

## **Symantec Privileged Access Manager - 4.1.7**

# Table of Contents

<b>Release Information.....</b>	<b>30</b>
<b>Reference Architecture.....</b>	<b>30</b>
Foundation Functional Feature.....	30
Foundation Physical Architecture.....	35
<b>Installation Requirements.....</b>	<b>42</b>
<b>Supported Environments.....</b>	<b>43</b>
<b>Cryptography.....</b>	<b>48</b>
<b>Release Comparison.....</b>	<b>49</b>
<b>New Features in 4.1.7.....</b>	<b>50</b>
<b>New Features and Enhancements in Earlier 4.x Releases.....</b>	<b>52</b>
New Features in 4.1.6.....	52
New Features in 4.1.5.....	53
New Features in 4.1.4.....	54
New Features and Enhancements in 4.1.3.....	55
New Features and Enhancements in 4.1.2.....	57
New Features and Enhancements in 4.1.1.....	60
New Features and Enhancements in 4.1.....	61
New Features and Enhancements in 4.0.....	63
<b>Known Issues.....</b>	<b>66</b>
<b>Resolved Issues in 4.1.7.....</b>	<b>71</b>
<b>Resolved Issues in Earlier 4.x Releases.....</b>	<b>72</b>
Resolved Issues in 4.1.6.....	72
Resolved Issues in 4.1.5.....	73
Resolved Issues in 4.1.4.....	75
Resolved Issues in 4.1.3.....	75
Resolved Issues in 4.1.2.....	76
Resolved Vulnerabilities and Issues in 4.0.4.....	78
Resolved Issues in 4.1.1.....	79
Resolved Issues in 4.1.....	80
Resolved Issues in 4.0.3.....	80
Resolved Issues in 4.0.2.....	81
Resolved Issues in 4.0.1.....	83
Resolved Issues in 4.0.....	85
<b>New and Revised External API Calls in 4.x and 4.x.x Releases.....</b>	<b>86</b>
<b>Revised Credential Manager CLI Commands in 4.x Releases.....</b>	<b>95</b>
<b>Access Free PAM Training Videos From the IMS Software Academy.....</b>	<b>96</b>

Threat Analytics Overview.....	133
<b>Deploying.....</b>	<b>136</b>
IP Addresses and Ports for Network Connectivity.....	137
Download PAM Installation Media.....	140
Deploy the VMware OVA Template.....	143
Deploy on an AWS Amazon Machine Image (AMI).....	146
Create AWS Objects.....	148
Configure Privileged Access Manager for AWS.....	151
Launch New AWS Instances (Optional).....	155
Connect to AWS Instances.....	156
Deploy a VHD on Microsoft Azure.....	157
Configure an Azure Connection.....	162
Clone a PAM Server Instance on VMware, AWS, or Azure.....	165
Deploy the Hardware Appliance.....	166
Configure Network Connections for the Appliance.....	173
Deploy the PAM Client.....	177
Configure How the Client is Made Available.....	183
Symantec PAM Client Silent Install.....	184
Symantec PAM Client Silent Uninstall.....	185
Use a Private Content Delivery Network to Distribute the PAM Client Installer.....	186
Ports Not Allowed for the Client.....	187

<b>Deploy the PAM Access Agent for Windows.....</b>	<b>188</b>
<b>How to Set Up a Cluster.....</b>	<b>194</b>
Cluster Deployment Requirements and Guidelines.....	196
Configure a Cluster.....	200
Add Sites to Your Cluster.....	202
Add a Member to a Site While the Cluster is Up.....	205
Change the IP Address of a Cluster Member.....	206
Tune a Cluster.....	207
Clustering Considerations for Appliances with Multiple Network Interfaces.....	207
Cluster Synchronization, Promotion, and Recovery.....	210
Primary Site Fault Tolerance.....	217
Configure Load Balancers to Determine the Availability of Cluster Nodes.....	217
<b>Install and Configure a Socket Filter Agent.....</b>	<b>217</b>
<b>Accessing PAM.....</b>	<b>223</b>
<b>Using PAM.....</b>	<b>226</b>
<b>Establish Connection Sessions and View Target Account Passwords.....</b>	<b>226</b>
Review the Access Page.....	226
Use the Limited Functionality Access Devices Panel on Standard Web Browsers.....	227
Use the Access Devices Panel from a Mobile Device.....	229
<b>Configure Your Account Settings.....</b>	<b>230</b>
Update Mobile User Password.....	232
<b>Display and Access Devices.....</b>	<b>233</b>
<b>Filter Views.....</b>	<b>236</b>
<b>View and Permit Views of Passwords.....</b>	<b>237</b>
<b>Set Up Java for Internet Explorer.....</b>	<b>237</b>
<b>Configuring a PAM Server.....</b>	<b>239</b>
Configure Global Settings.....	240
Configure RDP Proxy Service Settings.....	246
Default Administrator Accounts.....	246
Alternate Configuration Utility.....	247
Change Login for Config or Super User.....	248
Licensing and Product Usage Reporting.....	249
Configure Network Settings.....	251
Restrict Administrative Access.....	253
Additional Routes.....	254
Configure Container Network Settings.....	254
Custom Host File Entries.....	255
Authorize SNMP Polling.....	256
Add SNMP V3 Users.....	256

Enable SNMP Traps.....	256
Management Information Base (MIB) for SNMP Use.....	257
XCEEDIUM-MIB File.....	266
Configure Web Proxy Definitions.....	283
<b>Configure Security Settings.....</b>	<b>284</b>
Server Access Options Configuration.....	284
Secure Connections Using SSL Certificates.....	285
Create a Self-Signed SSL Certificate for Use in a Testing Environment.....	286
Obtain and Apply SSL Certificates for a Single-Server Production Environment.....	288
Obtain and Apply SSL Certificates for a Production Cluster.....	291
Extract Required Certificates and CRLs from a Single SSL Certificate.....	297
Certificate Revocation Update Options.....	303
Sign Java Applets.....	307
Delete a Certificate, CA Bundle, or CRL.....	307
Disable and Enable Cross-Site Scripting Attack Checking.....	308
Configure Enhanced Encryption for Stored Credentials.....	308
Configure SSH Proxy, SSH MindTerm, and TLS Cryptography Options.....	309
<b>Authenticate Users Logging in to the Server.....</b>	<b>310</b>
How to Set Up LDAP Servers for User Authentication.....	311
How to Configure Active Directory for User Authentication.....	314
Configure LDAP and RADIUS in Combination to Authenticate Users.....	316
How to Configure PKI Smart Card Authentication.....	317
How to Configure RADIUS or TACACS+ for Authentication.....	320
Configure PAM to Support RSA SecurID Authentication.....	322
Using SAML 2.0 to Authenticate Users.....	324
Configure PAM as a SAML Identity Provider (IdP).....	325
Configure PAM as a SAML Service Provider (SP).....	333
Azure AD as an Identity Provider (IdP).....	336
<b>Hardware Security Modules (HSMs) for Credential Manager.....</b>	<b>342</b>
Configure PAM to use a Safenet HSM.....	342
Configure PAM to use an Entrust nShield Connect or Connect XC HSM.....	345
Common HSM Features.....	350
<b>AWS Coordination.....</b>	<b>350</b>
<b>Configure and Manage Session Recording.....</b>	<b>354</b>
<b>Use Logs to Monitor Operations and User Sessions.....</b>	<b>360</b>
Purge Session Logs Automatically.....	361
Save or Purge Session Logs Manually.....	361
Configure an External MySQL Database for Session Logs (Optional).....	362
Configure a Splunk Server for Logging.....	363
Configure a Remote Syslog Server.....	365

Configure a Server Control User Activity Server.....	366
Troubleshoot User Interface Problems.....	367
<b>Diagnostics and Troubleshooting.....</b>	<b>369</b>
Configure and Obtain Diagnostic Logs.....	369
Configure Performance Graphs.....	372
Configure System Diagnostics, Maintenance, and Cluster Tuning Options.....	372
Networking Tools.....	374
<b>Set Up Email for Monitoring (Legacy).....</b>	<b>375</b>
<b>Microsoft Office 365 Configuration.....</b>	<b>375</b>
<b>Power, Reboot, and FIPS Mode Controls.....</b>	<b>376</b>
<b>Configure Date/Time Settings.....</b>	<b>378</b>
<b>Set Your Locale.....</b>	<b>381</b>
<b>Configure Custom Branding.....</b>	<b>382</b>
<b>Implementing Access Control.....</b>	<b>383</b>
<b>Configure Devices.....</b>	<b>386</b>
About Devices.....	387
Device Features.....	388
Discover Devices on Your Network.....	391
Device Setup.....	394
Import and Export Devices.....	399
Device Group Setup.....	402
Import LDAP Device Groups.....	404
Device and Device Group Management.....	408
Device Viewing.....	410
Set Up Access to a Target Device.....	411
Access Methods.....	411
Create TCP/UDP Services to Access a Device.....	414
Configure RDP Applications Templates.....	430
Configure Auto-Login for Windows RDP.....	431
Manage Command and Socket Filters.....	433
Set up Command Filters.....	433
Socket Filter Agent Support.....	437
Setting Up Transparent Login.....	440
SSH Connections.....	441
Set Up Transparent Login for RDP Servers.....	443
Import or Export Transparent Login Configurations.....	458
Configure Support for Citrix Virtual Apps Resources.....	458
<b>Configure Users.....</b>	<b>461</b>
User Roles.....	462
Import and Export Roles.....	468

Identify User Roles and Privileges.....	469
Create and Manage Users.....	474
Configure User Groups.....	479
Import LDAP User Groups.....	484
Import and Export Groups.....	490
Manage User Accounts.....	491
User Viewing.....	493
<b>Provision Access Policies.....</b>	<b>493</b>
Set Up a Policy.....	496
Import or Export Policies.....	499
Set Up an AWS Policy.....	501
Dynamic Addition of Devices and Target Accounts to the Access Page Based on Target Group Membership.....	501
Policy inspection.....	502
<b>Implementing Credential Manager.....</b>	<b>503</b>
Default Ports for Credential Manager.....	504
Credential Manager Operation Settings.....	508
Configure Email Preferences for Password View Policies.....	511
Specify a Target Server.....	521
Identify Target Applications and Connectors.....	522
Add an Active Directory Target Connector.....	525
Active Directory Target CLI Configuration.....	526
Active Directory Target Connector External API Configuration.....	530
Add an Active Directory SSH Key Target Connector.....	532
Active Directory SSH Key Target CLI Configuration.....	534
Active Directory SSH Key Target Application External API Attributes.....	536
Add an AWS Access Credentials Target Connector.....	538
AWS Access Credentials CLI Configuration.....	539
Add an Azure AD Target Connector.....	541
Add a BMC Remedy Target Connector.....	543
Add CA NIM Target Connectors.....	544
Add a Cisco Target Connector.....	544
Cisco Target CLI Configuration.....	546
Cisco Target Connector External API Configuration.....	554
Add an HP Service Manager Target Connector.....	562
Add an IBM i Target Connector.....	562
IBM i Target CLI Configuration.....	563
IBM i Target Connector External API Configuration.....	564
Add a Juniper Junos Target Connector.....	566
Juniper Junos Target CLI Configuration.....	566

Juniper Junos Target Connector External API Configuration.....	568
Add an LDAP Target Connector.....	570
LDAP Target Connector CLI Configuration.....	571
LDAP Target Connector External API Configuration.....	574
Add an MSSQL Target Connector.....	576
MSSQL Target Connector CLI Configuration.....	577
MSSQL Target Connector External API Configuration.....	578
Add an MSSQL Azure Managed Instance Target Connector.....	580
MSSQL Azure Managed Instance Target Connector CLI Configuration.....	581
MSSQL Azure Managed Instance Target Connector External API Configuration.....	582
Add a MySQL Target Connector.....	584
MySQL Target Connector CLI Configuration.....	585
MySQL Target Connector External API Configuration.....	586
Add an Oracle Target Connector.....	588
Oracle Target Connector CLI Configuration.....	588
Oracle Target Connector External API Configuration.....	592
Add a Palo Alto Target Connector.....	595
Palo Alto Target Connector CLI Configuration.....	597
Palo Alto Target Connector External API Configuration.....	601
Add a RADIUS/TACACS+ Secret Target Connector.....	605
Add a ServiceNow Target Connector.....	605
Office365 Integration Messages, SAML IdP and SP Messages.....	605
Add an SPML Target Connector.....	607
SPML Target Connector CLI Configuration.....	607
SPML Target Connector External API Configuration.....	609
Add a Sybase Target Connector.....	611
Upload a Sybase SDK JAR File for the Sybase Target Connector.....	612
Add the Sybase Target Application and Connector.....	612
Sybase Target Connector CLI Configuration.....	613
Sybase Target Connector External API Configuration.....	615
Add a UNIX Target Connector.....	616
UNIX Target Connector CLI Configuration.....	620
UNIX Target Connector External API Configuration.....	629
Add a VMware ESX/ESXi Target Connector.....	639
VMware ESX/ESXi Target Connector CLI Configuration.....	640
VMware ESX/ESXi Target Connector External API Configuration.....	641
Add a VMware NSX Controller Target Connector.....	643
VMware NSX Controller Target Connector CLI Configuration.....	644
VMware NSX Controller Target Connector External API Configuration.....	645
Add a VMware NSX Proxy Target Connector.....	647

VMware NSX Proxy Target Connector CLI Configuration.....	647
VMware NSX Proxy Target Connector External API Configuration.....	647
Add a WebLogic Target Connector.....	648
WebLogic Target Connector CLI Configuration.....	649
Add a Windows SSH Key Target Connector.....	651
Windows SSH Key Target Connector CLI Configuration.....	653
Windows SSH Key Target Connector External API Configuration.....	657
Add a Windows SSH Password Target Connector.....	663
Windows SSH Password Target Connector CLI Configuration.....	665
Windows SSH Password Target Connector External API Configuration.....	669
Add a Windows Remote Target Connector.....	675
Windows Remote Target Connector CLI Configuration.....	678
Windows Remote Target Connector External API Configuration.....	681
Add a Windows Proxy Connector.....	683
How to Install a Windows Proxy for Credential Manager.....	685
Add Windows Proxy Target Applications and Accounts.....	691
Windows Proxy Target Connector CLI Configuration.....	695
Windows Proxy Target Connector External API Configuration.....	698
View Windows Proxy Logs.....	700
API Key Target Connector.....	701
<b>Develop Custom Connectors for Remote Targets.....</b>	<b>701</b>
Deploy the Custom Connector Software.....	704
Sample server.xml File.....	712
Use an Alternate Custom Connector Server for Disaster Recovery.....	718
Use A2A to Secure the Keystore and Password (Optional).....	719
Try Out the Sample Custom Connectors.....	729
Learn How to Use the Custom Connector Components.....	734
UI Fields and Controls for Configuring Connectors.....	736
Web Service Endpoints for the Custom Connector.....	753
Build Your Custom Connector.....	758
Configure Custom Connectors Using the CLI.....	768
Troubleshoot Custom Connector Issues.....	770
<b>Configure SSH Key Pair Policies.....</b>	<b>773</b>
<b>Add Target Accounts to Target Applications.....</b>	<b>774</b>
Add Target Accounts using the CLI.....	778
Use Account Discovery to Add Target Accounts.....	783
Synchronize Target Account Passwords.....	786
Verify Synchronized Target Account Passwords.....	787
Schedule Password Updates and Verifications.....	789
Use an Alternate Account to Change Passwords (Optional).....	790

Configure Windows Remote Target Accounts.....	791
Configure MSSQL Target Accounts.....	793
Configure MSSQL Azure Managed Instance Target Accounts.....	794
Configure IBM i Target Accounts.....	796
Discover Active Directory Services and Scheduled Tasks.....	798
Cisco SSH Target Account Configuration.....	800
SSH Key Authentication for Accessing UNIX/LINUX Targets.....	804
Use SSH Key Discovery to Find Key Pairs.....	806
SSH Certificate Authentication for Accessing UNIX/LINUX Targets.....	811
Create an SSH Certificate Policy with the UI.....	814
Set the Privilege Elevation for UNIX Target Accounts.....	815
Oracle Target Account Configuration.....	815
Palo Alto Account Configuration.....	817
Configure Windows SSH Key Target Accounts.....	817
Configure Windows SSH Password Target Accounts.....	818
<b>Set Up Password Composition and View Policies.....</b>	<b>819</b>
Construct Password Composition Policies.....	819
Create a Password Composition Policy with the UI.....	821
Create a Password Composition Policy with the CLI.....	822
Establish Password View Policies.....	825
Create a Basic Password View Policy.....	826
Modify the Default Password View Policy.....	830
Configure Password View Policies That Require Approval of Requests.....	830
Require an Account Check-Out to View the Password.....	844
Enable Email Notifications for Viewed Passwords.....	850
Track Account Movement Across Active Directory OUs.....	851
See a List of Password View Requests.....	852
Make a Request to View a Password.....	852
<b>Configure Just in Time (JIT) Provisioning for MSSQL User Accounts.....</b>	<b>854</b>
Add the LDAP Domain Server Required for JIT Provisioning.....	855
Import LDAP User Groups for JIT Provisioning.....	856
Create a Device for the MSSQL Database That Requires JIT Provisioning.....	857
Create a Custom Workflow to Handle Just in Time Target Account Checkout and Check-in.....	857
Create a Target Application for the MSSQL Database Admin Account Used by JIT Provisioning.....	859
Create a Target Account for the MSSQL Database Administrator (for JIT Provisioning).....	859
Configure a Provisioned Account for JIT Provisioning.....	860
Create a Password View Policy for the JIT Provisioned Account.....	860
Create a Target Application for the JIT Provisioned Account.....	860
Create a Target Account for the MSSQL JIT Provisioned Account.....	861
(Optional) Restrict Users from Editing RDP User Name Values.....	862

Create an Access Policy for JIT LDAP Users.....	862
User Experience: Just in Time (JIT) Checkout and Check-in Operations.....	863
<b>Configure Just in Time (JIT) Provisioning for Azure SQL Managed Instance User Accounts.....</b>	<b>863</b>
Add the LDAP Domain Server Required for JIT Provisioning.....	864
Import LDAP User Groups for Azure SQL JIT Provisioning.....	865
Create a Device for the Azure SQL Managed Instance That Requires JIT Provisioning.....	866
Create a Custom Workflow to Handle Just in Time Target Account Checkout and Check-in.....	866
Provide an Administrator Account to Use to Access the Azure SQL Managed Instance for JIT Provisioning.....	868
Configure a Provisioned Account for Azure SQL Managed Instance JIT Provisioning.....	869
Create a Password View Policy for the JIT Provisioned Account.....	869
Create a Target Application for the JIT Provisioned Account.....	870
Create a Target Account for the Azure SQL Managed Instance JIT Provisioned Account.....	870
(Optional) Restrict Users from Editing Azure User Name Values.....	871
Create an Access Policy for Azure Managed Instance JIT LDAP Users.....	872
User Experience: Just in Time (JIT) Checkout and Check-in Operations.....	872
<b>Delegate Password Management Tasks to Groups.....</b>	<b>873</b>
Credential Manager Group Terminology.....	874
Add Credential Manager Target Groups.....	877
Add Credential Manager Requestor Groups.....	882
Manage Credential Manager Credential Groups.....	884
Add or Modify Credential Manager Roles.....	890
Configure Users with the Manage Credentials Privilege to View Passwords on the Access Screen.....	898
Configure a PAM User to View the Password History of Target Accounts.....	901
<b>Manage Credentials Between Applications (A2A).....</b>	<b>904</b>
Install and Activate an A2A Client on a Request Server.....	907
Uninstall the A2A Client.....	914
Target Aliases for A2A Target Accounts.....	915
Start or Stop an A2A Client.....	915
A2A Client Connection Security.....	916
Integrity Verification.....	916
Add A2A Requestors.....	918
Example Requestors.....	920
Configure A2A Authorization Mappings.....	922
View Unsuccessful A2A Client Requests.....	925
Run an Example Application.....	925
Modify the A2A Client Configuration File.....	926
How the A2A Client Configures Cache Credentials to Local Storage.....	928
View A2A Client Logs.....	928
Update an A2A Client Key.....	928
View A2A Client Status and Troubleshoot Connection Issues in a Cluster.....	929

Configure an A2A Client to Use Another Server.....	930
Configure A2A Client Failover in a Multisite Cluster.....	931
Configure A2A Client Event Polling.....	932
<b>Implementing Secrets Management.....</b>	<b>934</b>
<b>About Secrets Management and Roles.....</b>	<b>934</b>

## Release Information

---

Release 4.1.7 contains **5** new features and resolves **42** issues.

### IMPORTANT

#### Functional Changes Related to Cluster Status and Remote Storage Emails

In previous releases, Cluster Status emails and Remote Storage emails were sent to the SMTP server defined on the **Configuration, Monitor (Legacy)** panel, which could be different on each node in the cluster.

In 4.1.7, all Cluster Status emails and Remote Storage emails are sent to the SMTP server defined on the **Configuration, Email Settings** panel, which is defined once on the primary node and replicated to all nodes in the database. You must therefore define the SMTP server in the **Email Settings** for the Cluster Status and Remote Storage Status emails to continue to be sent from any node.

The SMTP server that is specified in **Email Settings** must also be visible from all nodes in the cluster. Otherwise, Remote Storage emails (which alert the user when primary or failover remote storage is mounted, dismounted, or out of contact) are not sent from any node which cannot see the SMTP server.

**Known Issue:** Cluster Status notification emails for quorum loss events are not being sent. All other cluster status email notifications are working as expected.

## Reference Architecture

The topics in this section describe a Reference Architecture which provides information relating the baseline functional feature and technical architecture that is required to deliver the Privileged Access Manager foundational solution.

This artifact is relevant only to the implementation of the foundational solution. The artifact can be superseded by more detailed design, implementation, test, and operational artifacts. The following phases or iterations of the project illustrate how other artifacts support the maturation of the solution functionally and technically.

**Use the table of contents to access the topics in this section.**

## Foundation Functional Feature

This section contains the following topics:

- [Planned End State](#)
- [Solution Personas](#)
- [Interaction of Personas](#)
- [Foundation Capability Privileged Access Management](#)
- [Foundation Functional User Stories](#)

## **Planned End State**

The Planned End State is based on the solution requirements. The end state may be extended during the design process. This section documents the actors, processes, and walk-throughs of the "as-built" solution.

The PAM planned solution is summarized in the following table:

Solution Outcome	Description
Enhanced security governance and compliance	<ul style="list-style-type: none"> <li>• Stores passwords for managed privileged accounts</li> <li>• Credentials are encrypted using an AES 256 cipher before being stored for maximum security. A CMVP FIPS 140-2 validate cryptographic kernel, or use of a Hardware Security Module are optionally available</li> <li>• Manages privileged account password rotation according to the policies configured in accordance with customer requirements.</li> <li>• Employs a zero-trust posture to granting access to privileged accounts and devices. Access is granted only on a need-to-know basis.</li> <li>• Implements the following workflows to access account passwords:               <ul style="list-style-type: none"> <li>— Privileged account password request based on the approval workflow</li> <li>— Verification of user authentication every time a privileged account password is viewed</li> <li>— Access to privileged accounts based on an Administrator role</li> </ul>               When a user logs in to the Web Portal to access privileged accounts, one or more of the workflows takes effect depending on the job.             </li> <li>• Provides detailed Audit functions</li> <li>• Provided Session Recording</li> </ul>
Integration with existing corporate systems	<ul style="list-style-type: none"> <li>• Active Directory/LDAP and SailPoint integrations to help streamline the management of key data elements</li> <li>• Service Desk integrations to provide enhanced workflow</li> <li>• SIEM/Splunk/Syslog integration for consolidated activity reporting and searching</li> <li>• Federated authentication sources including PIV/CAC, RADIUS, and other protocols</li> </ul>

## **Solution Personas**

The following table summarizes the solution personas and how they can use the Privileged Access Manager solution. Where applicable, the personas that are listed represent the most common personas within Privileged Access Manager. Personas are grouped by the capability in which they play a role:

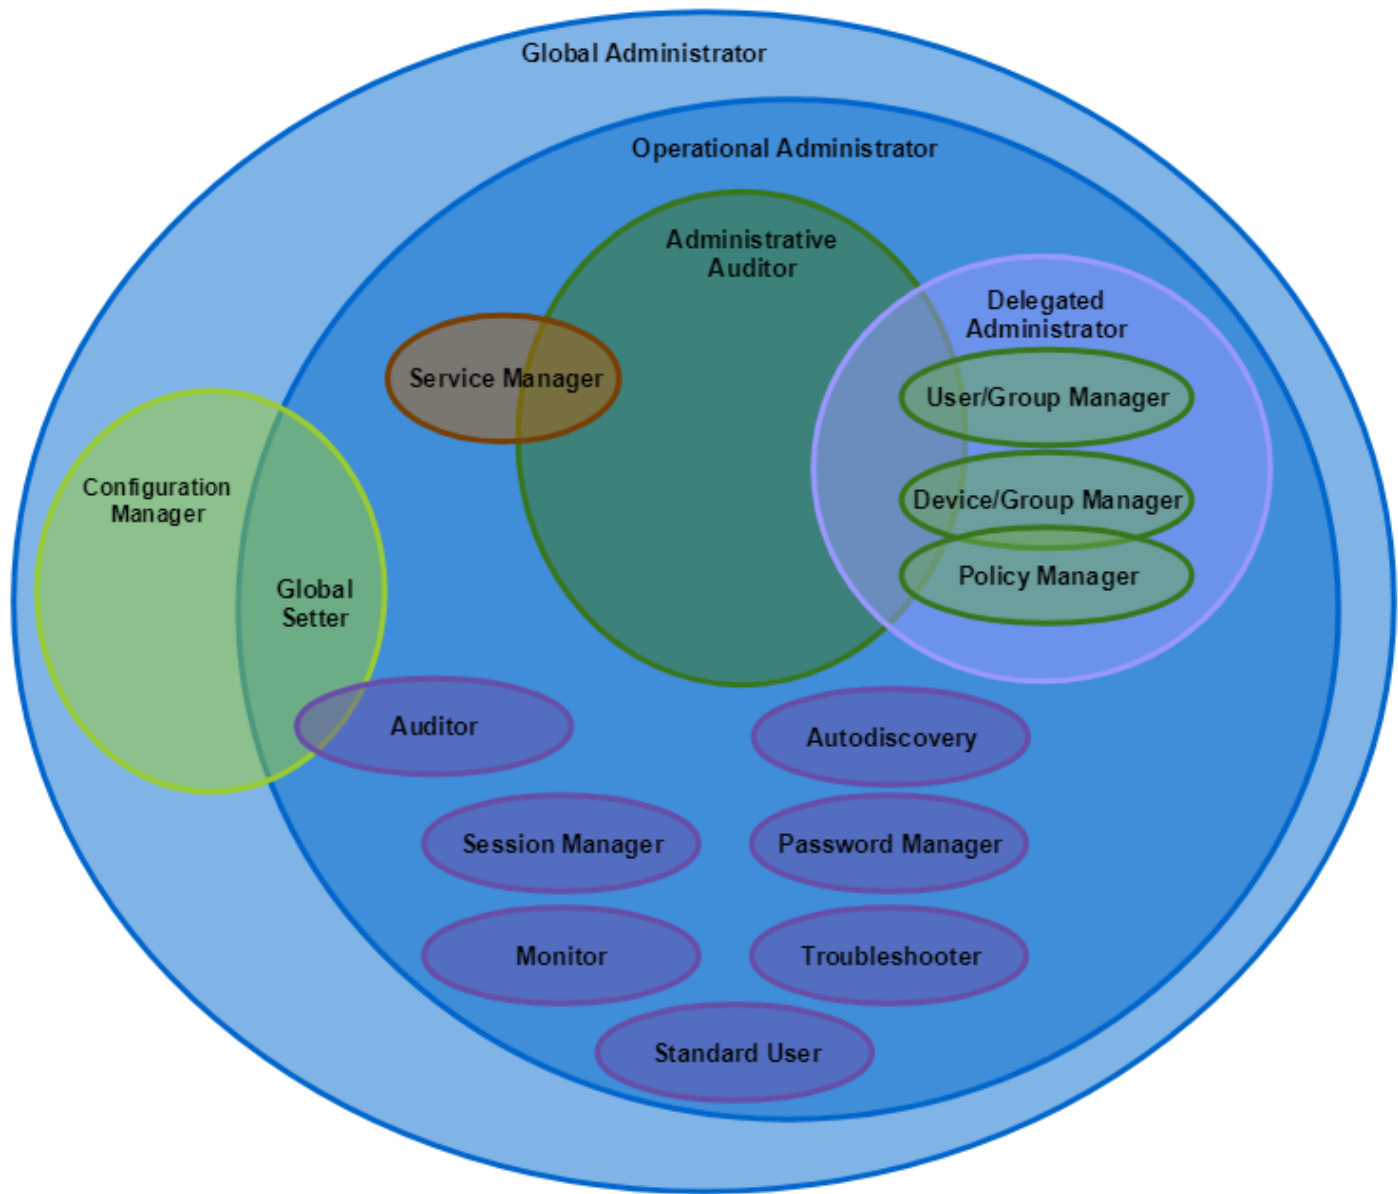

<b>Persona (Role)</b>	<b>Description</b>	<b>Expected Use of New Solution</b>
PAM Administrator	Administrator for PAM Solution	<ul style="list-style-type: none"> <li>• Manage the solution and solution configurations</li> <li>• Deploy and expand the solution footprint within the environment</li> <li>• Define which authorized end users/groups can access a Privileged ID password that is stored in the solution</li> <li>• Define which sets of end users/groups can access a solution-managed shared account</li> </ul>
PAM User	Individuals who are granted access to managed accounts and connect to the target devices through PAM.	<ul style="list-style-type: none"> <li>• Grant access to a Privileged ID using policies</li> <li>• Connect to the target/managed system using authorized privileged accounts</li> <li>• Depending on policy workflow, grants requests to reserve a privileged account password and releases when complete</li> </ul>
Access Approver	Individuals who approve/reject user requests to access managed accounts	Approves/rejects privileged password view requests submitted by the end user.
Security/Audit	Responsible for monitoring and reviewing security policies to ensure compliance with corporate standards and security levels	<ul style="list-style-type: none"> <li>• Review security policies</li> <li>• Review security events and reports</li> </ul>

## **Interaction of Personas**

Privileged Access Manager provides a preconfigured set of 17 roles that are mapped to the identified solution personas. This preconfigured set of privileges are required to perform various common activities. Roles are assigned to users and user groups when you configure or modify these objects.

The following Venn diagram shows the relationship of privilege and scope between the various out-of-the-box, predefined roles:

Figure 1: Venn Diagram of PAM Roles

The following list provides all the privileges that are assigned to each of the pre-configured roles shown in the previous graphic.

