed to check for patches. If so, then seload checks for patches in the staging area and runs all the patches that have the token set to run them. If the patch is applied successfully, the token to run is removed. However, the patch files are not removed. To remove the patch files from the staging area after patching, use the -x flag.
- **-x**  
seload removes the staging area files after it applies the patch.
- **-c**  
Indicates the configuration file. The product is shipped with patcher.ini as the default configuration file, but you can specify a different file.
- **-r**  
Removes the most recently installed patch.

### NOTE

When you use the -s flag, uxpatcher checks the current version of seload to determine if it includes the appropriate functionality. (This is only relevant on 12.8 SP1 and 14.01 because they were shipped without the functionality. SC141 is shipped with that functionality, so not necessary.

When you use the '-s' flag, uxpatcher checks that the patch contains seload. If so, it indicates that this patch must be applied without using the '-s' flag.

### Examples

Run the uxpatcher utility to install a patch immediately:

```
[root@rh74-2-filth02 patcher]# ./uxpatcher -c patcher.ini

CA ControlMinder uxpatcher v12.81.0.3131 - Patch Installer

Copyright (c) 2013 CA. All rights reserved.

Reading patch configuration file 'patcher.ini'

Reading files, section [MandatoryFiles].

    file: /opt/CA/AccessControl/bin/SEOS_syscall.70-3100-693-RHELX86_64.MP.ko version:
    12.81-0  3143

Reading files, section [OptionalFiles].
```

Schedule a new patch for the next restart:

```
[root@rh74-2-filth02 patcher]# ./uxpatcher -s -c patcher.ini

CA ControlMinder uxpatcher v12.81.0.3131 - Patch Installer

Copyright (c) 2013 CA. All rights reserved.

Reading patch configuration file 'patcher.ini'

Reading files, section [MandatoryFiles].

    file: /opt/CA/AccessControl/bin/SEOS_syscall.70-3100-693-RHELX86_64.MP.ko version:
    12.81-0  3143

Reading files, section [OptionalFiles].

Scheduling patch for next restart

Patch          : T47D091
```

Description : Test Patch for new uxpatcher

Product : AC

Build : 12.81-0 (2994)

Backup size : 1 KB

Checking patch data

Patch version matches installed product version.

Patch description matches the platform.

Patch T47D091 will be applied at next product restart.

#### Remove the most recently installed patch:

```
[root@rh74-2-filth02 patcher]# ./uxpatcher -r
```

CA ControlMinder uxpatcher v12.81.0.3131 - Patch Installer

Copyright (c) 2013 CA. All rights reserved.

You are about to remove the last applied patch, i.e. T47D091

Checking if backup files exist in /opt/CA/AccessControl/patch/T47D091

Do you want to remove patch T47D091? [n,y] y

Deleting directory /opt/CA/AccessControl/patch/T47D091

Unregistering patch T47D091

Successfully removed patch T47D091

## Services and Daemons in Detail

This section contains a complete alphabetic reference to all Privileged Access Manager daemons and services.

## Agent Manager Service

### Valid on Windows

The Privileged Access Manager Agent Manager service provides management services for the Privileged Access Manager plug-ins. The Privileged Access Manager Agent Manager service provides the plug-ins with the following services:

- Scheduling service manages the plug-ins schedules.
- Watchdog service verifies that the plug-ins are running and starts up plug-ins after failure.
- Messaging service provides the plug-ins with message queue services and stores messages in case the Enterprise Management Server is unavailable.

The Agent Manager registry key contains registry entries to let you fine-tune the Agent Manager. You can find the key in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\common\AgentManager
```

## Message Queues

### Valid on Windows

The Message Queue service manages the Message Queue that handles all inbound and outbound messages between the Enterprise Management Server and other Privileged Access Manager components. The Message Queue has a dedicated queue for each client component that communicates with the Enterprise Management Server, as follows:

- **Report Queue:**  
The Report Queue receives scheduled snapshots of the endpoint databases. The reporting service uses the snapshots to generate enterprise reports.
- **Audit Queue:**  
The Audit Queue receives audit events that occur on the endpoints. You can configure the Audit Log to collect the audit events.
- **Server to Endpoint Queue:**  
The Server to Endpoint Queue receives data from the Deployment Map Server (DMS) and then forwards the data to an endpoint.  
For example: When you deploy a UNAB config policy, the DMS sends the config policy to this queue. The UNAB agent then collects the policy from the queue and deploys the policy on the UNAB endpoint.
- **Endpoint to Server Queue:**  
The Endpoint to Server Queue receives information from endpoints and then forwards the information to the Deployment Map Server (DMS).  
For example, a UNAB endpoint sends a heartbeat notification to this queue. The DMS then collects the heartbeat notification from the queue and updates the endpoint status in its database.

## Web Service

### Valid on Windows

The Web Service manages the web-based applications that you use to manage an enterprise installation of Privileged Access Manager. The web-based applications are installed on the Application Server. The Application Server is installed by default on the Enterprise Management Server.

The Application Server contains the following web-based applications:

- Privileged Access Manager Enterprise Management: Lets you manage policies across your enterprise and configure UNIX Authentication Broker endpoints. Privileged Access Manager Enterprise Management also contains Shared

Account Management (SAM), which lets you manage privileged accounts across the enterprise and acts as a password vault for the privileged accounts.

- Privileged Access Manager Endpoint Management: Lets you administer and configure individual Privileged Access Manager endpoints through a central administration server.
- Privileged Access Manager Password Manager: Lets you manage Privileged Access Manager user passwords. You can modify the password of a Privileged Access Manager user or can force the user to change their own password when they next log in.

The WebService registry key contains registry entries to let you fine-tune the Web Service. You can find the key in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\WebService
```

**Note:** If you install the Enterprise Management Server on a UNIX computer, the eacws daemon manages the web-based applications.

## eacws Daemon

### Valid on UNIX

The eacws daemon manages the web-based applications that you use to manage an enterprise installation of Privileged Access Manager. The web-based applications are installed on the Application Server. The Application Server is installed by default on the Enterprise Management Server.

The Application Server contains the following web-based applications:

- Privileged Access Manager Enterprise Management - Lets you manage policies across your enterprise and configure UNIX Authentication Broker endpoints. Privileged Access Manager Enterprise Management also contains Shared Account Management (SAM). SAM lets you manage privileged accounts across the enterprise and acts as a password vault for the privileged accounts.
- Privileged Access Manager Endpoint Management - Lets you administer and configure individual Privileged Access Manager endpoints through a central administration server.
- Privileged Access Manager Password Manager - Lets you manage Privileged Access Manager user passwords. You can modify the password of a Privileged Access Manager user or force the user to change their own password when they next login.

### NOTE

If you install the Enterprise Management Server on a Windows computer, the Privileged Access Manager Web Service manages the web-based applications.

## KBLAudMgr Daemon Session Logging

### Valid on UNIX

The KBLAudMgr daemon manages the Keyboard Logger session recording agent. You use the Keyboard Logger to track privileged user sessions in UNIX and Linux endpoints. The Keyboard Logger records the interactive session, which you can replay when terminated and send to the Audit Log for analysis.

The [kblaudit] section of the seos.ini file contains tokens that let you fine-tune the Keyboard Logger agent.

## PolicyFetcher Daemon

### Valid on UNIX

The PolicyFetcher daemon performs the following tasks:

- Checks for deviations in the deployed policy at regular intervals
- Looks for deployment tasks on the DH
- Applies policy updates to the local Privileged Access Manager database (seosdb)
- Sends a heartbeat to the DH at regular intervals

Use the start DEVCALC selang command to start the deviation calculator. If you installed advanced policy management on the endpoint, the PolicyFetcher runs the deviation calculator for you.

## ReportAgent Daemon

### Valid on UNIX

The ReportAgent daemon manages the ReportAgent that sends report snapshots and audit events to the Distribution Server for inclusion in Privileged Access Manager, and UNIX Authentication Broker. You run the ReportAgent utility from the *ACSharedDir/bin* directory on a UNIX computer, where *ACSharedDir* is the default directory */opt/CA/PAMSCShared*. You can also use the *report\_agent.sh* script to configure, start, and stop the ReportAgent.

The [ReportAgent] section of the *accommon.ini* file contains tokens that control the behavior of the Report Agent daemon.

## ReportAgent Service (Windows)

### Valid On Windows

The ReportAgent Service manages the ReportAgent that sends report snapshots and audit events to the Distribution Server for inclusion in Privileged Access Manager, and UNIX Authentication Broker. The ReportAgent Service automatically runs on startup if you installed Privileged Access Manager on the endpoint and selected to install the ReportAgent.

The ReportAgent registry key contains registry entries to let you fine-tune the ReportAgent. You can find the key in the following location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\ComputerAssociates\AccessControl\ReportAgent
```

## sepmdd Daemon (UNIX)

The Policy Model daemon.

The sepmdd daemon is the PMDB daemon. The sepmdd daemon performs the following functions:

- Administers the Privileged Access Manager and UNIX databases of the Policy Model.
- Administers the subscriber database.
- Propagates changes from the PMDB to the subscriber databases.

You can find the sepmdd daemon in the *ACInstallDir/bin* directory. The daemon starts the PMDB if it is already created.

- **Syntax**

```
sepmdd policyModel
```

- **Parameters**

- *policyModel*  
The name of the Policy Model.

- **Other Files**

No other special files are used.

**NOTE****NOTE**

When you use `selang` and choose a Policy Model as your target (using hosts `pmd@hostname`), queries to `sepmdd` apply to the PMDB.

Queries do not apply to the various subscriber databases.

- Ensure that a PMDB does not become a subscriber of itself. If a PMDB is subscribed to itself, the Policy Model may block or the network may become overloaded, filling the disk in the process.
- When updating a Policy Model in the UNIX environment of `selang`, do not specify more than one user in the `newusr` command, or specify more than one group in the `newgrp` command.
- When updating UNIX file attributes from `selang`, the Policy Model generates a message stating that the command was passed to its subscribers.
- When working on a Policy Model, you cannot query the status of UNIX file attributes.
- If you set the value of `_shutoff_timeout_` to zero, the `sepmdd` daemon remains up and running indefinitely until you shut it off manually. Use the command `sepmdd -k` to shut down the Policy Model daemon.

**How sepmdd Works**

The Privileged Access Manager agent, `seagent`, starts `sepmdd`; You do not need to run `sepmdd` explicitly. The `sepmdd` daemon runs under the logical user id `_seagent` for Privileged Access Manager, and with the user id `root` in UNIX. You cannot designate another logical user under which `sepmdd` runs.

The PMDBs are stored in a common directory. Specify the name of the common directory with the `_pmd_directory_` token in the `[pmd]` section of the `seos.ini` file, on the station where the Policy Models reside. Each Policy Model resides in a subdirectory of the common directory. The name of the Policy Model is the name of the subdirectory in which it resides.

When `sepmdd` starts, it checks whether any subscriber databases need updating, and updates them if necessary. After this startup process, `sepmdd` waits for user requests. These requests are sent by the Policy Model management program, `sepmdd`, and by the `selang` utility, using `seagent`.

When `sepmdd` receives a request, it applies the request to the PMDB and it sends the result back to the user. If the request should be propagated, `sepmdd` propagates the update to its subscriber databases.

The `sepmdd` daemon attempts to update a subscriber database for the period that is specified in the `_QD_timeout_` token. If the maximum time elapses and the daemon does not succeed in updating a subscriber, it skips that particular subscriber and tries to update the remainder of the subscribers on its list. After it completes its first scan of the subscriber list, `sepmdd` then performs a second scan. During the second scan, it tries to update the subscribers that it did not succeed in updating during its first scan. During the second scan, it tries to update a subscriber until the connect system call times out (approximately 90 seconds).

**NOTE**

The `_QD_timeout_` token may exist in both the `seos.ini` and `pmd.ini` files. If it does, `sepmdd` uses the value in the `pmd.ini` file.

If a subscriber is unavailable during the second scan, `sepmdd` attempts to send it updates every 30 minutes. To modify this interval, set the `_retry_timeout_` token. Because the updates must be sent in the order in which they are received, `sepmdd` does not send subsequent updates to the subscriber database until it becomes available.

If you set the `pull_option` token in the `[pmd]` section of the subscriber database's `seos.ini` file to `yes`, the subscriber database is updated as soon as possible. `seagent` informs the parent Policy Models that the host is up for every Policy Model on the machine, and that its subscriber PMDBs are up, and `sepmdd` sends the update immediately.

Whenever `sepmdd` fails to update a subscriber database, it writes a warning message in the Policy Model error log. For more information about the Policy Model error log see the *Endpoint Administration Guide for UNIX*.

Privileged Access Manager attempts to qualify subscribers as they are added or deleted from the Policy Model.

To remove a subscriber from the list of unavailable subscribers, enter the following command:

```
sepmc -r policyModel subscriber
```

If a subscriber database rejects an update, as can occur if the subscriber database differs from the PMDB, sepmc writes an error message in the Policy Model error log and continues.

To view the error log, enter the following command on the host where the PMDB resides, enter:

```
sepmc -e policyModel
```

You can have sepmc automatically shut itself down after a period of inactivity. By default, however, sepmc does not shut itself down. If you want sepmc to shut itself down, set the `_shutoff_time_` token to a value greater than 0. This value indicates the minutes of inactivity that is allowed before sepmc shuts itself down. To shut sepmc down manually, enter:

```
sepmc -k policyModel
```

### **WARNING**

Do *not* use the UNIX command `kill -9` to shut down sepmc manually; this may destroy the PMDB.

## **UID/GID Synchronization**

As an administrator, you receive messages that refer to users by UID and to groups by GID. Verify that the UIDs and GIDs have the same meaning everywhere.

By default, the PMDB attempts to use the same UIDs and GIDs for new users and groups everywhere. You can help by providing the necessary conditions from the start as follows:

- Start with identical passwd files and identical group files.
- Make sure that the `synch_uid` token in the `pmd.ini` file is set to yes.

You can depend on compatibility between the UIDs and between the GIDs of your local database, your PMDB, and your PMDB subscribers if the following conditions exist:

- Your local database is a subscriber to your PMDB
- The PMDB is the only source of new users and new groups for your subscriber databases

If you create a user with a UID that is already in use in the PMDB or in some other subscriber computer, the individual update of the subscriber fails. In all other subscriber computers where no such conflict exists, the update succeeds.

An alternative to synchronizing your passwd and group files is to specify the UID of each new user and the GID of each new group explicitly.

## **Filter Mechanism**

You may want your PMDB to update the subscriber stations below it selectively. To define which records are sent to the subscriber stations, point the filter token in the `pmd.ini` file to a filter file. Updates to the subscriber stations are then limited to the records that pass the filter file.

A filter file consists of lines with six fields per line. The fields contain the following information:

- The form of access that is permitted or prohibited. The possible values are AUTHORIZE\_DELETE, AUTHORIZE\_MODIFY, CREATE, DELETE, DEPLOY, EDIT, FILESCAN, GET, SEOS\_ACCS\_READ, JOIN\_DELETE, JOIN\_MODIFY, MODIFY, READ, START, or UNDEPLOY.
- The environment that is affected. The possible values are AC, CONFIG, UNIX, NT, or NATIVE
- The class of the record. The possible values include all classes in Privileged Access Manager, including user-defined classes.
- The objects within the class that the rule covers. For example, User1, AuditGroup, or TTY1
- The properties that the record grants or cancels. For example, OWNER and FULL\_NAME in the filter line for user records means that any command having those user properties are filtered. You must enter each property exactly.
- Whether such records should be forwarded to the subscriber station or not. The possible values are PASS or NOPASS

You can use an asterisk in any field to mean all possible values. If more than one line covers the same records, the first applicable line is used.

In each line of the filter file, spaces separate the fields. In fields with more than one value, semicolons separate the values. Any line beginning with # is considered a comment line. Empty lines are not allowed. Here is an example of a line from a filter file:

CREATE	AC	USER	*	FULL-NAME;OBJ_T YPE	NOPASS
<i>form of access</i>	<i>environment</i>	<i>class</i>	<i>record name ( * =all)</i>	<i>properties</i>	<i>treatment</i>

For example, suppose that the file with this line is named TTY1\_FILTER, and the pmd.ini file of the Policy Model TTY1 contains the line filter=/opt/CA/PAMSC/TTY1\_FILTER. The Policy Model TTY1 does not send records that create Privileged Access Manager users with the FULL\_NAME and OBJ\_TYPE (Admin, auditor, and so on). The asterisk means regardless of name.

The following list shows the selang commands that are relevant for each access value:

Access	selang Command
AUTHORIZE_DELETE	authorize-
AUTHORIZE_MODIFY	authorize
CREATE	newres, newusr, newgrp, newfile
DELETE	rmres, rmusr, rmgrp, rmfile, join- (UNIX)
DEPLOY	deploy
EDIT	editres, editusr, editgrp, editfile
FILESCAN	search
GET	get devcalc
JOIN_DELETE	join-
JOIN_MODIFY	join
MODIFY	chres, chusr, chgrp, chfile, join (UNIX)
READ	list
START	start devcalc
UNDEPLOY	deploy- (undeploy)

Privileged Access Manager does not validate rules. If you enter an invalid value in a rule, the rule never matches an update transaction.

## Policy Model Service (sepmdd)

### Valid on Windows

Privileged Access Manager Policy Model Service (sepmdd) is the PMDB service. This service performs the following functions:

- Administers the Privileged Access Manager and Windows databases of the Policy Model
- Administers the subscribers database
- Propagates changes from the PMDB to the subscriber databases

SeOSAgent starts the sepmdd service. There is no need to run sepmdd explicitly. The two possible states for each Policy Model are Started and Stopped.

The PMDBs are stored in a common directory. The registry value `_pmd_directory_` in the subkey `HKLM\Software\ComputerAssociates\AccessControl\Pmd` specifies the name of the common directory. Each Policy Model resides in a subdirectory of the common directory. The name of the Policy Model is the name of the subdirectory in which it resides.

When sepmdd starts, it checks whether any subscriber databases need to be updated. If necessary, it updates them. After this startup process, the sepmdd service waits for user requests. User requests are sent by the Policy Model management utility `sepmdd` and by `selang` using the Privileged Access Manager Agent.

When a request is received, sepmdd applies it to the PMDB and sends the result back to the user. If the request should be propagated, sepmdd propagates the update to its subscriber databases.

The sepmdd service tries to update a subscriber database for 30 seconds. If this elapses and the service does not succeed in updating a subscriber, it skips that particular subscriber and tries to update the remainder of the subscribers on its list. After it completes its first scan of the subscriber list, sepmdd then performs a second scan, in which it tries to update the subscribers that it did not succeed in updating during its first scan. During the second scan, it tries to update a subscriber until the connect system call times out (approximately 90 seconds).

If a subscriber is unavailable during the second scan, sepmdd attempts to send it updates every 30 minutes.

Because the updates must be sent in the order in which they are received, sepmdd does not send subsequent updates to the subscriber database until it becomes available.

Each time sepmdd fails to update a subscriber database, a warning message is written in the Policy Model error log.

### Filter Mechanism

You may want your PMDB to update the subscriber stations below it selectively. To define which records to be sent to the subscriber stations, set the registry key string value to a filter file. Updates to the subscriber stations are then limited to the records that pass the filter file.

Here is an example:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\Pmd\PolicyModelName\Filter
```

A filter file consists of lines with six fields per line. The fields contain this information:

- **The form of access permitted or prohibited**  
Valid values are: `AUTHORIZE_DELETE`, `AUTHORIZE_MODIFY`, `CREATE`, `DELETE`, `DEPLOY`, `EDIT`, `FILESCAN`, `GET`, `SEOS_ACCS_READ`, `JOIN_DELETE`, `JOIN_MODIFY`, `MODIFY`, `READ`, `START`, or `UNDEPLOY`.
- **The environment affected**  
Valid values are: `AC`, `CONFIG`, `UNIX`, `NT`, or `NATIVE`.
- **The class of the record**  
Valid values include all classes in Privileged Access Manager, including user-defined classes.
- **The objects within the class that the rule covers**

For example: User1, AuditGroup, or COM2.

- **The properties that the record grants or cancels**

For example, including GROUPS and FULLNAME in the filter line for user records means that any command having those user properties is filtered. You must enter each property exactly as it appears.

- **Whether such records should be forwarded to the subscriber station**

Valid values are: PASS, NOPASS

**NOTE**

You can use an asterisk to mean all possible values in any field. If more than one line covers the same records, the first applicable line is used.

**NOTE**

In each line of the filter file, spaces separate the fields. In fields with more than one value, separate the values with semicolons. Any line beginning with # is considered a comment line. Empty lines are not allowed. Here is an example of a line from a filter file:

CREATE	AC	USER	*	FULLNAME;OBJ_T YPE	NOPASS
form of access	environment	class	record name ( * =all)	properties	treatment

If, for example, the file with this line is named Printer1\_Filter.flt and the registry key HKEY\_LOCAL\_MACHINE\Software\ComputerAssociates\AccessControl\Pmd\PM-\Filter contains the line C:\Program Files\CA\PAMSC\data\Printer1\_Filter.flt, then Policy Model PM-1 does not send records that create Privileged Access Manager users with the FULLNAME and OBJ\_TYPE (admin, auditor, and so on). The asterisk means regardless of name.

The selang commands that are relevant for each access value are:

Access	selang Command
AUTHORIZE_DELETE	authorize-
AUTHORIZE_MODIFY	authorize
CREATE	newres, newusr, newgrp, newfile
DELETE	rmres, rmusr, rmgrp, rmfile, join- (UNIX)
DEPLOY	deploy
EDIT	editres, editusr, editgrp, editfile
FILESCAN	search
GET	get devcalc
JOIN_DELETE	join-
JOIN_MODIFY	join
MODIFY	chres, chusr, chgrp, chfile, join (UNIX)
READ	list
START	start devcalc
UNDEPLOY	deploy- (undeploy)

**NOTE**

Privileged Access Manager does not validate rules; therefore, if you enter an invalid value in a rule, the rule will never match an update transaction.

## Registry Subkeys

Each PMDB has its own registry subkey under:

```
HKEY_LOCAL_MACHINE\Software\ComputerAssociates\AccessControl\Pmd
```

This subkey contains the values that define and determine the activity of the PMDB. The `sepmdd` utility creates a subkey, if it does not already exist, with the minimum number of entries needed.

- **Notes**

- When you use `selang` and choose a Policy Model as your target (using hosts `pmd@hostname`), queries to `sepmdd` apply to the PMDB but not to the various subscribers' databases.
- Ensure that a PMDB does not become a subscriber of itself. If a PMDB is subscribed to itself, the Policy Model may block or the network may become overloaded, filling the disk in the process.
- You cannot specify more than one user with the `newusr` command when you are working in the UNIX environment using `selang` to update a Policy Model.
- You cannot specify more than one group in the `newgrp` command when you are working in the UNIX environment using `selang` to update a Policy Model.
- When updating UNIX file attributes from `selang`, the Policy Model generates a message stating that the command has been passed to its subscribers.
- When working on a Policy Model, you cannot query the status of Windows file attributes.
- The `sepmdd` service remains active indefinitely until deactivated with the `-k` options.

## seagent Daemon

### Valid on UNIX

The `seagent` daemon accepts requests from remote stations, and applies them to the local Privileged Access Manager and UNIX databases, or to the PMDBs. This daemon also checks that the Watchdog daemon `seoswd` is running, and if it is not, restarts it.

#### NOTE

When you load Privileged Access Manager (`seload`) it also starts `seagent`; this daemon does not work independently and cannot be started using the `seagent` command.

`Seagent` waits for connections on the `seoslang2` TCP service (whose default value is 8891). When a connection request arrives, `seagent` forks a child process to handle the communication on the connection, and continues waiting for new connections.

The child processes of `seagent` get the requests from the client, and apply them to the local database.

The Agent is also responsible for the following points:

- Updating the UNIX user file `/etc/passwd`, the system shadow password file, and the UNIX group file `/etc/group`
- Alerting Policy Model daemons when an update is sent
- Alerting the parent Policy Models of both the local host and any Policy Model on the machine when a subscriber station (that has been down) is available for updating

Privileged Access Manager uses only port 8891. We recommended that you do not change this port.

The `seagent` agent uses the RPC mechanism and therefore the portmapper must be running on the local machine. For more information about the portmapper, check your system documentation.

This command has the following format:

```
seagent
```

**NOTE**

- [seoswd Daemon](#)
- [sepmdd Daemon \(UNIX\)](#)

**CA Privileged Access Manager Server Control Agent****Valid on Windows**

The Privileged Access Manager Agent service communicates with Privileged Access Manager clients through a proprietary application protocol over TCP/IP and manages security for Windows native resources. The Privileged Access Manager Agent service also checks that the Watchdog service is running, and if it is not, restarts it.

**NOTE**

When you load Privileged Access Manager it also starts the agent service; this service does not work independently.

You can run Privileged Access Manager agent service from a command-prompt window. This command has the following format:

```
seagent [start|remove|debug]
```

- **Start**  
Specifies to start the Privileged Access Manager agent service
- **Remove**  
Specifies to remove the Privileged Access Manager agent service from the operating system
- **Debug**  
Specifies to run the Privileged Access Manager agent service as a console for debugging purposes

**seosd Daemon****Valid on UNIX**

The Privileged Access Manager authorization daemon. The executable file seosd is the main Privileged Access Manager daemon. A daemon is a process that has disconnected from both its controlling TTY and its parent process. The Privileged Access Manager daemon makes the runtime decisions that are required to grant or deny access to a resource.

Only root can invoke seosd, and only a user with the ADMIN or OPERATOR attribute can shut it down.

The Privileged Access Manager daemon opens, reads, and updates the database. No other process can access this database while the Privileged Access Manager daemon is running. The Privileged Access Manager daemon also blocks any write, delete, or rename access to critical files. These files include the Privileged Access Manager audit and trace files and, optionally, the Privileged Access Manager binary files.

The seosd executable becomes a daemon only if one or both of the following conditions are true:

- The trace messages are not sent to the screen. You set the trace\_to token in the seos.ini file to *file*, *file*, *stop*, or *none*.
- You specify no argument (except-d) on the command line when invoking the utility.

If none of these conditions are true, seosd remains a regular process, which is connected to the terminal from which you invoked it.

During startup, seosd also invokes the following processes:

- seagent, the Privileged Access Manager agent daemon.
- seoswd, the Privileged Access Manager watchdog daemon.

The Privileged Access Manager daemon is initialized only after these daemons are also running. After initialization, these three daemons maintain a type of handshaking protocol to ensure that they are all alive and responding. If one of these daemons is found to be absent, one of the other two daemons automatically restarts it.

This command has the following format:

```
seosd [-d|argument]
```

#### NOTE

If you enter seosd with no arguments, it runs seosd as a daemon.

- *argument*  
Ignored. However, if you specify an argument, seosd remains a regular process.
- **-d**  
Runs seosd as a daemon and forces tracing to the trace\_file.

## Authorization Engine Service

### Valid on Windows

The Privileged Access Manager authorization engine manages access request decisions and database updates.

The Privileged Access Manager engine opens, reads, and updates the database. No other process can access this database while the Privileged Access Manager engine is running. The Privileged Access Manager engine also blocks any write, delete, or rename access to critical files. These files include the Privileged Access Manager audit and trace files and, optionally, the Privileged Access Manager binary files.

During startup, the engine service also invokes the following services:

- The Privileged Access Manager agent service.
- The Privileged Access Manager watchdog service.

The Privileged Access Manager engine service is initialized only after these services are also running. After initialization, these three services maintain a type of handshaking protocol to ensure that they are all alive and responding. If one of these services is found to be absent, one of the other two services automatically restarts it.

This command has the following format:

```
Seosd -start [<counter>]
Seosd -debug
```

- **-start [<counter>]**  
Starts Privileged Access Manager services and waits for a specified interval to verify that the services started.

#### NOTE

If you do not specify <counter>, Privileged Access Manager does not wait to check whether the services started.

- **-debug**  
Runs the utility as a console application for debug purposes.

#### NOTE

If you run seosd without any arguments, seosd executes as a service.

## selogrcd Daemon Collect Audit Records

### Valid on UNIX

Collector daemon for the Privileged Access Manager log routing system.

**Note:** selogrcd does not work in IPv6-only environments.

The Privileged Access Manager log routing daemons, selogrd and selogrcd, provide system administrators with convenient, selective access to the audit log records.

The selogrcd utility is the collection daemon. This daemon collects the selected audit log records sent by various satellite systems and stores them in the audit collection file. The default file is *ACInstallDir/log/seos.collect.audit*.

Two tokens enhance audit collection file management. Both tokens are in the [selogrd] section of the seos.ini file

- Use the Caudit\_size token to specify the maximum size of the audit collection file. When the file reaches this size, Privileged Access Manager creates a backup file and opens a new file.
- Use the CbackUp\_Date token to specify an automatic backup interval and timestamp for the audit collection file.

You can force selogrcd to start a new audit file by sending it a USR1 signal. Once you have the selogrcd process ID, send it a USR1 signal using a kill command such as:

```
kill -USR1 processID
```

When it receives a USR1 signal, selogrcd renames the existing audit file to *ACInstallDir/log/seos.collect.bak* and creates an audit file. You can also use a cron job to perform this task periodically. A sample script that performs this task is provided in the directory *ACInstallDir/samples/selogrcd*.

### NOTE

You can expand the functionality of the selogrcd daemon by writing programs at your site that use the APIs provided with Privileged Access Manager. For more information, see the *SDK Guide*.

This command has the following format:

```
selogrcd [-d] [-l lock-file-name]
```

- **-d**  
Specifies the debug mode. In this mode, selogrcd does not become a daemon. It sends debug information to the terminal.
- **-h**  
Displays the help for this utility.
- **-l lock-file-name**  
Specifies the name of the lock file to be used (*lock-file-name*). By default, selogrcd uses the file *ACInstallDir/lock/selogrcd*.

### NOTE

If you set selogrd to work on a different log file (such as a PMDB log file), the lock file has an extension based on the PMDB name or the data file name that was used as the parameter for the [selogrd command](#).

## selogrd Daemon Emit Audit Records

### Valid on UNIX

Emitter daemon for the Privileged Access Manager log routing system.

**Note:** selogrd does not work in IPv6-only environments.

The Privileged Access Manager log routing, daemons selogrd and selogrcd, provide system administrators with convenient, selective access to the audit log records.

The selogrd utility is the emitter daemon. This daemon performs the following tasks:

- Distributes selected local audit log records to the various destination hosts
- Reformats audit log records into email messages, ASCII files, or user windows
- Sends out notification messages that are based on audited events

#### NOTE

The Privileged Access Manager daemon must be up and running before the log routing daemons can collect any meaningful information on Privileged Access Manager events. If the Privileged Access Manager daemon is not running, selogrd routes only old audit records.

The log routing daemons use a configuration file to determine where each audit log record is sent, the format in which the log record is written, and which records are routed. By default, selogrd uses the *ACInstallDir/log/selogrd.cfg* audit log route configuration file. The names of the configuration file and other global environment variables that selogrd and selogrcd use are specified in the Privileged Access Manager initialization file, *seos.ini*.

The selogrd daemon periodically restarts and reads the configuration file. In addition, you can force the selogrd daemon to restart at a specified time. To do so, you must send the following HUP signal:

```
kill -HUP processID
```

- *processID*  
Defines the selogrd process ID. (Use the UNIX *ps* command to find it; see your UNIX documentation for more information.)

The selogrd utility provides API access for programmers working under Privileged Access Manager. The Logroute API allows programmers to incorporate their own options into the Privileged Access Manager audit log system to support in-house alerts that are not provided by the current log-routing facility. The Logroute API also allows programmers to use the log routing daemons to provide functions to their own programs. For more information about all the Privileged Access Manager APIs, see the *SDK Developer Guide*.

This command has the following format:

```
selogrd [-audit fileName] [-config fileName] [-d] \
[-data fileName] [-pmdb policy-model-name]
```

- **-audit *fileName***  
Defines the audit file to use instead of the file that is listed in *seos.ini* for the input audit file.
- **-config *fileName***  
Defines the configuration file to use instead of the file that is listed in *seos.ini* for the configuration file.
- **-d**  
Specifies to print debug messages.
- **-data *fileName***  
Defines the data file to use instead of the file that is listed in *seos.ini* to store routing progress information.
- **-h**  
Displays the help for this utility.
- **-pmdb *policy-model-name***  
Instructs selogrd where to route audit data from a PMDB. The command tells selogrd to send audit data from the PMDB that you specified in the command, to the audit file that you specified in the *audit\_log* token in the *pmd.ini* file of the PMDB.  
By default, selogrd uses the data file and lock file that consist of the Policy Model name. If you specify the data file or lock file or both on the command line, those files override the default values. The lock file and data file names should be different from those of the selogrd that route the audit data of the station. selogrd can only support Policy Model names of 12 characters.  
The audit data that is sent from a PMDB appears in the collected audit file as if it comes from a station with the name *policy-model-name@station-name*

## Task Delegation Service

### Valid on Windows

The task delegation service (SeSudo.exe) grants the required rights and privileges to ordinary users to enable them to perform administrative tasks while not being members of Windows high privileged groups. Example: the Administrators group.