- **accessAll** : Global Administrator, Operational Administrator, Standard User
- **manageAll** : Global Administrator, Operational Administrator, Standard User
- **monitorAll** : Global Administrator, Monitor, Operational Administrator
- **sessionRead** : Global Administrator, Operational Administrator, Session Manager

- **sessionManage** : Global Administrator, Operational Administrator, Session Manager
- **overviewRead** : Auditor, Global Administrator, Operational Administrator
- **toolsAll** : Global Administrator, Operational Administrator, Troubleshooter
- **loggingAll** : Auditor, Global Administrator, Operational Administrator
- **sessionRecordingRead** : Auditor, Configuration Manager, Global Administrator, Global Setter, Operational Administrator
- **globalSettingRead** : Auditor, Configuration Manager, Global Administrator, Global Setter, Operational Administrator
- **globalSettingManage** : Configuration Manager, Global Administrator, Global Setter, Operational Administrator
- **servicesRead** : Administrative Auditor, Global Administrator, Operational Administrator, Service Manager
- **servicesManage** : Global Administrator, Operational Administrator, Service Manager
- **servicesDelete** : Global Administrator, Operational Administrator, Service Manager
- **usersRead** : Administrative Auditor, Delegated Administrator, Global Administrator, Operational Administrator, User/Group Manager
- **usersManage** : Delegated Administrator, Global Administrator, Operational Administrator, User/Group Manager
- **usersDelete** : Delegated Administrator, Global Administrator, Operational Administrator, User/Group Manager
- **usersAssign** : Delegated Administrator, Global Administrator, Operational Administrator, User/Group Manager
- **userGroupRead** : Administrative Auditor, Delegated Administrator, Global Administrator, Operational Administrator, User/Group Manager
- **userGroupUpdate** : Delegated Administrator, Global Administrator, Operational Administrator, User/Group Manager
- **cacUserApproval** : Delegated Administrator, Global Administrator, Operational Administrator, User/Group Manager
- **socketFilterAgentRead** : Administrative Auditor, Delegated Administrator, Device/Group Manager, Global Administrator, Operational Administrator, Policy Manager
- **socketFilterAgentDelete** : Delegated Administrator, Device/Group Manager, Global Administrator, Operational Administrator, User/Group Manager, Policy Manager
- **devicesRead** : Administrative Auditor, Delegated Administrator, Device/Group Manager, Global Administrator, Operational Administrator
- **devicesManage** : Delegated Administrator, Device/Group Manager, Global Administrator, Operational Administrator
- **devicesDelete** : Delegated Administrator, Device/Group Manager, Global Administrator, Operational Administrator
- **devicesAssign** : Delegated Administrator, Device/Group Manager, Global Administrator, Operational Administrator
- **deviceGroupRead** : Administrative Auditor, Delegated Administrator, Device/Group Manager, Global Administrator, Operational Administrator
- **deviceGroupUpdate** : Delegated Administrator, Device/Group Manager, Global Administrator, Operational Administrator
- **policyRead** : Administrative Auditor, Delegated Administrator, Global Administrator, Operational Administrator, Policy Manager
- **policyManage** : Delegated Administrator, Global Administrator, Operational Administrator, Policy Manager
- **socketFiltersRead** : Delegated Administrator, Global Administrator, Operational Administrator, Policy Manager
- **socketFiltersManage** : Delegated Administrator, Global Administrator, Operational Administrator, Policy Manager
- **commandFiltersRead** : Administrative Auditor, Delegated Administrator, Global Administrator, Operational Administrator, Policy Manager
- **commandFiltersManage** : Configuration Manager, Global Administrator, Operational Administrator, Policy Manager
- **policyImport** : Global Administrator, Operational Administrator
- **policyExport** : Global Administrator, Operational Administrator
- **configurationManage** : Configuration Manager, Global Administrator
- **rolesRead** : Administrative Auditor, Global Administrator, Operational Administrator
- **Autodiscovery** : Auto Discovery, Global Administrator, Operational Administrator
- **credentialsManager** : Global Administrator, Operational Administrator, Password Manager

**NOTE**

You can also download a [spreadsheet](#) that presents the privileges that are assigned to each pre-configured role in a matrix format.

**Foundation Capability Privileged Access Management**

The following table summarizes the capability, the technology, and the primary user stories.

Aspect	Description
Capabilities	<ul style="list-style-type: none"> <li>Controls the access of authorized users and other identities to elevated privileges across multiple systems that are deployed in an organization</li> <li>Provides secure access to target systems, over specific protocols, using the managed credentials, without the users knowing the credential</li> </ul>
Content/Enabling Technology	<ul style="list-style-type: none"> <li>Privileged Access Manager</li> </ul>
Primary User Stories	<ul style="list-style-type: none"> <li>Password Vaulting (Shared Account)</li> <li>Interactive Login Usage</li> <li>Account Access Approval</li> <li>Manage End-User Privileged Access</li> <li>Syslog Forwarding</li> <li>Self-contained, hardened appliance delivery</li> </ul>

**Foundation Functional User Stories**

The following table summarizes the functional user stories and the personas that participate in them.

As a...	I want to...	So that...
PAM Administrator	Define which authorized end users can access a stored Privileged ID password.	I control access to the Privileged ID in the password vault.
PAM User	Check out a Privileged ID.	I can access the target system interactively without needing to remember the system password
PAM User	Request access to a Privileged ID	I have temporary access to a target device after my request is approved.
PAM User	View a credential of a privileged account.	I have access to see the credential of the target account.
Access Approver	Certify an end-user request for a Privileged ID.	I can approve only authorized requests to access Privileged ID passwords
Security/Auditor	Review audit events and reports.	I ensure compliance with corporate standards and security levels

**Foundation Physical Architecture**

This topic details the default configuration requirements for applications. Requirements can include port numbers for web services, database configuration, OS configuration, and supporting services. The information aligns with the associated baseline technical architecture, focusing on specific platform requirements and component configurations for the Privileged Access Manager solution.

## Foundation Logical Architecture

The following architecture graphics illustrate the most common, logical components when working with Privileged Access Manager.

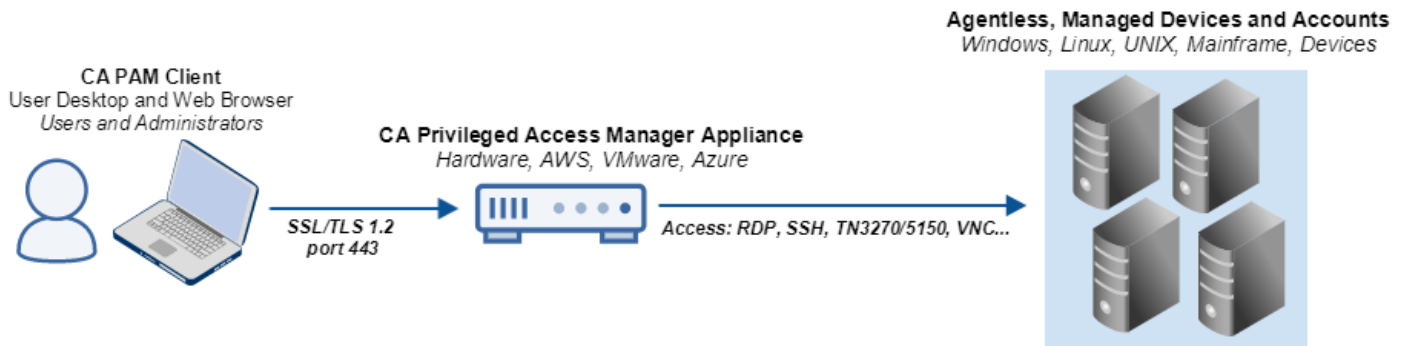

### NOTE

The only required logical architecture is a Privileged Access Manager appliance and a managed endpoint.

### Minimal Architecture

The following graphic shows a minimum architecture:

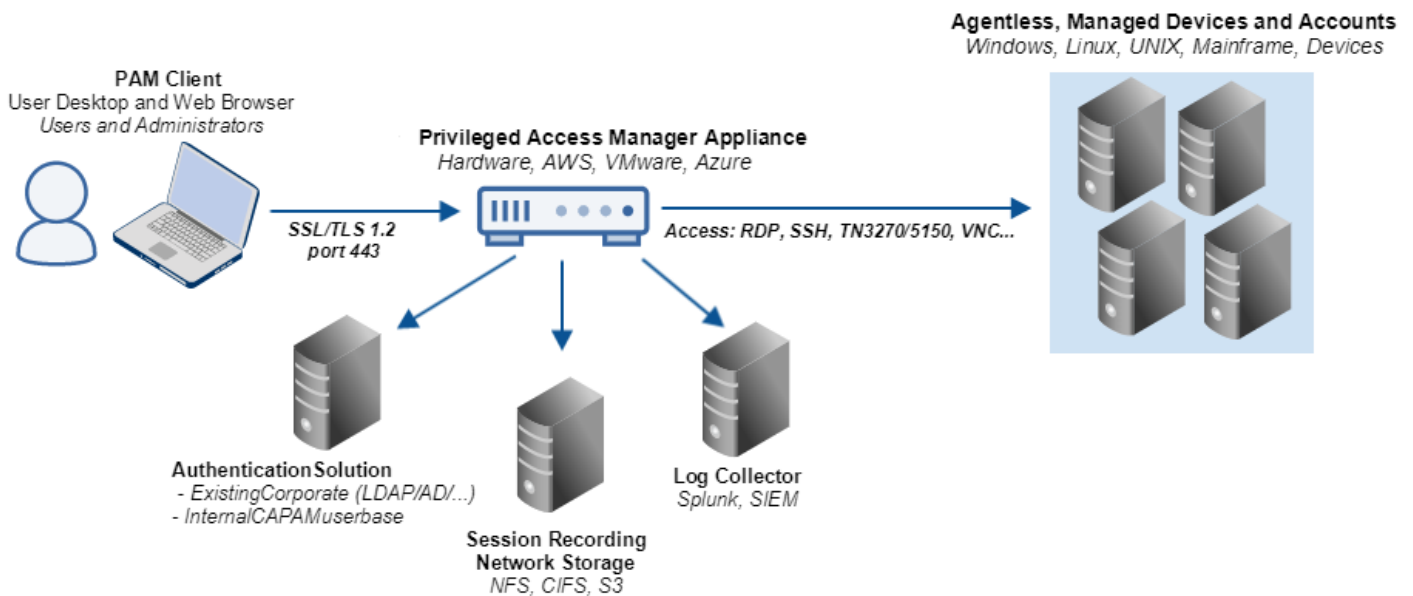

**Figure 2: Minimal PAM architecture**

### Advanced Architecture

The following graphic shows an advanced architecture:

**Figure 3: Advanced PAM Architecture**

## Solution Delivery

Privileged Access Manager is delivered as a self-contained, hardened appliance in the following forms:

- Physical hardware instance
- VMware - OVA
- AWS - AMI
- Azure - VHD

A single appliance contains all the necessary components to control privileged access in an environment.

Each appliance is a hardened appliance, which means that security measures are implemented to prevent any access to the appliance. All required configuration changes are available through the UI. Network tools are available to troubleshoot issues, such as firewall configurations.

In the rare case that a customer needs access, Broadcom Support is engaged to assist the customer in this task. This security posture prevents the on-site PAM Administrators from updating the appliance without an audit trail.

## Clustering

Appliances can be clustered together to satisfy *high availability*, *redundancy*, and *disaster recovery* requirements.

Privileged Access Manager supports clustering over a LAN and a WAN, under specific configurations. Administrators have the option of using single site clustering or multi-site clustering. Each cluster site is a logical grouping of PAM instances, which we recommend you deploy in a single data center.

### Single-and Multiple-Site Clusters

Configure a *single-site cluster* or *multi-site cluster* using the following guidelines to help determine which best suits your requirements:

- **Separation of administrative and access tasks:** To designate specific PAM nodes to handle global administrative functions (such as policy maintenance and credential rotation) and others to handle user requests for access to privileged devices, configure a [multi-site cluster](#). Address all administrative requests to the VIP of the Primary site and all access requests to the VIPs of Secondary sites.
- **Geographical distribution of data centers:** If all your PAM nodes are deployed at a single geographical location and you do not need to separate them for administrative and access tasks, you only require a [single-site cluster](#). If your PAM servers are deployed over multiple geographically dispersed locations, configure a [multi-site cluster](#).

### Single-Site Clusters

If all your PAM infrastructure is deployed at a single geographical location and you do not require separate administrative and access tasks between nodes, you only require a *single-site cluster*. PAM replicates data across all the nodes so that they operate as a single virtual system addressed by a single VIP.

#### NOTE

When you add another site to a single-site cluster, the first site you configured becomes the *Primary site* for the new multi-site cluster.

### Multi-Site Clusters

If your PAM environment is deployed over multiple geographically dispersed locations or if you want to designate specific nodes to handle administrative activities (recommended), configure a *multi-site cluster*. Each site in a multi-site cluster should contain at least two members. Multi-site clusters have one *Primary* site and one or more *Secondary* sites. Each site is addressed by its own VIP.

- **Primary site** members are co-located and are typically designated for administrative activities (policy maintenance, credential rotation). If user requests for access to privileged devices must also be handled at the same data center, create and designate a secondary site at the same location for that purpose. Data that is saved on one member of the Primary site is synchronously replicated across all Primary site members. Only one Primary site exists within a cluster at any time.

**NOTE**

The Primary site in a multi-site cluster behaves the same as a single-site cluster with the same properties. Primary sites and single-site clusters both use group replication to keep themselves in sync.

- **Secondary sites** are typically designated for access activities, that is, handling user requests for access to devices. Asynchronous replication is performed from the Primary site to Secondary sites. Replication allows Secondary site members to recover gracefully and continue operating should a network issue exist between the sites, like a brown-out or DC outage.

**NOTE**

A Secondary site can also be promoted to Primary site status, providing a warm backup if the Primary site goes down. For more information, see [Cluster Synchronization, Promotion, and Recovery](#).

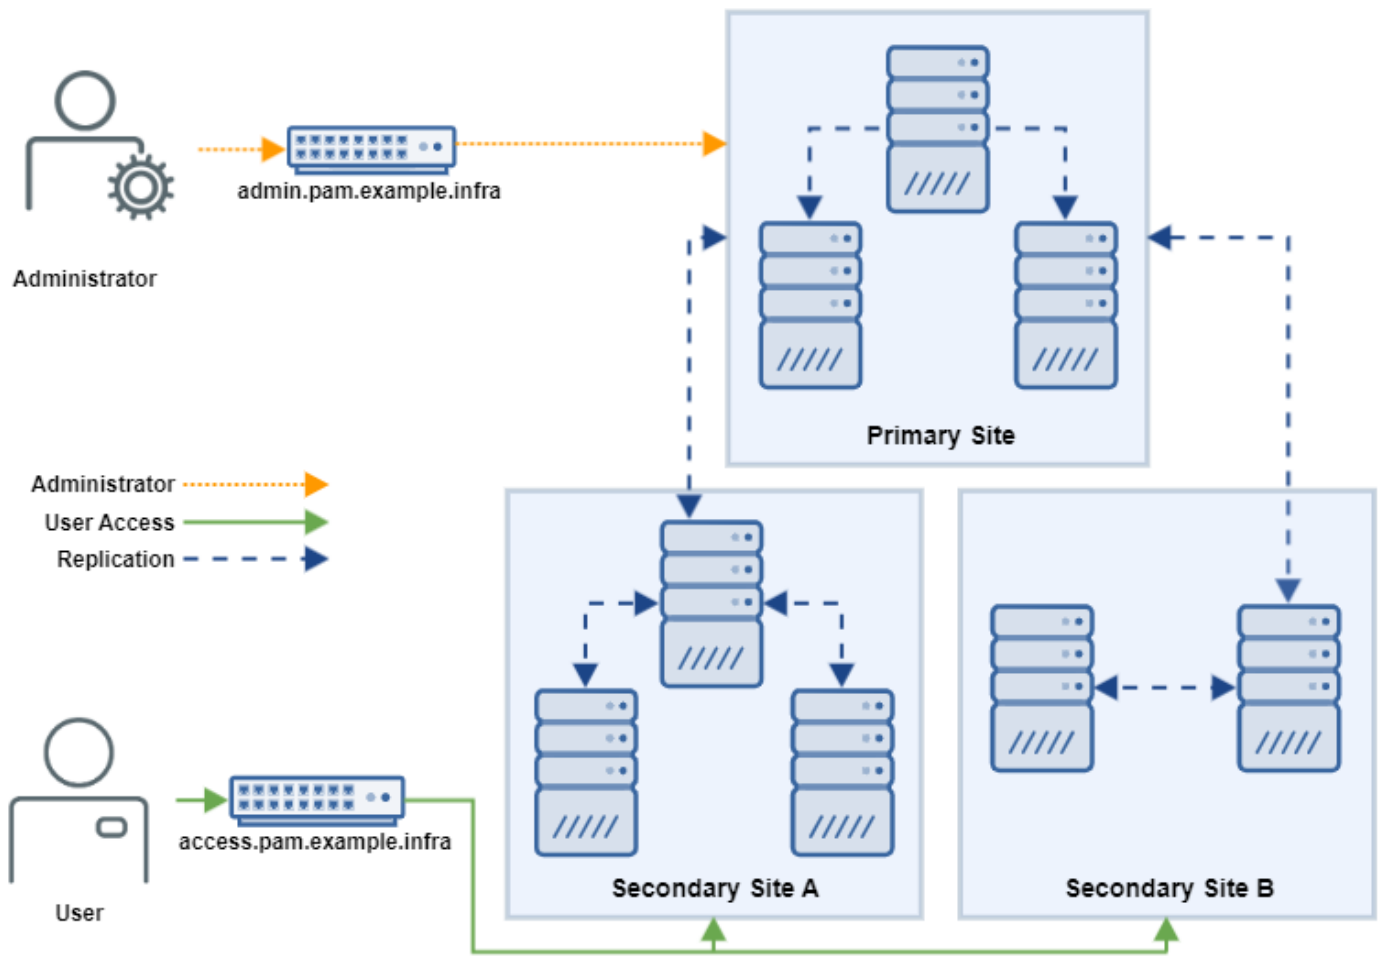

Sizing of a cluster is important and should be considered with customer corporate policies and procedures.

- **Primary site:** Three are recommended, with maximum of nine.
- **Secondary sites:** The number of sites can vary. At least one site per data center and two members per site are recommended.

For more information, see [Set Up a Cluster](#).

**Network Context*****Network Diagram – Foundation Physical Architecture***

The following diagram provides a reference implementation architecture design for the deployment of the Privileged Access Manager solution.

**Figure 4: Network Diagram - Foundation Physical Architecture****Foundation System Specification Requirements**

The specifications and requirements for the solution are defined in the following subsection.

Note the following information about sizing:

- Hardware-based PAM depends on third-party vendor specifications which is subject to change at any time
- Virtual based PAM (OVA, AMI, VHD) has required minimum specification for production grade systems

**Foundation Specification Architecture**

The minimum specification that is required for the Foundation Physical Architecture solution is given in the following table:

Node	Product, Versions, Options	Platform, OS, SP Level, Kernel Version	Memory, CPU, Processor, Speed, NIC Cards	Minimum Disk Space	Number Required (Recommended)
PAM	PAM 4.0	Hardened, Encrypted Linux	Memory: 16 GB Processor: 4 x Dual Core NIC: 1 – 1 GB	Recommended storage space for VM is 80 GB, however more is possible.	1 (4 - 2x2)
PAM Windows Proxy Server	PAM Windows Proxy Server	Windows 2012 R2 SE	Memory: 4 GB Processor: 2 x Dual Core		Optional, 2
NFS or CIFS Mount*		Windows 2012 R2 EE / Linux		500 GB – high network bandwidth; SSD preferred	2 per data center

\*NFS or CIFS mount is required for session recording data.

## Base System Configuration Requirements

### Node Configuration

No configuration of the appliances is required before installation. However, obtaining an appliance-specific license file is required.

### Solution Component Ports

All inbound traffic to PAM is over 443/TLS. The following table summarizes the outbound ports. For a comprehensive list of network ports for proper appliance functionality, see the [IP Address and Ports for Network Connections](#).

Source	Destination	Default Port	Port Type	Deployment Port	Other Comments
PAM	Windows Server	443	TCP	443	Windows Server connectivity with PAM Proxy – HTTPS
PAM	5250 Server	992	TCP	992	Credential Management – 5250 hosts
PAM	SMTP Server	25	TCP	25	SMTP Email Alerts
PAM	Windows Server	3389	TCP	3389	RDP Access
PAM	Syslog Servers	514	TCP	514	Syslog forwarding
PAM	Active Directory Instance	389	TCP	389	Active Directory Authentication
PAM	Active Directory Instance	636	TCP	636	Credential Management on Active Directory
PAM	CIFS Mount	139, 445	TCP	139, 445	Store for Session Recording
PAM	PAM Windows Proxy	135, 445, 27077	TCP	135, 445, 27077	WMI RPC

PAM Windows Proxy	PAM	443	TCP	443	PAM Windows Proxy
-------------------	-----	-----	-----	-----	-------------------

### Integrations

Privileged Access Manager integrates with many existing solutions and partners. The following table lists the most common components. Consult the **Configuration** section in the UI for a comprehensive list.

Component	Solution/Partner
Authentication	<ul style="list-style-type: none"> <li>• CA Single Sign On/SiteMinder</li> <li>• RSA</li> <li>• RADIUS</li> <li>• LDAP</li> <li>• Kerberos</li> <li>• PIV/CAC</li> <li>• SAML</li> </ul>
Auditing/Searching	<ul style="list-style-type: none"> <li>• Splunk</li> <li>• Syslog</li> <li>• SIEM</li> </ul>
APIs	<ul style="list-style-type: none"> <li>• Privileged Access Manager API/CLI</li> <li>• VMware NSX API</li> <li>• AWS APIs</li> </ul>
Cloud/Virtualization providers	<ul style="list-style-type: none"> <li>• VMware vCenter</li> <li>• AWS Management Console</li> <li>• Office 365</li> </ul>
Cryptography strength	<ul style="list-style-type: none"> <li>• OpenSSL</li> <li>• FIPS 104-2 compliance</li> <li>• HSM integration (onboard or from a third-party service)</li> </ul>
External Load Balancers	Health check-based balancing
Governance	<ul style="list-style-type: none"> <li>• CA Identity Management and Governance (IMAG)</li> <li>• SailPoint</li> </ul>
Service Desk	<ul style="list-style-type: none"> <li>• Remedy Service Desk</li> <li>• CA Service Desk</li> <li>• HP Service Manager</li> <li>• ServiceNow</li> <li>• Salesforce</li> </ul>
Secrets Management	Application-2-Application (A2A) for execution-time retrieval of credentials

### Common Configurations

The following table lists common configuration choices:

Business Function	Available Solutions
Authentication	Configure authentication for an existing customer implementation, using one of the various out-of-the-box options.

Users and user group membership management	In PAM, a policy matches a user or user group to a device (endpoint) or group of devices. Eliminate operational overhead by configuring users and their membership into user groups. Use Governance tools, such as CA IMAG or SailPoint, or using Active Directory/LDAP groups. When you manage users with these tools, they are automatically authorized and granted access to the appropriate devices and accounts in PAM.
Syslog/Splunk/SIEM integration	Access and Administration events are logged and available for audit purposes and can be sent to a third-party log aggregator. From the aggregator, customers generally adjoin PAM event information with events from other corporate systems to describe accurately user activity.
External Load Balancing	PAM provides a health check URL that informs load balancers whether an instance of PAM can receive traffic. <b>Note:</b> PAM is not a traditional n-tier application. Different use cases have caveats regarding when and how to use external load balancers. Also, external load balancers do not replace how and when the site-based VIPs are used within a PAM clustering configuration.

## Installation Requirements

Ensure that the following requirements are met before installing Privileged Access Manager.

### **Software Compatibility**

Before you upgrade, ensure that your existing installation is running a release and patch that you can upgrade to the current release. Verify whether you can upgrade by reviewing [Upgrading](#).

### **Hardware Appliance**

We have no special requirements for installing a Privileged Access Manager hardware appliance. Only general standalone computer hardware requirements apply.

The latest hardware appliance ships with 4 CPU cores (8 threads), 64 GB of RAM, and two 240 GB SSD. The appliance has 8 RJ45 network ports, and an expansion slot for a PCI card for HSM.

### **Virtual Instances**

Privileged Access Manager provides virtual images as VMware OVA, AWS AMI, and Azure VHD. When you provision these instances, we *recommend* the following parameters:

- Memory: 64 GB
- CPU: 8 cores (we support up to 512 CPU cores)
- Storage: 80 GB
- Disk Type: SSD

At a *minimum*, we require the following parameters:

- Memory: 16 GB
- CPU: 8 cores (we support up to 512 CPU cores)
- Storage: 80 GB
- Disk Type: SSD

**VMware OVA Instance**

One network interface is provided. Add extra required interfaces before its initial boot.

**AWS AMI Instance**

AWS specifications vary by region and over time. We suggest an AWS instance type of C4.4xlarge for production. For evaluation or testing, an instance type of M3 Medium is sufficient.

**Azure VHD Instance**

Azure specifications vary by region and over time. We suggest Azure size DS13 Standard for production. For evaluation or testing, an instance type of F2S Standard is sufficient.

## Supported Environments

**Deprecated Platform**

The Microsoft® Windows 2012 R2 platform is no longer supported for the PAM client.

**New Platforms**

Support for Windows 2022 and Red Hat 9 has been added in this release.

**At a Glance**

This content shows platform support for this version of the product. PAM ships as either a hardware or software-based appliance. In both cases, the operating system and database are included with the software package. We support the listed platforms for end-point Session Management, Credential Management, and ancillary agents. These agents (A2A Client, Socket Filter Agent, or PAM Workstation Client) are required for certain features of PAM.

The PAM Client is the recommended method for accessing the PAM UI. Various browsers, such as Chrome, Safari, Edge and Firefox can also be used with the following limitations:

- Microsoft Edge running in Internet Explorer mode is the only browser that still supports NPAPI, which is required for the device access applets. To use Microsoft Edge running in Internet Explorer mode, Java 8u-latest must be installed on the desktop.
- Microsoft Edge running in Internet Explorer mode does not support the [System Dashboard](#) or the [Management Console Cluster Dashboard](#).

**Session and Credential Management Platform Support**

Operating System Platforms	Supported?
IBM® AIX 7.2	✓
IBM® AIX 7.3	✓
Microsoft® Windows 10	✓
Microsoft® Windows 11	✓
Microsoft® Windows 2016	✓
Microsoft® Windows 2019	✓
Microsoft® Windows 2022	✓
Oracle® Solaris 11	✓
Red Hat® Enterprise Linux 7	✓

Operating System Platforms	Supported?
Red Hat® Enterprise Linux 8	✓
Red Hat® Enterprise Linux 9	✓
SuSE® Linux Enterprise Server 12.3-5	✓
SuSE® Linux Enterprise Server 15.0-2	✓

Databases (as Target Applications)	Supported?
IBM® DB2 v10.5 <sup>1</sup>	✓
IBM® DB2 v11.1 <sup>1</sup>	✓
IBM® DB2 v11.5 <sup>1</sup>	✓
MariaDB	✓
Microsoft® SQL Server 2014	✓
Microsoft® SQL Server 2016	✓
Microsoft® SQL Server 2017	✓
Microsoft® SQL Server 2019	✓
Oracle® 12c	✓
Oracle® 19c	✓
Oracle® 21c	✓
Oracle® MySQL 5.7	✓
Oracle® MySQL 8.x	✓

<sup>1</sup> IBM® DB2 is an OS credential. Use the UNIX connector. See product documentation.

Network Devices <sup>2</sup>	Supported?
Cisco™ ASA	✓
Cisco™ IOS	✓
Cisco™ TACACS+ Server	✓
Palo Alto PAN Server 6	✓
Palo Alto Devices (Layer 3, Option C configuration)	✓
Devices with *nix Operating Systems using SSHv2 connection	✓

<sup>2</sup> As Target Applications. Typically network devices use SSH protocol for user session establishment. Use the UNIX connector. See product documentation.

Mainframe <sup>3,4</sup>	Supported?
ACF2™ r15	✓
ACF2™ r16.0	✓
TopSecret® r15	✓
TopSecret® r16.0	✓

<sup>3</sup> Requires Broadcom LDAP for Mainframe System z/OS.

<sup>4</sup> Transparent Login functionality for Mainframe not supported.

Directories	Supported?
Symantec Directory v12	✓
Symantec Directory v14	✓
Microsoft® Active Directory <sup>5</sup>	✓
OpenLDAP v3 compliant	✓

<sup>5</sup> For any supported Windows Server.

Cloud & Virtualization Platforms	Supported?
Amazon Web Services™ Admin web console access	✓
Microsoft® Azure	✓
Microsoft® Office 365 Admin console access	✓
VMware vCenter 6.x	✓
VMware vCenter 7.0	✓

Web/Application Servers	Supported?
Apache Tomcat 7	✓
Apache Tomcat 8	✓
Apache Tomcat 9	✓
Oracle® Weblogic 10	✓

Threat Analytics (for PAM)	Supported?
Threat Analytics (for PAM) v2.3	✓
Threat Analytics (for PAM) v2.4	✓

IT Service Management Systems	Supported?
Service Desk Manager 14.1	✓
Service Desk Manager 17.0	✓
BMC Remedy 8.1	✓
BMC Remedy 9.1	✓
HP Service Manager 9.32	✓
HP Service Manager 9.41	✓
Salesforce Service Cloud (Winter 2015)	✓
ServiceNow (Istanbul)	✓
ServiceNow (Jakarta)	✓

## **PAM Client**

The PAM Client enables you to log in to PAM and perform administrator and end-user activities without a customer-installed web browser and Oracle Java engine. The Client removes the required maintenance of keeping Java and browser configurations compatible with PAM. You can run any PAM connection applets and can provide a complete substitute for the traditional PAM GUI using the Client.

The PAM Client is the recommended method for accessing the PAM UI. Various browsers, such as Chrome, Safari, Edge and Firefox can also be used with the following limitations:

- Microsoft Edge running in Internet Explorer mode is the only browser that still supports NPAPI, which is required for the device access applets. To use Microsoft Edge running in Internet Explorer mode, Java 8u-latest must be installed on the desktop.
- Microsoft Edge running in Internet Explorer mode does not support the [System Dashboard](#) or the [Management Console Cluster Dashboard](#).

You can download and install a PAM client version compatible with your workstation OS type from a button on the PAM GUI login page. The embedded JRE is downloaded with the client but PAM-served JARs download at runtime.

For MacOS, both Intel and ARM64 packages are provided.

PAM supports all versions of Linux supported by vendors.

<b>PAM Client (End-User Desktop Support)</b>	<b>Supported?</b>
Microsoft® Windows 10	✓
Microsoft® Windows 11	✓
Microsoft® Windows 2016	✓
Microsoft® Windows 2019	✓
Microsoft® Windows 2022	✓
Linux	✓
Apple macOS Big Sur	✓
Apple macOS Monterey	✓
Apple macOS Ventura	✓

## **PAM Access Agent**

The PAM Access Agent is a lightweight Windows alternative to the PAM Client.

<b>PAM Agent (End-User Desktop Support)</b>	<b>Supported?</b>
Microsoft® Windows 10 64-bit	✓
Microsoft® Windows 11 64-bit	✓

## **Mobile Support for PAM**

PAM offers limited support for mobile devices. The PAM browser user interface is optimized for password view requests and password check-in and check-out operations for mobile devices.