When a user attempts to perform an administrative task, such as to start or stop a Windows service, the task delegation service performs these tasks:

1. Communicates with the Privileged Access Manager engine service to verify that the user has is authorized to perform the task.
2. The Privileged Access Manager engine service does the following:
  - a. If the user is authorized to run the task, the Privileged Access Manager engine service authorizes the task delegation service to run the task.
  - b. If the user is not authorized to run the task, the Privileged Access Manager engine blocks the attempt.

Run the Privileged Access Manager task delegation service from a command-prompt window using the `sesudo` command. This command has the following format:

```
sesudo [-do [record] [parameters]] -list | -h]
```

- **-do [record] [parameter]**  
Specifies to execute the commands that are embedded in the [record] field with additional parameters
- **-list**  
Specifies to display a list available records that the user can execute
- **-h**  
Specifies to display the command help menu

### seoswd Daemon

#### Valid on UNIX

The Privileged Access Manager watchdog daemon.

The watchdog (seoswd) monitors the file information and digital signatures of programs that are defined in the database as trusted programs. Monitoring is performed in the background with a minimal load on the system. The Privileged Access Manager agent daemon seagent automatically starts seoswd.

The seoswd daemon performs the following functions:

- Monitors the programs that you defined in the PROGRAM class of the database. If the watchdog detects that a program was modified, it notifies the Privileged Access Manager daemon, seosd, which marks the program as

untrusted. The seosd daemon does not allow an untrusted program to run. The seosd daemon also marks the program's status change to untrusted in the database and creates an audit record.

- Monitors files that are defined as secured files. These files are defined in the SECFILE class in the database.
- Monitors seosd to ensure it is running. If the watchdog detects a problem with seosd, it automatically restarts it.
- The seoswd daemon uses the system log syslogd to notify the security administrators when it detects that seosd has stopped responding. All system log messages are submitted as AUTH facility. For more information on the system log facility, see your system man pages under the syslogd and syslog.conf sections.
- Reports several events to Privileged Access Manager, and creates audit records for programs and secured files that were found to be altered.
- Allows you to specify interval and fixed scanning schedules for trusted programs and secure files.
- The watchdog ignores any signal except SIGHUP; you cannot kill the seoswd daemon unless you first shut down seosd. However, if you execute the command `kill -SIGHUP pid`, the watchdog scans all trusted programs and secure files in the database.

There are two ways in which you can set up the Watchdog scanning mechanism:

1. Determine a start time and then repeat scans at a given interval.  
For example, when checking trusted programs, the Watchdog will start the first scan at *PgmTestStartTime* and will check all the trusted programs. Rescanning will take place *PgmTestInterval* seconds after the beginning of the previous scan.
2. Scan at given times.

#### NOTE

In both cases, the Watchdog will sleep periodically for a predetermined rest period (*PgmRest* seconds) during each scan. The Watchdog rests in order to prevent system overload.

You can choose to use one mechanism or both simultaneously. For example, starting at 12:00, scan every 4 hours as well as at 13:00 and 17:30.

In addition to the above mentioned mechanisms for routine scanning of the trusted programs and secured files, there is a way to perform a one-time scan on demand by sending a HUP signal (see token *SignalMinInterval*).

If you invoke seoswd without an argument, it runs as a daemon. If you invoke seoswd with the `-d` argument, it runs as a daemon, but displays all debug information on the terminal from which you invoked it.

## Watchdog Service

### Valid on Windows

The watchdog monitors the file information and digital signatures of programs that are defined in the database as trusted programs. Monitoring is performed in the background with a minimal load on the system. The Privileged Access Manager agent service automatically starts the watchdog service.

The watchdog service performs the following functions:

- It monitors the programs that you defined in the PROGRAM class of the database. If the watchdog detects that a program was modified, it notifies the Privileged Access Manager Engine, which marks the program as untrusted. The

engine service does not allow an untrusted program to run. The engine service also marks the status change of the program to untrusted in the database and creates an audit record.

- It monitors files that are defined as secured files. These files are defined in the SECFILE class in the database.
- It monitors the Privileged Access Manager engine service to ensure it is running. If the watchdog detects a problem with the service, it automatically restarts it.
- The service uses the system log to notify the security administrators when it detects that the engine service has stopped responding. All system log messages are submitted as AUTH facility.
- It reports several events to Privileged Access Manager, and creates audit records for programs and secured files that were found to be altered.
- It allows you to specify interval and fixed scanning schedules for trusted programs and secure files.

You can run Privileged Access Manager watchdog service from a command-prompt window. This command has the following format:

```
seoswd [start|remove|debug]
```

- **Start**  
Specifies to start the Privileged Access Manager watchdog service
- **Remove**  
Specifies to remove the Privileged Access Manager watchdog service from the operating system
- **Debug**  
Specifies to run the Privileged Access Manager watchdog service as a console for debugging purposes

## uxchecklogin Utility

### Valid on UNIX

The UNAB uxchecklogin utility simulates a user login to the endpoint. It is a useful tool for troubleshooting login problems. This utility drives the Pluggable Authentication Modules (PAM) stack using arguments that you specify on the command line and displays results of the integration progress from a particular service.

This command has the following format:

```
uxchecklogin [-u <user> [-w <password>]] [-s <servicename>] [-l <loops>] [-nonstop]
```

- **-u <user>**  
A username. If you do not supply a username, a temporary local user is created local storage. The username is used for the test, and deleted when the test is complete.
- **-w <password>**  
A user password. If you do not supply a password here, you supply one during the test.
- **-s <service>**  
The name of a service that is used for the test.
- **-l <loops>**  
The number of calls to the entire Pluggable Authentication Modules stack. By default, the Pluggable Authentication Modules stack is called once.
- **-nonstop**  
Do not stop the test because of Pluggable Authentication Modules stack returned values.

### Example

This example uses the username georgew and the sshd service.

```
/tmp> uxchecklogin -s sshd -u georgew
```

CA ControlMinder UNAB uxchecklogin v14.1.00.000 - Check user login

Copyright (c) 2013 CA. All rights reserved.

Password for georgew:

pam\_start OK.

pam\_set\_item PAM\_RHOST OK

pam\_set\_item PAM\_RUSER OK.

pam\_set\_item PAM\_TTY OK.

pam\_set\_item PAM\_OLDAUTHTOK OK.

pam\_set\_item PAM\_AUTHTOK OK.

-- Calling PAM stack --

Calling pam\_authenticate()

my\_converse() called, style of first msg is 1.

asked to prompt: 'Password: '

returning: '\*\*\*\*\*'

pam\_authenticate() returned PAM\_SUCCESS

Calling pam\_acct\_mgmt()

pam\_acct\_mgmt() returned PAM\_SUCCESS

Calling pam\_setcred()

pam\_setcred() returned PAM\_SUCCESS

```
Calling pam_open_session()

pam_open_session() returned PAM_SUCCESS

-- End of PAM stack call --

Test ended, return code is PAM_SUCCESS.
```

## postupdate-nss-gr Utility

### Valid on UNIX

The postupdate-nss-gr utility remaps UNAB-managed group data. Remapping uses the group name as the key while searching for an entry to be changed. It can modify name and gid attributes or both. To enable remapping, fill out the nss\_cache\_update\_post\_job token in the uxauth.ini file with the name of the postupdate-nss-gr utility. See [The uxauth.ini File](#).

The utility can be run in two modes: data preparation (data dump) and data remapping.

This utility has the following syntax:

```
postupdate-nss-gr -dump -v
```

- **-dump**Creates a template input file.
- **-v**Displays the mapped data and any mapping errors. You can remap group data in nss.db from the command line, with postupdate-nss-gr, rather than through the agent during UNAB runtime.

### Example

1. The following command creates the AD group data template for editing in /opt/CA/uxauth/etc/update-nss-gr.input:

```
/tmp> postupdate-nss-gr -dump
```

2. Initial data for groups that are being remapped (shown for Solaris):

```
/tmp> getent group | egrep 'staff|ingres|dba'

staff::1:

ingres::201:

dba::206:
```

```
dbadmin::61098:
```

```
busdba::61127:
```

3. The following is the content of the input file /tmp> head -12 /opt/CA/uxauth/etc/update-nss-gr.input:

```
#####
#          CA Technologies, Inc.   (c) 2017          #
#  #
#  Remapping rules for names and gid settings of AD groups in      #
#  UNAB's nss.db database.  Lines that start with # are comments.  #
#  A new setting of - means that the current value should remain   #
#  as is.  Group names are indexed, so they should be unique.     #
#####
#  Current name      =>  new group name          curgid => newgid
staff                =>  -                        ##   100 => -
ingres               =>  -                        100 => -
dba                  =>  -                        206 => -
```

4. The following is an example of the input file after editing:

```
#####
#          CA Technologies, Inc.   (c) 2017          #
#  #
#  Remapping rules for names and gid settings of AD groups in      #
#  UNAB's nss.db database.  Lines that start with # are comments.  #
#  A new setting of - means that the current value should remain   #
#  as is.  Group names are indexed, so they should be unique.     #
#####
```

#	Current name	=> new group name	curgid => newgid
	staff	=> ad_staff	100 => -
	ingres	=> ad_ingres	100 => 100
	dba	=> -	206 => 100

**NOTE**

Group names must comply with operating system restrictions, such as group name length. When entering new group names or a group id, consider that the UNIX/Linux name switch (NSS) facility exhibits an "aliasing" effect when several groups have the same group id.

5. You can apply mappings immediately, or by the agent during UNAB runtime. Applying them immediately can verify that mapping rules work as expected. The agent applies the mapping rules directly rather than through the corresponding update tool. The agent applies mapping rules to nss.db as a post update after it gets the data from AD. In the example below, the utility uses the -v argument to show its actions and warn about malformed input lines:

```
/tmp> postupdate-nss-gr -v

Changed group 'staff' attributes to ('ad_stuff', 100)

Changed group 'ingres' attributes to ('ad_ingres', 100)

Changed group 'dba' attributes to ('dba', 100)
```

**Using the Sekmodutil Tool**

The sekmodutil tool lists SEOS kernel modules for the current system, or for a specific OS, distribution or release. In addition, it allows users to remove unrelated kernel modules to save disk space. This tool can be distributed as a standalone tool to the existing installations and it will be included in the full installation package. You can access the following information by using the "sekmodutil -h".

**NOTE**

This tool has been integrated into the installers, both legacy installation and native installation, for Linux to remove kernel modules that support Linux distros other than the current system. By default, installers will remove unrelated modules. When doing installation interactively, the installer will prompt the following messages and the user can choose to keep those modules or not.

```
-----[ Clean up SEOS_syscall Modules ]-----
For Linux, the installer will install all SEOS_syscall modules from the
installation package.
This includes modules for other Linux distributions. For example, modules for
SLES, Oracle
Linux, or Ubuntu will also be installed on an RHEL system.

Do you want to keep unrelated SEOS_syscall modules? [N/y]:
```

During the installation, sekmodutil installs under the lbin subdirectory. The installer also creates sekmodcleanup as a symbolic link to sekmodutil. When running sekmodcleanup, it runs as "sekmodutil -x" to remove unrelated modules of the current system.

## Usage

This script, by default, lists SEOS\_syscall kernel modules for the specific OS and distro, if applicable, in the installed or specified directory.

```
Usage: sekmodutil [-D install_bin_dir] [-o OS] [-d distro]
        [-r major_release] [-m] [-x]
```

```
sekmodutil [-h]
```

## Arguments

- h      Print usage. All other arguments will be ignored.
- D install\_bin\_dir  
      Specify the directory where SEOS\_syscall modules are installed. If not specified, the default is the current installation bin directory.
- o OS  
      Select SEOS\_syscall modules for the specified OS. If not specified, the default is the current system. Valid values are: Linux, SunOS (Solaris), AIX or HP-UX. (case insensitive)
- d distro  
      For Linux only. Specify the distribution of the Linux system. This will be ignored if the OS is not Linux. If not specified and the current system is not Linux, this script will terminate with an error. If not specified and the current system is Linux, the default is the current system's distribution. Valid values are: Redhat, RHEL, Suse, SLES, Oracle, OEL, Ubuntu, CentOS, VMware or Debian. (case insensitive)
- r major\_release  
      Specify the major release. If not specified and the current system's OS matches with the OS specified, the default is the current system's release. If not specified and the current system's OS does not match with the OS specified, the default is all. Valid values are:  
       Redhat/Oracle/CentOS: 5, 6, 7, 8 or all  
       SuSE: 10, 11, 12, 15 or all  
       Ubuntu: 12.04, 14.04, 16.04, 17.04, 18.04 or all  
       Solaris: 8, 9, 10, 11 or all  
       AIX: 5.2, 5.3, 6.1, 7.1, 7.2 or all  
       HP-UX: 11.11, 11.23, 11.31 or all

This argument does not support VMware or Debian.

-x  
Remove all other modules. This argument will be ignored if the kernel module for the current host system could be removed.

### Examples

1. To list related SEOS kernel modules for the current host system: # sekmodutil
2. To list related SEOS kernel modules for the current host system and remove unrelated modules: # sekmodutil -x
3. To list SEOS kernel modules for RHEL 7: # sekmodutil -o linux -d rhel -r 7
4. To list SEOS kernel modules for all versions of Oracle Linux, # sekmodutil -o linux -d oracle -r all
5. To remove kernel modules that support other Linux distro, # sekmodutil -r all -x

## Audit Log Records

### Audit Event Types

The information Privileged Access Manager stores in the audit log is determined by the type of event it audits.

### Login Event

Login events describe an attempt to log in to Privileged Access Manager or a Privileged Access Manager protected host.

Audit records in this event have the following format:

```
Date Time Status Event UserName SessionID Details Reason Terminal Program AuditFlags
```

- **Date**

Identifies the date the event occurred.

**Format:** DD MMM YYYY

**NOTE**

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

**NOTE**

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Status**

Indicates the return code for the event.

**Values:** Can be one of:

- D (Denied) Denied the event because of insufficient authorization.
- P (Permitted) Permitted the event.
- W (Warning) Permitted the event because Warning mode is set although the access request violates an access rule.

- **Event**

Identifies the type of event this record belongs to.

**NOTE**

Privileged Access Manager Endpoint Management refers to this field simply as *Event*.

- **UserName**

Identifies the name of the accessor that performed the action that triggered this event.

- **SessionID**

Identifies the accessor's session ID.

**NOTE**

By default this field does not appear in a non-detailed seaudit output. To display this field in a non-detailed seaudit output, specify the `-sessionid` option in the seaudit command.

- **Details**

Indicates at which stage Privileged Access Manager decided what action to take for this event.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the authorization stage code. For a complete list of stage codes, run `seaudit -t`.

- **Reason**

Indicates the reason that Privileged Access Manager wrote an audit record.

**NOTE**

This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run `seaudit -t`.

- **Terminal**

Identifies the name of the terminal that the accessor used to connect to the host.

- **Program** Identifies the name of the program that triggered the event. That is, the program that the accessor used to try to log in. For Privileged Access Manager administration login, this is the module that logged in (selang, Web Service, and so on).

- **AuditFlags**

Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.

**NOTE**

If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

## Example: Login Event Message

The following audit record was taken from a detailed seaudit output.

```
28 Oct 2008 12:15:01 P LOGIN root 49047159:0000034b 59 2 _CRONJOB_ SBIN_CRON
Event: Login event
Status: Permitted
UserName: root
Terminal: _CRONJOB_
Program: SBIN_CRON
Date: 28 Oct 2008
Time: 12:15
```

```

Details: Resource UACC check
SessionID: 49047159:0000034b
AuditFlags: AC database user

```

This audit record indicates that on October 28th 2008, at 12:15:01 user root logged in to the protected host from terminal `_CRONJOB_` and ran a `SBIN_CRON` program. Privileged Access Manager permitted the operation because the resource's default access permissions permit this action (authorization stage code 59Resource UACC check). The product logged this event because the accessor's audit mode specifies that this event should be logged (reason code 2User audit mode requires logging).