PAM supports Chrome browser on Android and Safari browser on iOS.

**PAM A2A Client**

A2A integration allows administrators to provide authorization for applications to access privileged credentials for application to application transactions. An A2A client is installed on the Request server where the requesting application resides and has various security checks to maintain authorization control. Multiple programming and scripting languages can be used (see product documentation for integration details).

PAM A2A Client	Supported?
IBM AIX 7	✓
Microsoft® Windows 10	✓
Microsoft® Windows 11	✓
Microsoft® Windows 2016	✓
Microsoft® Windows 2019	✓
Microsoft® Windows 2022	✓
Red Hat® Enterprise Linux 7	✓
Red Hat® Enterprise Linux 8	✓
Red Hat® Enterprise Linux 9	✓
Oracle Solaris 11	✓

PAM A2A languages	Supported?
Java	✓
C++	✓
C	✓
C#	✓
PHP	✓
Python	✓
JavaScript	✓
Perl	✓
PowerShell	✓
Korn Shell	✓
C Shell	✓

**PAM Socket Filter Agent (SFA)**

Installed on an endpoint, the Socket Filter Agent is used to provide lateral containment (such as preventing administrators from “leap frogging” to another server)

PAM SFA Client	Supported?
IBM AIX 6.1 64-bit	✓
IBM AIX 7.1 64-bit	✓
Debian 6 32-bit	✓
Debian 6 64-bit	✓

PAM SFA Client	Supported?
Debian 7 32-bit	✓
Debian 7 64-bit	✓
HP-UX 11i v3 IA64	✓
Red Hat Enterprise Linux 6 32-bit	✓
Red Hat Enterprise Linux 6 64-bit	✓
Red Hat Enterprise Linux 7 64-bit	✓
Oracle Solaris 10 SPARC 64-bit	✓
Oracle Solaris 11 x86-64 (64-bit)	✓
SUSE Linux Enterprise Server 11 32-bit	✓
SUSE Linux Enterprise Server 11 64-bit	✓
SUSE Linux Enterprise Server 12 64-bit	✓
Microsoft® Windows 2016	✓
Microsoft® Windows 2019	✓
Microsoft® Windows 2022	✓

### Windows Proxy

The Windows Proxy is a Credential Manager component that enables updating Windows-based account passwords, and updating Windows service and scheduled task login account passwords.

PAM Windows Proxy	Supported?
Microsoft® Windows 10	✓
Microsoft® Windows 11	✓
Microsoft® Windows 2016	✓
Microsoft® Windows 2019	✓
Microsoft® Windows 2022	✓

### PAM SC Endpoint Agents

To implement PAM Server Control *host-based security*, install the following PAM SC endpoints, as required:

- **Endpoint Agents:** Install on Windows and UNIX servers that you want to secure with PAM SC.
- **UNAB Authentication Agent:** Install on UNIX servers with an Active Directory data store that you want to act as a single repository for all of your users.

For platform support information for PAM SC Endpoint agents, see the [Privileged Access Manager Server Control Endpoint Compatibility Matrix](#).

## Cryptography

Privileged Access Manager uses the following cryptographic algorithms and protocols:

- **Symmetric Encryption:** Advanced Encryption Standard (AES) Symmetric keys of 256 bit key length, defined in NIST FIPS PUB 197 and ISO/IEC 18033-3.
- **Asymmetric Encryption:** Transport Layer Security protocol follows IETF RFC 5246 version 1.2 (TLS 1.2) including optional Perfect Forward Secrecy Diffie Hellman key exchange elliptic curve (P-256 and P-384 supported).
- **Cryptographically secure entropy source:** For symmetric key generation Intel RDRAND (on PAM hardware or if present in the hypervisor hardware for OVF) which meets NIST SP800 90B.
- **Digital Signature:** Digital Signature Standard (compliant to FIPS 186-4) Elliptic Curve Digital Signature Algorithm (ECDSA) (P-256 and P-384 supported).
- **Hash Functions:** For integrity checks and comparison of User specific login credentials, SHA-2 hash is used either with 512 or 256 bits. In SSH-2 communication, HMAC can support either SHA 256 or 512
- **Digital Certificates:** Either RSA (2048 or 4096 key length) or ECDSA (Curve p-256 or p-384) certificates may be implemented on the PAM server.

## Release Comparison

This table compares the key features in 4.1.7 to those in the most recent active PAM 4.1.x releases:

Key Features	4.1.7	4.1.6	4.1.5	4.1.4	4.1.3
New Windows SSH Password and SSH Key Target Connectors	yes	no	no	no	no
PAM UI Dark Mode	yes	no	no	no	no
New External API methods for <a href="#">managing Credential Manager credential groups</a> and <a href="#">obtaining Credential Manager roles</a>	yes	no	no	no	no
PAM Client Control-F Search Support	yes	no	no	no	no
<a href="#">Send Cluster Status and Network Storage emails with TLS</a>	yes	no	no	no	no
<a href="#">System</a> and <a href="#">Cluster</a> Dashboards	yes	yes	no	no	no
<a href="#">LDAP Synchronization Scheduling</a>	yes	yes	no	no	no
<a href="#">Restrict API Key Role Group Inheritance for External API Users</a>	yes	yes	no	no	no
<a href="#">REST API Support for ServiceNow Integration</a>	yes	yes	no	no	no
<a href="#">Support for Azure SQL Managed Instance User Accounts</a>	yes	yes	yes	no	no
<a href="#">Just in Time (JIT) Provisioning for Azure SQL Managed Instance User Accounts</a>	yes	yes	yes	no	no
<a href="#">Active Directory</a> and <a href="#">Windows Remote</a> Target Connectors Now Support Kerberos Authentication	yes	yes	yes	no	no
<a href="#">Set Allowed TLS Communication Version</a>	yes	yes	yes	no	no
<a href="#">Changes to Oracle Target Connector Logic When Updating Target Accounts</a>	yes	yes	yes	no	no
<a href="#">JSON Message Format Option Added for Syslog and Splunk Server Logging</a>	yes	yes	yes	no	no
<a href="#">IPv6 Addressing Support</a>	yes	yes	yes	yes	no
<a href="#">Display a message to users at login</a>	yes	yes	yes	yes	yes
<a href="#">A2A Client for Red Hat Enterprise Linux Now Available As an RPM Package</a>	yes	yes	yes	yes	yes
<a href="#">Route OCSP Requests Through an OCSP Proxy Server</a>	yes	yes	yes	yes	yes
<a href="#">New option to hide "View Credential" link from users accessing a TCP/UDP service from the Access panel</a>	yes	yes	yes	yes	yes
<a href="#">Updated SPFD (Service Provider Daemon) logging</a>	yes	yes	yes	yes	yes

Key Features	4.1.7	4.1.6	4.1.5	4.1.4	4.1.3
PAM Client Supports ARM64 Architecture	yes	yes	yes	yes	yes
Support for AWS EC2 instances in the GovCloud Eastern Region (US-Gov-East) as well as eu-south-1 (Milan), eu-central-2 (Zurich), and eu-south-2 (Spain) in commercial cloud	yes	yes	yes	yes	yes
Number of Credential Manager groups that can be assigned to a user is no longer limited	yes	yes	yes	yes	yes
Admins can now see all target account information when scheduling a database back up	yes	yes	yes	yes	yes
Cluster key now cleared after a node leaves the cluster	yes	yes	yes	yes	yes

**NOTE**

For information about features in earlier 4.1.x releases, see the [4.1.2 Release Comparison](#).

## New Features in 4.1.7

This topic introduces the following new features and enhancements in PAM 4.1.7.

### Windows SSH Password and SSH Key Target Connectors

This release provides two new SSH-based target connectors that provide secure solutions for managing local privileged credentials on supported SSH-enabled Windows systems:

- **Windows SSH Key target connector**
- **Windows SSH Password target connector**

**NOTE**

The Windows SSH Key target connector is the most secure. Both new connectors are more secure than the Windows Remote target connector.

For more information, see:

- [Windows SSH Key Connector](#)
- [Windows SSH Password Connector](#)

### PAM UI Dark Mode

This release introduces an application color scheme setting that allows you to configure the PAM UI to be displayed using a new **Dark** mode instead of the existing **Light** mode (which is still the default). The application color scheme is configured as a **Global** setting, but can be overridden by local account settings after a user logs in.

**NOTE**

Dark mode is also not available on the PAM Agent or for all locations on other PAM UI platforms, including the following elements and components:

- PAM access methods (for example, RDP, SSH, and TELNET) launched from the **Access** page
- PAM LDAP Browser
- Session Recording Viewer
- Threat Analytics
- PAM Report output
- External API Documentation
- Online help
- Alternate Configuration Utility

For more information, see [Configure Global Settings](#) and [Configure Your Account Settings](#).

### **New External API Methods for Managing Credential Manager Credential Groups and Obtaining Credential Manager Roles**

**Managing Credential Manager credential groups:** In previous releases, you could only manage Credential Manager credential groups using the CLI interface. This release adds REST methods that allow you to do the same operations using the External REST API. For more information, see [Get Credential Manager Roles Using the External API](#).

**Obtaining Credential Manager Roles:** In previous releases, you could only get Credential Manager roles using the CLI interface. This release adds a REST method that allows you to get roles using the External REST API. For more information, see [Get Credential Manager Roles Using the External API](#).

### **PAM Client Control-F Search Support**

Previously, you could use the industry-standard Control-F keyboard shortcut to search PAM browser-based pages when accessing the PAM UI from a browser but not from the PAM Client. Examples of searchable pages include PAM reports, the Web Portal, the SAML IdP login page, and the Threat Analytics Console.

This release adds the same search functionality to the PAM Client. That is, when using the PAM client you can now use the Control-F keyboard shortcut to search the same pages as you can when accessing the PAM UI from a browser.

### **Support for Sending Cluster Status and Network Storage Emails Over a Secure TLS Connection**

PAM has provided the option to use TLS to secure the connection to the SMTP server configured for Credential Manager-related email messages (on the **Configuration, Email Settings** panel) since release 3.4.5. However, Cluster Status and Network Storage Status emails continued to be sent using the SMTP server configured on the **Configuration, Monitor (Legacy)** panel, which did not support a TLS connection.

In release 4.1.7, PAM uses the SMTP server that is configured to send Credential Manager-related email (which does support TLS) to also send Cluster Status and Network Storage Status emails.

#### **IMPORTANT**

After upgrading to 4.1.7, Cluster Status and Network Storage Status emails will only be sent if PAM is configured to send Credential Manager emails. If not, complete the procedure that is described in [Configure Email Preferences for Password View Policies](#) before or immediately after upgrade.

### ***Credential Manager Email Settings Used for Cluster Status and Network Storage Emails***

PAM uses the following settings from the **Configuration, Email Settings** panel to send Cluster Status and Network Storage emails:

- **Enable SMTP Server Authentication:** An account to use to authenticate with the SMTP server.
- **Hostname:** Identifies the SMTP server.
- **Port:** The port number of the SMTP server.
- **Enable TLS:** If set, secures the connection to the SMTP server using TLS.

### ***Other Configuration Settings Used to send Cluster Status Emails***

PAM uses the following settings that are defined on the **Configuration, Monitor (Legacy)** panel to send Cluster Status emails:

- **Admin Email:** The email address (or addresses) of the user (or list of users) to which Cluster Status emails are sent.
- **Appliance From Address:** An email address that specifies the "From" address of sent Cluster Status emails.

### ***Other Configuration Settings Used for Network Storage Status Emails***

PAM uses the following settings to send Network Storage Status emails:

- **"To" Address:** Network Storage Status emails are sent to the addresses of all users with the Global Administrator or Configuration Manager role.
- **Appliance From Address** (on the **Configuration, Monitor (Legacy)** panel): An email address that specifies the "From" address of sent Network Storage Status emails.

## New Features and Enhancements in Earlier 4.x Releases

The topics in this section describe the features and improvements provided in earlier Privileged Access Manager 4.1.x releases

Use the table of contents to access these topics.

### New Features in 4.1.6

This topic introduces the new features and enhancements in PAM 4.1.6.

#### System and Cluster Dashboards

This release provides the following dashboards for viewing and interpreting data about PAM nodes and clusters:

- **System Dashboard:** Available in the PAM UI, visualizes data about the current PAM instance
- **Cluster Dashboard:** Available in the Management Console, visualizes data about a PAM cluster.

Both dashboards show current and historical data that dynamically updates at specified intervals, making them valuable tools for monitoring performance and identifying trends over time.

For more information, see [System Dashboard \(Single Node\)](#) and [Management Console Cluster Dashboard](#).

#### LDAP Synchronization Scheduling

In this release, you can configure PAM to synchronize with LDAP servers according to a specified schedule. Scheduling allows you to avoid running the update during peak periods when PAM servers are experiencing heavy loads. In environments with multiple LDAP instances, you can also use scheduling to stagger the order and timing of refreshes for each instance. (Previously, you could only configure PAM to synchronize with LDAP servers according to a specified interval.)

For more information, see [How to Set Up LDAP Servers for User Authentication](#). (Look for Step 8 in the "Identify the LDAP Servers in Your Environment" procedure.)

#### Restrict API Key Role Group Inheritance for External API Users

The External REST API uses the role assignments that are defined in API keys associated with user accounts to authorize calls to its methods. By default, each API key has the same role assignments as those configured to determine the privileges of that account to use the PAM UI. The API key can therefore be used to access to the same functionality using the External API as its associated user account using the PAM UI.

In previous releases, you could edit an API Key definition to reduce its privileges to use the External API by removing roles that were *directly assigned* to the user account. However, you could not remove roles *inherited from user groups* of which the user was a member.

In this release you can also remove roles inherited from user groups of which the user is a member.

For more information, see [Deploy the External REST API \(Administrators\)](#).

#### REST API Support for ServiceNow Integration

In this release, you can configure PAM to connect to ServiceNow using the REST API protocol. Previously, the API exclusively used the SOAP web service interface (which is still the default) to connect to ServiceNow.

For more information, see [ServiceNow Integration](#).

## New Features in 4.1.5

This topic introduces the new features and enhancements in PAM 4.1.5.

### **Support for Azure SQL Managed Instance User Accounts**

This release provides a new *MSSQL Azure Managed Instance* application type and target connector that enables Credential Manager to manage accounts on an Azure SQL Managed Instance.

For more information, see [Add an MSSQL Azure Managed Instance Target Connector](#).

### **Just in Time (JIT) Provisioning for Azure SQL Managed Instance User Accounts**

This release provides *Just in Time (JIT)* provisioning, which allows you to dynamically provision and deprovision Azure SQL Managed Instance user accounts on demand.

JIT provisioning provides the following security enhancements for accessing your Azure SQL Managed Instance:

- Zero-trust security where user identities only exist on the Azure SQL Managed Instance during the checkout period.
- On-demand identity and access management with dynamic privileges that is auditable and can be subject to third-party approval.

For more information, see [Configure Just in Time \(JIT\) Provisioning for Azure SQL Managed Instance User Accounts](#).

### **Active Directory and Windows Remote Target Connectors Now Support Kerberos Authentication**

In this release, the Active Directory and Windows Remote target connectors have been updated to support Kerberos authentication.

For more information, see [Add an Active Directory Target Connector](#) and [Add a Windows Remote Target Connector](#).

### **Set Allowed TLS Communication Version**

In this release, you can use the **TLS Communication Allowed** feature to select the TLS communication version to use with a Utility Group:

- Selecting the **All Versions** option means that PAM uses your current TLS settings with a Utility Group.
- The **TLS V1.2** option means that PAM only uses TLS version 1.2 with a Utility Group.

For more information, see the section entitled [Step 6. Enable the TLS Settings](#), in the [Enabling Server Control TLS Settings](#) topic.

### **JSON Message Format Option Added for Syslog and Splunk Server Logging**

In this release, you can configure PAM to send log messages to Syslog and Splunk servers using the JSON message format. Previous releases supported XML and Space Delimited formats

For more information, see [Configure a Remote Syslog Server](#), [Configure a Splunk Server for Logging](#), and [Syslog Message Formats](#) (which contains JSON-formatted examples in the "Metric Detail JSON Example" and "Audit Detail JSON Example" sections).

### **Changes to Oracle Target Connector Logic When Updating Target Accounts**

The Oracle target connector credential update workflow has been modified to ensure endpoint Oracle server logs only reflect actual failed login attempts. Previous workflows still tested new, system-generated credentials prior to the update, resulting in extraneous errors. This workflow was a holdover from manual password generation. To ensure that

the PAM and endpoint Oracle Server log audit records only reflect actual failed login attempts, the Oracle target connector now does not attempt to log in with a new, system-generated password for an account being actively managed.

### **Functional Change**

#### **NOTE**

**The RSA client is updated in this release, requiring RSA server platform configuration changes!** For more information, see the [Register PAM as an Authenticating Device on the RSA SecureID Authentication Manager Server](#) section of the [Configure the Product for RSA SecurID](#) topic.

## **New Features in 4.1.4**

The PAM 4.1.4 release focuses on one major new feature: *IPv6 addressing support* and provides *one functional change*.

### **IPv6 Addressing Support**

This release updates PAM to support IPv6 addressing so that it can operate in an IPv6 environment.

#### **NOTE**

All PAM components have been updated to support IPv6 addresses with the following exceptions, which remain IPv4-only in this release:

- PAM SC Utility Appliances
- PAM SC endpoints
- Sybase target connectors

### **IPv6 Addressing Functional Examples**

The following list shows some functional examples of the use of IPv6 addressing in a PAM environment:

- Administrators can now use IPv6 addresses when configuring the PAM cluster. For more information, see [Configure a Cluster](#).
- Administrators can download the PAM installation software from an IPv6 address. For more information, see [Deploy the PAM Client](#).
- Users can now log in to the PAM Client using an IPv6 address. For more information, see [Privileged Access Manager Client Reference](#).

### **Key IPv6 Addressing Configuration Settings**

The following entries show some of the most significant configuration settings that are required to enable and use IPv6 addressing:

- *Enable PAM IPv6 addressing*, configure a default IPv6 gateway, and configure IPv6-compatible network Interfaces on the **Configuration, Network, Network Settings** panel. For more information, see [Configure Network Settings](#).
- Configure IPv6 addresses when configuring the PAM cluster. For more information, see [Configure a Cluster](#).

### **Functional Change**

In this release, the **Docker Network Settings** panel has been renamed to **Container Network Settings** and the controls on it are changed. For more information, see [Configure Container Network Settings](#).

#### **NOTE**

There are also some changed and new External API calls related to the container network changes. For more information, see [New and Revised External API Calls in 4.x and 4.x.x Releases](#).

## New Features and Enhancements in 4.1.3

This topic introduces the new features and enhancements in PAM 4.1.3.

This release includes the following new features:

- [Display a Message to Users at Login](#)
- [A2A Client for Red Hat Enterprise Linux Now Available As an RPM Package](#)
- [Route OCSP Requests Through a Proxy Server](#)
- [New Option to Hide "View Credential" Link From Users Accessing a TCP/UDP Service from the Access Panel](#)

### NOTE

For the list of enhancements, see [New Functional Enhancements](#).

### Display a Message to Users at Login

In this release, you can configure a message that appears when a user logs in to the PAM UI. Examples of the types of notifications you might want to present in these messages include the following items:

- Planned maintenance
- Availability of training for new available features
- Process changes

For more information, see [Display a Message to Users at Login](#).

### A2A Client for Red Hat Enterprise Linux Now Available As an RPM Package

This release adds an RPM package for Red Hat A2A Clients. Using this package with a Red Hat native package manager (YUM or DNF) to install the client provides the following benefits:

- To support the efficient installation of the A2A Client on multiple request servers, you can place the RPM package in a central repository of a package handler rather than download it to each host.
- Package handlers can identify from the RPM that the A2A Client requires the **libidn** library and can resolve this dependency by installing the correct version automatically, if necessary. (You have to do these actions manually when using the standard UNIX install script.)
- Package handlers can identify an existing A2A Client that was installed from an RPM package and can upgrade it automatically. (A2A Clients that were installed using the UNIX install script do not support upgrades.)

For more information, see [Install and Activate an A2A Client on a Request Server](#).

### Route OCSP Requests Through a Proxy Server

This release allows you to configure a proxy server to allow requests and responses through the firewall.

For more information, see [Route OCSP Requests Through a Proxy Server](#).

### New Option to Hide "View Credential" Link From Users Accessing a TCP/UDP Service from the Access Panel

In previous releases, when a TCP/UDP Service was configured with **Application Protocol** set to **Disabled**, a **View Credential** link was displayed when a user selected the corresponding service icon on the **Access** panel:

In this release, you can set the new **Hide Credential** configuration setting configuring a TCP/UDP service to hide the **View Credential** link.

For more information, see [Create TCP/UDP Services to Access a Device](#).

### **New Functional Enhancements**

This release adds support for the following functional changes:

- [Support for Additional AWS Regions Enabled](#)
- [Admins Can Now See All Target Account Information When Scheduling a Database Backup](#)
- [Updated SPFD \(Secure Port Forwarding Daemon\) Logging](#)
- [Number Of Credential Manager Groups That Can Be Assigned To A User Is No Longer Limited](#)
- [Cluster Key Now Cleared After a Node Leaves the Cluster](#)
- [PAM Client Supports ARM64 Architecture](#)

### **Support for Additional AWS Regions Enabled**

This release adds support for AWS instances for three new European regions: eu-south-1 (Milan), eu-central-2 (Zurich), and eu-south-2 (Spain), as well as the GovCloud Eastern region (US-Gov-East).

For information, see [Configure Privileged Access Manager for AWS](#).

### **Admins Can Now See All Target Account Information When Scheduling a Database Backup**

PAM administrators, can now see all target account information when you schedule a database backup. Target account information includes the target account name, device, type, and target account device name. Also, the UI now shows the device that is associated with the account.

Previously, the administrator could only see the target account name when scheduling a database backup, and not this additional information. If two or more accounts had the same name, it was impossible to determine the correct account because you were unable to see any supporting account information.

For more information, see the [Schedule a Backup of the Database](#).

### **Updated SPFD (Secure Port Forwarding Daemon) Logging**

To configure WolfSSL logging levels, use the **SPFD Log Level** on the **Configuration, Diagnostic Logs** panel, which now includes revised and new options.

For more information, see [Configure and Obtain Diagnostic Logs](#).

### **Number Of Credential Manager Groups That Can Be Assigned To A User Is No Longer Limited**

In prior releases, by default you could assign only 10 Credential Manager groups to a user. (Although this limit could be increased to 25 using a procedure provided by Broadcom Support). In this release, there is no limit to the number of groups that you can assign regardless of whether you were previously using the default or expanded limit.

### **Cluster Key Now Cleared After a Node Leaves the Cluster**

In earlier releases, the cluster key was retained in the configuration information of a node after that node had left the cluster, had been ejected from the cluster, or the cluster was reset. In this release, the key is cleared when a node leaves the cluster for any reason.

### **PAM Client Supports ARM64 Architecture**

In this release, the PAM Client adds native support for Apple ARM64 architecture. Installation packages for both MacOS Intel and MacOS ARM64 platforms are now available for download and deployment. Existing PAM Clients for MacOS will continue to use Intel binaries when they self-update to 4.1.3. A fresh install of PAM Client is required to deploy ARM64 binaries.

## **New Features and Enhancements in 4.1.2**

This topic introduces the new features and enhancements in PAM 4.1.2.

### **Updated Cryptographic Providers**

This release provides the following cryptographic provider updates:

- For servers running in FIPS mode, the WolfSSL module has been updated to a version that incorporates the FIPS 140-2 validated FIPS Object Module (FOM) under CMVP Certificate #3389.
- For servers not running in FIPS mode, OpenSSL has been replaced with WolfSSL but does not use the validated FOM. This change does not affect established Key-Encryption-Key or Server Key (Data-Encryption-Key) currently in use.

### **Support for the ed25519 Cryptographic Algorithm**

This release supports the ed25519 cryptographic algorithm for more secure SSH communications during **credential management** and **access management**.

#### ***Credential Management***

For credential management, Cisco and UNIX target connectors can now use the following new, more-secure cryptographic algorithms in non-FIPS mode:

- Key Exchange algorithm: curve25519-sha256,curve25519-sha256@libssh.org
- Server Host Key: ssh-ed25519

For more information about this and other supported security algorithms for credential management using Cisco and UNIX target connectors, see the [Review Strong Cryptography on Cisco and UNIX Target Connectors](#) section of the [Upgrade Prerequisites for 4.1.2](#) topic.

#### **NOTE**

Prior to upgrading to **4.1.2**, if the **Use supported algorithm** checkbox option was selected for all the algorithms under the SSH-2 tab, this checkbox continues to stay selected, or will get cleared (that is, unchecked), depending on the version of PAM from that you are upgrading.

Upgrading from **4.1 to 4.1.2** preserves the **Use supported algorithm** checkbox option. This upgrade path also adds the newly Key exchange algorithm curve25519-sha256, curve25519-sha256@libssh.org, and Server Host Key ssh-ed25519 to the default list as high priority algorithms, and connectors continue working using the recommended list. No user action is required.

Upgrading from **4.0.x to 4.1.2** will NOT preserve the **Use supported algorithm** checkbox option: this check becomes cleared (that is, unchecked). Review the algorithms for every application, and either provide a customized list, or select the **Use supported algorithm** checkbox option, and let the connectors use the recommended list. This upgrade path uses the new Key exchange algorithm curve25519-sha256, curve25519-sha256@libssh.org, and Server Host Key ssh-ed25519 as high priority algorithms set by the recommended list. User action is required.

## Access Management

For access management, ed25519 cryptographic algorithm is now one of the preferred cryptographic algorithms to help secure SSH communications using SSH Proxy and SSH Mindterm. In addition to supporting the ed25519 cryptographic algorithm, the following algorithm changes were made to SSH Proxy and SSH Mindterm:

### SSH Proxy

- Added to the PAM recommended list of Key Exchange for non-FIPS mode only: curve25519-sha256
- Server Host Keys algorithms added to the PAM recommended list of Server Host Keys for non-FIPS mode only: ssh-ed25519,ecdsa-sha2-nistp256,ecdsa-sha2-nistp384,ecdsa-sha2-nistp521
- Server Host Keys algorithms added to the PAM recommended list of Server Host Keys for FIPS Mode: ecdsa-sha2-nistp256,ecdsa-sha2-nistp384,ecdsa-sha2-nistp521
- *Unsupported* Server Host Keys: ssh-ed25519-cert-v01@openssh.com,ssh-rsa-cert-v01@openssh.com,ecdsa-sha2-nistp384-cert-v01@openssh.com,ecdsa-sha2-nistp256-cert-v01@openssh.com,ecdsa-sha2-nistp521-cert-v01@openssh.com

#### NOTE

If an existing cryptographic configuration for SSH Proxy is configured to use one of the unsupported algorithms, remove them using the PAM UI, and then save the configuration settings. If the unsupported algorithms are not removed from the customized Server Host Key list, the PAM UI will not allow any updates to be done to SSH Proxy cryptography algorithms.

### SSH MindTerm

Key Exchange:

- Added to the PAM recommended list for non-FIPS mode only: curve25519-sha256,diffie-hellman-group14-sha256
- Added to the PAM recommended list for FIPS Mode: diffie-hellman-group14-sha256
- Added to the PAM supported list for non-FIPS mode: curve25519-sha256,diffie-hellman-group14-sha256,diffie-hellman-group16-sha512,diffie-hellman-group18-sha512
- Added to PAM supported list for FIPS mode: diffie-hellman-group14-sha256,diffie-hellman-group16-sha512,diffie-hellman-group18-sha512

Server Host Key:

*Added* to the PAM recommended list for both FIPS and non-FIPS mode: ecdsa-sha2-nistp256,ecdsa-sha2-nistp384,ecdsa-sha2-nistp521

#### NOTE

If the **Use default** option was selected on either the **SSH-Proxy** and/or the **SSH Mindterm** tabs, after upgrade to 4.1.2, this option becomes cleared (that is, unchecked) due to a change in the recommended algorithm. Select the **Use default** option, and continue using the updated PAM recommended list. You can also customize the algorithm selection.

For more information about this and other supported and recommended lists of the security algorithms for access management, see the [Review Strong Cryptography for Access Management - SSH Proxy and SSH Mindterm](#) section of the [Upgrade Prerequisites for 4.1.2](#) topic.

### **PAM Client Supports Apple macOS Ventura**

In this release, the PAM Client adds support for Apple macOS Ventura.

### **Web Proxy Support**

This release adds the ability to configure *web proxy definitions* to represent physical (or virtual) web proxies in your network. Use web proxy definitions when configuring [services to access web portals](#) if the network firewall would block a direct connection to the portal.

For more information, see [Configure Web Proxy Definitions](#).

#### **NOTE**

This feature was originally implemented in the 4.0.4 release.

### **Access Panel Improvements**

#### **NOTE**

In this release, the title of the list of devices on the **Access** panel is changed to **Access Devices**.

In previous releases, you could only use the **Access** panel when logged into the PAM UI from a PAM client, PAM Agent, or Internet Explorer.

In this release, a *limited* version of the **Access Devices** panel available when logged in to the PAM UI from a standard browser (for example, Chrome, Edge, Firefox, or Safari) allows you to do the following tasks:

- Obtain the credentials of any target account (of a target application maintained on a Privileged Access Manager device) for which you have privileges in the **Access Devices** table.
- View the details of any credentials that you are using in the **Passwords currently in use** table.

For more information, see [Use the Limited Functionality Access Devices Panel on Standard Web Browsers](#).

#### **NOTE**

This feature was originally implemented in the 4.0.4 release.

### **Improved Session Recording Reconciliation**

PAM runs the following *session recording reconciliation processes* that identify session recordings that do not have a corresponding metadata file or database entry. If a discrepancy is found, the reconciliation processes reconcile that discrepancy by creating the missing element:

- **Most Recent Recordings:** Reconciles recent (up to three days old) session recordings. Runs hourly.
- **All Other Recordings:** Reconciles other session recordings. Runs daily.
- **Restored Recordings:** Reconciles session recordings [recovered from archives](#). Runs hourly.

For more information, see [Configure and Manage Session Recording](#).

The **System Activity** tab on the **System Info** pane provides detailed information about the status of each reconciliation process. For more information, see [View System Information](#).

#### **NOTE**

This feature was originally implemented in the 4.0.4 release.

### **Session Recording Storage Configuration Security Enhancement**

Previously, when a CIFS share was configured as the session recording external storage provider, the PAM UI showed the password of the CIFS administrator in clear text. In this release, the CIFS administrator password is obscured.

#### **NOTE**

To configure external storage for session recording, navigate to the **Configuration, Logs, Session Recording** panel and select the **External Storage** tab.

#### **NOTE**

This feature was originally implemented in the 4.0.4 release.

### **Remote Storage Session Recording Performance Improvement**

To mitigate performance issues initiating session recordings on remote storage, PAM now writes the session recordings for each day in a correspondingly named subdirectory ( *YYYYMMDDPAM* ). This change in infrastructure is transparent to session viewers; the physical location of files is not shown on the **View Session Recordings** panel.

#### **NOTE**

This feature was originally implemented in the 4.0.4 release.

## **New Features and Enhancements in 4.1.1**

This topic introduces the new features and enhancements in PAM 4.1.1.

### **PIV Authentication and Authorization Activity Now Included for Management Console**

In this release, the Management Console supports The following PIV authentication and authorization functionality:

- **Authorized users can access the Management Console UI using PIV Authentication:** Authorized users can access the Management Console UI using PIV Authentication.
- **Authorized Admins can approve PIV-users from the Management Console:** Admins can now also approve all PIV logins from either the Management Console web-UI or the standard PAM web-UI.

Access the following topic links to learn how you can now use the [Management Console](#) to [approve Smart Card users logins](#), and [configure Active Directory for user authentication](#).

### **Just in Time (JIT) Provisioning for MSSQL User Accounts**

This release provides *Just in Time (JIT)* provisioning, which allows you to dynamically provision and deprovision Microsoft SQL Server (MSSQL) user accounts on demand.

JIT provisioning provides the following security enhancements for accessing your SQL Server database:

- Zero-trust security where user identities only exist on SQL Server during the checkout period.
- On-demand identity and access management with dynamic privileges that is auditable and can be subject to third-party approval.

For more information, see [Configure Just in Time \(JIT\) Provisioning for MSSQL User Accounts](#).

### **Extended Timeout Functionality Allows Long Jobs to Run Unattended Without Timing Out**

In this release, a new *Extended Timeout* option allows users who must run lengthy jobs (such as database backups) to specify a value longer than the global **Connection Idle Timeout** (formerly named **Applet Timeout**) value. When **Extended Timeout** is enabled in an associated access policy, users are prompted to optionally specify a longer idle timeout (up to the new global **Maximum Connection Idle Timeout** setting) when starting an access session. For more information, see [Set Up a Policy](#).

## **Improved PAM SC Device Matching**

PAM can automatically match Server Control devices. However, if a match fails, PAM defaults to creating a device. With this release, the match process is more accurate, and you now have more control over the match criteria. Even if the match does not succeed and PAM creates a device, you can still edit the Name and Address fields of the device. For more information, see [Associating PAM SC Devices with PAM Devices](#).

## **Configure the CIDR Docker Network Settings**

As a PAM Administrator, you can edit the CIDR used by Docker in PAM. For more information, see [Configure Docker Network Settings](#).

## **Enable or Disable TLS Ciphers**

The Super, Global Admin, or Configuration administrators can now disable or enable cipher suites that are used by the PAM Cryptography security settings. For more information, see the **Enable or Disable TLS Cipher Options** section of the [Configure SSH Proxy, SSH MindTerm, and TLS Cryptography Options](#) topic.

## **Enabling Server Control TLS Settings**

As an administrator, you can use the **TLS Settings** screen to specify your own root certificate, a corresponding public key certificate, a corresponding private key, and an optional passphrase for the private key as **Secrets**. After configuring the **TLS Settings**, you can assign them to Utility Groups. OnePAM then distributes the configured root certificate and the public and private keys to individual Utility Groups whenever the pam-dh service on a Utility Appliance restarts. For more information, see [Enabling Server Control TLS Settings](#).

## **Remote Storage Session Recording Performance Improvement**

To mitigate performance issues initiating session recordings on remote storage, PAM now writes the session recordings for each day in a correspondingly named subdirectory (`YYYYMMDDPAM`). This change in infrastructure is transparent to session viewers; the physical location of files is not shown on the **View Session Recordings** panel.

## **Full Backup Of Hardware Appliances When Applying Hotfixes That Require A Reboot is Now Optional**

When applying a hotfix *that requires a reboot* to a 4.1.1 (or later) PAM hardware appliance, full backup of the appliance is now optional.

# **New Features and Enhancements in 4.1**

This topic introduces the new features and enhancements in PAM 4.1.

## **Secrets Management**

Secrets management is access control for human users and programs to sensitive and privileged information. That information might include X509 certificates, connection strings, tokens, configuration parameters, encryption keys, credentials, and so on.

PAM Secrets Management lets you control access to any information that your organization regards as secret, wants to protect, and wants to provide fine grained, auditable authorization. That information might include X509 certificates, connection strings, tokens, configuration parameters, encryption keys, credentials, and so on. PAM gives Security Teams the ability to store, audit, and securely share this information with authorized recipients: people or processes.

For more information about Secrets Management, see [Secrets Management Overview](#).

---

### **Clusters Now Support External Load Balancers to Handle Site Traffic**

Previously, PAM only offered an internal load-balancing solution in which requests addressed to a site VIP were redirected by the site leader to the least-loaded site member using a software-based load-balancing algorithm. This release supports the use of an external load balancer to redirect requests that are addressed to the site VIP to the least loaded site members using its own load-balancing algorithm.

For more information about using external load-balancing, see [Internal and External Load-Balancing](#)

### **Download Advanced Metrics Files To Assist Broadcom Support Troubleshoot Your Issue**

In this release, you can download *advanced metrics files* that Broadcom Support can import into their own test systems to analyze items that are related to an issue you are encountering.

For more information about downloading advanced metrics files, see [Configure Diagnostic Logs](#).

### **New Option Allows Use of Checksums During Upgrade**

This release provides a new **Show Checksums** option that recomputes the checksum value of a downloaded file to verify that the file was not corrupted during the upload process. Compare this newly generated value with the value of the checksum file included in the downloaded zip file.

For more information, see [Upgrade](#).

### **Troubleshooting Tools for Policies Deployed on Server Control Devices and Device Groups**

This release provides tools that help with troubleshooting policies that are deployed on Server Control Devices and device groups.

For more information, see [Troubleshoot Policies Deployed on Server Control Devices](#) and [Troubleshoot Policies Deployed on Server Control Device Groups](#).

### **Troubleshooting Tools for Policies Deployed on Server Control UNAB Devices and Device Groups**

This release provides tools that help with troubleshooting policies that are deployed on Server Control UNAB devices and device groups.

For more information, see [Troubleshoot Policies Deployed on UNAB Devices](#) and [Troubleshoot Policies Deployed on UNAB Device Groups](#).

### **Utility To Extract PIM Shared Account Management Data When Migrating to PAM**

This release provides a utility that extracts PIM Shared Account Management (SAM) data to enable migration from PIM to PAM.

For more information, see [Extract PIM Shared Account Management \(SAM\) Data](#).

### **Exportable PAM SC Device Agent Status Report**

In this release, you can export a report showing PAM SC Device agent status.

For more information, see [View Server Control Endpoint Agent Status on the Device Agent Status Screen](#).

### **Credentials Obtained for Viewing by Dual Authorization Can Now Be Viewed or Used for Auto Connect**

Previously, if a credential was obtained for viewing by a dual authorization password view request, it could only be viewed, not used for auto-connect. In this release, if a credential is approved for viewing it is also approved for auto-connect. However, it is still the case that if a credential is approved for auto-connect, it can only be viewed by canceling the auto-connect request and submitting a new request for viewing (and that request being approved).

## New Features and Enhancements in 4.0

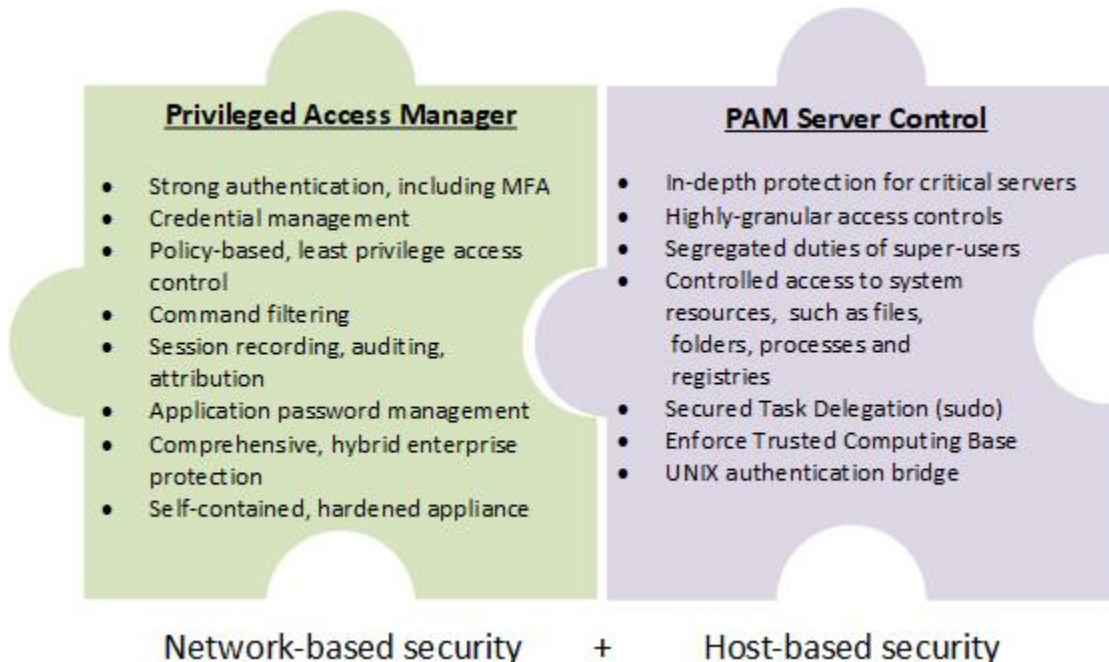

### PAM Server Control Unification

The primary new feature in this release is the *Server Control Module*, which unifies all the capabilities of the standalone *Privileged Identity Manager (PIM)* and *Privileged Access Manager Server Control (PAM SC)* products.

PIM and PAM SC are comprehensive and mature solutions that provide host-based security for your most sensitive systems whether they are physical, virtual, or cloud-based. They provide active, comprehensive security software solution for open systems, tied dynamically to the operating system. Each time a user requests a security-sensitive operation, such as opening a file, substituting a user ID, or obtaining a network service, the product intercepts the event in real time and evaluates the validity of the operation before passing control to the native OS functions.

PIM and PAM SC are highly scalable and provide fine-grained access controls, auditing, and UNIX authentication bridging across servers from a central management console. Server Control is uniquely capable of enforcing access controls on powerful native superuser accounts, like the UNIX and Linux root and Windows administrator.

By unifying the capabilities of PIM and PAM SC in the Server Control Module, PAM adds powerful host-based security to its existing network-based security. This combination of capabilities is shown in the following diagram:

For detailed information about the features and benefits of unifying PAM SC with PAM, see [PAM SC Integration Highlights](#).

### External Directory Authentication and Auto Registration of Privileged Users

This feature provides the ability for PAM to auto-register users at run time both for authentication and authorization without importing the entire user group members. This ensures that the large, and frequently changing Users' group member relationship update does not affect PAM performance or cause a breach in governance rules due to access changes. The authentication is always performed through the External Directory (Groups and User Groups only). See [How to Configure Active Directory for User Authentication](#).

### **Removal of Ambiguity when Multiple Roles are Assigned across Multiple Target Groups**

With this release, the Credential Manager role only applies to the objects scoped by the Credential Manager Target Group in the same Credential Manager Credential Group. Previously, all Credential Manager Roles applied to all Credential Manager Target Groups that the user was a member of.

Security checking has been enhanced around target accounts, passwords, and target applications. Users who have created custom roles need to verify that these roles continue to work in this release. Additional Credential Manager privileges may need to be added to the roles. Also, changes made to fix privilege mixing when a user belongs to multiple credential user groups may also alter a user's access to Credential Management features. See [Delegate Password Management Tasks to Groups](#).

### **Ability to Use SFTP or SCP for File Transfers through SSH Proxy**

You can configure a TCP/UDP SSH Service to do the file transfer operations for a native SFTP or SCP application. Session recording is not activated when either of these features are invoked (the files are not copied into the recording). See [Create an SSH Service to Access a Device](#).

### **Expanded Support for Target Application Creation and Updates Using the External API**

This release adds API support to create and update three Target Application types: Active Directory, Windows Remote, and Windows Proxy. Prior to this release, the ability to create target applications for Windows devices was only available using the CLI interface. The ability to do the same operations using the External REST API means users no longer need to switch between CLI and REST for their automation CRUD operations (\*nix is already available). See [Active Directory Target Connector External API Configuration](#), [Windows Remote Target Connector External API Configuration](#), and [Windows Proxy Target Connector External API Configuration](#).

### **Ability to Use HTML Browser-Only Access to View Credentials on a Secondary Site**

This release unblocks the ability to view credentials and do password approvals from the Credentials, Account screen on the secondary site when using HTML5 compliant browsers. (Prerequisite: remove the Standard User role.) See [How to Set Up a Cluster](#).

### **Ability to Determine the Action for Authenticating a PKI User without Revocation Information**

This release provides the ability to determine if a PKI user should be authenticated when a CRL is invalid or when the CRL and OCSP cannot be reached or are not provisioned in PAM. This option, "When Revocation Information is Unavailable," is enabled when you download CRLs automatically, manually, or when you use OCSP. See [Secure Connections Using SSL Certificates](#).

### **Password View Request Updates**

This Release includes the following updates to the Password View Request feature:

- The Reason Description and Reference Code fields are mandatory when a user attempts to view or access an account which has the Reason Required for View option or the Reason Required for Auto Connect option enabled in the Password View Policy. See [Create a Basic Password View Policy](#).
- A Comments field for a Password View Request is available when the Reason Required for View option or the Reason Required for Auto Connect option is enabled in the Password View Policy. This field is optional, and allows requesters to enter any comments that they want to record with the Password View Request. These comments can be reviewed by an auditor for normal Password View Requests or by the Approver in Dual Authentication or Retrospective Approval workflows. You can also use the Comments field with the [viewAccountPassword](#) CLI command with the new optional Comments parameter.
- A banner is displayed on Password View Requests when the Reason Required for View or Reason Required for Auto-connect option is enabled in the Password View Policy. This banner can contain information about what users need

to enter in the Reason Description and Reference Code fields when they attempt to view a password for an account. You can set this banner on the Credential Manager General Settings page or the Password View Policies page. If set as part of the Password View Policy, it takes priority over the General Setting. See [Create a Basic Password View Policy](#) and [Credential Manager Operation Settings](#). The following CLI commands have been updated or have added parameters that support this feature: [viewAccountPassword](#), [addPasswordViewPolicy](#), [updatePasswordViewPolicy](#), and [setSystemProperty](#).

### **Ability to Update the PAM Host File when Deployed in Restricted High Security Data Centers**

This feature enables users to update the PAM host file from the PAM user interface when doing so through Symantec PAM Support assisted Remote SSH Debug Access is not permitted. See [Custom Host File Entries](#).

### **Enable Public Key Authentication**

You can configure a TCP/UDP Service to connect to a target device using the Public Key Authentication method for a native SSH Application. See [Create an SSH Service to Access a Device](#).

### **Ability to Customize the SSH Cipher Suite Used by PAM for Connections**

PAM provides the ability to configure a subset of ciphers used by SSH connections for accessing devices. The option to configure older vulnerable KEX/Ciphers/HMAC allows the management of legacy devices where newer ciphers are not supported or for systems that have not yet been updated to support the secure default cipher suite of PAM. See [Configure SSH Proxy, SSH MindTerm, and TLS Cryptography Options](#).

### **Keep Alive Sessions**

Support for a configuration option in Symantec Privileged Access Manager (PAM) to enable SSH to save keep alive sessions so that user do not have timeout issues with their sessions. See [Create TCP/UDP Services to Access a Device](#).

### **Web Portal Traffic**

Support for all web portal traffic to be routed through a configured proxy. No user interface changes were made as a result of this feature.

If Symantec ProxySG is configured as a proxy in the PAM client, the following policy configuration change is required on the ProxySG to allow protocols such as SSH and RDP through the ProxySG:

Change:

```
<ssl-intercept>
ssl.forward_proxy (https)
```

To:

```
<ssl-intercept>
ssl.forward_proxy (stunnel)
```

The stunnel configuration allows the ProxySG to intercept other protocols that are tunneled through SSL/TLS, not just HTTPS.

### **The Ability to Run a Network Mapping Job from the PAM Configuration Page**

With the Bulk Network Scan tool, Administrators can run a bulk scan of their network (Host/Port) to determine the status of ports (open/filtered). See [Configure Global Settings](#) and [Networking Tools](#).

### **"Disallow Max Class Repeat" Password Composition Policy**

This password composition policy prevents passwords from containing consecutive characters from the same class. Uppercase, lowercase, numeric, and special characters are the class types.

Example: If MaxClassRepeat is set to 2, then ABcc34^& is allowed, but not AABcc34^&

See [Construct Password Composition Policies](#).

### **Deploy Threat Analytics in Azure**

The PAM Threat Analytics Module, in vhd format, is now supported for deployment in the Microsoft Azure cloud environment. See [Deploy the Symantec Threat Analytics Server](#).

### **New Access Mode in the "Available Credentials" Panel if Credentials are Unavailable**

The "Credential Unavailable" access mode is displayed when credentials are out of sync and have a password view policy with check in/check out or exclusive lock options. The credentials are still presented to the user in the "Available Credentials" panel, but are not actionable.

When a single credential with the access mode "Credential Unavailable" is configured for auto login, a warning popup is displayed and no auto login occurs.

## **Known Issues**

This section describes the currently known issues and workarounds, where available.

### **NOTE**

#### **New Issues in 4.1.7:**

- [SSH Certificate Authentication with an RSA-Based SSH Certificate Authority May Fail with Older Unix/Linux Target Devices](#)
- [Quorum Loss Email Notifications Not Being Sent](#)
- [Local PAM Container Configuration Changes Applied Using the External API Require Server Reboot](#)

### **IPv6 Limitations**

All PAM components support IPv6 addressing with the following exceptions, which remain IPv4-only in this release:

- PAM SC Utility Appliances
- PAM SC endpoints
- Sybase target connectors
- MSSQL Azure Managed Instance target connectors (The Microsoft Azure SQL Managed Instance does not support IPv6 addressing at this time.)

### **Cryptography Issues**

#### ***SSH Certificate Authentication with an RSA-Based SSH Certificate Authority May Fail with Older Unix/Linux Target Devices***

**Symptom:** Configuring PAM with an RSA-based SSH Certificate Authority may fail with older Unix/Linux target devices.

**Workaround:** Some older Unix/Linux variants versions of the sshd server may not support the current default RSA Certificate Signature algorithm: rsa-sha2-512. The previous RSA-based certificate signature algorithm, rsa-sha, was deprecated in 2021 and is no longer considered safe. Try using an ECDSA-based SSH Certificate Authority, or upgrade your sshd server to a more recent version, if possible.

***PKI authentication fails on FIPS-enabled PAM servers when one TLS 1.2 ECDSA cipher is selected (DE545999)***

PKI authentication fails with an "err\_ssl\_client\_auth\_no\_common\_algorithms" error when *one* of the following TLS 1.2 ciphers is enabled for inbound TLS 1.2 traffic:

- TLS\_ECDHE\_ECDSA\_WITH\_AES\_256\_GCM\_SHA384
- TLS\_ECDHE\_ECDSA\_WITH\_AES\_128\_GCM\_SHA256

#### **NOTE**

There is no issue if you enable both ciphers.

### ***Unsupported Cryptographic Algorithms in Credential Management Workflows***

The following algorithms are not supported in Credential Management workflows.

- Key exchange algorithm: curve25519-sha256
- Server Host Key algorithm: ssh-ed25519

### **Client Issues**

#### ***Cannot Install PAM Client on Mac Silicon Using a Command Line***

**Symptom:** An Admin tries to use a terminal to install the PAM Client on Mac hardware using the following command:

```
sudo ./CAPAMClientInstall.app/Contents/MacOS/CAPAMClientInstall
```

The installation fails and displays the following message:

```
"java" cannot be opened because the developer cannot be verified.
macOS cannot verify that this app is free from malware.
```

**Workaround:** Use Interactive install. After you download the installer file, extract the file, and then run the PAM Client installer.

#### ***Error Message Appears when Launching an RDP Access Method Using PAM Client on a Linux System***

**Symptom:** The following error message appears while launching the RDP Access method using the PAM Client on a Linux system:

```
Unable to load library libpcsclite.so.1 : libpcsclite.so.1 : cannot open shared object: No such file or
directory
```

**Workaround:** To be able to launch the RDP access method, install the **PC/SC Lite smart card** package on a Linux system.

#### ***RDP Client Does Not Support Custom Clipboard Formats (DE532444)***

The RDP Client supports only the following standard clipboard formats for copy and paste operations:

- CF\_TEXT
- CF\_UNICODETEXT
- CF\_DIB

The RDP Client therefore does not support applications that use custom clipboard formats to handle data that cannot be translated into a standard clipboard format. Performing a cut and paste operation in such an application via the RDP client can result in data loss.

**Workaround:** Use the RDP proxy to run applications that use custom clipboard formats.

#### ***User Resource Limit with the A2A Client on an AIX Host***

There is a resource limit when using the A2A Client on UNIX host. The recommended data segment size for user resource limit (ulimit -d) is 1 GB. You have three options.

To **temporarily** increase the data segment size to 1 GB to meet OpenJDK requirements:

**NOTE**

If you do not make a more permanent change as shown in the following options, you must run these commands each time before you start the A2A client

1. Before starting the A2A client, run the following command.

```
ulimit -d 1000000
```

2. Run the following command to start the A2A client (Use your real path if A2A is not installed in /opt/catech):

```
/opt/catech/cspmclient/bin/cspmclntd start
```

To make the data segment size change **permanent for the specified user**, modify the user setting via the AIX chuser command.

**NOTE**

The unit is represented in the number of 512-byte blocks.

```
chuser -d 2000000 root
```

To make a **system-wide change**, edit **/etc/security/limits** to increase the value.

**CA PAM Client Shows an IdP Login Form Instead of an Error Message (DE334815)**

If SAML is not properly configured, the CA PAM Client is displaying a login form. The Client should show the error "An error occurred while processing your request. Please contact your help desk for assistance."

**"Cannot load JVM options" error when launching PAM client on Japanese Windows computer (DE314263)**

Privileged Access Manager does not support installing the CA PAM Client in directories whose names include Japanese characters. If you install the CA PAM Client on a Japanese-language computer, select the Typical option. On the click Install Folder step, enter a folder with no Japanese characters.

**Older Linux installations require more libraries (DE137968)**

This issue occurs when the PAM Client is installed on a workstation that uses older versions of Linux. The PAM Client uses the libXss.so.1 library from libXScrnSaver and the libgconf package. These libraries and packages might not be included in older versions of Linux.

**Workaround:** Ensure libXScrnSaver and libgconf are available on the workstation before you install the PAM Client.

**Credential Management Issues****DeleteTargetAccount CLI Command fails to return expected success response (DE546881)**

The DeleteTargetAccount CLI command successfully deletes the requested target account and returns a status code 400 success message, but does not return expected target account details.

**Account with elevated privileges in Cisco IOS is not supported by Cisco target connector (DE158580)**

An account in Cisco IOS that has Elevated Privileges level 15 is not required to provide credentials when "enable" command is used. That configuration is currently not supported by the Cisco target connector. Such an account cannot be managed by the target application.

**Workaround:** Use another account with privilege level 0 to manage the level 15 account.

**Upgrade Issues****Secondary Backup Drive can cause an upgrade issue (AMI upgrade only)**

If you are upgrading the appliance on an AMI, remove any secondary backup drive that you added for the previous upgrade to 3.0. If you fail to remove the secondary drive, the upgrade completes without producing an error, but your appliance version is not upgraded.

**If Upgrading PAM, then You Must Also Upgrade SFAs**

If you upgrade PAM running in FIPS mode to 4.1.1, then you must also upgrade Socket Filter Agents (SFA) running on Windows target devices to 4.1.1. Until you upgrade Windows SFA devices to 4.1.1, no SFA devices can report violations to PAM instances.

After upgrading a PAM instance running in either FIPS or Non FIPS mode to 4.1.1, you must also upgrade all instances of Windows Socket Filter Agent to 4.1.1 before using ECDSA certificates for inbound TLS connections.

## **Other Issues**

### ***Local PAM Container Configuration Changes Applied Using the External API Require Server Reboot***

You must reboot the PAM server to apply changes that you make to a Local PAM Container using either of the following External API calls:

- `/cspm/ext/rest/config/network/container/local/ipv4`
- `/cspm/ext/rest/config/network/container/local/ipv6`

### ***Quorum Loss Email Notifications Not Being Sent***

Cluster Status notification emails for quorum loss events are not being sent. All other cluster status email are working. The internal defect tracking number for this issue is DE594849.

### ***IPv6 Cluster for PAM Instances Deployed in Azure Cannot Use a Floating IP as the IPv6 VIP Address***

If you want to use an IPv6 cluster for PAM instances deployed in Azure, you cannot use a Floating IP as the IPv6 VIP address. You must use an external load balancer while configuring the IPv6 VIP address. For more information, see *Add Sites to Your Cluster*.

### ***IPv6 Local Loopback Address for RDP Proxy TCP/UDP Services is Not Compatible with Socket Filtering***

A policy using socket filtering that allows access to an RDP Proxy service will have its local IP address for the RDP Proxy Service overridden when the end-user invokes the service. All RDP Proxy instances using socket filtering on an individual user's desktop will then bind to the same local loopback IPv4 address.

If the RDP Proxy TCP/UDP Service defines an IPv6 local IP address ("::1"), then invoking that service in the PAM Client results in the specified IPv6 address being overridden with an IPv4 address.

**Workaround:** An RDP Proxy TCP/UDP Service with a configured client application designed to expect an IPv6 local IP address (<Local IP> surrounded with square brackets) must be modified to expect an IPv4 local IP address (<Local IP> with no square brackets) when socket filtering is in use.

### ***RDP Proxy Does Not Enforce the Connection Idle Timeout Global Setting***

The RDP Proxy does not enforce the **Connection idle Timeout** (formerly **Applet Timeout**) global setting, which is intended to specify the number of minutes of inactivity before a connection with an external device times out.

### ***Selecting Both the "Reason Required for View" and "Reason Required for AutoConnect" PVP Options Generates Duplicate Reports (DE504579)***

Selecting both the **Reason Required for View** and **Reason Required for AutoConnect** PVP options for an application triggers duplicate events that appear twice in the **View Password Requests** report.

**Workaround:** None.

### ***SAML SSO Newly-Configured in 4.1 Does Not Work with an External Load Balancer Address (DE531855)***

Existing configurations that use SAML SSO with external load balancers should continue to work. However, using SAML SSO directly with an external load balancer in the new, more-tightly integrated option in 4.1, does not presently work.

**When configuring SAML connections, the SAML Test button only works for SSL/TLS certificates signed by a Certificate Authority**

Previously, when configuring an Azure connection or PAM as the Service Provider (SP), the SAML **Test** button would work if the IDP had a self-signed or Certificate Authority-signed SSL or TLS certificate. In this release, a security improvement prevents the button from working for self-signed certificates.

#### ***Start of deprecation of the sftpsftp service***

PAM supports file transfers using SSH. As a result, the sftpsftp service is being deprecated over time, in favor of SSH. For this release, sftpsftp service continues to work as expected. However, some sftpsftp error messages are not localized and display only in English.

#### ***Windows 2016 and Windows 2019 not recognized in Device Discovery (DE346437, DE475642)***

Device Discovery does not reliably discover Windows 2016 or Windows 2019. You can set the Default OS to either Windows 2016 or Windows 2019, or manually change the OS after discovery.

#### ***SFA with blacklist throws "Access Denied" message for non-blacklisted IP when launching SSH Proxy service (DE281461)***

An SSH Proxy connection is not terminated in the following circumstances. A Socket Filter Agent with a Blacklist and an SSH Proxy is added to the same device. The Blacklist is configured with the action "Logout of terminal device." A user selects "Restart Session" on the Access page, then selects the SSH Proxy service, and auto-login. The user enters "ssh DeviceIP" of a device that is not blacklisted. An "Access denied" message appears. The connection should be established, but is not.

#### ***Keyboard Mapping Issues (DE158692)***

When using a Linux or Mac OS client, keyboard mapping of some keys for languages other than English would not work correctly for some keyboards.

#### ***Unable to log in to Privileged Access Manager using RADIUS when Two RADIUS Servers are configured (DE172566)***

Redundant RADIUS servers sometimes fail for CHAP authentication when used with One Time Passwords (OTP). This problem causes login failures.

**Workaround:** In the UI, configure the RADIUS server responsible for OTP as the last server in the list of configured RADIUS servers.

#### ***Wrong OS name appears after installing up Windows Proxy***

The user installed a Windows Proxy on a server (such as Windows Server 2016). However, the wrong OS Name appears when the user looks at Credentials -> Manage Targets -> Proxies -> Update -> Type Info

This conflict occurs because the user added an environment variable called JAVA\_TOOL\_OPTIONS, with a value different from the OS name. For example, the user entered JAVA\_TOOL\_OPTIONS: "-Dos.name=Windows 7".

The value specified in the JAVA\_TOOL\_OPTIONS is taking priority showing the OS name instead of actual OS name.

**Workaround:** Because the user customized the OS, the user has to remove the environment variable to view the actual OS in the proxies screen.

#### ***The OS Type and Version Occasionally Improperly Defined During Device Discovery (DE563059)***

PAM Device Discovery uses network scanning along with a set of heuristic rules to identify the operating system (OS) versions for remote systems. However, the results might not be exact, as these results depend on the end user's specific remote servers and network configurations. For example, the OS of a well-hardened server might be more difficult to correctly recognize than a wide-open endpoint OS installation.

**Workaround:** You must confirm these results, which may require manually adjusting the OS versions in the administrative UI.

#### ***Windows AWS instances are incorrectly listed as "Windows 2008" systems on the Devices page (DE492599)***

When Windows AWS devices, for example Windows 2016 Server or Windows 2019 Server, are imported as devices, the associated Operating System entry is incorrectly stated as "Windows 2008" on the **Devices** page.

***Displaying the AWS Access Key Alias, using the Use Alias option, is not Supported in All Sections of the UI and Reports***

On the **AWS Settings** tab, selecting the **Use Alias** option displays the more user-friendly value in the User interface (UI) for the AWS-generated **Access Key ID**. However, the **Access Key Alias** field value may not be available in all sections of the UI. In these sections, the Access Key ID appears instead of Access Key Alias.