## Logout Event

### Valid on UNIX

Logout events describe an attempt to log out from Privileged Access Manager or a Privileged Access Manager protected host.

#### NOTE

Logout events are only supported on UNIX. Privileged Access Manager does not actually intercept logout. Instead, it assumes logout occurs when the last process for the session terminates.

Audit records in this event have the following format:

```
Date Time Status Event UserName SessionID Details Reason Terminal AuditFlags
```

- **Date**

Identifies the date the event occurred.

**Format:** DD MMM YYYY

#### NOTE

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

#### NOTE

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Status**

Indicates that a user logout occurred.

**Value:** O (Logout)

- **Event**

Identifies the type of event this record belongs to.

#### NOTE

Privileged Access Manager Endpoint Management refers to this field simply as *Event*.

- **UserName**

Identifies the name of the accessor that performed the action that triggered this event.

- **SessionID**

Identifies the accessor's session ID.

#### NOTE

By default this field does not appear in a non-detailed seaudit output. To display this field in a non-detailed seaudit output, specify the `-sessionid` option in the seaudit command.

- **Details**

Indicates at which stage Privileged Access Manager decided what action to take for this event.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the authorization stage code. For a complete list of stage codes, run `seaudit -t`.

- **Reason**

Indicates the reason that Privileged Access Manager wrote an audit record.

**NOTE**

This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run `seaudit -t`.

- **Terminal**

Identifies the name of the terminal that the accessor used to connect to the host.

- **AuditFlags**

Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.

**NOTE**

If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

### Example: Logout Event Message

The following audit record was taken from a detailed seaudit output.

```
29 Jan 2009 17:23:33 O LOGOUT root 49 2 computer.com
Event type: Logout
Status: Logout
User name: root
Terminal: computer.com
Date: 29 Jan 2009
Time: 17:23
Details: Logout detected after last process terminated
Audit flags: AC database user
```

This audit record indicates that on January 29th 2009, Privileged Access Manager detected that the last session process for the user root working on the remote terminal computer.com has closed, and so assumes that the user logged out of the system (authorization stage code 49Logout detected after last process terminated).

### Login Account Enabled Event

#### Valid on UNIX

Login account enabled events describe events where serevu enables a user log in.

Audit records in this event have the following format:

```
Date Time Status Event UserName Details Reason Terminal Program AuditFlags
```

- **Date**

Identifies the date the event occurred.

**Format:** DD MMM YYYY

**NOTE**

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

**NOTE**

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Status**

Indicates serevu enabled user login.

**Value:** E (Login enabled)

- **Event**

Identifies the type of event this record belongs to.

**NOTE**

Privileged Access Manager Endpoint Management refers to this field simply as *Event*.

- **UserName**

Identifies the name of the accessor that performed the action that triggered this event.

- **Details**

Indicates at which stage Privileged Access Manager decided what action to take for this event.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the authorization stage code. For a complete list of stage codes, run seaudit -t.

- **Reason**

Indicates the reason that Privileged Access Manager wrote an audit record.

**NOTE**

This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run seaudit -t.

- **Terminal**

Identifies the name of the terminal that the accessor used to connect to the host.

- **Program**

Identifies the name of the program that triggered the event.

- **AuditFlags**

Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.

**NOTE**

If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

### Example: Login Account Enabled Event Message

The following audit record was taken from a detailed seaudit output.

```
13 Jan 2009 17:05:00 E LOGINENABLE test1 0 5 computer.com serevu
Event type: Login account enabled
Status: Login enabled
User name: test1
Details: Stage code 0
```

```

Terminal: computer.com
Date: 13 Jan 2009
Time: 17:05
Program: serevu
Audit flags: AC database userLogin account disable -

```

This audit record indicates that on January 13th 2009, the serevu daemon enabled user test1 to log in from the terminal computer.com. Privileged Access Manager logged this event because the serevu daemon requested the audit (reason code 5CA Privileged Access Manager serevu utility requested auditing).

## Login Account Disabled Event

### Valid on UNIX

Login account disabled events describe events where serevu disables a user log in.

Audit records in this event have the following format:

```
Date Time Status Event UserName Details Reason Terminal Program AuditFlags
```

- **Date**

Identifies the date the event occurred.

**Format:** DD MMM YYYY

**NOTE**

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

**NOTE**

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Status**

Indicates serevu disabled user login.

**Value:** I (Login disabled)

- **Event**

Identifies the type of event this record belongs to.

**NOTE**

Privileged Access Manager Endpoint Management refers to this field simply as *Event*.

- **UserName**

Identifies the name of the accessor that performed the action that triggered this event.

- **Details**

Indicates at which stage Privileged Access Manager decided what action to take for this event.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the authorization stage code. For a complete list of stage codes, run seaudit -t.

- **Reason**

Indicates the reason that Privileged Access Manager wrote an audit record.

**NOTE**

This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run seaudit -t.

- **Terminal**

Identifies the name of the terminal that the accessor used to connect to the host.

- **Program**

Identifies the name of the program that triggered the event.

- **AuditFlags**

Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.

**NOTE**

If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

**Example: Login Account Disabled Event Message**

The following audit record was taken from a detailed seaudit output.

```
13 Jan 2009 16:53:26 I LOGINDISABLE test1          0  5 computer.com      serevu
Event type: Login account disable
Status: Login disabled
User name: test1
Terminal: computer.com
Date: 13 Jan 2009
Time: 16:53
Program: serevu
Details: Stage code 0
User Logon Session ID: 496b629c:00000003
Audit flags: AC database user
```

This audit record indicates that on January 13th 2009, the serevu daemon prevented user test1 from logging in from the terminal computer.com. Privileged Access Manager logged this event because the serevu daemon requested the audit (reason code 5CA Privileged Access Manager serevu utility requested auditing).

**Password Attempt Event****Valid on UNIX**

Password attempt events describe an attempt by an accessor to log in with an incorrect password.

Audit records in this event have the following format:

```
Date Time Status Event UserName Details Reason Terminal Program AuditFlags
```

- **Date**

Identifies the date that the event occurred.

**Format:** DD MMM YYYY

**Note:** Privileged Access Manager Endpoint Management formats the date display according to your computer settings.

- **Time**

Identifies the time that the event occurred.

**Format:** HH:MM:SS

**Note:** Privileged Access Manager Endpoint Management formats the time display according to your computer settings.

- **Status**  
Indicates an incorrect password attempt.  
**Value:** A (Password attempt)
- **Event**  
Identifies the type of event this record belongs to.  
**Note:** Privileged Access Manager Endpoint Management refers to this field simply as *Event*.
- **UserName**  
Identifies the name of the accessor that performed the action that triggered this event.
- **Details**  
Indicates at which stage Privileged Access Manager decided what action to take for this event.  
**Note:** The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message that is associated with the authorization stage code. For a complete list of stage codes, run seaudit -t.
- **Reason**  
Indicates the reason that Privileged Access Manager wrote an audit record.  
**Note:** This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record that you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run seaudit -t.
- **Terminal**  
Identifies the name of the terminal that the accessor used to connect to the host.
- **Program**  
Identifies the name of the program that triggered the event.
- **AuditFlags**  
Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.  
**Note:** If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

#### Example: Password Attempt Event Message

The following audit record was taken from a detailed seaudit output.

```
13 Jan YYYY
16:21:12 A LOGIN          admin          17  8 localhost.localdomain login

Event: Password attempt

Status: Password attempt

UserName: admin

Terminal: localhost.localdomain

Date: 13 Jan YYYY

Time: 16:21

Program: login
```

Details: Attempt rejected by the native environment

User Logon Session ID: 525f8d59:0000010a

AuditFlags: AC database user

This audit record indicates that on January 13, YYYY, the user admin attempted to change the account password. The attempt was rejected by the native environment because of a login failure (authorization stage code 17 attempt rejected by the native environment). The pam\_seos module logged this event (reason code 8 pam support UNIX failed login).

## Resource Access Event

Resource access events describe access attempts to resources, for example, FILE, TERMINAL, PROGRAM, and more. The audit record data in this event can appear in other records, for example, a LOGIN event when an accessor attempts to access a TERMINAL resource. Although the event record in this case is of the LOGIN type, the audit record data that appears in the record is one of the Resource Access Event messages.

Audit records in this event have the following format:

```
Date Time Status Class UserName SessionID Access Details Reason Resource Program Terminal EffectiveUserName
AuditFlags
```

### NOTE

In UNIX or Linux, the *AuditFlags* parameter precedes the *EffectiveUserName* parameter

- **Date**

Identifies the date the event occurred.

**Format:** DD MMM YYYY

### NOTE

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

### NOTE

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Status**

Indicates the return code for the event.

**Values:** Can be one of:

- D (Denied)Denied the event because of insufficient authorization.
- P (Permitted)Permitted the event.
- W (Warning)Permitted the event because Warning mode is set although the access request violates an access rule.
- N (Notify)Permitted the event and notifies that an attempt to access a permitted resource occurred.
- F (Failed)Permitted, but the Operating System command failed.

- **Class**

Identifies the class that the resource being accessed belongs to.

- **User Name**

Identifies the name of the accessor that performed the action that triggered this event.

- **User Logon Session ID**

Identifies the accessor's session ID.

**NOTE**

By default this field does not appear in a non-detailed seaudit output. To display this field in a non-detailed seaudit output, specify the `-sessionid` option in the seaudit command.

- **Access**

Identifies the type of attempted access that triggered this event.

**Example:** Read

**NOTE**

Access values depend on the class the intercepted resource belongs to. For more information on the access authority for each class, see the *selang Reference Guide*.

- **Details**

Indicates at which stage Privileged Access Manager decided what action to take for this event.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the authorization stage code. For a complete list of stage codes, run `seaudit -t`.

- **Reason**

Indicates the reason that Privileged Access Manager wrote an audit record.

**NOTE**

This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run `seaudit -t`.

- **Resource**

Identifies the name of the actual resource that is being accessed or updated.

- **Program**

Identifies the name of the program that triggered the event. That is, the program that the accessor used to try to access the resource.

- **Terminal**

Identifies the name of the terminal that the accessor used to connect to the host. (UNIX and Windows.)

- **Effective User Name**

Identifies the name of the native OS effective user that triggered this event. This is different from the user name if the user substitutes (surrogates) to a different user or runs a `setuid` program.

- **Audit Flags**

Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.

**NOTE**

If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

### Example: Resource Access Event Message

The following audit record is taken from a detailed seaudit output.

```
18 Nov 2008 15:23:56 D FILE          admabc  4922ae61:00000132 Read      69   3 /tmp/one          /usr/
local/bin/tcsh localhost      admabc
Event type: Resource access
Status: Denied
Class: FILE
Resource: /tmp/one
Access: Read
User name: admabc
```

```

Terminal: localhost
Program: /usr/local/bin/tcsh
Date: 18 Nov 2008
Time: 15:23
Details: No Step that allowed access
User Logon Session ID: 4922ae61:00000132
Audit flags: AC database user
Effective user name: admabc

```

This audit record indicates that on November 18th 2008, at 15:23:56 the user admabc used UNIX tcsh shell program from the local computer to try and read the protected /tmp/one file resource. Privileged Access Manager denied the operation because there are no rules in the database that authorize this type of access (authorization stage code 69No step that allowed access). Privileged Access Manager logged this event because the resource's audit mode specifies that this event should be logged (reason code 3Resource audit mode required logging).

## Untrust Message Event

Untrust events describe warning messages that the Privileged Access Manager Watchdog generates for events.

Audit records in this event have the following format:

```
Date Time Status Class Module Details MessageID/errno File
```

- **Date**  
Identifies the date that the event occurred.  
**Format:** DD MMM YYYY  
**Note:** Privileged Access Manager Endpoint Management formats the date display according to your computer settings.
- **Time**  
Identifies the time that the event occurred.  
**Format:** HH:MM:SS  
**Note:** Privileged Access Manager Endpoint Management formats the time display according to your computer settings.
- **Status**  
Indicates untrust occurred.  
**Value:** U (Untrust)
- **Class**  
Identifies the Privileged Access Manager class that the resource that triggered the Watchdog message belongs to.  
**Values:** PROGRAM or SECFILE
- **Module Name**  
Displays the name of the Privileged Access Manager Watchdog.  
**Value:** seoswd
- **Details**  
Indicates why the untrust event occurred.  
**Note:** The audit record that you see in a non-detailed seaudit output displays a number in this field. This number is known as the untrust reason code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message that is associated with the untrust reason code. For a complete list of password quality codes, run seaudit -t.
- **Message ID**  
(UNIX only) Indicates the reason Privileged Access Manager untrusted the PROGRAM or SECFILE.  
**Note:** The audit record that you see in a non-detailed seaudit output displays a number in this field. This number is known as the status code and does not show in a detailed output or in Privileged Access Manager Endpoint

Management. To understand the status code, run `seaudit -Stat untrust_code`. This field displays only if the authorization stage code is 1. In all other cases, the `errno` field displays instead.

- **errno**

Indicates the return value of the `errno` variable (the error code for the error condition).

**Values:** can be one of:

**0**No error. This value is returned only if the authorization stage code is 1. In this case, the `errno` field is not displayed and the Message ID field displays instead.

*errno*A non-zero integer that is the error.

**Note:** To find out the meaning for the error, on UNIX, see `/usr/include/errno.h` or `/usr/include/sys/errno.h` file on the local computer. On Windows, enter the following command on the local computer: `net helpmsg errno`

- **File**

Identifies the full pathname of the protected resource that triggered the Watchdog message.

### Example: Untrust Message Event Message

The following audit record was taken from a detailed `seaudit` output.

```
18 Nov YYYY 14:01:18 U PROGRAM      seoswd                1 11776 /tmp/testsuiteid

Event type: Untrust message

Class: PROGRAM

Module name: seoswd

Message ID: 11776

Date: 18 Nov YYYY

Time: 14:01

File: /tmp/testsuiteid

Details: Stat information changed on file system

Audit flags: AC database user
```

This audit record indicates that on November 15 of the specified year, the Watchdog marked the program `/tmp/testsuiteid` as untrusted (U). The program was untrusted because the file status information was modified (untrust reason code 1File information changed on file system).

### Example: Use `seaudit -Stat` to See Why a Program Was Untrusted (UNIX)

The following `seaudit -Stat` output shows you how you can get more detailed information about the Watchdog message ID that an audit record mentions.

```
# seaudit -Stat 11776

CA PAMSC seaudit v12.01.00.45 - Audit log lister

Copyright (c) YYYY CA. All rights reserved.
```

The MODE of the file was changed

The INODE of the file was changed

The SIZE of the file was changed

The MTIME of the file was changed

Running the `seaduit -Stat` command with the message ID, displays a list of changes to the file. In this example, the MODE, INODE, SIZE, and MTIME of the file changed. As a result Privileged Access Manager marked this file as an untrusted file.

## Inbound Network Connection Event

Inbound network connection events indicate incoming traffic to the protected host. Inbound network events are audited in two forms (according to the class activation in the local database). Both audit event types contain identical information but in different view. For example, one audit event contains HOST as the class name while the other event displays TCP as the class name.

Audit records in this event have the following format:

```
Date Time Status Event Service Details Reason Host Program
```

- **Date**  
Identifies the date the event occurred.  
**Format:** DD MMM YYYY  
  
**NOTE**  
Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.
- **Time**  
Identifies the time the event occurred.  
**Format:** HH:MM:SS  
  
**NOTE**  
Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.
- **Status**  
Indicates the return code for the event.  
**Values:** Can be one of:
  - D (Denied)Denied the event because of insufficient authorization.
  - P (Permitted)Permitted the event.
  - W (Warning)Permitted the event because Warning mode is set although the access request violates an access rule.
- **Event Type**  
Identifies the type of event this record belongs to.  
  
**NOTE**  
Privileged Access Manager Endpoint Management refers to this field simply as *Event*.
- **Service**

Identifies the name of the service that the connection used.

- **Details**

Indicates at which stage Privileged Access Manager decided what action to take for this event.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the authorization stage code. For a complete list of stage codes, run seaudit -t.

- **Reason**

Indicates the reason that Privileged Access Manager wrote an audit record.

**NOTE**

This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run seaudit -t.

- **Host name**

Identifies the name of the host the network traffic originated from.

- **Program**

(UNIX only) Identifies the name of the program the accessor is attempting to run.

### Example: Inbound Network Connection Event Message

The following audit record was taken from a detailed seaudit output.

```
17 Nov 2008 12:22:04 D HOST          telnet          173  3 computer.org.com      /usr/sbin/inetd
Event type: Inbound network connection
Status: Denied
Host name: computer.org.com
Service: telnet
Program: /usr/sbin/inetd/
Date: 17 Nov 2008
Time: 12:22
Details: HOST entry day & time restrictions
Audit flags: AC database user
```

This audit record indicates that on November 17th 2008, an accessor attempting to access the host computer.org.com using the telnet service to run the inetd program was denied due to day and time restrictions imposed on the protected host (authorization stage code 173HOST entry day & time restrictions). Privileged Access Manager logged this event because the resource's audit mode specifies that this event should be logged (reason code 3Resource audit mode required logging).

### Outbound Network Connection Event

Outbound network connection events indicate outbound traffic to the protected host. Outbound network events are audited in two forms (according to the class activation in the local database). Both audit event types contain identical information but in different view. For example, one audit event contains HOST as the class name while the other event displays TCP as the class name.

Audit records in this event have the following format:

```
DateTimeStatusClassServiceUserNameDetailsReasonHostProgramTerminal AuditFlags
```

- **Date**

Identifies the date the event occurred.

**Format:** DD MMM YYYY

**NOTE**

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

**NOTE**

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Status**

Indicates the return code for the event.

**Values:** Can be one of:

- D (Denied) Denied the event because of insufficient authorization.
- P (Permitted) Permitted the event.
- W (Warning) Permitted the event because Warning mode is set although the access request violates an access rule.

- **Class**

Identifies the name of the class.

- **Service**

Identifies the name of the service that the connection used.

- **User Name**

Identifies the name of the accessor that performed the action that triggered this event.

- **Details**

Indicates at which stage Privileged Access Manager decided what action to take for this event.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the authorization stage code. For a complete list of stage codes, run seaudit -t.

- **Reason**

Indicates the reason that Privileged Access Manager wrote an audit record.

**NOTE**

This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run seaudit -t.

- **Host name**

Identifies the name of the target host.

- **Program**

Identifies the name of the program that triggered the event.

- **Terminal**

Identifies the name of the terminal that the accessor used to connect to the host.

- **User Logon Session ID**

Identifies the accessor's session ID.

**NOTE**

By default this field does not appear in a non-detailed seaudit output. To display this field in a non-detailed seaudit output, specify the -sessionid option in the seaudit command. The user logon session ID field is added only to events that were generated as a result of TCP or CONNECT class definitions.

- **Audit Flags**

Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.

**NOTE**

If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

**Example: Outbound Network Connection Event Message**

The following audit record was taken from a detailed seaudit output.

```
21 Jan 2009 15:37:43 D TCP          telnet      root        408 2 computer.org /usr/bin/telnet computer.com

Event type: Outbound network connection
Status: Denied
Host name: computer.org
Service:telnet
Program: /usr/bin/telnet
User name: Administrator
Terminal: computer.com
User name: root
Date: 21 Jan 2009
Time: 15:37:43
Details: Default access of TCP service
User Logon Session ID: 4977248c:0000012a5248
Audit flags: AC database user
```

This audit record indicates that on January 21st, 2009, the administrator opened an outgoing connection from the terminal computer.org to the computer named computer.com via the telnet service. Privileged Access Manager denied this operation because of the defaccess property of the TCP record. (authorization stage code 408Default of TCP service). Privileged Access Manager logged this event because the AUDIT\_MODE property for the accessor matches the record's result. (reason code 2User audit mode requires logging).

**Security Database Administration Event**

Security database administration events describe actions performed by a Privileged Access Manager administrator or a sub-administrator with appropriate privileges that were intercepted by the product.

Audit records in the event have the following format:

```
Date Time Status Event Class Admin Details Reason Object TerminalCommand AuditFlags
```

- **Date**

Identifies the date the event occurred.

**Format:** DD MMM YYYY

**NOTE**

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

**NOTE**

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Status**

Indicates the return code for the event.

**Values:** Can be one of:

- D (Denied) Denied the event because of insufficient authorization.
- S (Success) Permitted the event.
- F (Failed) Failed the event.

- **Event Type**

Identifies the type of event this record belongs to.

**NOTE**

Privileged Access Manager Endpoint Management refers to this field simply as *Event*.

- **Class**

Identifies the class that the resource being administered belongs to.

- **Administrator**

Identifies the name of the administrative user that executed the selang command.

- **Details**

Indicates at which stage Privileged Access Manager decided what action to take for this event.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the authorization stage code. For a complete list of stage codes, run seaudit -t.

- **Reason**

Indicates the reason that Privileged Access Manager wrote an audit record.

**NOTE**

This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run seaudit -t.

- **Object**

Identifies the name of the resource that is being administrated.

- **Terminal**

Identifies the name of the terminal that the accessor used to connect to the host.

**NOTE**

If the command originated from a parent policy model, this field displays the fully qualified PMD name.

- **Command**

Displays the selang command that the user executed.

- **Audit Flags**

Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.

**NOTE**

If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

- **Command type**

Identifies the type of the database administration command that this event describes.

Values can be one of:

- **Add user:** For newusr command
- **Add group:** For newgrp command
- **Add resource:** For newres or newfile commands
- **Modify user:** For chusr command
- **Modify group:** For chgrp command
- **Modify group membership:** For join command
- **Modify resource:** For chres command
- **Modify resource access:** For authorize command
- **Remove user:** For rmusr command
- **Remove group:** For rmgrp command
- **Remove resource:** For rmres or rmfile commands
- **Set options:** For setoptions command
- **Add/Modify user:** For editusr command
- **Add/Modify group:** For editgrp command
- **Add/Modify resource:** For editres or editfile commands
- **Administrative command:** For other commands

### Example: Security Database Administration Event Message

The following audit record was taken from a detailed seaudit output.

```
05 Nov 2008 15:45:12 S UPDATE      FILE      DOMAIN_NAME\computer 305  0 dfdok      computer.com cr file
dfdok defacc(r)
Event type: Security database administration
Command type: Modify resource
Status: Successful
Administrator: DOMAIN_NAME\computer
Class: FILE
Object: dfdok
Terminal: computer.com
Date: 05 Nov 2008
Time: 15:45
Details: Command successful for ADMIN user.
Command: cr file dfdok defacc(r)
Audit flags: AC database user
```

This audit record indicates that on November 5th 2008, Privileged Access Manager denied access from an administrator attempting to update a file by executing the command `cr file dfdok defacc(r)` on the protected host logging from the terminal `computer.com` (authorization stage code 305Command allowed for ADMIN user).

### Startup Event

Privileged Access Manager startup events describe the startup sequence of Privileged Access Manager services (Windows) or daemons (UNIX).

Audit records in the event have the following format:

```
DateTime M Event Service
```

- **Date**  
Identifies the date the event occurred.  
**Format:** DD MMM YYYY

**NOTE**

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

**NOTE**

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Event Type**

Identifies the type of event this record belongs to.

**NOTE**

Privileged Access Manager Endpoint Management refers to this field simply as *Event*.

- **Service**

seosd - the main Privileged Access Manager daemon or service. The seosd daemon or service controls the start up and shutdown sequences of the product.

**Example: Daemon Start Event Message (UNIX)**

The following audit record was taken from a detailed seaudit output.

```
02 Nov 2008 15:41:06 M START                                seoswd
Event type: Daemon start
Daemon: seoswd
Date: 02 Nov 2008
Time: 15:41
Audit flags: AC database user
```

This audit record indicates that on November 2nd 2008 the seoswd Watchdog started.

**Example: Engine Service Start Event Message (Windows)**

The following audit record was taken from a detailed seaudit output.

```
02 Nov 2008 15:34:48 M START                                seosd
Event type: Engine service start
Engine service: seosd
Date: 02 Nov 2008
Time: 15:34
Audit flags: AC database user
```

This audit record indicates that on November 2nd 2008, the seosd service engine, responsible for starting up Privileged Access Manager, started.

**Shutdown Event**

Privileged Access Manager shutdown events describe shutdown processes that are performed by an administrator or sub-administrator user with privileges to shutdown the system.

Audit records in this event have the following format:

```
Date Time M Event UserName SessionID Details Service AuditFlags
```

- **Date**  
Identifies the date that the event occurred.  
**Format:** DD MMM YYYY  
**Note:** Privileged Access Manager Endpoint Management formats the date display according to your computer settings.
- **Time**  
Identifies the time that the event occurred.  
**Format:** HH:MM:SS  
**Note:** Privileged Access Manager Endpoint Management formats the time display according to your computer settings.
- **Event Type**  
Identifies the type of event this record belongs to.  
**Note:** Privileged Access Manager Endpoint Management refers to this field simply as *Event*.
- **User Name**  
Identifies the name of the accessor that performed the action that triggered this event.
- **User Logon Session ID**  
Identifies the accessor's session ID.  
**Note:** By default this field does not appear in a non-detailed seaudit output. To display this field in a non-detailed seaudit output, specify the -sessionid option in the seaudit command.
- **Details**  
Indicates at which stage Privileged Access Manager decided what action to take for this event.  
**Note:** The audit record that you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message that is associated with the authorization stage code. For a complete list of stage codes, run seaudit -t.
- **Daemon (UNIX) / Engine service (Windows)**  
Identifies the name of the Privileged Access Manager daemon (UNIX) or service (Windows) that was shut down.  
**Value:** seosd (the Privileged Access Manager Engine).
- **Audit Flags**  
Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.  
**Note:** If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

#### Example: Shutdown Event Message on UNIX

The following audit record was taken from a detailed seaudit output.

```
24 Sep YYYY 15:40:46 M SHUTDOWN      root      452 seosd
```

```
Event type: Daemon shutdown
```

```
User name: root
```

```
Daemon: seosd
```

```
Date: 24 Sep YYYY
```

```
Time: 15:40:46
```

```
Details: User is ADMIN or SPECIAL
```

```
User Logon Session ID: 48da26ce:00000142
```

Audit flags: CA PAMSC database user

This audit record indicates that on September 24th of the specified year, the user root who was attempting to shutdown Privileged Access Manager was permitted to do so because the user has the ADMIN attribute (authorization stage code 452User is ADMIN or SPECIAL).

### Example: Shutdown Event Message on Windows

The following audit record was taken from a detailed seaudit output.

```
23 Dec YYYY 12:56:20 D SHUTDOWN      tst002                460 seosd
```

Event type: Engine service shutdown

User name: tst002

Engine service: seosd

Date: 10 Feb 2009

Time: 12:56

Details: User is not allowed to shutdown CA PAMSC

User Logon Session ID: 00000000:04c240d5

Audit flags: AC database user

This audit record indicates that on December 23rd of the specified year, the Privileged Access Manager shut down was denied because the user tst002 is not allowed to shutdown the product (authorization stage code 460User is not allowed to shutdown Privileged Access Manager).

### Password Verification Event

Password verification event type messages indicate that a user failed to change his account's password.

Audit records in this event have the following format:

```
DateTime Status EventUserName DetailsReason AuditFlags
```

- **Date**

Identifies the date the event occurred.

**Format:** DD MMM YYYY

**NOTE**

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

**NOTE**

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Status**

Indicates the return code for the event.

**Value:** F (Failed)Failed to change the account password.

- **Event Type**

Identifies the type of event this record belongs to.

**NOTE**

Privileged Access Manager Endpoint Management refers to this field simply as *Event*.

- **User Name**

Identifies the name of the user to which the password attempt was applied.

- **Details**

Indicates why the password change attempt failed.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the password quality code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the password quality code. For a complete list of password quality codes, run seaudit -t.

- **Reason**

Indicates the reason that Privileged Access Manager wrote an audit record.

**NOTE**

This field does not display in a detailed seaudit output or in Privileged Access Manager Endpoint Management. The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the reason code. For a complete list of reason codes, run seaudit -t.

- **Audit Flags**

Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.

**NOTE**

If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

**Example: Password Verification Event Message**

The following audit record was taken from a detailed seaudit output.

```
02 Dec 2008 10:23:47 F PASSWORD      test1          1 10
Event type: Password verification
Status: Failed
User name: test1
Details: Password too short
Audit flags: AC database user
```

This audit record indicates that on December 2nd 2008, the user attempting to change his account password was denied because the password did not meet the minimum required number of characters, as defined by the password policy (authorization stage code 1Password too short). Privileged Access Manager logged this event message according to an explicit request (reason code 10An explicit request to log the operation was received).

**Trace Message On a User**

Trace messages on user events describe an attempt to open, run, or use a protected resource.

Audit records in this event have the following format for Windows:

```
Date Time Status Event UserNameSessionID RealUID RealUsername Class Resource DetailsAuditFlags Trace
```

Audit records in this event have the following format for UNIX:

```
Date Time Status Event UserNameSessionID EffectiveUsername RealUsername Class Resource DetailsAuditFlags
Trace
```

- **Date**

Identifies the date the event occurred.

**Format:** DD MMM YYYY

**NOTE**

Privileged Access Manager Endpoint Management formats the date display according to your computer's settings.

- **Time**

Identifies the time the event occurred.

**Format:** HH:MM:SS

**NOTE**

Privileged Access Manager Endpoint Management formats the time display according to your computer's settings.

- **Status**

Indicates the return code for the event.

**Values:** Can be one of:

- D (Denied)Denied the event because of insufficient authorization.
- P (Permitted)Permitted the event.
- W (Warning)Permitted the event because Warning mode is set although the access request violates an access rule.

**NOTE**

In a detailed seaudit output this field displays the trace information.

- **Event Type**

Identifies the type of event this record belongs to.

**NOTE**

Privileged Access Manager Endpoint Management refers to this field simply as *Event*.

- **User Name**

Identifies the name of the accessor that performed the action that triggered this event.

- **User Logon Session ID**

Identifies the accessor's session ID.

- **Real User ID**

Identifies the user ID of the user who invoked the process.

**Note:** (UNIX) This field does not appear in non-detailed seaudit output.

- **Real user name**

Identifies the name of the user performing the traced action.

- **Effective user ID**

(UNIX only) Indicates the ID of the native OS effective user ID.

**Note:** This field does not appear in non-detailed seaudit output.

- **Effective User Name**

Identifies the name of the native OS effective user that triggered this event. This is different from the user name if the user substitutes (surrogates) to a different user or runs a setuid program.

- **Class**

Identifies the class that the resource being accessed belongs to.

- **Resource**

Identifies the name of the actual resource that is being accessed or updated.

- **Details**

Indicates at which stage Privileged Access Manager decided what action to take for this event.

**NOTE**

The audit record you see in a non-detailed seaudit output displays a number in this field. This number is known as the authorization stage code. In a detailed output or in Privileged Access Manager Endpoint Management, the audit record displays the message associated with the authorization stage code. For a complete list of stage codes, run seaudit -t.

- **Trace information**

Displays the trace detail information including the class, resource, and action that was performed on that resource or the result of that action.

- **Audit Flags**

Indicates whether the accessor is internal (Privileged Access Manager database user) or an enterprise user.

**NOTE**

If the accessor is an enterprise user, the audit record you see in a non-detailed seaudit output displays the string "(OS user)" in this field. Otherwise, this field remains empty.

### Example: Trace Message On a User Event Message on UNIX

The following audit record was taken from a detailed seaudit output.

```
03 Nov 2008 10:38:47 P TRACE      root      490dadd:00000140 john      root      FILE      /
home/jon/file.txt  55 FILE    > Result: 'P' [stage=55 gstag=55 ACEEH=8   rv=0 (/home/john/file.txt
Event type: Trace message on a user
Date: 03 Nov 2008
Time: 10:38
Details: Resource ACL check
Trace information: FILE    > Result: 'P' [stage=55 gstag=55 ACEEH=8   rv=0 (/home/john/file.txt
Class: FILE
Resource: /home/admin/file.txt
User name: root
Real user ID: 108
Real user name: john
Effective user ID: 108
Effective user name: root
User Logon Session ID: 490dadd:00000140
Audit flags: AC database user
```

This audit record indicates that on November 3rd 2008, a trace message was logged due to an administrator attempt to access a resource belonging to a FILE class. The administrator was permitted to access according to the ACL of the accessed resource (authorization stage code 55Resource ACL check).