## Resolved Issues in 4.1.7

The following table lists the issues that are resolved in release 4.1.7:

Case Number	Internal Defect ID	Resolved Issue
33308508	DE554754	A2A takes interpreter name instead of script name when running Python2 or Python3 scripts.
33401497	DE563110	Primary master failing to start, freezing at "PAM server is starting up."
33404824	DE563495	Vaults are not decrypting Secrets
33529972	DE578466	Delete Key in UNIX SSH applet incorrectly sends a backspace command.
33545614	DE578602	Connecting to a target server via RDP incorrectly displays a popup window which must be clicked multiple times to dismiss.
33571101	DE584927	Some Microsoft Entra ID pages do not load, preventing the use of PAM to manage Entra ID identities
33577016	DE582738	On certain machines, using an A2A script fails to get the hash from the PAM UI or the CLI.
33579613	DE583479	Mac users Cannot Copy/Paste in GitLab Web Portal.
	DE562323	Some keys on non-US keyboards not working when using PAM to access the vSphere Web Portal.
33581135	DE583025	PAM UI sessions experiencing poor performance accessing primary site nodes, with the mysql-slow.log file filling up with the same slow query against the event table on the site and replication leader.
33582305	DE585746	Policy import progress bar stuck at 0% even though policies are imported.
33584316 / 33626804	DE583267 / DE588273	Failover check for authentication using UPN fails during password rotation.
33582259	DE582719	Potential Apache ActiveMQ vulnerability.
33587675	DE586403	Active Directory synchronization is not updating the Target Device OS version.
33588631	DE583599	Database backup scheduler gets stuck trying to send a file to old target server.
33592412	DE583645	RADIUS reauthentication prompt does not work when accessing the PAM UI from a browser.
33594351	DE584380	PVRs created by a user account that no longer exists are not expiring or getting deleted.
33598560	DE585110	Session recordings initiated for PuTTY SSH services that are terminated withing seconds get stuck in status "Recording in Progress."
33600566	DE585218	RDP Proxy failed to connect to target Windows machines after TLS renegotiation strict mode is set.
33600570	DE585086	PAM client user session never times out due to inactivity if you filter on a column on the <b>Credentials</b> , <b>Manage Targets</b> , <b>Accounts</b> page and stay there.
33604447	DE585489	RDP session recordings with size 1K and the status "Encoding Error" cannot be viewed.

Case Number	Internal Defect ID	Resolved Issue
33607589	DE585851	Reason Required text has length constraints.
33612778	DE586647	Radius authentication fails when there is a ' [ ' or ' ] ' in the secret.
33642044	DE589954	Potential cross-site scripting vulnerability detected on the <a href="https://pam_server_ip_or_name/cspm/app/feature/app.html?feature=StandAloneConfig">https://pam_server_ip_or_name/cspm/app/feature/app.html?feature=StandAloneConfig</a> page in the PAM UI.
33642247	DE589966	AIX auto-login fails after password update.
33626476	DE587975	PAM not prompting users logging in using RSA SecurID authentication for a required OTP or dual authentication code.
33631825	DE588930	Password change rollback on anchor server does not complete when using compound servers.
33649470	DE591024	Session recording share outages on some cluster nodes.
33649787	DE591016	Conflict when using special characters on RDP box.
33652430	DE592503	LDAP servers are not synchronizing according to the specified schedule.
33654724	DE591544	DB Backup CIFS Mount failure after updating windows password.
33655152	DE593239	Scheduled LDAP synchronization fails with incorrect "Failed due to the cluster state" message.
33656873	DE591690	searchAuthorization CLI fails with Requestserver.id above int value.
33663788	DE592421	In <b>Global Settings, Maximum Password Length</b> can be set to any value.
33667416	DE593038	TCP/UPD services configured to do WinSCP or FileZilla file transfer operations fail if the connection ID password contains an "@" character followed by a "/" character, with or without other characters between them.
33668509	DE593047	DNs that include a comma in the common name that are copied from Active Directory do not paste correctly into PAM and the resulting DN is not valid.
33674760	DE593939	Unusual high disk utilization errors on all primary cluster nodes.
33023767 / 33412626	DE529787 / DE538447	TA2A clients are not notified about password updates in real time.
33596265 / 33573053	DE584388 / DE565112 / DE583391	Session recording for a specific user results in an Encoding Error and remains unviewable.

## Resolved Issues in Earlier 4.x Releases

The topics in this section describe the issues resolved in earlier 4.x releases,

**Use the table of contents to access these topics.**

### Resolved Issues in 4.1.6

The following table lists the issues that are resolved in Release 4.1.6:

Case Number	Internal Defect ID	Resolved Issue
33397585	DE565344	Post upgrade to 4.1.1, customer encounters sporadic "PAM-CM-0539: A database error occurred" messages.
33437583	DE566771	Non-empty Credential Management groups can be deleted.
33453784	DE573513	The "Credential History" button periodically disappears for various users.
33463017	DE570135	LDAP users are removed after LDAP errors during a refresh.
33477737	DE570601	PAM-CMN-0020 error when trying to view session logs.

Case Number	Internal Defect ID	Resolved Issue
33502602	DE573958	Receiving an Illegal Argument Exception error when accessing RDP to any Windows server.
33502648	DE574802	LDAP Device Group Refresh for one specific Group leads to a PAM-CMN-1172 error: "Your session has been terminated by a CA PAM administrator."
33520701	DE577434	SSH and RDP proxy Services are not getting started automatically when the Client Application path is set in Service.
33534837	DE578280	The RADIUS reauthentication prompt does not work in Threat Analytics for PAM 4.1.3.
33537429	DE580064	The Administrative Activities report immediately fails with an Error Code=803 and a NullPointerException.
33543414	DE579035	Assignable as "Yes" is incorrect for any unassignable User Groups, such as imported LDAP User Groups.
33550004	DE578917	The <b>Secrets &gt; Vaults</b> page is missing items.
33552223	DE579195	Daily process to purge binary logs older than 72 hours also purges all other binlogs, not just ones more than 72 hours old.
33552223	F133290	Add the ability to disallow group inherited permissions for users and API key.
33559656	DE582060	Unable to see the devices on an LDAP Device group.
33564431	DE581098	JAVA JDK interferes with PAM client 4.1.3.
33567728	DE581160	Some site VIPs stopped working after a 4.1.5 upgrade.
33568815	DE581696	Inconsistent Credential Source IDs in API Output
33572772	DE581659	Privileged accounts reports are not working post upgrade to 4.1.5.
33574824	DE581859	Customer is unable to copy a password to the clipboard in the PAM client.
33578770	DE582241	Cannot download and restore database backups on a MAC client.
33582217	DE582740	PAM nodes are unreachable but can still be pinged.
33578010	DE582477	SSO sessions are being reused by other users.

## Resolved Issues in 4.1.5

The following table lists the issues that are resolved in Release 4.1.5:

Case Number	Internal Defect ID	Resolved Issue
33406321	DE565052	Transparent login configuration is lost on a policy update.
33463974	DE568796	Hotfix 4.1.2.03 removes branding when applied to the system.
33514551	DE574727	UI not coming back from stopping the cluster
33506256	DE574061	Primary Appliance GUI stuck and not coming back after hot fix patch.
33492084	DE572188	RHEL9 with SecureCRT the related password is not transparently injected (that is user is being prompted to provide the Password)
33378964	DE564433	ILO Web portal failing to load tab.
33500828	DE575014	Login not happening and working automatically for TCP/UDP service.
33483399	DE571278	All staged patches purged on all nodes after applying one patch to secondary site nodes.
33437594	DE571188	Error 401 obtained in web browser after a logged in user properties are modified elsewhere

Case Number	Internal Defect ID	Resolved Issue
33453152	DE567972	User cannot login with some issued PIV cards. PKI authentication failed with the following error: Client chain certificate time-frame not valid
33448037	DE567134	Weaknesses detected during a PCI DSS scan for port 5249.
33461015	DE570295	Cannot Open Multiple SSH Sessions At Once
33478241	DE570563	If, when attempting to create a Target Account, the operation failed, the credential would be recorded in the metrics log for the failed creation. Only when the syslog was already configured (by selecting <b>Configuration, Logs, Syslog</b> ), the clear text password of the failed creation would be forwarded to syslog.
33462268	DE574330	PAM-CM-8014 error when modifying a secret.
33527388	DE576239	User Filter is not working as expected in Manage Vault.
33450215	DE567336	Error PAM-SEC-00017 appears when trying to save a secret.
33452974	DE568313	AD users temporarily deleted while patching the cluster.
33190981 / 33446426 / 3345742682 / 3345742682 / DE568592 / DE572351	DE5742682 / DE568592 / DE572351	Core dumps and restarts after inactivity when logging in through LDAP and RSA.
33282392	DE552803	User is unable to raise breakglass request from PAM Client.
33441179	DE566491	Long delays after upgrade to 4.1.2 for any activity involving listing of target accounts
33471375	DE569713	In 4.1.3, PVPs with Exclusive Checkout Cannot Be Updated Through the CLI
33398543	DE562340	Docker logging configuration update.
33453817	DE568384	PAM Manage Server Control error when creating a new policy. Specifically, any policy where you include an space before the CRLF will fail to be created.
33500417	DE573133	SAML IdP Metadata Refresher Cron job not running on PAM appliance.
33419367	DE566281	Accounts PDF Report incorrect.
33437557	DE566093	PIV CAC showing incorrect certificates.
33467542	DE569720	RDP Applet Exception when PAM Client on MacOS with Apple Chip: PAM Client on MacOS ARM64 Ventura cannot RDP to any Windows server.
33473462	DE570320	"Warning" dialogue but with no content in dashboard.
33447320	DE567462	Cannot delete any target server if any account with custom workflow is checked out
33395677	DE561984	Issue with accessing a specific Web Portal in PAM
33484068	DE571049	PAM-UI-2730 message syntax error.
33450855	DE569721	Maintenance Mode Turns on Automatically.
33498510	DE578207	Verification and target account password view are not showing on screen even though the user has CM privileges.
33492271	DE571948	An error on the access panel occurs when the "Set or Change local application" link in the secure tunnel popup is selected.
33434678	DE566435	Deleting CM objects such as target server from database is very slow.
33412582	DE572081	Poor A2A client performance.
33486218	DE572096	PAM GUI could not reboot appliance when applying a hotfix.
33495205	DE572409	PAM-CMN-5517 error appears when trying to modify a user.
33401357	DE562434	The UTA failover mechanism does not update the config map appropriately when switching the cluster primary sites. The multisite failover of UTA servers does not happen.

Case Number	Internal Defect ID	Resolved Issue
33393430 / 33138451	DE561989 / DE538741	Web Portal auto-logon stopped working.
33403046	DE562740	A2A 402 null errors are seen due to long processing time in PAM.
33412626 / 33141455	DE529787 / DE538447	A2A clients not notified on password updates in real time.
33519406	DE575780	Error Message not displaying while deleting Master Account.
33422520 / 33370144	DE564941 / DE559812	Long delays when joining a cluster or rebooting a node in the active cluster.
33535422	DE577282	After upgrade to 4.1.4 the SNMP v3 user get removed

## Resolved Issues in 4.1.4

The following table lists the issues that are resolved in Release 4.1.4:

Case Number	Internal Defect ID	Resolved Issue
33460514	DE568381	Dashboard does not load and reports the following error: "Unexpected token END OF FILE at position 0."
33424190, 33408206	DE564126, DE564764	UNIX target connector failures.

## Resolved Issues in 4.1.3

The following table lists the issues that are resolved in Release 4.1.3:

Case Number	Internal Defect ID	Resolved Issue
33380450	DE561227	Old cluster configuration found on removed node during cluster stop process, due to there being a risk of restarting the original database.
33291201 33316348	DE554423 DE554424	Increased CPU usage and performance issues occur after upgrading to PAM 4.1.1.
33401573	DE563081	The health page displays a node's status as OK, even while the node is still loading.
33409055	DE563208	Target Account selection broken for scp protocol option in DB backup scheduler.
33315067	DE556673	Selecting Credentials > Report > Activities to graph activities with thousands of events causes the system to hang.
33330092	DE557057	The PAM Agent port redirection is active even if Agent is stopped
33306178	DE552984	Session logs sent to the syslog are missing time zone information.
33308508	DE554754	A2A takes the interpreter name instead of the script name when running python2 or python3 scripts.
33320207	DE558502	Password rotation scheduled job for Nexus device fails while manual update is successful
33287995	DE551359	The LDAP refresh does not update all device groups, and is hung.
33385421	DE561225	User cannot download the ECDSA Private Key. Therefore, the User cannot download the key file to generate ECDSA certificates for their cluster.
33401157	DE562441	Approval workflow is not working across the cluster.
33408206 33424190	DE564126 DE564764	Failed to establish a communications channel to the remote host.
33398895	DE565158	Exclusive checkout not working with dual authorization.

Case Number	Internal Defect ID	Resolved Issue
33389593 33397005	DE561574 DE562066	The PAM client prompts to save the password for a target account when exiting a screen.
33404824	DE563495	Vaults are not decrypting Secrets
33391034	DE561500	Logstash container is not started when PAM is rebooted without shutting down Cluster.
33393424	DE561745	Deleting a PAM user leaves orphaned email recipients.
33393427	DE563496	Filtering devices by tags on Device > Manage Devices displays only the first page.
33296691	DE552544	LDAP refresh is not removing devices from LDAP groups that were deleted in Active Directory. The target device cannot be deleted when the custom connector has been deleted while there is an application with that application type in PAM.
33339379 33372710	DE556776 DE560320	User cannot use the internal RDP Applet to RDP to any servers
33357151	DE560991	Some devices export incorrect data flags for A2A devices.
33372255	DE559785	After upgrading to PAM 4.1.1, the Privileged Accounts report displays empty results.
33341409	DE556781	Users can access and browse Internet pages within the PAM Client, allowing users to by-pass their internet proxy.
33305029	DE553877	When a user inherits a CM group and is an approver for a PVP, modifying the user displays error PAM-CMN-0155.
33341109	DE557099	A PVP approver with roles and Credential Manager groups inherited through a user group can be removed from the user group without generating an error.
33093691 33319494 33134089 33106482	DE536414 DE554338 DE540076 DE535427	High CPU usage causing multiple problems, with session recording as the main suspect
33114722	DE538976	Cannot verify Azure accounts in PAM 4.0.1.
33362625	DE559581	Cluster node reboot makes the Management Console show an incorrect cluster status.
33366878 33393814	DE559518	Web Portal is not caching credentials across multiple tabs
33283665	DE551325	While the cluster service appears to be in sync, the primary node is inaccessible.
33242692	DE552779	A2A XML Credential Retrieval error: Cannot execute the cspmclient64.exe with the XML Option (-x) for any Unix Type Application Target Users.
33245266	DE548256	Erratic problems with ServiceNow integration related to multiple bc-fips JAR versions.
33325668	DE555952 DE555342	Password Authority error after switching user from Local CAC to LDAP Imported method
33407999	DE563310	Users listed as Dual Authorization users are not removed from the LDAP Group if they leave that LDAP group.

## Resolved Issues in 4.1.2

The following table lists the issues that are resolved in Release 4.1.2:

Case Number	Internal Defect ID	Resolved Issue
33082121	DE533603	PAM node becomes inaccessible due to thousands of stale xcd_spfd_wolfssl processes.
33124675	DE537765	PAM Agent authentication fails when the password includes a "&" character.

Case Number	Internal Defect ID	Resolved Issue
33140114	DE537866	Credential Manager reports do not honor time zone setting when using the "Today" option.
33155561	DE539518	Change of UPN does not get updated in cspm.user_filter_view table
33157811	DE539317	Auto-login to ACF2 MF with BlueZone client fails and exposes password.
33200818	DE546097	Rotating a password for an AD account with a forward slash (/) fails with a PAM-CM-0762 error
33204647	DE545447	PAM-CM-0964 error is seen when trying to add a generic secret to a vault.
33224536	DE547384	External API call GET /cspm/ext/rest/devices/{id}/policies returns an error after a target account is deleted.
33224672	DE545335	Potential vulnerability: HTTP Track/Trace method is enabled in PAM Windows Proxy.
33232801	DE546388	"Restore of local database content failed! Sleeping and retrying..." error on secondary nodes at cluster startup.
33238600	DE548615	A2A mapping navigation is not working properly.
33242683	DE547290	Inconsistent REST API responses related to internal groups for vaults are seen.
33248660	DE553291	Socket Filter Agent throws inappropriate "Access Denied" error messages when the user is only attempting to access an application on the local machine.
33248788	DE547840	Users remain as PVP approvers when user group is deleted.
33255102	DE548628	_JAVA_OPTIONS setting prevents PAM Client installer and executable from running.
33262155	DE549198 DE549545	SysInfo showing out of date information regarding cryptographic providers.
33264356	DE549181	JIT Access MS SQL returns an error from the Secondary site.
33277675	DE550450	API calls taking longer and causing high CPU utilization.
33292969	DE551840	TLS 1.2 Cipher selection only partially working.
33298241	DE552235	Cannot save session recording purge policy when a value is specified for the <b>Remove Restored Recordings Older than</b> option.
33300755	DE552518	PAM Windows Proxy server operations cause java.lang. NumberFormatException errors in PAM Tomcat log file.
33312158	DE553978	Sessions requiring Dual Authorization no longer work if the "Maximum Connection Idle Timeout (Minutes)" parameter is set to zero.
33254076 33257866	DE549357 DE548519	Web portal not working after upgrade.
33326765	DE555102	Search for request servers is failing with PAM-CMN-0039 error.
33307427	DE553100	External API call DELETE /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId} deletes incorrect target application.
33308720	DE553158	Vulnerability detected in A2A client version 4.12.3.
33319402	DE554250	Session recording service fails to start after reboot.
33247664	DE547612	(Alternate) Configuration utility not working.
33340925	DE556861	PAM will not save web portal service definitions with an exclamation mark ("!") – a valid special character – in the launch URL, displaying a "The url contains an invalid character" error.

## Resolved Vulnerabilities and Issues in 4.0.4

This content lists the vulnerabilities addressed and issues resolved in 4.0.4.

### Vulnerabilities Addressed

This section lists the vulnerabilities that were addressed in 4.0.4:

- CVE-2022-25625 - A malicious unauthorized PAM user can access the administration configuration data and change the values.
- Exploitable vulnerability: a scan revealed the HTTP Track/Trace method is being enabled for PAM Proxy. (Case Number: 33224672/Defect ID: DE545335)
- PAM Windows Proxy 4.0.3 vulnerability due to MS DLL - msvcr80.dll (CVE-2010-3190) (Case Number: 33191371/Defect ID: DE542546)

### Resolved Issues

The following table lists the issues that are resolved in Release 4.0.4:

Case Number	Defect ID	Description
33096730	DE535191	Sort order by host name does not work correctly.
33185343	DE542171	Authentication module for SCIM and other CSPM (Java) REST APIs does not take into account the authentication method API when examining the SAML scenario.
33087758	DE536543	PIV logins with PAM in FIPS mode do not work.
33202249	DE543170	API error on updating User Group from LDAP+RADIUS to LDAP+RSA.
33013715	DE527882	PAM AWS Session freezes when uploading to the s3 bucket.
33127557	DE536999	PAM-CM-1129 incorrectly states that password view request is autoconnect only.
33079322 33071256	DE532840 DE532337	Device creation via Rest API fails with internal server error 500/Using API to onboard devices can produce duplicate devices.
33108399	DE537405	Web portal cannot access without an update with learning mode.
33135166	DE537390	Rest API error creating policies with multiple RDP application services.
33108398	DE537756	"Credential Manager User Group" name changed to "ActiveMQ Group."
33140120	DE537883	Administrative Activities report has no recognizable order.
33160324	DE539318	AS400 connector uses non-SSL port 8476 with SSL/TLS enabled.
33157220	DE539133	Aliases not displaying when a user group is assigned to a credential group.
33134089	DE540076	Session disconnected due to a problem with session recording.
33197558	DE543412	Cannot delete new Credential Manager user groups (copies of predefined groups).
33196417	DE542762	SSH Certificate authentication fails when user has no defined email address.
33023767 33141455	DE529787 DE538447	A2A clients are not notified on password updates in real time.
33082121	DE533603	PAM node becomes inaccessible due to thousands of stale xcd_spfd_wolfssl processes.
33121139	DE536409	Cannot upload PAM upgrade patch to Management Console.
33155561	DE539518	UPN change causes user to lose custom views.
33141455 33204647	DE545447	PAM-CM-0964: Password policy not found when trying to create a secret.

Case Number	Defect ID	Description
33224536	DE547384	The REST API call GET /cspm/ext/rest/devices/{id}/policies returns an error after a target account is deleted.
33257866	DE548519	Web portal autologin is not working when there are multiple redirections before the login page.
33262155	DE549198 DE549545	The PAM UI and Sysinfo file incorrectly list "CA Technologies C-Security Kernel" as a cryptographic provider.

## Resolved Issues in 4.1.1

The following table lists the issues that are resolved in Release 4.1.1:

Internal Defect ID	Case Number	Resolved Issue
DE532440	32986225	Management Console cannot stage 4.0.x Upgrade Patches
DE528579	32987568	RADIUS login failure when using CHAP
DE529787	33023767	A2A clients are not notified on password updates in real time
DE530254	33042317	Account discovery error on HP-UX devices
DE532085	33064591	After updating the system certificate on a cluster node, the informational message that appears incorrectly states that you must <i>stop the cluster</i> and restart the appliance to make the certificate change take effect. You do not need to stop the cluster.
DE532844	33067185	Cannot discover accounts on machines that have had previous discoveries
DE532840	33079322	Device creation using External API fails with internal server error 500
DE536543	33087758	PIV logins with PAM in FIPS mode do not work.
DE535191	33096730	Sorting by Host Name not working in password approval list
DE534791	33103566	External API calls not working
DE527882	33013715	Uploading files to S3 on the AWS console freezes the session
DE537756	33108398	"Credential Manager User Group" name incorrectly changed to "ActiveMQ Group"
DE537405	33108399	Web portal autologin fails unless updated with learning mode
DE536792	33111464	List of target accounts incorrectly displayed for credential source when a user has Secrets Management roles
DE536409	33121139	Cannot upload PAM upgrade patch to Management Console
DE536418	33124294	External API not working
DE537351	33129022	Custom logo reverts to default setting after upgrade
DE537883	33140120	Administrative Activities report entries not properly ordered
DE537390	33135166	Rest API error creating policies with multiple RDP Application services
DE540076	33134089	Sessions disconnect due to a problem with session recording
DE539133	33157220	Aliases not displaying when user group is assigned to a credential group
DE539318	33160324	IBM i connector uses non-SSL port 8476 with SSL/TLS enabled
DE539974	3316195	Attempting to view A2A mapping fails with "PAM-CM-0039: Unable to perform operation. Please contact System Administrator" error
DE542171	33185343	SCIM-related API calls not working

Internal Defect ID	Case Number	Resolved Issue
DE543412	33197558	Cannot delete new Credential Manager user groups created by copying predefined groups
DE528965 DE532591	32955254 33073759	Node reboot negatively affects the cluster status in the Management Console
DE543170	33202249	API error on updating User Group from LDAP+RADIUS to LDAP+RSA

## Resolved Issues in 4.1

The following table lists the issues that are resolved in Release 4.1:

Internal Defect ID	Case Number	Resolved Issue
DE524280	32959034	PAM suddenly stops load-balancing incoming requests to a cluster member on the primary and secondary sites when the encrypted shared key on the cluster is not the same as the one on the VIP node.
DE526940	32967277	Archived audit logs are missing most accounting information.
DE526407	32987666	User accounts are getting disabled for no reason.
DE529787	33023767	Password changes are not being updated in a timely manner on A2A clients on which credential caching is enabled.
DE529663	33040420	Only one AWS Management Console session can be opened from the PAM Access page. Attempting to launch another session fails with a "You must first log out before logging into a different AWS account," even after closing the first session.
DE526914	32989235	Too many core dumps are getting stored on the PAM server (only the 20 latest should be preserved) because the rotation process cannot delete filenames that contain spaces or special characters.
DE525485	32940895	Autologin to web portal failing when using a target account configured with a password view policy with "Reason required for autoconnect" enabled.
DE529550	33030265	REST API calls to cluster interface GB8 fail.

## Resolved Issues in 4.0.3

The following table lists the issues that are resolved in Release 4.0.3:

Case Number	Defect ID	Resolved Issue
32820122	DE512341	Problem applying the upgrade package.
32940895	DE525485 DE525953	Web portal is not working with "Reason Required For Auto Connect" in PVP
32955254 33073759	DE528965 DE532591	Management Console not working.
32959034	DE524280	PAM suddenly stops load-balancing incoming requests to a cluster member on the primary and secondary sites when the encrypted shared key on the cluster is not the same as the one on the VIP node.
32967277	DE526940	Archived audit logs are missing most accounting information.
32987666	DE526407	User accounts are getting disabled for no reason.
32989235	DE526914	Too many core dumps are getting stored on the PAM server (only the 20 latest should be preserved) because the rotation process cannot delete filenames that contain spaces or special characters.

Case Number	Defect ID	Resolved Issue
33023767	DE529787	Password changes are not being updated in a timely manner on A2A clients on which credential caching is enabled.
33030265	DE529550 DE531588	Rest API calls to cluster interface GB8 fail after upgrade.
33040270	DE530736	PAM SAML SSO with JIT doesn't work on secondary PAM Appliance.
33040420	DE529663	Cannot open multiple AWS Management Console sessions after upgrade to 4.0.1.
33056234	DE531171 DE531376	Splunk syslog not showing session logs.
33064591	DE532085	Message that appears after changing a PAM server certificate incorrectly instructs you to stop the cluster before rebooting the server to apply the new certificate when you only need to reboot the server.
33067185	DE532844	After upgrade, PAM fails to discover new accounts on machines on which accounts had previously been discovered.
33078530	DE532968	The start and end dates returned by the "Data Range" value in report headers are incorrect (one year later than the actual dates).
33103566	DE534791	External API call "User" failing.

## Resolved Issues in 4.0.2

The following table lists the issues that are resolved in Release 4.0.2:

Case Number	Defect ID	Resolved Issue
32233314 / 32383169	DE482249	Proxy performance improvements.
32785147	DE510015	Passwords in PAM cannot be viewed or used for auto-connect.
32490309	DE493997	Windows Proxy from a different domain incorrectly used, resulting in the failure of password verification or update attempts.
32563475	DE503744	Auto-login to a ZOS Mainframe not working when using a model 5 terminal type.
32610867	DE498310	SSH Keys are rotating but not saving to the database.
32638752	DE502730	Unable to execute SSH commands if another SSH is already executing commands.
32671486	DE505743	Added A2A Scripts disappears from the list of scripts available. It is not located in any mapping and it is not searchable. Subsequently unable to remove A2A request device in GUI as well.
32714267	DE508360	Credential Manager reports display incorrect or future dates for columns. such as Password Created.
32747867	DE509503	PAM client is not getting launched using explicit proxy setting
32752042 / 32763845	DE507465 / DE508590	PAM Client prevents further SSH applet connections after an applet tries to connect to unreachable target device
32776382	DE509870	Users cannot login to the PAM client on macOS due to loopback address errors.
32779575	DE510873	Incorrect information in View Password Requests report
32789121	DE510233	LDAP user group refresh problem where users get deleted.
32802876	DE512520	A premature cluster start after an accidental stop causes a full outage for all nodes in the cluster.
32809511	DE518338	Delegated admin has problems adding users to groups.

Case Number	Defect ID	Resolved Issue
32809895	DE511409	SAML authentication problems due to missing TAP Administrators user group
32811228	DE511974	DoD Strong Password bug in PAM4.0
32814484	DE512177	Tomcat session recording catalina.out file size becomes too large when setting the Applet Log Level to Debug.
32827869	DE512910	Access side syslog message truncated to 1024 characters
32789634	DE510261	Cluster master is inaccessible after a brief replication problem.
32828253	DE513634	Problem loading session recording viewing screen.
32831195	DE513252	Session recordings stuck in Encoding In-Progress state
32848774 / 32852643	DE514993 / DE515243	PAM is not updating group membership of the user based on the IDP response
32854120	DE516709	Policy Manage GUI while Adding/Updating policy creates unexpected results.
32854290	DE515213	Getting blank results when running a Bulk Network Scan.
32855889	DE516045	Custom Connector Target Manager only sends one master account to the custom connector.
32858788 / 32884203	DE517067 / DE517915	The following command generate a Request error: listPasswordViewRequestByRequestorSummary
32864079	DE515971	Login Integration does not work when an LDAP user's OU contains an ampersand (&) in the string.
32937420	DE522439	Web Portal with long service name fails if Route Through PAM is checked
32865962	DE517268	After upgrading to PAM 4.0 or 4.0.1, SCIM related API calls no longer work. The following error message appears: "PAM-CM-4075: Error processing request. Please contact Administrator."
32878934	DE518613	Ability to list Policy deployed and Assigned is not working when attempting using the RestAPI.
32880524	DE521176	Alias listing is unavailable in global administrator role.
32881227	DE518202	Sorting by columns is incorrect.
32886091	DE518049	Users unable to login with "CA PAM is starting up" error.
32894799	DE519841	Unable to access web portal from PAM appliances when using IE
32906058	DE520239	Cluster node stuck in a quorum loss mode due to stale marker files.
32900507	DE520217	Cluster Logs not viewable
32908070	DE520357 / DE526157	Rotating passwords with the Use elevated privileges with authentication enabled produces a "PAM-CM-1349" error.
32910260	DE520553	Vulnerability exposed via PAM online help in PAM UI
32914638	DE521200	VNC applet does not work with VNC authentication.
32914749	DE520579	A2A installer on Windows creates a bad Perl library CSPM_CLIENT_WIN.pm
32914976	DE521328	Windows Proxy Connection Status not reflecting lastupdate and date attributes.
32918907	DE520812	Cannot apply hotfix after uploading to PAM.
32925384	DE521365	Uninformative PAM-UI-2401 error logged when user deletion fails
32927723	DE521644	AIDE report received from PAM appliance, warning about a change in the /var/www/htdocs/uag/gatekeeper.ini file.
32937499	DE522434	Improper Policy Export Formatting causes a PAM-CMN-0668 error when importing the CSV
32937506	DE522436	LDAP User Groups are not Exported to a CSV file.

Case Number	Defect ID	Resolved Issue
32941242	DE526696	A utility group cannot be deleted if a PAM appliance is from an upgrade, resulting in a Utility Group Delete Error.
32950088	DE523607	Fix for log4j vulnerability (EventForwarder).
32964959 / 32967539	DE524228 / DE524391	Credential Manager Reports show incorrect year.
32968279	DE524434	300+ Active users were incorrectly flagged and disabled due to inactivity.
32974762	DE525066	New AWS Access key displays only the key ID to users instead of the friendly name.
32978211	DE526604 / DE525318	Log4J jar update required for the PAM client.
32978647	DE528037	Trying to upload IDP metadata file into PAM displays error.
32980978	DE526583	TCF with a uiDefinition using a TARGET Account cannot remove an assigned account in PAM 4.0.
32982908	DE525925	Only some target accounts appear in a list associated with a server host name.
32986498	DE525791	Need log4j patch with the latest log4j2 version 2.17.1.
32860526 / 32889747	DE516465 / DE518511	PAM-CMN-0155 error appears when removing CM Group from user due to PVP, despite user belonging to the user group with same CM group. Cannot update (unlock) user with inherited approver role.
33010780	DE527886	Fixed Access Page Filter Columns availability.
33019179	DE528189	Problems with Radius passcode prompt after upgrading from 3.4.2 to 4.0.1.
32820122	DE512341	Problem applying the upgrade package.
33060174	DE531472	HDD 99%; GUI not accessible after upgrade to 4.0.2

## Resolved Issues in 4.0.1

The following table lists the issues that are resolved in Release 4.0.1:

Case Number	Defect ID	Resolved Issue
20055428	DE448496	Discover Services that Use AD Accounts.
20305839 01258661 31800936	DE451560, DE409443, DE451579	Idle Sessions are not being terminated.
32095417	DE471602	Auto-login not working consistently with TN3270
32105667	DE470660	PAM UI reporting a "communication failure" error when password update takes more than 2 minutes.
32192407	DE485417	PAM Agent Login Problem
32193181	DE485677	Windows Proxy fails to update the scheduled task credentials for AD accounts.
32236359	DE484446	Every LDAP login to Secondary Node leads to two internal SYSTEM-related error messages.
32317657	DE482868	Attempt to delete a user who defined a custom session log report leaves a corrupt user behind
32328545	DE485272	When customizing a session log report, the XSSO and SSO transaction types are missing from the <b>Available Transactions</b> list on the <b>Transactions</b> tab of the <b>Create Report</b> dialog.
32375184	DE489607	Device Import/Export Failure
32446011	DE488413	Moving a target account configured for view in a policy to a different target app corrupts the policy.

Case Number	Defect ID	Resolved Issue
32448660	DE488977	PAM client pops up a "Login failed" message and closes the web portal on acknowledgment even though login was successful.
32451951	DE489945	The comments that are entered for Retrospective Approval are missing on the approval pop-up.
32489126	DE496979	Customizing the email body of password view policy causes duplicates emails.
32514173	DE492397	Problems with default AWS Management Console SSO service access list in PAM
32514991	DE492544	Documented filter not working for CLI command listTargetAccounts.
32519909	DE503233	PAM-CMN-0020/PAM-CMN-2293 errors occur and the user cannot log in to the target if "<" or ">" is included in the Password view reason.
32521806	DE493750	Query filters not working after customizing the status mapping in NIM for ServiceNow.
32534674	DE499203	Branch user unable to log in after removed from a different domain group in a Microsoft Active Directory with multiple Domains
32539544	DE495646	PAM Agent loading slowly
32570723	DE496953	Syslog Forwarder Message Format broken
32570756	DE494895	PAM allows deletion of device with target accounts that manage other accounts, leaving broken accounts behind.
32579168	DE495931	Unauthorized Access to Service Controller messages when access session terminations should be logged.
32608331	DE500455	RDP application keeps showing the previous RDP application session.
32615613	DE499657	SecureCRT prompts for password instead of passcode.
32624867	DE498458	User import fails when their first name exceeds 30 characters.
32629271	DE501994	Cannot log in with PAM Agent when "User Must Accept License" is checked.
32632737	DE499783	Management Console not staging tasks
32633111	DE499165	Old DB backup used for cluster resync.
32653380	DE500287	Cluster restore to DB failures are not caught.
32676592	DE501702	CSPM running out of memory
32687188	DE502550	Accounts CSV report still contains many entries spanning two lines in 3.4.3.
32705829	DE504075	PAM cannot manage MSSQL accounts with a dash in the name.
32705872	DE503759	When a Java app runs a remote CLI command against PAM on a secondary site node, that node becomes unavailable.
32707139	DE503715	Files with Special Characters being created
32707978	DE503873	Over time, attempts to update and verify target accounts stop working and the PAM administrator receives a "communication failure" error. Also, accessing session recordings causes excessively high memory usage.
32708252	DE503776	PAM Console fails to start.
32709768	DE504247	AD account update breaks services and tasks when Proxy is unavailable.
32735389	DE506904	Leaving and rejoining a cluster corrupts the PAM instance and prevents the UI from starting.
32741194	DE506662	Compacting the database using an outdated method from an older version of MySQL that did not officially support any native means to compact the database.
32743243	DE506255	Improper access for users with multiple Credential Manager roles

Case Number	Defect ID	Resolved Issue
32751528	DE507244	Scheduled Jobs not running at the correct time.
32753632	DE507293	Functionally unnecessary IPv6 TCP ports 9092 and 9093 are open and listening in PAM 4.0 and should be closed.
32769335	DE509522	DEV appliance went down when its custom connector became unavailable.
32777404	DE509262	Scheduled job not honoring "Use Same Password" flag if the first account update fails.
32778828	DE509721	Radius MFA authentication fails when the password length exceeds 48 characters.
32783777	DE509421	Cannot view passwords after (cluster) restart.
32823462	DE513563	Unable to connect to an Oracle DB using TLS 1.2.
32828088	DE513689	Upgrade fails over existing device entries with a uag.host.os value that does not match any OS type in uag.os.
32837549	DE514899	Setting the <b>Disable Inactive after (Days)</b> option to zero ("0") on the <b>Global Settings</b> panel <b>Accounts</b> tab is intended to <i>prevent</i> users from ever being disabled due to inactivity. However, it is actually causing all users (except the "super" admin) to be disabled after zero days of inactivity.
32838772	DE515155	Not able to change the default password for the config user.
32255005, 32428015	DE481379, DE498725	Unable to synchronize AWS Key Pair accounts
32387108, 32689321	DE490271, DE503075	Verify using account not working when used a custom Unix prompt for the other account
32400096, 32437216	DE487536, DE488190	Session hangs after Transparent Login from Default SSH App.
32511527, 32567759	DE493913, DE500445	Command-Line Filter Violations and Session Log Updates not happening.
32528090, 32511285	DE493419, DE493987	SSH access using PAM applet got disconnected randomly.
32615976, 32633152	DE498218, DE499400, DE500342	Automatic login using the SSH Tunnel service fails after upgrade.
32656828, 32541064	DE501493, DE500778	Thousands of "session_recording" messages are recorded in the transaction logs when users access any of the defined Web Portals.
32695378, 32740566	DE503026	UI runs slowly after an LDAP device refresh runs.
32780662, 32840634	DE512345, DE514051	Authentication issue on account (PAM)
32922527	DE514260, DE521083	Disabled DSApiUser/MCApiUser user accounts prevent Utility Servers from starting.
N/A	DE497234	Database backup for quorum loss mode fails.

## Resolved Issues in 4.0

The following table lists the issues that were resolved in Release 4.0:

Case Number	Defect ID	Resolved Issue
31819149	DE456073	Incorrect auto archive warning messages appear in the PAM Client dashboard even after a successful auto archive: PAM-CMN-3136: Metrics auto archive failed. Please check Settings, Credential Manager Settings, Auto-Archive. PAM-CMN-3137: Audit Log auto archive failed. Please check Settings, Credential Manager Settings, Auto-Archive.
32170627	DE475046	Session recording not working on one of three primary site nodes

Case Number	Defect ID	Resolved Issue
32509351	DE492450	XSIE Extracts do not export Target Accounts
32549376	DE495930	After upgrading to 3.4.2 the session log export to an external database may have duplicate entries

## New and Revised External API Calls in 4.x and 4.x.x Releases

This content lists the new and revised External API calls in PAM 4.0 and later 4.x and 4.x.x releases. For detailed information about any of these calls, refer to the [API Explorer](#) in the product UI.

### New Calls in 4.1.7

The following calls were added in 4.1.7 and are applicable in all later (by date) 4.1.x and 4.x releases:

Method	Function
POST /cspm/ext/rest/credentialUserGroups	Provide support for managing Credential Manager credential groups using the External API.
PUT /cspm/ext/rest/credentialUserGroups/{id}/users	
PUT /cspm/ext/rest/credentialUserGroups/name/{name}/users	
PUT /cspm/ext/rest/credentialUserGroups/{id}/userGroups	
PUT /cspm/ext/rest/credentialUserGroups/name/{name}/userGroups	
PUT /cspm/ext/rest/credentialUserGroups/name/{name}	
PUT /cspm/ext/rest/credentialUserGroups/name/{name}	
GET /cspm/ext/rest/credentialUserGroups/userName	
GET /cspm/ext/rest/credentialUserGroups/{id}/eligibleUsers	
GET /cspm/ext/rest/credentialUserGroups/userName/{name}/eligibleUsers	
GET /cspm/ext/rest/credentialUserGroups/{id}	
GET /cspm/ext/rest/credentialUserGroups/{id}/protectedUserGroups	
GET /cspm/ext/rest/credentialUserGroups/name{name}/protectedUserGroups	
GET /cspm/ext/rest/credentialUserGroups/{id}/protectedUsers	
GET /cspm/ext/rest/credentialUserGroups/name{name}/protectedUsers	
GET /cspm/ext/rest/credentialUserGroups/name/{name}/eligibleUserGroups	

Method	Function
GET /cspm/ext/rest/credentialUserGroups/{id}/eligibleUserGroups	
GET /cspm/ext/rest/credentialUserGroups	
GET /cspm/ext/rest/credentialUserGroups/name/{name}	
DELETE /cspm/ext/rest/credentialUserGroups/{id}	
DELETE /cspm/ext/rest/credentialUserGroups/name/{name}	
GET /cspm/ext/rest/credentialRoles	<a href="#">Get Credential Manager Roles Using the External API.</a>

### Revised Calls in 4.1.7

The following calls External API methods were revised in 4.1.7 and the revisions are applicable in all later (by date) 4.x and 4.x.x releases

Call	Revision
POST /api.php/v1/devices.json/{id}/targetApplications PUT /api.php/v1/devices.json/{id}/targetApplications	Added support for the following target applications: <ul style="list-style-type: none"> <li><a href="#">Windows SSH Key</a></li> <li><a href="#">Windows SSH Password</a></li> </ul> (Select the corresponding entry for details of the new configuration field attributes introduced by each application type.)

### Revised Calls in 4.1.6

The following calls were revised in 4.1.6 and the revisions are applicable in all later (by date) 4.x and 4.x.x releases:

Call	Revision
POST /api.php/v1/users.json	Now allows you to <a href="#">specify the Access Manager user groups from which an API Key inherits roles</a> by adding or removing their IDs from the <code>groupIds</code> array that has been added to the <code>apiKeys</code> array.
PUT /api.php/v1/users.json	Now allows you to <a href="#">specify the Access Manager user groups from which an API Key inherits roles</a> by adding or removing their IDs from the <code>groupIds</code> array that has been added to the <code>apiKeys</code> array.
GET /api.php/v1/users.json	Now returns the <a href="#">IDs of Access Manager user groups from which an API key inherits roles</a> in the <code>groupIds</code> array that has been added to the <code>apiKeys</code> array.
GET /api.php/v1/users.json{id}	Now returns the <a href="#">IDs of Access Manager user groups from which an API key inherits roles</a> in the <code>groupIds</code> array that has been added to the <code>apiKeys</code> array.

## Revised Calls in 4.1.5

The following calls were revised in 4.1.5 and the revisions are applicable in all later (by date) 4.x and 4.x.x releases:

Call	Revision
GET /cspm/ext/rest/config/splunk/splunksettings	"JSON" is now a supported value for the field <code>splunkMessageFormat</code> .
PUT /cspm/ext/rest/config/splunk/splunksettings	
GET /cspm/ext/rest/config/logs/syslog	"JSON" is now a supported value for the field <code>syslogMessageFormat</code> .
PUT /cspm/ext/rest/config/logs/syslog	
GET /api.php/v1/devices.json/{id}/targetApplications	Now returns <code>enableKerberos</code> in the response body of target applications of type <a href="#">Active Directory</a> or <a href="#">Windows Remote</a> .
GET /api.php/v1/devices.json/{id}/targetApplications/{applicationId}	
POST /api.php/v1/devices.json/{id}/targetApplications	Now allows you to enable Kerberos authentication when creating an <a href="#">Active Directory</a> or <a href="#">Windows Remote</a> target application. To do so, add <code>"enableKerberos": "t"</code> to the request body. When creating a Kerberos-enabled <a href="#">Windows Remote</a> target application, you can enable it to support a different domain controller lookup type than an existing Kerberos-enabled Windows Remote target application in the same domain. To do so, add <code>"overrideDnsType": "t"</code> to the request body.
PUT /api.php/v1/devices.json/{id}/targetApplications	Now allows you to enable or disable Kerberos authentication when updating an <a href="#">Active Directory</a> or <a href="#">Windows Remote</a> target application. To do so, add <code>"enableKerberos": "t"</code> to the request body. When updating a Kerberos-enabled <a href="#">Windows Remote</a> target application, you can now modify the value of an existing <code>overrideDnsType</code> ("t" or "f") entry in the request body to change whether it supports a different domain controller lookup type than an existing Kerberos-enabled Windows Remote target application in the same domain.
GET /api.php/v1/users.json	Now returns an <code>extendedIdentities</code> parameter, which lists alternate accounts that are configured to access RDP applets, Mainframe applets, and Azure SQL Managed Instances. Possible list entries are RDP User Name, Mainframe Display Name, and Azure User Name.
GET /api.php/v1/users.json{id}	Now returns an <code>extendedIdentities</code> parameter, which lists alternate accounts that are configured to access RDP applets, Mainframe applets, and Azure SQL Managed Instances. Possible list entries are RDP User Name, Mainframe Display Name, and Azure User Name.

Call	Revision
POST /api.php/v1/users.json	Now allows you to optionally specify an <code>extendedIdentities</code> parameter that specifies an alternate account to use to access RDP applets, Mainframe applets, or Azure SQL Managed Instances. Possible list entries are RDP User Name , Mainframe Display Name , and Azure User Name .
PUT /api.php/v1/users.json	Now allows you to modify an <code>extendedIdentities</code> parameter, specifying an alternate account to use to access RDP applets, Mainframe applets, or Azure SQL Managed Instances. Possible list entries are RDP User Name , Mainframe Display Name , and Azure User Name .

### New Calls in 4.1.4

The following calls were added in 4.1.4 and are applicable in all later (by date) 4.1.x and 4.x releases:

Call	Function
GET /cspm/ext/rest/config/network/container/local/ipv6	Get the <a href="#">Local PAM Container IPv6 Subnet CIDR</a> .
PUT /cspm/ext/rest/config/network/container/local/ipv6	Set the <a href="#">Local PAM Container IPv6 Subnet CIDR</a> .

### Replaced Calls in 4.1.4

The following calls were replaced in 4.1.4. The revisions are applicable in all later 4.1.x and 4.x releases:

Call	Revision
<ul style="list-style-type: none"> <li><b>Old:</b> GET /cspm/ext/rest/config/network/docker/local/status</li> <li><b>New:</b> GET /cspm/ext/rest/config/network/container/local/status</li> </ul>	<ul style="list-style-type: none"> <li><b>Old:</b> Returned the status of the local PAM Docker daemon.</li> <li><b>New:</b> Returns the status of the <a href="#">Local PAM Container daemon</a>.</li> </ul>
<ul style="list-style-type: none"> <li><b>Old:</b> GET /cspm/ext/rest/config/network/docker/local</li> <li><b>New:</b> GET /cspm/ext/rest/config/network/container/local/ipv4</li> </ul>	<ul style="list-style-type: none"> <li><b>Old:</b> Returned the local PAM Docker CIDR.</li> <li><b>New:</b> Returns the <a href="#">Local PAM Container IPv4 network bridge address</a>.</li> </ul>
<ul style="list-style-type: none"> <li><b>Old:</b> GET /cspm/ext/rest/config/network/docker/utilityAppliances</li> <li><b>New:</b> GET /cspm/ext/rest/config/network/container/utilityAppliances</li> </ul>	<ul style="list-style-type: none"> <li><b>Old:</b> Returned the Utility Appliances Docker CIDR.</li> <li><b>New:</b> Returns the <a href="#">Utility Appliance Container IPv4 network bridge address</a>.</li> </ul>
<ul style="list-style-type: none"> <li><b>Old:</b> PUT /cspm/ext/rest/config/network/docker/local</li> <li><b>New:</b> PUT /cspm/ext/rest/config/network/container/local/ipv4</li> </ul>	<ul style="list-style-type: none"> <li><b>Old:</b> Set the local PAM Docker CIDR.</li> <li><b>New:</b> Sets the <a href="#">Local PAM Container IPv4 network bridge address</a>.</li> </ul>

Call	Revision
<ul style="list-style-type: none"> <li><b>Old:</b> PUT /cspm/ext/rest/config/network/docker/utilityAppliances</li> <li><b>New:</b> PUT /cspm/ext/rest/config/network/container/utilityAppliances</li> </ul>	<ul style="list-style-type: none"> <li><b>Old:</b> Set the Utility Appliance Docker CIDR.</li> <li><b>New:</b> Sets the <a href="#">Utility Appliance Container IPv4 network bridge address</a>.</li> </ul>

### New Calls in 4.1.3

The following calls were added in 4.1.3 and are applicable in all later (by date) 4.1.x and 4.x releases:

Call	Function
GET /cspm/ext/rest/system/userLoginMessage/{id}	Get the configured <a href="#">login message</a> with the specified <i>id</i> .
GET /cspm/ext/rest/system/userLoginMessage	Get a list of <a href="#">login messages</a> . This list has either zero or one message.
PUT /cspm/ext/rest/system/userLoginMessage/{id}	Set or update the <a href="#">login message</a> with the specified <i>id</i> .
POST /system/unhideUserLoginMessageForAllUsers	Unhide a <a href="#">login message</a> configured for all users.
POST /cspm/ext/rest/user/hideUserLoginMessage	Hide the <a href="#">login message</a> for the user who is associated with the API key that is used for authentication.
POST /cspm/ext/rest/user/unhideUserLoginMessage	Unhide the <a href="#">login message</a> for the user who is associated with the API key that is used for authentication.

### Revised Calls in 4.1.3

The following calls were revised in 4.1.3 and the revisions are applicable in all later 4.1.x and 4.x releases:

Call	Revision
GET /api.php/v1/services.json/{id} GET /api.php/v1/services/tcpudp.json	All GET methods now accept the <code>hideCredentialLink</code> field in <code>fields</code> input parameters, and returns the <code>hideCredentialLink</code> value for service objects.
GET /cspm/ext/rest/configProperties	Now returns details of a configured <a href="#">login message</a> : "name" : "userLoginMessage"
POST /api.php/v1/services/tcpudp.json PUT /api.php/v1/services/tcpudp.json	Both support the new optional parameter <code>hideCredentialLink</code> . If <code>View Credential</code> is disallowed when establishing a service, specify <code>t</code> to prevent a <code>View Credential</code> link from appearing on the Access page. The default is <code>f</code> , to allow a <code>View Credential</code> link. This parameter only applies to TCP/UDP Services with the <code>Application Protocol Disabled</code> .

## New Calls in 4.1.2

The following calls were added in 4.1.2 and are applicable in all later (by date) 4.x and 4.x.x releases:

Call	Function
GET /cspm/ext/rest/proxies/web	Get all web proxies. Originally implemented in 4.0.4.
GET /cspm/ext/rest/proxies/web/{id}	Retrieve the web proxy with the specified id. Originally implemented in 4.0.4.
POST /cspm/ext/rest/proxies/web	Create a web proxy. Originally implemented in 4.0.4.
PUT /cspm/ext/rest/proxies/web/{id}	Update a web proxy. Originally implemented in 4.0.4.
DELETE /cspm/ext/rest/proxies/web/{id}	Delete the specified web proxy. Originally implemented in 4.0.4.

## Revised Calls in 4.1.2

The following calls were revised in 4.1.2 and the revisions are applicable in all later (by date) 4.x and 4.x.x releases:

Call	Revision
GET /api.php/v1/devices.json/{id}/targetApplication	<p>Previously, you required the <b>Read Devices</b> Access Control privilege (and appropriate Credential Manager privileges) to use these calls to target applications or target accounts for a device. This was inconsistent with the PAM UI, on which you did <i>not</i> require the Read Devices privilege to create, update, or target applications or accounts. These calls are now compatible with the UI – the Read Devices privilege is no longer required to perform these operations using the external REST API.</p> <p>The <b>Read Devices</b> privilege is still required to obtain the Device ID, which is required for all target application and target account calls.</p>
GET /api.php/v1/devices.json/{id}/targetApplications/{applicationId}	
GET /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts	
GET /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts/{accountId}	
POST /api.php/v1/devices.json/{id}/targetApplications	
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts	
PUT /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts	
PUT /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts	
DELETE /api.php/v1/devices.json/{id}/targetApplications	
/api.php/v1/devices.json/{id}/targetApplications	
GET /api.php/v1/services.json	Now optionally includes webProxyID and webProxyName . Originally implemented in 4.0.4.

Call	Revision
GET /api.php/v1/services.json/{id}	Now optionally includes webProxyID and webProxyName . Originally implemented in 4.0.4.
POST /api.php/v1/services/tcpudp.json	The POST body can now optionally include webProxyID or webProxyName , or both. Originally implemented in 4.0.4.
PUT /api.php/v1/services/tcpudp.json	The PUT body can now optionally include webProxyID or webProxyName , or both. Originally implemented in 4.0.4.

### New Calls in 4.1.1

The following calls were added in 4.1.1 and are applicable in all later (by date) 4.x and 4.x.x releases:

Call	Revision
GET /cspm/ext/rest/config/crypto/tlsciphers{version}	Get TLS cipher suites that are currently enabled and disabled.
PUT /cspm/ext/rest/config/crypto/tlsciphers{version}	Enable or disable TLS cipher suites.
POST /api.php/v1/system/processes/sessionRecordingPurging.json	Launches the session recording purge process for the session recording mount attached to the current instance of PAM.
POST /api.php/v1/system/processes/sessionRecordingReconciliation.json	Launches all types of session reconciliation purge (mostRecent, recoverPAM, allOthers) for the session recording mount attached to the current instance of PAM.
PUT /cspm/ext/rest/config/logs/sessionRecordingPurge	Update session recording purge settings.

### Revised Calls in 4.1.1

The following calls were revised in 4.1.1 and the revisions are applicable in all later (by date) 4.x and 4.x.x releases:

Call	Revision
GET /api.php/v1/passwords/viewRequests.json	Added new connectionTimeout filter. If specified in the request, any timeout greater or equal to the specified value is returned. In any case, the connection timeout is now returned for all relevant password view requests.
GET /api.php/v1/policies.json/	Now returns hasExtendedTimeout indicating whether policies have the <b>Extended Timeout</b> option set with a value of <i>t</i> (for true) or <i>f</i> (for false).
GET /api.php/v1/policies.json/{id}	Now returns hasExtendedTimeout indicating whether the specified policy has the <b>Extended Timeout</b> option set with a value of <i>t</i> (for true) or <i>f</i> (for false).
GET /api.php/v1/policies.json/{userOrGroupId}/{deviceOrGroupId}	Now returns hasExtendedTimeout indicating whether the specified policy has the <b>Extended Timeout</b> option set with a value of <i>t</i> (for true) or <i>f</i> (for false).
POST /api.php/v1/policies.json/{userOrGroupId}/{deviceOrGroupId}	Added support for configuring extended timeout functionality by specifying a value of <i>t</i> (for true) or <i>f</i> (for false) in the hasExtendedTimeout parameter.

Call	Revision
GET /api.php/v1/services/tcpudp.json POST /api.php/v1/services/tcpudp.json PUT /api.php/v1/services/tcpudp.json	Added support for keepaliveInterval, SCP, SFTP, and publicKeyAuthentication for the SSH Application protocol type.
DELETE /api.php/v1/passwords/checkedIn.json/{accountId}	New error messages if the account does not have checkin enabled or have exclusive checkout enabled.

### New Calls in 4.0

The following calls were added in release 4.0 and are available in all later (by date) 4.x and 4.x.x releases:

Call	Description
GET /api.php/v1/deviceGroups.json/{id}/utilityGroup	For the Utility GroupD specified by {id}, returns information on the internal state of the individual Utility Appliances that make up the utility group.
GET /api.php/v1/devices.json/{id}/unabConfig PUT /api.php/v1/devices.json/{id}/unabConfig	Get or update the UNAB config tokens for the device that is specified by {id}.
GET /api.php/v1/deviceGroups.json/{id}/unabConfig PUT /api.php/v1/deviceGroups.json/{id}/unabConfig	Get or update the UNAB config tokens for the device group that is specified by {id}.
GET /cspm/ext/rest/sc/policies/audit	Get the Server Control Policy Deployment Audit Log.
GET /cspm/ext/rest/sc/policies/{policyId}/version/current	Get the current Server Control Policy Script version by Policy id.
GET /cspm/ext/rest/sc/policies/{policyId}/versions	Get Server Control Policy Script versions by Policy id.
GET /cspm/ext/rest/sc/policies/{policyId}/version/{versionId}	Get a specific Server Control Policy Script version by Policy id.
GET /cspm/ext/rest/sc/policies/{policyId}/assignment	Get assigned devices and device group to a policy by Policy id.
GET /cspm/ext/rest/sc/policies/{policyId}/assignment/devices	Get assigned devices to a Server Control Policy by Policy id.
GET /cspm/ext/rest/sc/policies/{policyId}/upgradable/devices	Get a list of devices that can be upgraded to the latest version of Server Control Policy by Policy id.
GET /cspm/ext/rest/sc/policies/{policyId}	Get a specific Server Control Policy by Policy id.
GET /cspm/ext/rest/sc/policies/{policyId}/downgradable/devices	Get a list of devices that can be downgraded to the specified policy version by Policy id.
GET /cspm/ext/rest/sc/policies/{policyId}/assignment/deviceGroups	Get assigned device groups to a Server Control Policy by Policy id.
GET /cspm/ext/rest/sc/policies/{policyId}/upgradable/deviceGroups	Get a list of device groups that can be upgraded by Policy id.
GET /cspm/ext/rest/sc/policies	Get Server Control Policies
POST /cspm/ext/rest/sc/policies	Create a Server Control Policy and initial Script version.
POST /cspm/ext/rest/sc/policies/{policyId}/version	Create a Server Control Policy Script version.

Call	Description
PUT /cspm/ext/rest/sc/policies/{policyId}/assignment	Assign devices and device groups to the latest finalized Server Control Policy Script version.
PUT /cspm/ext/rest/sc/policies/{policyId}	Update a Server Control Policy description.
PUT /cspm/ext/rest/sc/policies/{policyId}/assignment/upgrade	Upgrade devices to the latest finalized Server Control Policy Script version.
PUT /cspm/ext/rest/sc/policies/{policyId}/assignment/downgrade	Downgrade devices to the specified Server Control Policy Script version
PUT /cspm/ext/rest/sc/policies/{policyId}/version	Update a Server Control Policy Script version.
DELETE /cspm/ext/rest/sc/policies/{policyId}/assignment	Unassign devices and device groups from a Server Control Policy.
DELETE /cspm/ext/rest/sc/policies/{policyId}	Delete a specific Server Control Policy by id.
GET /cspm/ext/rest/sc/unab/policies/audit	Get the UNAB Policy Deployment Audit Log.
GET /cspm/ext/rest/sc/unab/policies/{policyId}	Get a specific UNAB Policy by Policy id.
GET /cspm/ext/rest/sc/unab/policies	Get UNAB Policies.
POST /cspm/ext/rest/sc/unab/policies	Create a UNAB Policy.
PUT /cspm/ext/rest/sc/unab/policies/{policyId}	Update the associated users and user groups of a UNAB Policy.
DELETE /cspm/ext/rest/sc/unab/policies/{policyId}	Delete a specific UNAB Policy by id.

### Revised Calls in 4.0

The following calls were revised in 4.0 and the revisions are applicable in all later 4.x releases:

Call	Revision
GET /api.php/v1/deviceGroups.json/ PUT /api.php/v1/deviceGroups.json/	Added new provision type "Utility Group" to represent PAM SC Utility Groups.
POST /api.php/v1/devices.json/{id}/targetApplications PUT /api.php/v1/devices.json/{id}/targetApplications	Added support for three new values in the applicationType field: <ul style="list-style-type: none"> <li><a href="#">windows (Windows Proxy)</a></li> <li><a href="#">windowsRemoteAgent (Windows Remote)</a></li> <li><a href="#">windowsDomainService (Active Directory)</a></li> </ul> (Select the corresponding entry for details of the new configuration field attributes introduced by each application type.)
GET /api.php/v1/services/tcpudp.json POST /api.php/v1/services/tcpudp.json PUT /api.php/v1/services/tcpudp.json	Added support for keepaliveInterval, SCP, SFTP, and publicKeyAuthentication for the SSH Application protocol type.
DELETE /api.php/v1/passwords/checkedIn.json/{accountId}	New error messages if account does not have checkin enabled or have exclusive checkout enabled. Function

## Revised Credential Manager CLI Commands in 4.x Releases

### Revised Call in 4.1.7

The following call was revised in 4.1.7 and this revision is applicable in all later 4.x releases:

Command	Revision
<code>addTargetApplication</code>	<p>Added support for the following target applications:</p> <ul style="list-style-type: none"> <li><a href="#">Windows SSH Key</a></li> <li><a href="#">Windows SSH Password</a></li> </ul> <p>(Select the corresponding entry for details of the new configuration field attributes introduced by each application type.)</p>

### Revised Calls in 4.1.5

The following calls were revised in 4.1.5 and these revisions are applicable in all later 4.x releases:

Command	Revision
<code>addTargetApplication</code>	<p>When adding an Active Directory or Windows Remote target application, you can use the optional <code>Attribute.enableKerberos</code> parameter to enable or disable Kerberos authentication.</p> <p>When adding a Windows Remote target application with Kerberos enabled, you can also use the optional <code>Attribute.overrideDnsType</code> parameter to specify whether to allow a different DNS lookup type for this target application than for others in the same domain.</p> <p>For more information, see <a href="#">Active Directory Target CLI Configuration</a> and <a href="#">Windows Remote Target Connector CLI Configuration</a>.</p> <p>When adding an MSSQL Azure Managed Instance target application, you must use the following parameters with the specified values:</p> <ul style="list-style-type: none"> <li><code>TargetApplication.type : mssqlAzureMI</code></li> <li><code>Attribute.extensionType : mssqlAzureMI</code></li> </ul> <p>For more information, see <a href="#">MSSQL Azure Managed Instance Target Connector CLI Configuration</a>.</p>

### Revised calls in 4.1.1

The following calls were revised in 4.1.1 and these revisions are applicable in all later 4.x releases:

Command	Revision
<code>listPasswordViewRequestSummary</code> <code>listPasswordViewRequestSummaryByRequestor</code>	<p>The returned list of password view requests now includes connection idle timeout values if they are specified.</p>
<code>searchPasswordViewPolicy</code> <code>searchPasswordViewRequestSummary</code> <code>searchPasswordViewRequestSummaryByRequestor</code>	<p>New optional parameter: <code>PasswordViewRequest.connectionTimeout</code> can be used to filter results for requests with connection idle timeouts greater than or equal to the specified value (in minutes). (Useful for identifying extended timeout requests.)</p>

## Revised calls in 4.0

The following calls were revised in 4.0 and these revisions are applicable in all later 4.x releases:

Command	Revision
viewAccountPassword	New optional parameter: <code>PasswordViewRequest.comments</code> which specifies comments to be added to the view password request.
addPasswordPolicy updatePasswordPolicy	New optional parameters: <ul style="list-style-type: none"> <li>• <code>Attribute.disallowSameClassRepeat=boolean</code></li> <li>• <code>Attribute.maxClassRepeat=numeric</code></li> </ul>
addPasswordViewPolicy updatePasswordViewPolicy	New optional parameter: <code>PasswordViewPolicy.passwordViewRequestBanner</code> which defines banner text to be displayed on the Password View Policy.

## Access Free PAM Training Videos From the IMS Software Academy

The Broadcom Identity Management Security division **IMS Software Academy** provides free education videos to help you get the most out of your IMS products.

Visit the [IMS Software Academy](#), create your account, and get started today.