### Example: Trace Message On a User Event Message on Windows

The following audit record was taken from a detailed seaudit output.

```
10 Nov 2008 10:14:53 P TRACE      MACHINE\Administrator 00000000:172ef9ef MACHINE\john MACHINE\john
WINSERVICE _default    1059 WINSERVICE > (C:\WINDOWS\system32\services.exe) Result: 'P' [stage=1059
gstag=1059 ACEEH=6   rv=0x0 (WebClient)]      Why? Default record universal access check
Event type: Trace message on a user
Date: 10 Nov 2008
Time: 10:14
Details: Default record universal access check
Trace information: WINSERVICE > (C:\WINDOWS\system32\services.exe) Result: 'P' [stage=1059 gstag=1059 ACEEH=6
rv=0x0 (WebClient)]      Why? Default record universal access check
```

```

Class: WINSERVICE
Resource: _default
User name: MACHINE\Administrator
Real user name: MACHINE\john
User Logon Session ID: 00000000:172ef9ef
Audit flags:AC database user

```

This audit record indicates that on November 10th 2008, a trace message was triggered due to an administrator attempting to access the resource \_default belonging to the WINSERVICE class. The administrator was permitted access because of a record universal access check (authorization stage code 1059Default record universal access check).

## Audit Records

Each record in the audit log contains data that is arranged in columns. Two columns (date and time stamps) are common to all types of records. The remaining columns and the data they contain depend on the type of event that triggered the creation of the audit record.

### NOTE

The order, number, and content of columns that you see for an audit log record depend on the method you choose to view the audit log. Some fields do not display in Privileged Access Manager Endpoint Management, seaudit output, or the detailed seaudit output. Also, if you use the seaudit utility, the options you specify may also determine the number, order, and content of the columns.

## How To Identify the Event Type of an Audit Record

To understand the content of an audit record, you must first identify the event type of the audit record. This is because the data the record contains depends on the type of event that triggered the creation of the audit record.

### NOTE

The order, number, and content of columns that you see for an audit log record depend on the method you choose to view the audit log. Some fields do not display in Privileged Access Manager Endpoint Management, seaudit output, or the detailed seaudit output. Also, if you use the seaudit utility, the options you specify may also determine the number, order, and content of the columns.

To identify the event type of an audit record:

- If you are viewing audit records in Privileged Access Manager Endpoint Management, the event type the audit record belongs to displays in the first column of the Audit Records Result pane.  
To display more information about the audit record, click the link audit event type in the first column.
- If you are viewing audit records in seaudit output, you need to display the detailed output (-detail option) to see the event type.

Once you identify the event type, you can go on to interpret the rest of the message detail.

### Example: Audit Records in CA Privileged Access Manager Endpoint Management

The following image shows you how Endpoint Management presents audit events:

Audit Records Result

Access: Read
User name: TM123VM-AC\Administrator
User Logon Session ID: 00000000:05647d29
Terminal: TM123VM-AC
Program: C:\WINDOWS\system32\services.exe
Date: 19 Dec 2008
Time: 16:46
Details: Default record universal access check
Audit flags: AC database user

```

## Authorization Stage Codes for Inbound Network Connection Events

Authorization stage codes for inbound network connection events describe at which stage Privileged Access Manager decided what action to take for the incoming network connection event.

Authorization Stage Code	Indicates
150 Check Class Table	The class could not be found in the Privileged Access Manager database. Privileged Access Manager may write this message to the audit log if there is a problem in the product database. To correct this problem, use the dbmgr utility to rebuild the CA product database. <b>Important!</b> Use the dbmgr utility only with the guidance of support personnel during problem resolution. For assistance, contact CA Support at <a href="http://ca.com/support">http://ca.com/support</a> .
153 HOST entry asterisk in inetacl	Indicates that Privileged Access Manager permitted or denied a connection from a protected host, because the host INETACL contains an asterisk (*). An asterisk specifies any sequence of zero or more characters and therefore matches all services when used in INETACL.
156 HOST entry inetacl	Privileged Access Manager permitted or denied a connection from the protected host, because the host INETACL lists the connection service.
157 HOST Class UACC	Privileged Access Manager permitted or denied a connection from the protected host, because of the default access authority value defined for the host UACC class.
159 HOST entry service range ACL	Privileged Access Manager permitted or denied a connection from the protected host, because the connection service is within the host INETACL range.
163 No rule granting access to service	Privileged Access Manager denied a connection from the host, because it did not find a rule permitting access. Check the HOST class access rules for that host.
164 HOST group inetacl	Privileged Access Manager permitted or denied a connection from the protected host, because the GHOST object's INETCAL lists the connection service.
165 HOST group service range ACL	Privileged Access Manager permitted or denied a connection from the protected host, that is a member of the GHOST host group object, because the connection service is within the host group's INETACL range.
166 HOST group asterisk in inetacl	Privileged Access Manager permitted or denied a connection from a protected host that is a member of the GHOST host group object, because the host group's INETACL contains an asterisk (*). An asterisk specifies any sequence of zero or more characters and therefore matches all services when used in INETACL.
167 HOSTNET (network or IP mask match) inetacl	Privileged Access Manager permitted or denied a connection from the protected host, because the HOSTNET record INETACL lists the connection service.
168 HOSTNET (network or IP mask match) service range	Privileged Access Manager permitted or denied a connection from the protected host, because the connection service is within the HOSTNET record INETACL range.

169 HOSTNET (network or IP mask match) inetacl asterisk	Privileged Access Manager permitted or denied a connection from a protected host, because the HOSTNET record INETACL contains an asterisk (*). An asterisk specifies any sequence of zero or more characters and therefore matches all services when used in INETACL.
170 HOSTNP (hosts name pattern) inetacl	Privileged Access Manager permitted or denied a connection from the protected host, because the HOSTNP record INETACL lists the connection service.
171 HOSTNP (hosts name pattern) service range	Privileged Access Manager permitted or denied a connection from the protected host, because the connection service is within the HOSTNP record INETACL range.
172 HOSTNP (hosts name pattern) inetacl asterisk	Privileged Access Manager permitted or denied a connection from a protected host, because the HOSTNP record INETACL contains an asterisk (*). An asterisk specifies any sequence of zero or more characters and therefore matches all services when used in INETACL.
173 HOST entry day & time restrictions	Privileged Access Manager denied access to a protected host, because the attempted access was outside the day and time restrictions in the HOST record.
174 HOST group day & time restrictions	Privileged Access Manager denied access to a protected host group, because of the day and time restrictions in the GHOST record.
175 HOSTNET (network or IP mask match) day & time restrictions	Privileged Access Manager denied access to a protected host, because of the day and time restrictions in the HOSTNET record.
176 HOSTNP (hosts name pattern) day & time restrictions	Privileged Access Manager denied access to a protected host, because of the day and time restrictions in the HOSTNP record.
177 HOST_default day & time restrictions	Privileged Access Manager denied access to a protected host, because of the day and time restrictions in the HOST_default record.
178 HOST_default inetacl	Privileged Access Manager permitted or denied access to a protected host, because of the values in the HOST_default INETACL.
179 HOST_default service range	Privileged Access Manager permitted or denied access to a protected host, because the connection service is within the HOST_default record INETACL range.
180 HOST_default service asterisk	Privileged Access Manager permitted or denied access to a protected host, because the HOST_default record INETACL contains an asterisk (*). An asterisk specifies any sequence of zero or more characters and therefore matches all services when used in INETACL.
404 HOST entry in TCP service ACL	Privileged Access Manager permitted or denied access from a HOST, because the TCP record ACL lists the HOST.
405 GHOST entry in TCP service ACL	Privileged Access Manager permitted or denied access from a HOST, because the TCP record ACL lists the GHOST of which the HOST is a member.
406 HOSTNET entry in TCP service ACL	Privileged Access Manager permitted or denied access from a HOST, because the TCP record ACL lists the HOSTNET network of which the HOST is a part.
407 HOSTNP entry in TCP service ACL	Privileged Access Manager permitted or denied access from a HOST, because the TCP record ACL lists the HOSTNP set of which the HOST is a part.

## Authorization Stage Codes for Log In and Log Out Events

Authorization stage codes for log in and log out events describe at which stage Privileged Access Manager decided what action to take for the log in or log out event.

Authorization Stage Code	Indicates
2 Fetching user object	A login attempt failed because Privileged Access Manager could not load user information, such as user mode, terminal, or login program. Privileged Access Manager may write this message to the audit log if the database is corrupt or the product did not start correctly.
3 Terminal checking for login terminal source	Privileged Access Manager permitted or denied login according to the <b>TERMINAL</b> class rules.
5 User suspend checking	Privileged Access Manager denied login, because the user account is suspended.
6 User expiration checking	Privileged Access Manager denied login, because the user account is expired, as defined in the user's profile.
7 User day-time checkings	Privileged Access Manager denied login, because the user attempted to log in at a time outside the permitted day and time for the product database.
8 Password validity checkings	<b>Valid on UNIX</b> Privileged Access Manager checked a user's password to ensure it conformed to the password rules. Privileged Access Manager may write this message to the audit log when a login attempt failed because a user's password did not conform to the product's database password rules.
9 User grace login checkings	Privileged Access Manager denied login, because the user account has exhausted its grace login attempts.
10 Password expired with no more grace logins	Privileged Access Manager denied login because the password is expired. The user did not change their password within the password interval limit and no grace count after password expiration is configured, neither in the user's profile group's definition nor in the product's global definitions.
11 Building the user ACEE	Privileged Access Manager successfully generated the ACEE for the user.
12 User inactivity days check	Privileged Access Manager denied login, because the user was inactive for a period that exceeded the permitted inactive interval. The permitted inactive interval is defined in the user's profile or global product settings.
13 Too many logins for user	Privileged Access Manager denied login, because the user has exceeded the maximum allowed number of simultaneous logins from different terminals. The maximum allowed number of simultaneous logins is defined in the 'Maxlogins' properly value in the user's profile or global product settings
14 Active HOLIDAY check	Privileged Access Manager denied login, because the user attempted to log in during the restricted holiday dates. The restricted holiday dates are defined in the <b>HOLIDAY</b> class.

15 Login Application (LOGINAPPL) check	<b>Valid on UNIX</b> Privileged Access Manager denied login, because of the LOGINAPPL class rules.
16 User Groups day-time checking	Privileged Access Manager denied login, because the user attempted to log in at a time outside the permitted day and time for the user or for one of the user's group.
17 Attempt rejected by the native environment	The login attempt failed due to the native environment settings. Logged by Privileged Access Manager PAM module.
18 User without domain restriction	<b>Valid on Windows</b> Privileged Access Manager denied login, because the user did not provide a domain name.
19 No reason to deny – allow login	Privileged Access Manager permitted login, because the login attempt passed all check stages, providing that the login authorization has a TERMINAL object assigned to. Viewing this event stage message may indicate that the login authorization was triggered by a Privileged Access Manager authorization API that does not have the terminal name specified.
20 'Logical' user check	Privileged Access Manager denied login, because the product does not permit 'logical' users (users with the <i>logical</i> property set) to log in.
49 Logout detected after last process terminated	<b>Valid on UNIX</b> Privileged Access Manager detected a user logout event occurring after the last process terminated.

## Authorization Stage Codes for Outbound Network Connection Events

Authorization stage codes for outbound network connection events describe at which stage Privileged Access Manager decided what action to take for the outbound network connection event.

Authorization Stage Code	Indicates
400 _default service in class TCP	Privileged Access Manager permitted or denied access to a protected host, because of the _default object permissions in the TCP record for the connecting service.
401 Class UACC of TCP services	Privileged Access Manager permitted or denied access to a protected host, because of the value of the TCP object in the UACC class.
402 Day and time restrictions on TCP service	Privileged Access Manager denied access to a TCP service, because of the day and time restrictions in the TCP record.
403 ACL read stage of TCP service	Privileged Access Manager permitted or denied access to the TCP service, because of the ACL read property in the TCP record. The product may write this message to the audit log if the database is corrupt.
408 Default access of TCP service	Privileged Access Manager permitted or denied access to the TCP class service, because of the defaccess property of the TCP record.  <b>Note:</b> This event message also applies to incoming TCP events to indicate an inbound connection to the HOST.

409 CACL read stage of TCP service	Privileged Access Manager denied access to the TCP service, because of the CACL read property in the TCP record. The product may write this message to the audit log if the database is corrupt.
410 HOST entry for USER in TCP service CACL	Privileged Access Manager permitted or denied access to a HOST object for a specified USER or XUSER. The product used the access rules in the CACL of the TCP service to determine whether to permit or deny access.
411 GHOST entry for USER in TCP service CACL	Privileged Access Manager permitted or denied access to a GHOST object for a specified USER or XUSER object. The product used the access rules in the CACL of the TCP service to determine whether to permit or deny access.
412 HOSTNET entry for USER in TCP service CACL	Privileged Access Manager permitted or denied access to a HOSTNET object for a specified USER or XUSER object. The product used the access rules in the CACL of the TCP service to determine whether to permit or deny access.
413 HOSTNP entry for USER in TCP service CACL	Privileged Access Manager permitted or denied access to a HOSTNP object for a specified USER or XUSER object. The product used the access rules in the CACL of the TCP service to determine whether to permit or deny access.
414 HOST entry for GROUP in TCP service CACL	Privileged Access Manager permitted or denied access to a HOST object for a specified GROUP or XGROUP object. The product used the access rules in the CACL of the TCP service to determine whether to permit or deny access.
415 GHOST entry for GROUP in TCP service CACL	Privileged Access Manager permitted or denied access to a GHOST object for a specified GROUP or XGROUP object. The product used the access rules in the CACL of the TCP service to determine whether to permit or deny access.
416 HOSTNET entry for GROUP in TCP service CACL	Privileged Access Manager permitted or denied access to a HOSTNET object for a specified GROUP or XGROUP object. The product used the access rules in the CACL of the TCP service to determine whether to permit or deny access.
417 HOSTNP entry for GROUP in TCP service CACL	Privileged Access Manager permitted or denied access to a HOSTNP object for a specified GROUP or XGROUP object. The product used the access rules in the CACL of the TCP service to determine whether to permit or deny access.
418 HOST entry for User '*' in TCP service CACL	Privileged Access Manager permitted or denied access to a HOST for a user, because the HOST record CACL contains an asterisk (*). An asterisk specifies all defined users.
419 GHOST entry for User '*' in TCP service CACL	Privileged Access Manager permitted or denied access to a HOST belonging to GHOST class for a user, because the GHOST record CACL contains an asterisk (*). An asterisk specifies all defined users.
420 HOSTNET entry for User '*' in TCP service	Privileged Access Manager permitted or denied access to a HOSTNET object for a user, because the HOSTNET record CACL contains an asterisk (*). An asterisk specifies all defined users.
421 HOSTNP entry for User '*' in TCP service CACL	Privileged Access Manager permitted or denied access to a HOSTNP object for a user, because the HOSTNP record CACL contains an asterisk (*). An asterisk specifies all defined users.

## Authorization Stage Codes for Password Verification Events

Authorization stage codes for password verification events describe at which stage Privileged Access Manager decided what action to take for the password verification event.

Authorization Stage Code	Indicates
0 Password quality verified	The user successfully changed their password, and that the new password meets all of the password quality rules.
1 Password too short	The password change failed, because the length of the new password does not comply with the password policy for minimum password length.
2 Password contains user name	The password change failed, because the new password contains the user's user name.
3 Too few lowercase letters in password	The password change failed, because the new password does not contain enough lower case letters according to the minimum defined in the password policy.
4 Too few capital letters in password	The password change failed, because the new password does not contain enough capital letters according to the minimum defined in the password policy.
5 Too few numeric characters in password	The password change failed, because the new password does not contain enough numeric characters according to the minimum defined in the password policy.
6 Too few other characters in password	The password change failed, because the new password does not contain enough other characters according to the minimum defined in the password policy.
7 Too many repetitions of same char in password	The password change failed, because the new password contains too many repeating characters according to the maximum defined in the password policy.
8 Same as current password	The password change failed, because the new password is the same as the current password. You should select a password that you have not used before.
9 Password previously used. Select a different password	The password change failed, because the new password was previously used. You should select a password that you have not used before.
10 Too few alphabetic characters in password	The password change failed, because the new password does not contain enough alphabetic characters according to the minimum defined in the password policy.
11 Too few alphanumeric characters in password	The password change failed, because the new password does not contain enough alphanumeric characters according to the minimum defined in the password policy.
12 Password was changed recently, cannot be changed again at this time	The password change failed, because the password was recently changed and cannot be changed at this time. You should change the password only after the minimal password age period has passed according to the minimum defined in the password policy.
13 Password is contained by a previous password or vice versa	The password change failed, because the new password contains a previous password or is part of a previous password. You should ensure that the new password does not contain a previous password, and is not part of a previous password.

14 Password contains previous password pattern	The password change failed, because the new password contains pattern from the previous password according to the sub_str_len defined in the password policy.
16 Password too long	The password change failed, because the new password is too long according to the maximum defined in the password policy.
20 Passwords do not match	The password change failed, because the new password does not match the password entered in the confirm password field.
21 Cannot include predefined prohibited characters	The password change failed, because the new password contains prohibited characters according to the password policy.
22 Password previously used	Privileged Access Manager denies access because the password that you entered was used before. Make sure that the new password you use conforms with the password policy rules.
23 Password is contained by a previous password or vice versa	The password change attempt failed because the password used is contained by a previous password or that the previous password is contained in the new password. You should select a new password that does not contain a previously used password.
24 Password is in dictionary file	The password change failed, because the new password is defined in the DICTIONARY class or DICTIONARY file. You should select a password that is not defined in the DICTIONARY class or in the DICTIONARY file.
100 Bad arguments	<p>The password change failed, because invalid data was sent to the authorization engine.</p> <p>Privileged Access Manager may write this message to the audit log when one of the following occurs:</p> <ul style="list-style-type: none"> <li>• A memory problem</li> <li>• A mismatch between versions of Privileged Access Manager various modules to a recent upgrade of the product</li> </ul> <p>Verify that there are no mixed Privileged Access Manager environments and that the client and server use the same version of the product. For assistance, contact CA Support at <a href="http://ca.com/support">http://ca.com/support</a>.</p>

## Authorization Stage Codes for Resource Access Events

Authorization stage codes for resource access events describe at which stage Privileged Access Manager decided to take action for the resource access event.

Authorization Stage Code	Indicates
50 Security LABEL check of resource	<p>Privileged Access Manager denied access to the resource, because <i>one</i> of the following is true for the user who tried to access the resource:</p> <ul style="list-style-type: none"> <li>• The resource security label has a higher security level than the user security label</li> <li>• The user does not have a security label</li> </ul>

51 Security LEVEL check of resource	Privileged Access Manager denied access to the resource, because <i>one</i> of the following is true for the user who tried to access the resource: <ul style="list-style-type: none"> <li>The resource has a higher security level than the user</li> <li>The user does not have a security level</li> </ul>
52 Category check of resource	Privileged Access Manager denied access to the resource, because the resource is assigned a security category that is not assigned to the user.
53 Resource DAYTIME check	Privileged Access Manager denied access to the resource, because the user attempted access at a time outside the permitted day and time for the resource.
54 OWNER check of resource	Privileged Access Manager permitted access to a resource, because the accessing user owns the resource.
55 Resource ACL check	Privileged Access Manager permitted or denied access to the resource, because the resource ACL lists the user.
56 In resource group ACL check	Privileged Access Manager permitted or denied access to the resource, because the resource group ACL lists list the user.
57 User group in resource ACL	Privileged Access Manager permitted or denied access to the resource because the user group ACL list at least one of the resource.
58 User group in resource group ACL	Privileged Access Manager permitted or denied access to the resource, because the resource group ACL lists at least one of the user group.
59 Resource UACC check	Privileged Access Manager permitted access to the resource, because of the resource's default settings.
61 User is OPERATOR on resource	Privileged Access Manager permitted access to the resource, because the user has the OPERATOR attribute. The OPERATOR attribute lets users bypass authorization procedures for read and chdir access for FILE resources. On UNIX, Privileged Access Manager writes this message to the trace file only, and does not write the message to the audit log file.
62 UACC check for Class of unprotected resource	Privileged Access Manager permitted or denied access to a resource that does not have a record in the product database, based on the defaccess value in the resource class.
63 Program Conditional Access	Privileged Access Manager permitted or denied access to the resource, because the resource PACL lists the program and the user or one of the user's groups.
64 User '*' in resource ACL	Privileged Access Manager permitted or denied access to the resource, because the resource ACL contains an asterisk (*). An asterisk specifies all defined users.
65 User is AUDITOR on resource	Privileged Access Manager permitted access to the audit file, because the user has the AUDITOR attribute. The AUDITOR attribute lets users bypass authorization procedures for read and chdir access requests. Privileged Access Manager writes this message to the trace file only, and does not write the message to the audit log file.
69 No step that allowed access	Privileged Access Manager denied access to the resource because it could not find a rule that let the user access the resource.

70 OWNER check of resource's group	Privileged Access Manager permitted access to the resource because the user attempting to access the resource is the owner of one of the resource's groups.
75 User '*' in resource group ACL	Privileged Access Manager permitted or denied access to the resource because the resource group ACL contains an asterisk (*). An asterisk specifies all defined users.
76 Resource denied ACL check	Privileged Access Manager denied access to the resource, because the resource NACL lists the user.
77 In resource group denied ACL check	Privileged Access Manager denied access to the resource, because the resource group NACL lists the user.
78 User group in resource denied ACL	Privileged Access Manager denied access to the resource, because the resource NACL lists at least one of the user groups.
79 User group in resource group denied ACL	Privileged Access Manager denied access to the resource, because the resource group NACL lists at least one of the user groups.
80 User '*' in resource denied ACL	Privileged Access Manager denied access to the resource, because the resource NACL contains an asterisk (*). An asterisk specifies all defined users.
81 User '*' in resource group denied ACL	Privileged Access Manager denied access to the resource, because the resource group NACL contains an asterisk (*). An asterisk specifies all defined users.
82 Group of resource DAYTIME check	Privileged Access Manager denied access to the resource, because the user attempted to access the resource at a time outside the permitted day and time for the resource group.
86 Resource calendar ACL check for user	Privileged Access Manager permitted or denied access to the resource, because the user attempted to access the resource at a time permitted or denied by the resource CALACL.
87 Resource group calendar ACL check for user	Privileged Access Manager permitted or denied access to the resource, because the user attempted to access the resource at a time permitted or denied by the resource group CALACL.
88 Resource calendar ACL check for user groups	Privileged Access Manager permitted or denied access to the resource, because the user attempted to access the resource at a time permitted or denied because the user is a member of one of the groups that are listed in the resource CALACL.
89 Resource group calendar ACL check for user groups	Privileged Access Manager permitted or denied access to the resource, because the user group attempted to access the resource at a time permitted or denied because the user is a member in one of the group's that are listed in the resource CALACL.
90 User * in resource calendar ACL	Privileged Access Manager permitted or denied access to the resource, because the resource CALACL contains an asterisk (*). An asterisk specifies all defined users.
91 User * in resource groups calendar ACL	Privileged Access Manager permitted or denied access to the resource, because the resource group CALACL contains an asterisk (*). An asterisk specifies all defined users.
92 Attempt to rename the path of a protected resource	<b>Valid on Windows</b> Privileged Access Manager denied a request to rename a protected file or registry entry.

200 Class checks not active	Privileged Access Manager permitted access to a resource, because the resource class is inactive. When a resource class is inactive, the setoptions list command displays the class activity as 'No'.
201 Loading the user information	Privileged Access Manager could not authorize a request, because it failed to retrieve a user's information.
202 Resource in WARNING mode	Privileged Access Manager permitted access to a resource, because the resource is in Warning Mode.
203 Access for the resource is MAXIMUM_ALLOWED	<b>Valid on Windows</b> When permitted, indicates that Privileged Access Manager assigned maximum access rights to the registry handle. When denied, indicates that Privileged Access Manager blocked access to the registry handle.
204 Class in WARNING mode	Privileged Access Manager permitted access to a resource, because the resource class is in Warning Mode.
210 Special kernel module load check	<b>Valid on UNIX</b> Privileged Access Manager permitted or denied the loading or unloading of the kernel module, based on the KMODULE class definitions.
250 Executing an untrusted program	Privileged Access Manager denied an attempt to execute an untrusted program.
251 Using deniable parameter	Privileged Access Manager denied an attempt to execute sesudo command, because the command syntax contains parameters the SUDO record defines as prohibited.
252 Relative path specified by an _abspath user	<b>Valid on UNIX</b> Privileged Access Manager denied an attempt to execute a program that was specified by a relative path, because the user attempting to execute the program is a member of the '_abspath' group.
253 Permitted sesudo job	Privileged Access Manager permitted an attempt to execute a sesudo command.
254 sesudo command failed	<b>Valid on UNIX</b> A sesudo command failed to execute on the operating system.
440 Invalid calendar was detected	Privileged Access Manager denied access because of an error in getting the calendar information. Example: a memory problem or calendar table corruption.
441 Calendar does not allow access	Privileged Access Manager denied access because the calendar object's definitions associated with the accessed resource do not allow access at this time.
1050 Default Record Security Label Check	Privileged Access Manager denied access to the default record, because <i>one</i> of the following is true for the user who tried to access the resource: <ul style="list-style-type: none"> <li>The resource security label has a higher security level than the user security label</li> <li>The user does not have a security label</li> </ul>
1051 Default Record Security Level Check	Privileged Access Manager denied access to the default resource, because <i>one</i> of the following is true for the user who tried to access the resource: <ul style="list-style-type: none"> <li>The resource has a higher security level than the user</li> <li>The user does not have a security level</li> </ul>

1052 Default Record Category Check	Privileged Access Manager denied access to the default resource, because the resource is assigned a security category that is not assigned to the user.
1053 Default Record Day and Time Check	Privileged Access Manager denied access to the default resource, because the user attempted access at a time outside the permitted day and time for the resource.
1054 Default Record OWNER Check	Privileged Access Manager permitted access to the default resource, because the accessing user owns the default resource.
1055 Default Record ACL Check for User	Privileged Access Manager permitted or denied access to the default resource, because the resource ACL lists or does not list the user
1056 Default Record Group ACL Check For User	Privileged Access Manager permitted or denied access to the default resource, because the resource group ACL lists or does not list the user.
1057 Default Record ACL Check for User Groups	Privileged Access Manager permitted read or chdir access to the default resource. Privileged Access Manager writes this message to the trace file only, and does not write the message to the audit log file.
1058 Default Record Group ACL Check for User Groups	Privileged Access Manager permitted or denied access to the default resource, because the resource group ACL lists or does not list the user group.
1059 Default Record Universal Access Check	Privileged Access Manager permitted access to the default resource, because of the resource's default settings.
1061 Default Record OPERATOR Attribute Check	Privileged Access Manager permitted access to the default resource, because the user has the OPERATOR attribute. The OPERATOR attribute lets users bypass authorization procedures for read and chdir access requests. Privileged Access Manager writes this message to the trace file only, and does not write the message to the audit log file.
1062 Default Record Class Global Universal Access	Privileged Access Manager permitted or denied access to the default resource that does not have a record in the product database, based on the defaccess value in the resource class.
1063 Default Record Program Conditional Access	Privileged Access Manager permitted or denied access to the default resource, because the resource PACL lists or does not list the program accessing the resource.
1064 User '*' in _default record ACL	Privileged Access Manager permitted or denied access to the default resource, because the resource ACL contains an asterisk (*). An asterisk specifies all defined users.
1069 No Rule Granting Access to Default Record	Privileged Access Manager denied access to the default resource because it could not find a rule that let the user access the resource.
1202 Default Record in WARNING Mode	Privileged Access Manager permitted access to the default resource, because the resource is in Warning Mode.
1250 Default Record is Set Untrusted	Privileged Access Manager denied an attempt to execute the default untrusted program.

## Authorization Stage Codes for Security Database Administration Events

Authorization stage codes for security database administration events describe at which stage Privileged Access Manager decided what action to take for the security database administration event.

Authorization Stage Code	Indicates
300 Undefined Privileged Access Manager user	Privileged Access Manager denied access to the system, because the accessing user could not be found in the product database. Check the user account profile.
301 An attempt to delete last ADMIN user	Privileged Access Manager denied a request to do one of the following: <ul style="list-style-type: none"> <li>Delete the last ADMIN user from the product database</li> <li>Remove the ADMIN attribute from the only user that is assigned the ADMIN attribute</li> </ul>
302 An attempt to delete user root	<b>Valid on UNIX</b> Privileged Access Manager denied an attempt to delete the system root account.
303 User trying to change their own password	Privileged Access Manager denied a user attempt to use a <code>selang</code> command to change their own password. On UNIX, change your password using the <code>sepass</code> utility. On Windows, change your password using native password management tools.
304 Nonauditor user trying to set audit mode	Privileged Access Manager denied a user attempt to change the audit mode of a record, because the user does not have the AUDITOR attribute. To let the user change the audit mode of a record, assign the user the AUDITOR attribute.
305 Command allowed for ADMIN user	Privileged Access Manager permitted an action, because the user requesting the action has the ADMIN attribute.
306 Showuser (myself) , Showxusr allowed	Privileged Access Manager permitted a user or an external user to display the properties of their own record in the product database. This message is not written as an audit record.
307 User trying to set categories they do not have	Privileged Access Manager denied an attempt to assign a security category to a user, because the user attempting to assign the security category does not possess that security category themselves.
308 User trying to set a security-label they do not have	Privileged Access Manager denied an attempt to assign a security label to a user, because the user attempting to assign the security label does not possess that security label themselves.
309 User trying to set security-level greater than the user's own	Privileged Access Manager denied an attempt to assign a security level to a user, because the user has a lower security level than the security level they are attempting to assign.
310 NonADMIN user trying to set user-mode	Privileged Access Manager denied an attempt to set an administrative attribute, because the user attempting to set the attribute does not have the ADMIN attribute.
311 Command allowed for object owner	Privileged Access Manager permitted an action, because the user owns the record.
312 Native file owner can define it to Privileged Access Manager	<b>Valid on UNIX</b> Privileged Access Manager permitted an action, because the file owner defined the file to the product.  <b>Note:</b> A file owner can define a file to Privileged Access Manager when the <code>use_unix_file_owner</code> token in the <code>lang</code> section of the <code>seos.ini</code> file is set to yes.

313 Command allowed for a GROUP-ADMIN user	Privileged Access Manager permitted a user with the GROUP-ADMIN attribute to modify a record within the group.
314 GROUP-ADMIN user can join join- to group	Privileged Access Manager permitted a user with the GROUP-ADMIN attribute add or remove a user to the group.
315 GROUP-AUDITOR ADMIN can list the group	Privileged Access Manager permitted a user to list the properties of a record within a group, because the user has the GROUP-ADMIN or GROUP-AUDITOR attribute for that group.
316 An auditor can list any object	Privileged Access Manager permitted a user with the AUDITOR attribute to display data in the database.
317 An OPERATOR can list any object	Privileged Access Manager permitted a user with the OPERATOR attribute to display data in the database
318 A GROUP-AUDITOR can list objects in group scope	Privileged Access Manager permitted a user with the GROUP-AUDITOR attribute to display data about the group in the database.
319 A GROUP-OPERATOR can list objects in group scope	Privileged Access Manager permitted a user with the GROUP-OPERATOR attribute to display data about the group in the database.
320 Command allowed for CLASS-ADMIN user	Privileged Access Manager permitted the action, because the action was performed by a user listed in the ACL of the ADMIN class.
321 Command allowed for PWMANAGER ADMIN with access	Privileged Access Manager permitted a user to change a password, because the user has the PWMANAGER or ADMIN attribute.
322 There is no rule allowing this operation	Privileged Access Manager denied an operation, because no rule that permitted the operation was found.
324 User changing their own password using sepass	Privileged Access Manager permitted a user to use the sepass utility or the password policy model to change their password.
326 User created 'Login Information' for themselves	Privileged Access Manager permitted a user to created login information for themselves.
327 Command allowed for GROUP-PWMANAGER	Privileged Access Manager permitted the command, because the user that executed the command has the GROUP-PWMANAGER attribute.
329 A PWMANAGER enabled a user	Privileged Access Manager permitted a user to enable (re-activate) another user, because the user that enabled the other user has the PWMANAGER attribute.
330 Command allowed for DOMAIN change	<b>Valid on Windows</b> Privileged Access Manager permitted the user to change the DOMAIN class, for example, adding new computers to the domain
331 Command allowed for PWMANAGER	Privileged Access Manager permitted the command to execute, because the user that executed the command has the PWMANAGER attribute.
332 Changing native flags allowed for PWMANAGER	<b>Valid on Windows</b> Privileged Access Manager permitted the user to modify the account flags assigned to a user account, because the user has the PWMANAGER attribute.
333 Changing 'must change password next logon' attribute is allowed for PWMANAGER	<b>Valid for Windows</b> Privileged Access Manager permitted the user to modify the 'must change password next logon' attribute for a user account, because the user has the PWMANAGER attribute.

334 Command allowed for GROUP-PWMANAGER	Privileged Access Manager permitted the command, because the user that executed the command has the GROUP-PWMANAGER attribute
335 Editing 'Login Information' is allowed for PWMANAGER	Privileged Access Manager permitted the user to edit the 'Login Information' attribute for a user account, because the user has the PWMANAGER attribute.
336 Command allowed for auditor user	Privileged Access Manager permitted a user to execute a command, because the user has the AUDITOR attribute.
337 Failed to reconcile command with database information	Privileged Access Manager did not execute a command, because the objects embedded in the command do not exist in the product database. Check the command syntax before you re-execute the command.
338 Creating a command from an implicit request	Privileged Access Manager created a command that originated from an implicit request.
339 SEOS_syscall module unload readiness check	<b>Valid on UNIX</b> An accessor is executing the 'secons scl' command to check if there are processes running in the intercepted syscalls. The product does not permit unloading the SEOS_syscall module.
340 Command allowed for ADMIN group	<b>Valid on UNIX</b> Privileged Access Manager permitted an action, because the user has the ADMIN attribute.
341 Command allowed for AUDITOR group	<b>Valid on UNIX</b> Privileged Access Manager permitted an action, because the user has the AUDITOR attribute.
342 Command allowed for OPERATOR group	Privileged Access Manager permitted an action, because the user has the OPERATOR attribute.
343 Command allowed for PWMANAGER group	<b>Valid on UNIX</b> Privileged Access Manager permitted an action, because the user has the PWMANAGER attribute.
344 Command allowed for SERVER group	<b>Valid on UNIX</b> Privileged Access Manager permitted an action, because the user has the SERVER attribute.

## Authorization Stage Codes for Shutdown Events

Authorization stage codes for shutdown events describe at which stage Privileged Access Manager decided what action to take for the shutdown event.

Authorization Stage Code	Indicates
451 User is an OPERATOR	Privileged Access Manager permitted the shutdown request, because the user that executed the shutdown sequence has the OPERATOR attribute.
452 User is ADMIN or SPECIAL	Privileged Access Manager permitted the shutdown request, because the user executing the shutdown sequence has the ADMIN attribute assigned to him.

453 _seagent is allowed to shutdown Privileged Access Manager	<b>Valid on UNIX</b> Privileged Access Manager permitted the shutdown request, because _seagent is permitted to shut down the product.
455 Daemon shut down by root (UNIX)	<b>Valid on UNIX</b> The seosd Daemon was shut down by root after the watchdog requested a restart.
456 Daemon shut down by watchdog	<b>Valid on Windows</b> The watchdog has requested a Privileged Access Manager license so it can restart the engine.
460 User is not allowed to shutdown Privileged Access Manager	Privileged Access Manager denied the shutdown request, because the requesting user is not permitted to shut down the product.
600 Attempting to Terminate Privileged Access Manager	Privileged Access Manager denied the shutdown request, because the user attempted to terminate the product by executing the kill command.

## Authorization Stage Codes for Trace Message On a User

Authorization stage codes for trace events on a user describe at which stage Privileged Access Manager decided what action to take for the user activity event.

Authorization Stage Code	Indicates
994 Informational Message	A user accessed the trace audit records. This is an informative message only, viewed by running the seaudit tr command.
995 Unauthorized Access to Internal Resource	An accessor attempted an unauthorized access to an internally protected FILE resource. Example: seos.audit records.
996 Authorized Access to Internal Resource	Privileged Access Manager permitted access to the resource by an internal bypass. Example: reading /etc/passwd.
997 User Can Execute a setuid setgid Directory	<b>UNIX only</b> Privileged Access Manager bypassed an event because an accessor attempted to execute a directory marked with a setuid \setgid flag bit. This stage is part of a TRACE record message.
998 Authorization is Configured as 'Audit Mode Only'	<b>Windows only</b> Privileged Access Manager is set to work in 'Audit Mode Only'.
999 Resource not Protected (Check if Rules Exists)	Privileged Access Manager permits access to an unprotected resource.

## Authorization Stage Codes for Untrust Message Events

Authorization stage codes for untrust message events describe at which stage Privileged Access Manager decided on what action to take for the untrust message event.

Authorization Stage Code	Indicates
0 A general error occurred during Watchdog file checking	An error occurred while Privileged Access Manager fetched the file information. The product can write this message to the audit log if the file is untrusted. Check the system logs for more information.
1 Stat information of PROGRAM or SECFILE was changed	Data changed in a record in the PROGRAM or SECFILE classes. Privileged Access Manager can write this message to the audit log if it detects an attempt to tamper with a program or file. Check the audit events, system logs, and trace records for the program or file. If an administrator changed the program or file, consider re-trusting the changed program or file.
4 CRC check of PROGRAM or SECFILE changed	The Cyclic Redundancy Check (CRC) changed of a record in the PROGRAM or SECFILE class. Check the system logs, event log files, and trace records for the program or file.
5 Cannot stat file of PROGRAM or SECFILE	Privileged Access Manager failed to retrieve file information for the specified file. The product can write this message to the audit log if one of the following events occurs: <ul style="list-style-type: none"> <li>• The file name or directory changed</li> <li>• The file name or directory does not exist</li> <li>• The access permissions of the file</li> <li>• The system is out of memory</li> </ul> To determine the possible cause of the error, check the system log files.
7 MD5 signature of PROGRAM or SECFILE changed	The MD5 signature changed for a record in the PROGRAM or SECFILE classes. Check the system log files, audit messages, and trace logs for the program or file.
8 SHA1 signature of PROGRAM or SECFILE changed	The SHA1 signature changed for a record in the PROGRAM or SECFILE classes. Check the system log files, audit messages, and trace logs for the program or file.
10 SHA256 signature of PROGRAM or SECFILE changes	The SHA256 signature changed for a record in the PROGRAM or SECFILE classes. Check the system log files, audit messages, and trace logs for the program or file.
11 SHA384 signature of PROGRAM or SECFILE changed	The SHA384 signature changed for a record in the PROGRAM or SECFILE classes. Check the system log files, audit messages, and trace logs for the program or file.
12 SHA512 signature of PROGRAM or SECFILE changed	The SHA512 signature changed for a record in the PROGRAM or SECFILE classes. Check the system log files, audit messages, and trace logs for the program or file.

## Reason Codes That Specify Why a Record Was Created

Reason codes that specify why a record was created describe at which stage Privileged Access Manager decided what audit record to create for the event.

Reason Code	Why Privileged Access Manager Logged this Operation
0 No specific request to log the operation	No specific request to log in the operation exists so it was logged by default.
2 User audit mode requires logging	The audit property of the accessor or its profile matches the record's result. Example: an action performed by a user with the FAILURE value set for the AUDIT_MODE property is logged only when the user fails to access a protected resource.
3 Resource audit mode required logging	The RAUDIT property of the resource matches the record's result.
4 Resource in WARNING mode	A WARNING property was set to the resource or to the resource's class.
5 Privileged Access Manager serevu utility requested auditing	<b>Valid on UNIX</b> The serevu utility requested the audit record. Example: when a user attempt to log in fails.
7 Outbound connection record	<b>Valid on UNIX</b> A successful outbound connection occurred.
8 Privileged Access Manager pam support UNIX failed login	<b>Valid on UNIX</b> The Privileged Access Manager PAM module requested the audit. Example: in an event of a failed password login attempt.
9 Daytime restrictions check of CALENDAR class	A daytime restrictions check of a CALENDAR class required logging an audit record.
10 A specific request to log operation	A specific request was made to log the operation. Example: attempting to kill the Privileged Access Manager daemons.
11 Privileged Access Manager secons utility requested auditing	<b>Valid on UNIX</b> The Syscall monitor option is sued (secons-scl).

## selang Reference Guide

This guide provides information about Privileged Access Manager selang command, database classes and properties, and Windows values. This guide is also provided with Privileged Access Manager, which offers enterprise management and reporting capabilities, and advanced policy management features.

### Command Line Interpreter

#### Contents

Privileged Access Manager is administered through a command shell that is known as selang, the Privileged Access Manager command language. The selang command language lets you make definitions in the Privileged Access Manager database. The selang command language is the command definition language.

The selang utility is located in the bin directory of your Privileged Access Manager installation. When you enter the selang shell, a special selang prompt appears. The exact form of the prompt depends on your working environment. The prompt looks similar to this:

PAMSC>

The selang command shell operates on the local database by default. To operate on the Privileged Access Manager database of a different station, specify the hosts command before entering the selang commands.

**selang Utility** Run the Privileged Access Manager Command Line

The selang utility invokes a command shell that provides access to the Privileged Access Manager database and the native environment. The database is updated dynamically by issuing selang commands from within the command shell.

#### NOTE

The result of the execution of the command is sent to the standard output unless you include the -o option.

This command has the following format on UNIX:

```
selang [{-c command|-f file}] [{-d path|-p pmdb}] [-o file] [-r file] [-s] \
```

```
[-u userpass]
```

```
selang [-l] [-o file] [-r file] [-s] [-u userpass]
```

This command has the following format on Windows:

```
selang [{-c command|-f file}] [{-d path|-p pmdb}] [-o file] [-r file] [-s] [-v]
```

```
selang [-l] [-o file] [-r file] [-s] [-v]
```

- **-c *command***

Specifies the selang command to execute. After selang executes the command, it exits.

If *command* contains any spaces, enclose the entire string in quotation marks. For example:

```
selang -c "showusr rosa"
```

- **-d *path***

Specifies that selang commands update the database in the defined path.

**Note:** You can only specify a local database.

- **-f *file***

Specifies that selang commands are read from the defined file rather than from the standard input of the terminal. As selang executes the commands in the input file, the line number of command being executed appears on the screen. The selang prompt does not appear on the screen. After selang executes the commands in *file*, it exits.

- **-h**

Displays the help for this utility.

- **-l**

Specifies that selang updates the default local database, usually *ACInstallDir/seosdb* (where *ACInstallDir* is the directory where you installed Privileged Access Manager).

You do not need to specify this option with -d or -p.

**NOTE**

This option replaces `selang`. It is only valid when `seosd` is not running, and only a Privileged Access Manager administrator with sufficient native privileges to update the database files can execute it.

- **-o *file***  
Specifies that `selang` output is written in the specified file. Each time that you invoke `selang`, it creates a new, empty file. If you specify the name of an existing file, `selang` writes over the information currently in the file.
- **-p *pmdb***  
Specifies that `selang` commands update the database of the defined PMDB, which must be in the local station (this is the database in the PMDB subdirectory). Changes to the database are not propagated to subscribers.

**NOTE**

This option is not valid if either `sepmdd` or `seosd` is running on the specified PMDB. This option is not the same as using the *hosts command*.

**WARNING**

Do not make changes that require propagation in this mode. If you use native mode when making updates, Privileged Access Manager updates only the native host files (as defined in the product configuration options).

- **-r *file***  
Specifies that `selang` reads the commands from the defined file. The file should consist of commands in normal `selang` syntax, which is separated by semicolons or line breaks. After you execute the commands in *file*, `selang` prompts the user for input.  
If you do not define a file for this option, `selang` uses the `.selangrc` file in your home directory.
- **-s**  
Specifies that `selang` opens in silent mode, without displaying the copyright message.
- **-u *user pass***  
(UNIX only) Specifies a username and password for running `selang`.  
To use this option, set the `check_password` token in the `seos.ini` file to `yes`. This token causes Privileged Access Manager to prompt you with Enter your password when you run `selang -u`. You have three attempts to log in. The token `no_check_password_users` in the `[lang]` section of the `seos.ini` file contains a list of users that bypass the password checking during a login to `selang`.

**NOTE**

If the `check_password` token is set to `no` (the default), `selang` does not require any passwords.

- **-v**  
(Windows only) Writes command line to output.

Usage notes:

- If `-h` is used, all other options are ignored.
- You cannot use the `-c` option with the `-f` option.
- You cannot use the `-d` option with the `-p` option.
- If you specify `-d` or `-p`, you do not need to specify `-l`.

## Features of the `selang` Command Shell

After you enter the `selang` command shell, the following prompt appears:

```
PAMSC>
```

When the prompt appears, you can enter `selang` commands. Enter commands that are separated with a semi-colon (;). To enter a command on more than one line, type a backslash (\) at the end of a line to continue typing the command on the

next line. You can edit the command line. Use the left and right arrow keys to move around within the line. You can insert characters by typing them directly in place, and delete characters with the standard Backspace and Delete keys, or on UNIX, by pressing Ctrl+D.

selang supports many of the command line entry features available in UNIX shell tcsh and other smart shells. These include the following features:

- Special characters
- Shortcut keys
- Command history
- Special features

#### NOTE

On UNIX, you can use a *UNIX exit* which is a program that you can specify-a shell script or an executable-to run automatically before or after a user or group is added or updated. For more information about UNIX exits, see the *Endpoint Administration Guide for UNIX*.

## Special Characters

selang supports the following special characters:

Character	Description	Meaning
# or *	Pound (hash) or asterisk	At the beginning of a line, indicates that the line is a comment; the line is not executed. Comment lines are useful when inputting the selang commands from a file.
!	Exclamation mark	At the beginning of the line, indicates that the rest of the line is a shell command. selang sends the command to the operating system shell program for execution; Privileged Access Manager does not execute the line.
\	Backslash	As the last character of a line, indicates the command continues on the following line.
;	Semicolon	Terminates a command and introduces a new command on the same line.
	Pipe	Sends the output of the preceding command to the input of the succeeding command (the specified <i>pipe</i> ).

## Shortcut Keys

selang supports the following shortcut keys:

Key	Valid on	Meaning
Up-arrow, Down-arrow, or ^	All	Used to navigate and retrieve a command from the command history.
Tab	UNIX	Serves for word completion.

Ctrl+D	UNIX	With the cursor positioned at the end of the line, displays a list of words that match the word completion string in the command line.  With the cursor positioned anywhere else on the line, deletes the character to the right of the cursor.
Esc, Esc Ctrl+2	UNIX	Displays the help text for the command in the command line. All the text in the command line is preserved, so that you can continue typing the command from where you left off.
F1	Windows	Inserts the previous command, character by character.
F2	Windows	Displays a window with the instruction: Enter char to copy up to: When you enter a character from the previous command, selang enters the command up to the first instance of the character. If the character occurs more than once in the command, you can press F2 again to insert up to the next instance.  Use Backspace to cancel.
F3	Windows	Enters the previous command (same as up arrow).
F4	Windows	Edits the previous instruction. Displays a window with the instruction: Enter char to delete up to:  Use Backspace to cancel.
F5	Windows	Enters the previous command (same as up arrow).
F6	Windows	Enters a Ctrl Z (^Z) in the command line. This allows you to press Enter and continue entering the command on the next line.
F7	Windows	Displays a window listing the command history. You can use the up and down arrows to select any previous command.  Use Esc to cancel.
F8	Windows	Enters the previous command, as the up arrow does, but with the cursor positioned at the beginning of the command line rather than at the end.
F9	Windows	Displays a window with the instruction: Enter command number: The number you enter inserts the command with the corresponding number in the F7 listing.  Use Esc to cancel.

## Command History

selang stores executed commands in a *history list*. Use the up and down arrow keys to display commands in the command line from the history list. To see only the commands that start with a specific character or string, type the

beginning of the command before using the up and down arrows. When you press *Enter*, the text currently displayed in the command line is executed.

To view previously issued commands, enter the history command.

The selang command shell supports the following shortcuts that use the commands stored in the history list:

Shortcut	Runs
<b>^^</b> [ <i>string</i> ]	The previous command. If you specify <i>string</i> , selang appends it to the original command.
<b>^n</b> [ <i>string</i> ]	The <i>n</i> th command in the history list, where <i>n</i> is a positive integer. If you specify <i>string</i> , selang appends it to the original command.
<b>^-n</b> [ <i>string</i> ]	The <i>n</i> th command from the end of the list, where <i>n</i> is a positive integer. If you specify <i>string</i> , selang appends it to the original command.
<b>^mask</b> [ <i>string</i> ]	The most recently issued command that begins with <i>mask</i> , where <i>mask</i> is a text string. If you specify <i>string</i> , selang appends it to the original command.

#### NOTE

On Windows, you can use the F7 key to view the history list.

## Special Features

You can use several additional techniques to save keystrokes in the selang command shell.

#### NOTE

Record and class names are case-sensitive on UNIX but not on Windows.

- **Command Recognition**