### Access the IMS Software Academy

To access the free education videos, open the [IMS Software Academy](#) in a browser, then do one of the following steps to access the content:

- Log in using your existing Broadcom credentials.
- If you do not have Broadcom credentials, register by providing your corporate email address.

Once logged in, the **Dashboard** page opens, as shown in the following screen capture:

The screenshot displays the IMS Software Academy dashboard. At the top, there is a search bar labeled "Search for enrolled courses" and a "Dashboard" button. Below the header, a banner features logos for IMS Software Academy, Broadcom Software, Symantec VIP, Symantec PAM, Symantec SiteMinder, and Layer7 API Management. The main content area is divided into two columns. The left column shows "Total Number of Courses" with 4 Enrolled Courses and 0 Completed Courses, and a "Recent Activity" section listing three enrollments in Layer7 API Management courses. The right column displays two course cards: "Symantec VIP Authentication Hub Basics" (2 Modules, 0% progress) and "Layer7 API Management Basics" (10 Modules, 0% progress).

### Locate the PAM Courses

If you know the specific name of a course, enter it in the **Search Catalog** field at the top of the screen. Otherwise, do the following steps to access the PAM catalog:

1. Select the **Dashboard** button in the top left.
2. Select the **Catalog** entry from the drop-down menu that appears.
3. Select the **Privileged Access Manager (PAM)** entry from the **Category** drop-down menu.
4. Select **Apply**.
5. The PAM course catalog opens, displaying the newest five courses. To access previous courses, use

the page selector  at the bottom of the course list.

### Available PAM Courses

The following Privileged Access Manager courses are currently publicly available:

- **Symantec PAM Competency - Threat Analytics:** The modules in this course describe how to integrate Symantec PAM and Symantec Threat Analytics to evaluate the risk of privileged user activity to detect and mitigate threats from suspicious activity.
- **Symantec PAM Competency - PAM Server Control:** The modules in this course provide a complete foundational understanding of the integrated PAM Server Control module, which provides host-based security for your most sensitive physical, virtual, or cloud-based systems.
- **Symantec PAM Competency - Architecture:** The modules in this course describe the core PAM architecture and also that of PAM Utility Appliances, which are required to support PAM Server Control.
- **Symantec PAM Basics:** The modules in this course cover a wide range of foundational information, including overviews of essential Symantec PAM concepts, upgrade best practices, and how to plan and implement a high-availability PAM cluster.
- **Symantec PAM - What's New in Symantec PAM 4.0:** This video provides a brief overview of Symantec PAM followed by presentations and demos of the new features in version 4.0.
- **Symantec PAM - Tech Talk: Mitigating Against the Pwnkit Vulnerability:** This Tech Talk discusses how to mitigate the threat of the Pwnkit vulnerability.
- **Symantec PAM - Secrets Management Overview:** This course provides an Overview and Demo of the Secrets Management functionality that was introduced in PAM 4.1.
- **Symantec PAM - Secrets Management Secret Types:** This course provides an overview of the types of secrets that are managed by the secrets management functionality that was introduced in PAM 4.1.
- **Symantec PAM - April Tech Talk - Secrets Management:** This Tech Talk delves deeper into the PAM secrets management functionality.

Not seeing any courses that interest you? Let us know what you would like to learn more about, and we will add it to the list of potential future offerings.

## Related Products

The following products integrate with Privileged Access Manager but are released independently:

- Socket Filter Agents (SFAs) – To use SFAs, see [Socket Filter Agent Support](#).
- A2A Manager Clients – To use the A2A Client, see [Add and Run Credential Manager A2A Requestors](#).
- Windows Proxy – To use the Windows Proxy, see [Add a Windows Proxy Connector](#) and [How to Install a Windows Proxy for Credential Manager](#).

For information about which Privileged Access Manager releases support these products, see [Supported Environments](#). To download the software, go to the [Download Management](#) page on the Support site. In the top field of the page, start entering "Privileged Access" and then select the product page when it becomes available. The product downloads become available.

### NOTE

#### Support Site Notes:

- For the A2A Client, the software is named **Privileged App to App Manager**.
- For the Windows Proxy, the software is under Privileged Access Manager - DEBIAN and under Privileged Access Manager Credential Manager - DEBIAN.

## Upgrading

You can upgrade directly to PAM 4.1.7 from existing environments running the following release versions:

- **3.4.x:** 3.4, 3.4.1, 3.4.2, or 3.4.3, 3.4.4, 3.4.5, or 3.4.6.
- **4.0.x:** 4.0, 4.0.1, 4.0.2, 4.0.3, 4.0.4, 4.0.5, 4.1, 4.1.1, 4.1.2, 4.1.3, 4.1.4, 4.1.5, or 4.1.6.

### NOTE

To upgrade from a 3.3.x environment, first upgrade to 4.0. For more information, see the [4.0 upgrade documentation](#).

The supported direct upgrade paths are illustrated in the following diagram:

### TIP

We recommend that you test the upgrade in a non-production environment before you upgrade your production environment.

**To upgrade successfully, do the following procedures:**

### NOTE

If your PAM environment is deployed as a multisite cluster, refer to [Upgrading Across a Multi-Site Cluster](#) before you begin the upgrade process.

1. Complete the [Upgrade Prerequisites](#).
2. Use the appropriate procedure to upgrade your PAM server or servers:
  - [Upgrade a Single Appliance to 4.1.7](#)
  - [Upgrade Appliances in a Cluster to 4.1.7](#)
3. If you have deployed PAM SC, [upgrade your PAM SC Utility Appliances](#)
4. Upgrade auxiliary components, as applicable:
  - [Upgrade a Socket Filter Agent \(SFA\)](#)
  - [Upgrade a Credential Manager A2A Client](#)
  - Upgrade a Windows Proxy ([uninstall the old Windows Proxy software](#), then [install the new version](#))
5. If you have deployed PAM SC, upgrade the following components:

- [PAM SC Utility Appliances](#)
- [PAM SC Endpoints](#)

### **Upgrades and FIPS Mode Operation**

If PAM is already operating in FIPS mode, the PAM server remains in FIPS mode when you upgrade to a newer release. Any upgrade-related cryptographic changes that relate to FIPS mode compliance will be clearly stated in this topic and in the Release Information section.

To move from commercial (Non-FIPS) to FIPS mode operation, you must make changes to licensed products. Please contact your assigned Account Director for more details.

## **Upgrade Prerequisites for 4.1.7**

Complete the following upgrade prerequisites before starting the upgrade to 4.1.7:

### **Verify That Your Environment Is Running a Supported Version In the Upgrade Path**

Verify that your environment is running one of the following releases that are supported for direct upgrade to 4.1.7:

- 3.4, 3.4.1, 3.4.2, 3.4.3, 3.4.4, 3.4.5, or 3.4.6
- 4.0, 4.0.1, 4.0.2, 4.0.3, 4.0.4, 4.0.5, 4.1, 4.1.1, 4.1.2, 4.1.3, 4.1.4, 4.1.5, or 4.1.6.

#### **NOTE**

For more information about upgrade paths, see [Upgrading](#).

### **Review Minimum Free Space**

Ensure that your hard drive has **at least 16 GB of space available** (64 GB recommended) to upload, decompress, and install the new release. Two seemingly unrelated errors can be caused by insufficient disk space:

- PAM-CMN-1344: Problem applying the upgrade package. Details: Error verifying the authenticity of the upgrade package! This error occurs because there is not enough space to decrypt the encrypted upgrade file.
- PAM-CMN-3349: Cannot upgrade because patch is not HMAC signed. This error occurs because there is not enough space to extract required files after decryption.

### **Back Up Your Privileged Access Manager Appliance**

Before you upgrade a Privileged Access Manager appliance, create a backup of your appliance instance. If the upgrade is unsuccessful, you can revert to the backup.

#### **WARNING**

Back up your appliance, even if you backed it up before a previous upgrade.

Depending on the type of appliance you have, follow the relevant guidelines:

- **Privileged Access Manager Hardware appliances:** The upgrade procedure backs up a hardware appliance to its second hard drive before initiating the upgrade. No action is required at this time. For more information, see [Upgrade a Single Appliance to 4.1.7](#).
- **VMware appliances:** Take a snapshot of the VMware OVA. For specific instructions on creating a snapshot of an OVA, see the [VMware documentation](#).
- **AWS AMI appliances:** Take a snapshot of the AMI instance. For specific instructions on backing up an AMI instance, see the [AWS documentation](#).
- **Azure VM appliances:** Take a snapshot of the VM instance. For specific instructions on backing up an Azure instance, see the [Azure documentation](#).

If you take a snapshot while the instance is operating, the snapshot can take a long time to complete. To save time and storage media, shut down the instance and then take the snapshot.

### **Put Your Appliance Into Maintenance Mode**

Put your appliance into [Maintenance Mode](#) before initiating the upgrade.

### **Prepare the Hardware Appliance**

When upgrading a physical appliance, Privileged Access Manager copies the primary drive data (including database and configuration files) onto its backup drive before applying the update. If there is any issue with the upgrade, you can restore your appliance to its preupgrade state from the backup.

If an upgrade error occurs, follow the instructions in [Recover the Hardware Appliance](#).

### **Ensure Clustering Ports are Open**

If you are upgrading a cluster, ensure that ports 3307, 13307, and 8443 are open. These ports are required for the enhanced clustering in this release. See [Cluster Deployment Requirements](#) for more information.

### **Review Strong Cryptography on Cisco and UNIX Target Connectors**

Release 4.1.7. supports the latest recommended strong cryptography for secure SSH communications in Cisco and UNIX target connectors. All target servers must support at least one of the security algorithms from each of the following categories:

Privileged Access Manager 4.1.7 supports the following algorithms:

<b>Cryptographic Algorithms</b>	<b>Non-FIPS mode Supported List</b>	<b>FIPS mode Supported List</b>	<b>Deprecated algorithms*</b>
Cipher	<ul style="list-style-type: none"> <li>• aes128-gcm@openssh.com</li> <li>• aes256-gcm@openssh.com</li> <li>• aes128-ctr</li> <li>• aes256-ctr</li> <li>• aes128-cbc</li> <li>• aes256-cbc</li> </ul>	<ul style="list-style-type: none"> <li>• aes128-gcm@openssh.com</li> <li>• aes256-gcm@openssh.com,</li> <li>• aes128-ctr</li> <li>• aes256-ctr</li> <li>• aes128-cbc</li> <li>• aes256-cbc</li> </ul>	<ul style="list-style-type: none"> <li>• aes192-ctr</li> <li>• aes192-cbc</li> <li>• 3des-ctr</li> <li>• 3des-cbc</li> <li>• blowfish-cbc</li> <li>• arcfour256</li> <li>• arcfour128</li> <li>• arcfour</li> </ul>

\**Deprecated algorithms* will continue working in PAM to support backward compatibility. Using newer and more secure algorithms is recommended.

You can disable the deprecated algorithms on the SSH-2 tab of the UNIX or Cisco target application configuration. For more information, go to [Add a UNIX Target Connector](#). Read the instructions for the SSH-2 Tabs - Cipher, Hash, Key Exchange, Compression, Server Host Key.

### Review Strong Cryptography for Access Management - SSH Proxy and SSH MindTerm

Release 4.1.7 supports the latest recommended strong cryptography for more secure SSH communications for Access Management using SSH Proxy and SSH Mindterm. These algorithms are listed in the PAM UI under **Configuration, Security, Cryptography**. All target servers must support at least one of the cryptographic algorithms from each of the algorithm sections. PAM has three lists (also called categories or sets) of cryptographic algorithms:

- **Supported:** All the algorithms supported by PAM. This list appears in the PAM UI on Cryptographic pages when you select the eye icon next to every algorithm.
- **Recommended:** All the algorithms that PAM strongly recommends customers to use. PAM, by default, only uses the algorithms from the "recommended" list. This list is also used when "Use Default" is checked.
- **Allowed/customized:** By default, this is a recommended list. This list is a customized version of algorithms specified by end users in the PAM UI.

PAM 4.1.7 uses the following list of algorithms:

SSH Proxy Cryptographic Algorithms				
Cryptographic Algorithms	Non-FIPS mode Supported List	Non-FIPS mode Recommended List	FIPS mode Supported List	FIPS mode Recommended List
Cipher	<ul style="list-style-type: none"> <li>• aes128-gcm@openssh.com</li> <li>• aes256-gcm@openssh.com</li> <li>• chacha20-poly1305@openssh.com</li> <li>• aes128-ctr</li> <li>• aes192-ctr</li> <li>• aes256-ctr</li> </ul>	<ul style="list-style-type: none"> <li>• aes128-gcm@openssh.com</li> <li>• aes256-gcm@openssh.com</li> <li>• chacha20-poly1305@openssh.com</li> <li>• aes128-ctr</li> <li>• aes192-ctr</li> <li>• aes256-ctr</li> </ul>	<ul style="list-style-type: none"> <li>• aes128-gcm@openssh.com</li> <li>• aes256-gcm@openssh.com</li> <li>• chacha20-poly1305@openssh.com</li> <li>• aes128-ctr</li> <li>• aes192-ctr</li> <li>• aes256-ctr</li> </ul>	<ul style="list-style-type: none"> <li>• aes128-gcm@openssh.com</li> <li>• aes256-gcm@openssh.com</li> <li>• chacha20-poly1305@openssh.com</li> <li>• aes128-ctr</li> <li>• aes192-ctr</li> <li>• aes256-ctr</li> </ul>

**NOTE**  
**Next Step:**

- [Upgrade a Single Appliance to 4.1.7](#)  
or
- [Upgrade Appliances in a Cluster to 4.1.7](#)

## Upgrade a Single Appliance to 4.1.7

This content describes how to upgrade the PAM software to 4.1.7 on a *single* hardware or virtual appliance.

### NOTE

To upgrade a clustered appliance, see [Upgrade Appliances in a Cluster to 4.1.7](#).

Allow sufficient time to upgrade. The process takes some time to complete because it backs up your previous software, configuration, and provisioning database. Do not interrupt it.

### Review the Upgrade Prerequisites

Before you upgrade, [review the prerequisites](#) and verify that they have been met.

### Download the Patch

Download the software for this release from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

### Prepare for the Upgrade

Complete this procedure before starting the upgrade.

#### Follow these steps:

1. Confirm that all [prerequisites](#) are completed.
2. Log in to the PAM UI as a Configuration Manager or Global Administrator. You must have privileges to modify Configuration options and Global Settings.
3. To prevent users from logging in during the upgrade, turn on **Maintenance Mode** from **Configuration, Diagnostics, System**.
4. If your installation uses an NFS, CIFS, or Amazon S3 mount to store session recordings, ensure that the mount is up:
  - a. Navigate to **Configuration, Logs, Session Recording**.
  - b. Select the **External Storage** tab.
  - c. In the **Primary Mount Settings** section, confirm that **Mount Status** states "mounted".

After you are finished with this procedure, perform the upgrade.

### Perform the Upgrade

After you prepare for the upgrade, apply the upgrade patch.

#### Follow these steps:

1. From the PAM UI, navigate to **Configuration, Upgrade**.
2. In the **Upgrade History** section, confirm that the installed upgrades include any necessary patches to upgrade to the current release. For more information about the necessary patches, see [Upgrading](#).
3. Select **Choose File** and browse to the **CAPAM\_4.1.7.p.bin** file.
4. Select **Upload and Apply** to apply the patch automatically after the file uploads, or select **Upload** and **Apply** separately. The upgrade begins.

### NOTE

#### Appliance Backups:

Manually backup virtual appliances *before* performing the upgrade (see [Upgrade Prerequisites](#)).

Hardware appliances are backed up automatically during the upgrade process according to their model and current PAM version:

- On a 304L hardware appliance, the upgrade procedure automatically performs a full backup (to its second hard drive) before initiating the upgrade.
- On a 404L hardware appliance, *if you are upgrading from 4.1.1*, the upgrade procedure asks you if you want to perform a full backup before initiating the upgrade process. If you are upgrading from any other version, the upgrade procedure automatically performs a full backup before initiating the upgrade process. (The same as on the 304L appliance.)

### **WARNING**

Depending on the size of your database, the upgrade might take a long time to complete. Keep your browser open until you see a reboot message. Do not interrupt the upgrade process.

5. After the upgrade is complete, a dialog appears. Select **OK** to reboot the appliance.

### **IMPORTANT**

If you are running the upgrade procedure using the PAM Client, you must terminate it while the PAM server reboots so that it will update itself to the new version when you start it again after the upgrade is complete. Follow these steps:

1. When a dialog stating "Your session connection is lost. The session will be terminated. Re-login to continue" select the **OK** button.
2. To terminate the PAM Client, select the **X** button in the upper right corner of the next screen.
3. Proceed to Step 6.

### **TIP**

If the reboot message still appears in the PAM UI or the LCD display (hardware appliance) after 5 minutes, continue to Step 6.

6. When the reboot is complete, log back in to the PAM UI. If you are using the PAM Client, wait while it updates itself to the new PAM version.

### **NOTE**

If you cannot initially log in, wait from 15 to 30 minutes and try again.

7. Review the following items to confirm that the upgrade is successful:
  - The **Upgrade History** section shows the correct file name, with the current time and date.
  - The correct release number is shown in the **Version** field on the **System Info** pane.
8. Continue to complete any post upgrade procedures.

## **Post Upgrade Procedures**

After the upgrade completes successfully, complete the relevant post-upgrade tasks:

- [Clear the Browser and JRE caches](#)
- [Update the Credential Manager Remote CLI and Java API](#)
- [Verify OCS Smart Card for Entrust nShield HSM is Installed](#)
- [Change the Login Timeout](#)

### **WARNING**

If you turned on Maintenance Mode, turn it off after you complete the post-upgrade tasks.

### ***Clear Browser and JRE Caches***

Instruct users who connect to the PAM appliance through a web browser to clear their browser and JRE caches before they log in again. Communicate this instruction to administrators *and* standard users.

**Follow these steps:**

1. For each browser that you use to access Privileged Access Manager, clear its cache, and close it.
2. Clear the Java cache in the Java JRE.
3. Restart the browser.

If you do not clear the Java cache, the following error message appears on the Access page:

The Access page failed to load. Please verify that Java is installed and is enabled in your browser, and that the Next-generation Java Plug-in is enabled. If so, then the download of the Java applet might be taking too long. Please try again. If the problem persists, please contact your administrator.

**Update the Credential Manager Remote CLI and Java API**

If you use the Remote CLI or Java API to manage Credential Manager, update to the 4.1.7 version of RemoteCLI zip on your designated client system. For more information, see [Install and Set Up the Remote CLI and Java API](#).

**Verify That the OCS Smart Card for Entrust nShield HSM is Installed**

On the hardware appliance or a VMware OVA, the Credential Manager can work with an Entrust nShield HSM for hardware encryption.

After you upgrade, ensure that the OCS smart card for the HSM is inserted into the Entrust nShield HSM.

The smart card is necessary in the following situations:

- Before you reboot PAM
- Before you restart a cluster
- After you apply a patch

After PAM is successfully communicating with the HSM, you can remove the card.

**Revert the Login Timeout**

If you changed the Login Timeout before doing the upgrade, change it back to your preferred setting. Navigate to **Settings, Global Settings** and set the **Login Timeout**.

## Upgrade Appliances in a Cluster to 4.1.7

This content describes how to upgrade the PAM software on all cluster members without removing them from the cluster. This method is the simplest, but it keeps your cluster offline for the longest amount of time. If minimal downtime is a priority for your environment, see [Migrating Across a Multi-Site Cluster](#) for alternative methods to upgrade a cluster.

To upgrade the software on all the appliances in a cluster, follow these instructions:

**NOTE**

To upgrade a single (unclustered) appliance, see [Upgrade a Single Appliance to 4.1.7](#).

**Review the Upgrade Prerequisites**

Before you upgrade, [review the prerequisites](#).

**Download the Patch**

Download the software for this release from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

## Prepare Cluster Members for the Upgrade

Complete the following procedure on *each member* of the cluster before starting the upgrade.

### Follow these steps:

1. Confirm that all appliances are running the same release version and have the same patch set. To verify this information, navigate to **Configuration, Upgrade**, and review the Upgrade History.

#### WARNING

If the appliances in the cluster are a mix of releases or patch sets, upgrade each mismatched appliance to the same release and patch set. Ensure that the version you upgrade to supports an upgrade to the latest release (see [Upgrading](#)). If the release and patch match but they are not at a version that can be upgraded, contact CA Support for instructions.

2. Confirm that all [prerequisites](#) are completed.
3. Log in to the PAM UI as a Configuration Manager or Global Administrator. You must have privileges to modify Configuration options and Global Settings.
4. To prevent user from logging in during the upgrade, turn on **Maintenance Mode** from **Configuration, Diagnostics, System**.
5. If your installation uses an NFS, CIFS, or Amazon S3 mount to store session recordings, ensure that the mount is up:
  - a. Navigate to **Configuration, Logs, Session Recording**.
  - b. Select the **External Storage** tab.
  - c. In the **Primary Mount Settings** section, confirm that **Mount Status** states "mounted".

After you are done preparing, perform the upgrade.

## Perform the Upgrade

The following procedure is the simplest method to upgrade a cluster, but the cluster is down for the longest amount of time. If limiting downtime is a priority over simplicity, go to [Migrating Across a Multi-Site Cluster](#) to learn about an alternative upgrade method.

#### NOTE

We recommend using the PAM UI in a web browser to upgrade the Privileged Access Manager appliance.

### Follow these steps:

1. If clustering is active, turn it off at any of the cluster members.  
**To turn off the cluster:**
  - a. Log in as an administrator with configuration privileges (for example, "config" or "super").
  - b. Navigate to **Configuration, Clustering**, and select the **Cluster Status** tab.
  - c. Select **Turn Cluster Off** at the bottom of the page. Wait until a notification indicates that synchronization is off.
2. At the cluster member to be upgraded:
  - a. Navigate to **Configuration, Upgrade**.
  - b. In the **Upgrade History** section, confirm that your installed upgrades include all necessary patches for upgrading to the current release. See [Upgrading](#) for more information.
  - c. Select **Choose File** and browse to the **CAPAM\_4.1.7.p.bin** file.
  - d. Select **Upload and Apply** to apply the upgrade automatically after the file uploads, or select **Upload** and **Apply** separately. The upgrade begins.

#### NOTE

#### Appliance Backups:

Manually backup virtual appliances *before* performing the upgrade (see [Upgrade Prerequisites](#)).

Hardware appliances are backed up automatically during the upgrade process according to their model and current PAM version:

- On a 304L hardware appliance, the upgrade procedure automatically performs a full backup (to its second hard drive) before initiating the upgrade.
- On a 404L hardware appliance, *if you are upgrading from 4.1.1*, the upgrade procedure asks you if you want to perform a full backup before initiating the upgrade process. If you are upgrading from any other version, the upgrade procedure automatically performs a full backup before initiating the upgrade process. (The same as on the 304L appliance.)

**WARNING**

Depending on the size of your database, the upgrade might take a long time to complete. Keep your browser open until you see a reboot message. Do not interrupt the upgrade process.

- e. After the upgrade is complete, a dialog appears. Select **OK** to reboot the appliance.

**IMPORTANT**

If you are running the upgrade procedure using the PAM Client, you must terminate it while the PAM server reboots so that it will update itself to the new version when you start it again after the upgrade is complete. Follow these steps:

1. When a dialog stating "Your session connection is lost. The session will be terminated. Re-login to continue" select the **OK** button.
2. To terminate the PAM Client, select the **X** button in the upper right corner of the next screen.
3. Proceed to Step f.

**TIP**

If the reboot message still appears in the PAM UI or the LCD display (hardware appliance) after 5 minutes, continue to Step f.

- f. When the reboot is complete, log back in to the PAM UI. If you are using the PAM Client, wait while it updates itself to the new PAM version.

**NOTE**

If you cannot initially log in, wait from 15 to 30 minutes and try again.

- g. Review the following items to confirm that the upgrade is successful:
- The **Upgrade History** section shows the correct file name, with the current time and date.
  - The correct release number is shown in the **Version** field on the **System Info** pane.

3. Repeat step 2 for every cluster member.

**WARNING**

**SailPoint Users Note:** If you have integrated a SailPoint database in PAM before this upgrade, follow these steps:

- The server that previously had the SailPoint integration must be specified as the first member of the primary site cluster.
- The cluster must be turned on from that cluster member.

Failure to follow these steps results in a total loss of the PAM SailPoint database. This loss happens because the first member of the primary site is the database initialization source when you turn on a cluster. If the SailPoint database exists only on another member, it is overwritten. Beginning with version 3.3.1, the SailPoint database is replicated to all members, so this step is unnecessary when upgrading to subsequent versions.

4. On the *primary cluster member*, turn clustering back on:
- a. Log in to the primary member and confirm that all data is restored.
  - b. Navigate to **Configuration, Clustering**.
  - c. Select **Turn Cluster On** at the bottom of the page. Wait approximately 5 minutes until Status indicates that clustering is now on.
5. Complete any required [post-upgrade procedures](#).

## Post Upgrade Procedures

After the upgrade completes successfully, complete the relevant post-upgrade tasks:

- [Clear the Browser and JRE caches](#)
- [Update the Credential Manager Remote CLI and Java API](#)
- [Verify OCS Smart Card for Entrust nShield HSM is Installed](#)
- [Change the Login Timeout](#)

### WARNING

Important! If you turned on Maintenance Mode, turn it off after you complete the post-upgrade tasks.

### **Clear Browser and JRE Caches**

Instruct all users who connect to Privileged Access Manager through a web browser to clear their browser and JRE caches before they log in again. Communicate this instruction to administrators *and* standard users.

### **Follow these steps:**

1. For each browser that you use to access Privileged Access Manager, clear its cache, and close it.
2. Clear the Java cache in the Java JRE.
3. Restart the browser.

If you do not clear the Java cache, the following error message appears on the Access page:

The Access page failed to load. Please verify that Java is installed and is enabled in your browser, and that the Next-generation Java Plug-in is enabled. If so, then the download of the Java applet might be taking too long. Please try again. If the problem persists, please contact your administrator.

### **Update the Credential Manager Remote CLI and Java API**

If you use the Remote CLI or Java API to manage Credential Manager, update to the 4.1.7 version of `RemoteCLI` zip on your designated client system. For more information, see [Install and Set Up the Remote CLI and Java API](#).

### **Verify OCS Smart Card for Entrust nShield HSM is Installed**

On the hardware appliance or a VMware OVA, the Credential Manager can work with a Entrust nShield HSM for hardware encryption.

After you upgrade, ensure that the OCS smart card for the HSM is inserted into the Entrust nShield HSM.

The smart card is necessary in the following situations:

- Before you reboot PAM
- Before you restart a cluster
- After you apply a patch

After PAM is successfully communicating with the HSM, you can remove the card.

### **Change the Login Timeout**

If you changed the Login Timeout before doing the upgrade, change it back to your preferred setting. Navigate to **Settings, Global Settings** and set the **Login Timeout**.

## Upgrading Across a Multi-Site Cluster

Upgrade strategies differ depending on your priorities. Consider whether you want to minimize the complexity of the upgrade, or minimize cluster downtime. These priorities can determine the upgrade method.

**TIP**

Cluster configurations and requirements can vary considerably. To discuss your upgrade options, contact Broadcom Support.

Some of the methods for upgrading a multi-site cluster are described in the following topics:

Regardless of which method you use, remember these guidelines:

- Always back up your data before upgrading
- Do not run mixed PAM release versions in a cluster.
- Be mindful not to lose any data. The database of the primary member in the primary site holds the data. This database gets replicated. Any changes to a member outside of a live cluster can break cluster synchronization. For example, exercising an access method which changes the password on a target device breaks synchronization.
- The upgrade takes a long time to complete. To allow time to upload and upgrade, remove the timeout. Navigate to **Settings, Global Settings** and set the **Login Timeout** to 0. Log out and log back in to ensure the change.

**Upgrade Method to Limit Downtime**

This section explains *one* upgrade method. The goal of this phased upgrade is to limit how long the cluster is off line. This method is not the only way to upgrade a cluster.

**WARNING**

This phased upgrade is a guideline. This process is not intended as the sole resource for upgrading a multi-site cluster to limit downtime. You might have other processes and resources, such as runbooks, that are specific for your infrastructure. Use those resources together with this phased procedure.

The following phases explain the upgrade flow of a multi-site cluster across several data centers.

***Phase One***

The following graphic illustrates the following steps:

1. Remove all secondary members except one from the cluster at each secondary site. The picture shows one of the two secondary members at each secondary site that is removed from the cluster. The red systems represent removed members.  
The capacity of the cluster is reduced but no outage occurs.
2. Upgrade each removed cluster member to the current release.  
You can observe how long it takes to upgrade each member to estimate the upgrading of the entire cluster.

**Figure 5: Phase 1 Cluster Migration****Phase Two**

The second phase reflects a full outage of the cluster. The intention of this phase is to allow only the administrator access to cluster members, not users.

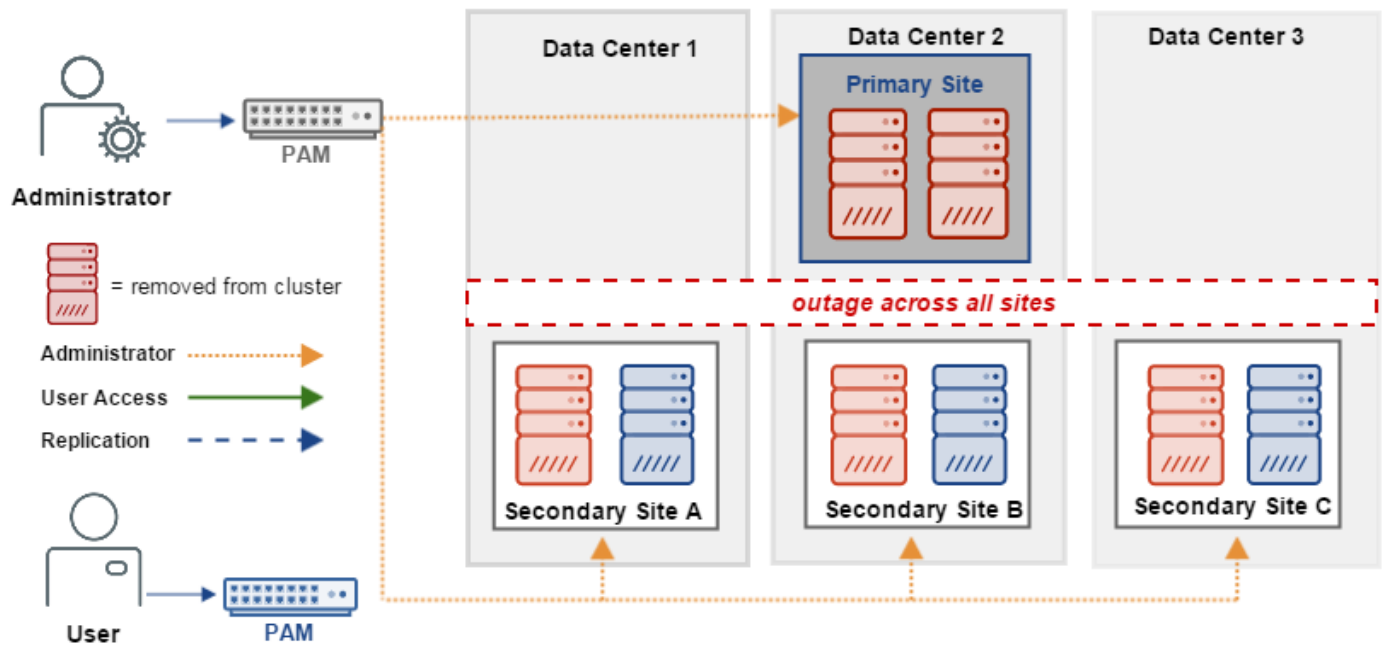

The following graphic reflects the results of these steps:

3. Turn off the cluster.
4. Upgrade the primary members to the current release. In the cluster configuration, list the upgraded primary member first in the list of members.  
You do not have to remove the primary members from the cluster configuration.
5. At the primary site, add back the already upgraded secondary site members.

**TIP**

In a multi-site deployment, operation can resume after adding back only one upgraded node from *each* secondary site. After you turn on the cluster, upgrade each remaining member. To add that member back to an active cluster, select **Subscribe to Active Cluster**.

6. While still at the primary site, remove the existing *non-upgraded* secondary site members from the configuration.

**Figure 6: Phase 2 Cluster Migration****Phase Three**

The third phase brings the upgraded cluster members back online, closing the outage window.

The following graphic shows the phase three steps:

7. Turn on the cluster from the primary member. The primary member is the first one in the list of primary site members.
8. Verify that the primary member data is available across all data centers.

At this point, the cluster is live and users can access resources again.

**Figure 7: Phase 3 Cluster Migration****Phase Four**

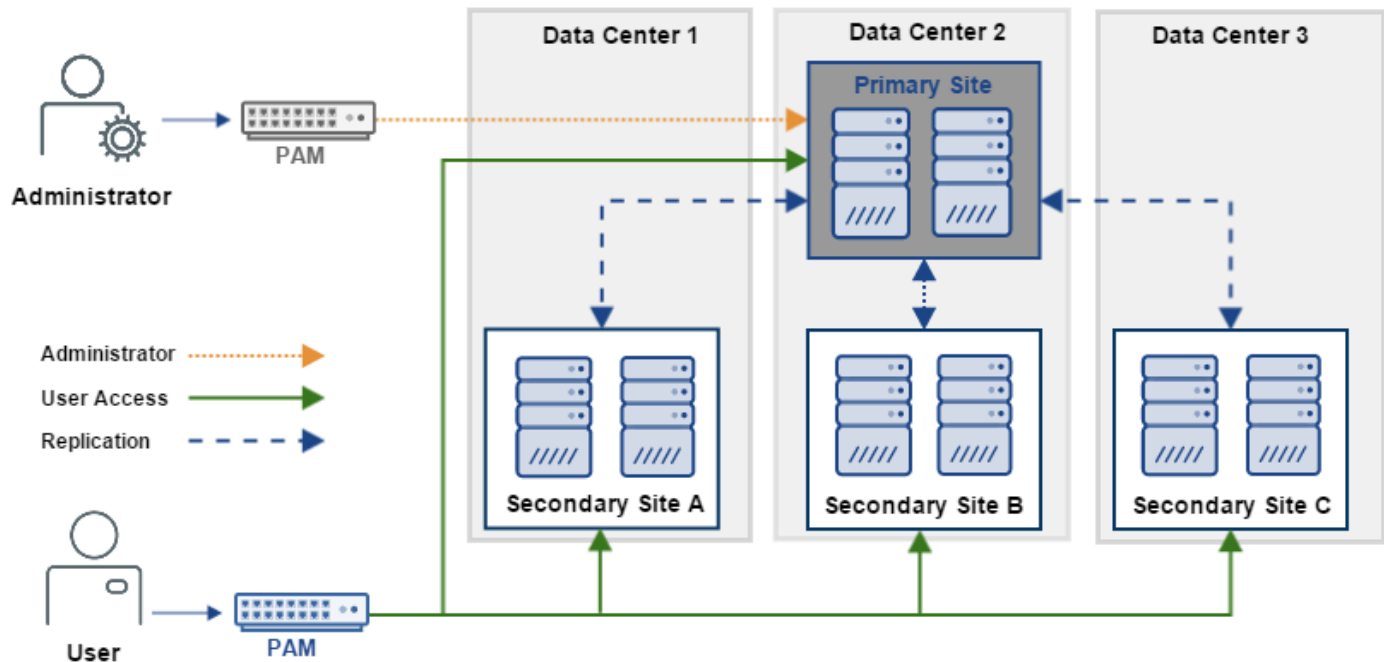

The fourth and final phase brings the remaining secondary members back into the cluster.

The following picture shows the final steps:

9. Upgrade the remaining secondary members to the current release.

10. At each upgraded secondary member, subscribe that member to the active cluster.

**Figure 8: Phase 4 Cluster Migration**

### **Alternative Methods for Upgrading a Multi-Site Cluster**

You might have priorities other than limiting the downtime of your cluster. Consider the following alternative methods for upgrading a multi-site cluster:

- Upgrade each cluster member without removing the member from the cluster.
- Upgrade secondary members then restart the cluster.

#### ***Upgrade Cluster Members Without Removing Them from the Cluster***

**Advantage:** This method is the simplest.

**Disadvantage:** The cluster is offline for the longest timeframe.

#### **Process:**

1. Turn off the cluster.
2. Upgrade all members. You *do not* have to remove the members from the cluster.
3. Turn on the cluster.

#### ***Upgrade Secondary Members Then Restart the Cluster***

##### **NOTE**

This method modifies phase 4 in the previous illustration.

**Advantage:** This method provides a simple way to add upgraded secondary members back into the cluster. An administrator has to change the cluster configuration at the primary site only one time, and not at each new secondary site member.

**Disadvantage:** A brief second outage of the cluster is required.

#### **Process:**

1. Upgrade the secondary members that you removed.

2. Stop the cluster.
3. From a primary site member, add the secondary members back into the cluster.
4. Start the cluster.

### ***Change the Login Timeout***

If you changed the Login Timeout before doing the upgrade, change it back to your preferred setting. Navigate to **Settings, Global Settings** and set the **Login Timeout**.

### **Detailed Upgrade Instructions**

For specific instructions on upgrading cluster members, go to the upgrade instructions for the appropriate release.

## **Upgrade a Socket Filter Agent (SFA)**

This content describes how to upgrade a Socket Filter Agent.

### **Download the Socket Filter Agent Software**

Download the software for this component from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

### **Upgrade a Linux or UNIX Socket Filter Agent**

Use this procedure to upgrade your Linux or UNIX Socket Filter Agent.

#### **Follow these steps:**

1. Access the computer with the Linux or UNIX SFA to be upgraded. Ensure that the Linux or UNIX SFA is operating.
2. Run the latest Linux or UNIX SFA installer. If you have a pre-existing SFA, the installer updates all files as required. The installer automatically stops the required daemons before the upgrade and restarts them after the upgrade.

### **Upgrade a Windows Socket Filter Agent**

Use this procedure to upgrade your Windows Socket Filter Agent (SFA).

#### **Follow these steps:**

1. Access the computer with the Windows SFA to be upgraded. Ensure that the Windows SFA is operating.
2. Access the Windows Services console and stop the **CA Technologies Socket Filter** service.

#### **NOTE**

The SFA service name is a configurable value. If you have configured a different SFA service name, locate and stop that service name.

3. Uninstall the old Windows SFA.
4. Run the latest Windows SFA installer to install a new SFA.
5. Restart the **CA Technologies Socket Filter** service.

#### **NOTE**

#### **More information:**

- [Install and Configure a Socket Filter Agent](#)

## **Upgrade a Credential Manager A2A Client**

This content describes how to upgrade an existing Credential Manager A2A Client.

## **A2A Client Credential Caching**

The A2A Client maintains the cache *only* in memory. The local storage cache is read only. If there is a power failure, the appliance can recover the cache. If for any reason the appliance is not available, the local storage serves as an alternative cache. For more information about this setting, see [Modify the A2A Client Configuration File](#).

## **Download the A2A Client Software**

Download the software for this component from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

## **Upgrade the A2A Client on UNIX Systems**

To upgrade an A2A Client on UNIX:

1. Uninstall any existing A2A Client.
2. Install the new A2A Client.
3. Activate the request server.

### **Uninstall the Existing A2A Client on UNIX (Required)**

Before you install a new A2A Client, you must uninstall the existing Client.

#### **WARNING**

If you changed to the default A2A Client configuration file, back up this file.

#### **Follow these steps:**

1. Stop the A2A Client using this command:

```
$CSPM_CLIENT_HOME/cspmclient/bin/cspmclientd stop
```

where `CSPM_CLIENT_HOME` is your installation directory, for example `/opt/catech`

2. Run the uninstall script by entering:

```
$CSPM_CLIENT_HOME/cspmclient/bin/cspmclient_uninstall
```

This script removes all A2A Client directories and files.

3. Reboot the system.

### **Install a New A2A Client on UNIX**

Install and configure the A2A Client on all request servers.

#### **NOTE**

Do not install more than one A2A Client on the same host. If an A2A Client already exists, installing into the same directory overwrites that client.

#### **Follow these steps:**

1. Open a shell command window and navigate to the location of the unzipped A2A Client installation package:

```
cd unzip_location/
```

2. Enter the following commands:

```
chmod u+x setup_unix
```

3. Start the installation script by entering the following command:

```
./setup_unix host_type processor_size cspm_client_home server_address
```

**host\_type:** Specifies the type of UNIX host. Enter `Linux` or `SolarisSparc`

**processor\_size:** Specifies whether to install the 32-bit or 64-bit A2A Client. Enter `32` or `64`.

**cspm\_client\_home:** Names the installation directory for the A2A Client software

*server\_address*: Identifies the IP address or fully qualified domain name (FQDN) of the appliance. If you specify the FQDN, it must match the name in the appliance SSL certificate.

4. If you are upgrading a pre-3.0.1 A2A Client and you want to use local storage caching, enable this caching. Only caching in memory is enabled by default.

Follow these steps:

- a. Navigate to the A2A Client configuration file (*cspm\_client\_config.xml*). The file is in *cspm\_client\_home/catech/cspmclient/config*.
- b. Set the `<preserveCacheBetweenRestarts>` tag to `true`.
- c. Start the A2A Client service by entering: `cspmclientd start`
- d. When prompted, enter a password for local authentication.

### WARNING

Store this password securely. When the `<preserveCacheBetweenRestarts>` tag is set true, the password is required every time the A2A Client is started.

- e. Log in to the PAM UI.
  - f. Navigate to **Credentials, Manage A2A, Clients**.
  - g. Select the A2A Client and select **View** button.
  - h. Select the **Change Key** button.
  - i. Select **Close**.
  - j. Stop the A2A Client service by entering: `cspmclientd stop`
5. Restart the client by entering: `cspmclientd start`

### Activate the Request Server on UNIX

After you install the A2A Client, [activate the request server](#).

### Upgrade the A2A Client on Windows Systems

To upgrade the A2A Client on Windows:

1. Uninstall the existing A2A Client.
2. Install the new A2A Client.
3. Activate the request server.

### Uninstall the Existing A2A Client on Windows (Required)

Before you install a new A2A Client, you must uninstall the existing Client.

### WARNING

If you changed the A2A Client configuration file, back up this file.

Follow these steps:

1. Stop the A2A Client using *one* of the following methods:
  - Use the Windows Services administrative tool and stop the `cspmclientd` service.
  - Open a Command Prompt window and enter: `net stop cspmclientd`
2. Launch the uninstall executable using *one* of the following methods:
  - From the **Control Panel, Programs and Features**, select the **PAM A2A Client**.
  - Navigate to: `%CSPM_CLIENT_HOME%\cspmclient\Uninstall_Password_Authority.CSPM_CLIENT_HOME` is the installation directory, for example, `C:\cspm\cloakware`. Select `Uninstall Password Authority.exe` or `Uninstall PAM A2A Client.exe`. The executable name depends on the existing client version.

The Uninstall window displays.
3. **Select Uninstall.**

When the uninstall finishes, the **Uninstall Complete** window displays. You might need to remove files manually. If so, the uninstaller identifies the files that you must remove.

4. Select **Done**.
5. Reboot the system.

### **Install a New A2A Client on Windows**

Install and configure the A2A Client on all request servers. Installation of more than one A2A Client on the same host is not supported. If an A2A Client already exists in a directory, installing into the same directory overwrites that client.

When you execute the installation from an account that contains special characters, the installation wizard fails. To avoid this problem, right-click the executable file and select **Run As**. The **Run As** dialog opens and prompts for an alternate username and password to use for the installation. Specify the account credentials and continue with the installation.

#### **Follow these steps:**

1. Unzip the installation package.
2. Open a Command window and navigate to the `clients\win` subdirectory.
3. Start the installation wizard by entering `setup_windows32_java.exe` or `setup_windows64_java.exe`. The installation begins.
4. In the **Introduction** window, select **Next**.
5. In the **Choose Install Folder** window, enter, or select the folder where you want to install A2A Client. Select **Next**. Do not use the space character in the name of any A2A Client installation folder, the root folder, or the installation subfolder.
6. In the **Server Information** window, enter the Fully Qualified Domain Name (FQDN) of the appliance in the **Server Name** field. select **Next**.
7. In the **Choose Log Directory** window, enter a path name for the installation log file directory or use the default path name. Select **Next**.
8. In the **Pre-Installation Summary** window, validate the installation information then select **Install**. The **Installing Password Authority Client** window appears and shows the progress of the installation. When the installation finishes, the **Install Complete** window appears.
9. Select **Done**.
10. If you are upgrading a pre-3.0.1 A2A Client and you want to use local storage caching, enable this caching. Only caching in memory is enabled by default.
  - a. Navigate to the A2A Client configuration file (`cspm_client_config.xml`). The file is in `cspm_client_home\cloakware\cspmclient\config`.
  - b. Set the `<preserveCacheBetweenRestarts>` tag to `true`.
  - c. From the Windows Services administrative tool, start the **cspmclientd** service.
  - d. Open a Command Prompt window and enter the following commands:
 

```
set CP=%CSPM_CLIENT_HOME%\cspmclient\lib\cspmclient.jar;%CSPM_CLIENT_HOME%\cspmclient\lib\bc-fips-1.0.0.jar

java -classpath %CP% com.cloakware.cspm.client.ClientDaemonManager authenticate
```
  - e. When prompted, enter a password for local authentication.

#### **WARNING**

Store this password securely. when the `<preserveCacheBetweenRestarts>` tag is set true, the password is required every time the A2A Client is started.

- f. Log in to the PAM UI.
- g. Navigate to **Credentials, Manage A2A, Clients**.
- h. Select the A2A Client and select **View** button.
- i. Select the **Change Key** button.

- j. Select **Close**.
11. Stop and restart the **cspmclientd** service:
  - If you use the Windows Services administrative tool, stop the **cspmclientd** service then restart it.
  - If you use a command window, enter: `net stop cspmclientd` followed by `net start cspmclientd`

### **Activate the Request Server on Windows**

After you install the A2A Client, [activate the request server](#).

## **Upgrade PAM SC Utility Appliances to Support PAM 4.1.x**

If you are using integrated PAM SC, deploy `pam-utility-appliance-1.0.0.09` patch to upgrade all active Utility Appliances (that is, members of Utility Groups) to support PAM.

### **Follow these steps:**

1. Download the `pam-utility-appliance-1.0.0.09.p.zip` patch archive from the [Broadcom Support](#) and extract its contents (a `.bin` and a `.sha256` file) to a local drive.
 

**IMPORTANT**

Do not discard downloaded patch files. If you later add Utility Appliances to a new or existing Utility Group, these patch files are required to reupload and restage each patch (unless you must change the existing Patch Level).
2. Open the PAM UI and navigate to **Configuration, Utility, Patches, Utility Appliance Patches**.
3. On the **Available Patches** tab, select **Upload**.
4. On the dialog that opens, select **Choose File**, locate, and select (`pam-utility-appliance-1.0.0.09.p.bin`), and then select **Upload**.
5. Verify that the file information is correct and select **Save**.
 

The patch is uploaded to the PAM server and the service updates that it contains are added to the list of patches that are available to stage.
6. Do the following steps for each listed Utility Appliance service patch.
  - a. Select the service patch and select **Stage**.
  - b. On the dialog that opens, verify that the patch information is correct and select **Yes**.

### **NOTE**

Take a note of the name of each patch that you stage to identify which services to update in Step 7.

7. Select the **Patch Level** tab and do the following steps to update each service that you staged in Step 6:
  - a. Select the appropriate entry from the following list of displayed services and then select **Update**.
    - `pam-dh`
    - `pam-loginintegration`
    - `pam-activemq`
    - `pam-config`
    - `pam-eventforwarder`
    - `reloader`
    - `pam-a2a`
    - `activemq-config`
    - `pam-policyorchestrator`
  - b. On the dialog that opens, select the new patch version from the drop-down box and select **OK**.

### **NOTE**

If no patch is staged for this service, the drop-down box is empty, and you cannot continue.  
The service is updated and the new patch version is displayed in the patch level list.

**NOTE**

For information about how to delete unused patches and view information about applied patches, see [Deploy and Manage Utility Appliance Update Patches](#).

# Introduction

Privileged Access Manager is an automated solution for privileged access management. Privileged Access Manager enables centralized management of local and remote high-risk users in physical, virtual, and cloud environments. The core product enables you to secure access to critical infrastructure for privileged and third-party users by combining device access control and privileged credential management:

- **Network-based Device Access Control:** Uses your existing identity and access management infrastructure to facilitate stronger or multi-factor authentication for privileged users. For more information, see [Access Control Overview](#).
- **Password Access Control (Credential Manager):** Provides password access control that enables you to manage the setting of, storage of, and access to passwords. For more information, see [Credential Manager Overview](#).

## Core Product Overview

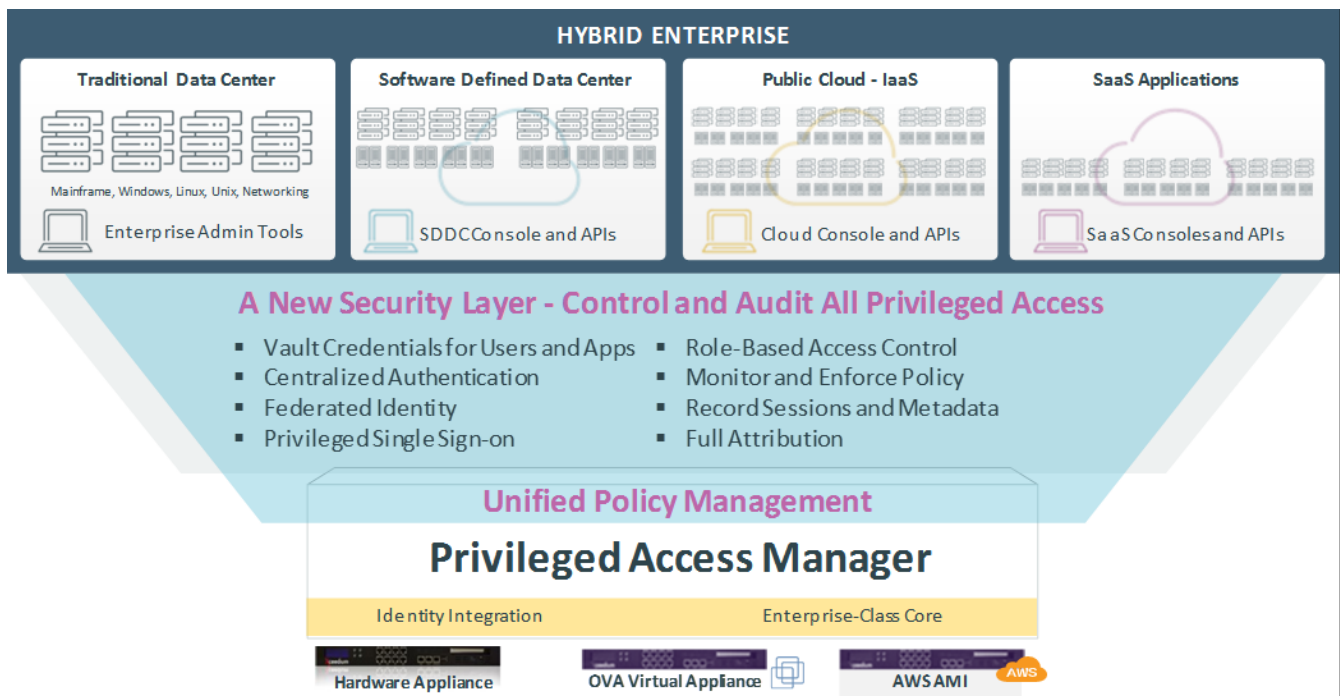

Privileged Access Manager core functionality enhances security by automatically doing the following tasks using policies that you define:

- Protecting sensitive administrative credentials such as root and administrator passwords
- Controlling privileged user access
- Monitoring and recording privileged user activity across all IT resources

PAM is available in the following form factors:

- Rack-mounted, hardened hardware appliance
- Open Virtual Appliance (OVA)
- Amazon Machine Instance (AMI)
- Virtual Hard Disk (VHD) for Azure

The following diagram provides an overview of the Privileged Access Manager solution.

These capabilities enable single sign-on by hiding credentials from the user while providing access to resources. Privileged users do not need to know anything about the target account. Privileged users only need their Privileged Access Manager account credentials. With Microsoft Terminal Services, user access can be further restricted to single Windows applications.

The product compartmentalizes high-risk users, alerting, remediating, tracking, recording, and reporting on all user activities inside the entire heterogeneous IT infrastructure. Administrators, application developers, vendors, and technical contractors can securely access critical IT resources from inside and outside the organization without gaining a footprint on the network. Auditors can monitor all user events and view centralized reports for accountability and testing of controls. You can use the product to balance audit and compliance requirements with the need for operational efficiency.

## **Core Functional Highlights**

Privileged Access Manager offers the following core features:

- **Granular Policy Enforcement**  
Policy enforcement compartmentalizes high-risk users using integrated Java applets with a reverse port-tunneling access technology that provides segregation of critical IT infrastructure components and separation of duties that easily meets compliance requirements. Users are contained within these compartments through the Symantec LeapFrog Prevention™ technology, which employs a whitelist/blacklist approach, blocking users from leaving authorized areas at the socket level.
- **User Activity Monitoring**  
User activity monitoring watches user activity with real-time alerts for attempted policy violations. Administrators are notified immediately when an access violation has been attempted, detected, and prevented. Access might be terminated when a user attempts to access an unauthorized system or device.
- **User Event Recording**  
User event recording provides centralized tracking of all activities and events using session recording and playback capabilities. An administrator can have complete visibility into user activities in CLI sessions. You can configure event recording that is based on individual user profiles or individual back-end devices. All command-line activity is monitored, recorded, and archived for audit and compliance purposes.
- **Centralized Reporting**  
Centralized reporting provides comprehensive, customized audit and compliance reports for any user-initiated events. The reports can include usage data and attempted security violations. You can also run automated reports that are focused on the compliance of individual users. You can configure the automated reports to run at predetermined intervals and then distribute the reports using email.

## **Other Capabilities**

Privileged Access Manager also offers the following other capabilities:

- **Secrets Management:** Provides access control for human users and programs to sensitive and privileged information (secrets). That information might include X509 certificates, connection strings, tokens, configuration parameters, encryption keys, credentials, and so on. For more information, see [Secrets Management Overview](#).
- **Host-Based Device Access Control (Unified PAM Server Control):** If enabled, *PAM Server Control* functionality adds the powerful *host-based security* capabilities from the standalone Privileged Identity Manager (PIM) and Privileged Access Manager Server Control (PAM SC) products. For more information, see [PAM Server Control \(Host-Based\) Access Control Overview](#).
- **Threat Analytics:** A powerful tool for identifying anomalies in PAM user behavior and implementing policies to dynamically mitigate potential insider threats or breaches by external threat actors. The Threat Analytics Console assists you in analyzing the collected data with rich graphical visualizations. For more information, see [Threat Analytics Overview](#).

## PAM (Network-Based) Access Control Overview

Privileged Access Manager network-based access control uses your existing identity and access management infrastructure. The appliance integrates with Active Directory and LDAP-compliant directories, and authentication systems like RADIUS. Integrated with advanced authentication tools like CA Advanced Authentication and others.

PAM access control facilitates stronger or multi-factor authentication for privileged users. In addition, the product fully supports enabling technologies like PKI/X.509 certificates and security tokens. Its support for Personal Identity Verification/Common Access Cards (PIV/CAC) ensures compliance with U.S. Federal Government HSPD-12 and OMB M-11-11 mandates.

PAM access control employs a unique "Deny All, Permit by Exception" (DAPE) security model to control access for high-risk users with zero footprint on the network. Users are granted visibility only to authorized areas. This security model also offers a centralized, secure access channel for administrators. Administrators gain a single point of entry and view to critical IT infrastructure.

The product also provides centralized tools for operational efficiency, and integration with centralized authentication policy engines.

**This section has the following other contents:**

### Access Target Devices

You can access a target device from Privileged Access Manager in one of these ways:

- Access Method – A proprietary Java applet to make a connection using one of several standard protocols (SSH, RDP, others)
- Service – Privileged Access Manager invokes a local third-party application from your client (for example, PuTTY on a Windows PC) to handle the connection
- RDP Application – Privileged Access Manager uses the RDP protocol to invoke a specific application on a target Windows OS Device

### Setting Up PAM access control

To set up PAM access control, create records that represent your managed objects. At the top level, your managed objects are the devices that you manage (and their properties) and user accounts.

The baseline-managed objects are devices and users. A policy is the relationship between a device (or device group) and a user (or user group). A policy specifies the tasks that each user is permitted to do with each device. A policy also can specify whether to record all or some of a user session with the device, permitted or not.

For more information, see [Configure Policies to Provision User Access to Devices and Applications](#).

## Credential Manager Overview

Credential Manager is a part of the Privileged Access Manager product. Credential Manager lets you manage how privileged credentials are set, stored, changed, and updated. Credentials include:

- Privileged account user name and passwords, such as UNIX `root`
- RSA key pairs
- Application-to-application (A2A) account credentials. A2A accounts are used by automated processes to access server resources. The A2A feature replaces credential instances that are embedded in insecure scripts and configuration files. These instances are replaced with a single instance in the secure appliance. You can then change server credentials as often as necessary and automate the management of server credentials.

This section introduces the following concepts:

## **Privileged Users**

Privileged accounts have the necessary rights to log and administer a system. The appliance recognizes and manages two types of privileged users:

- A person with rights to access and administer a system and the applications on that system. A privileged user likely uses shared, centrally stored credentials for access to a high-privilege target account. Examples of privileged accounts include the UNIX `root` account or a Windows Administrator account.
- A request script or application that automates a process. Such a script requires a centrally stored password to log in to an application using a privileged account.

Privileged users maintain accounts at the remote target system where the applications reside. These remote devices process or consume submitted credentials.

## **Credential Security**

Credential changes get recorded in a secure database on the appliance. Credential Manager encrypts target credentials before storing in a secure database. The cryptographic connector is the mechanism for storing credentials, and you can use this mechanism to customize how your credentials are encrypted. The cryptographic connector uses a 256-bit cryptographic kernel for maximum security.

## **Related Credential Manager Information**

For more information about Credential Manager, use the table of contents to access the subtopics.

## **Credential Manager Components**

Credential Manager is integrated with the appliance. Credential Manager uses the following components:

- **UI and CLI:** You can configure Credential Manager features using the **Privileged Access Manager** UI or command-line interface (CLI).
- **Credential Manager Database:** The appliance is the centralized secure server and database that secures credentials.
- **Windows Proxy:** (Only required to support Windows target servers). The Windows Proxy is one of three Windows components available to manage passwords for Windows accounts. (The Windows Remote Connector and the Active Directory Connector are the others). The Windows Proxy also can manage Windows services and scheduled tasks. Unlike the other two Windows connectors, the Windows Proxy is installed on the remote server in your target domain.
- **A2A Client:** (Only available with the A2A license.) The A2A Client is software that runs on a request server. The A2A Client manages communication with the appliance and decrypts requested credentials.

The following graphic highlights some of the components:

**Figure 9: Credential Manager Components**

## Password Management and Requests

You can use the Credential Manager functions of PAM to manage passwords in the following ways:

- Change passwords on a regular schedule or when the password reaches a specified expiration. Scheduled password changes use automatically generated passwords that conform to your specified password composition policies. You configure password composition policies on a per target application basis.
- Configure password view policies and the actions that are taken after a password is viewed.
- Schedule password verification. If passwords become out-of-sync, Credential Manager can alert you.
- Allow authorized users to view current and historical target account credentials

### A2A Password Requests

You can integrate applications that use a hard-coded user name and password with Credential Manager. The integration lets you replace the hard-coded credentials with a runtime credential request and target alias. As shown in the following figure, Credential Manager uses the target alias to determine which credentials are being requested. The application requesting the target account credentials is known as the requestor. The server hosting the requestor is known as the request server. The activity of integrating your requestor with Credential Manager is known as A2A integration.

For requestors to retrieve credentials successfully, you must authorize them. Requestor authorizations are known as authorization mappings.

## Password Security

Credential Manager encrypts target credentials before storing them. When a requestor requests credentials, the credentials remain encrypted as they are transferred over the network. The A2A Client, which you must install on the request server, decrypts the credentials before passing them along to the requestor. For more information about cryptography in this product, see [Configure Enhanced Encryption for Stored Credentials](#).

## Policies to Create and View Passwords

Credential Manager allows you to create policies to:

- Specify the rules to which passwords must conform to ensure that they meet the unique security needs of your organization
- Automatically change the account password for synchronized accounts once it is viewed
- Ensure that only one person at a time can view an account password
- Ensure that an account password is only revealed after a specific approver has authorized it

## How Does Password Management Work?

The following figure illustrates how Credential Manager provides password management for privileged users and A2A password requests.

**Figure 10: Password Management Flow**

**For privileged user password requests:**

1. Passwords are stored securely in a central repository on the appliance.
2. Administrators use the UI or CLI to authenticate themselves.
3. The administrator searches for the desired account or navigates to it.
4. If the password viewing policy allows, the administrator views the account password. If a policy specifies it, the password on the target can be updated automatically.

**For A2A password requests:**

5. An application requests a password from the appliance.
6. The application substitutes the credential into a connection string.
7. As determined by a password policy, the password gets updated on the target server and the appliance.

## Credential Manager Password Flow

Privileged Access Manager Credential Manager manages passwords for the following situations :

- Synchronized updates of target account passwords.
- A password request from an administrator to access a privileged account.
- A password request from an application to access a target account.

The following sections describe sample use cases.

**Synchronized Target Password Updates**

When you add target account passwords in Credential Manager, it contacts the target server to validate that the password is correct. Once validated, target account passwords update directly in Credential Manager. This feature is named *target account synchronization*. The appliance initiates the flow for target account password updates and Credential Manager then pushes the new password to the target account.

When a target account is a Windows account or Windows service, the appliance directs the Windows Proxy to perform the password verification and update.

**Figure 11: Credential Manager Password Flow****Privileged Account Password Requests**

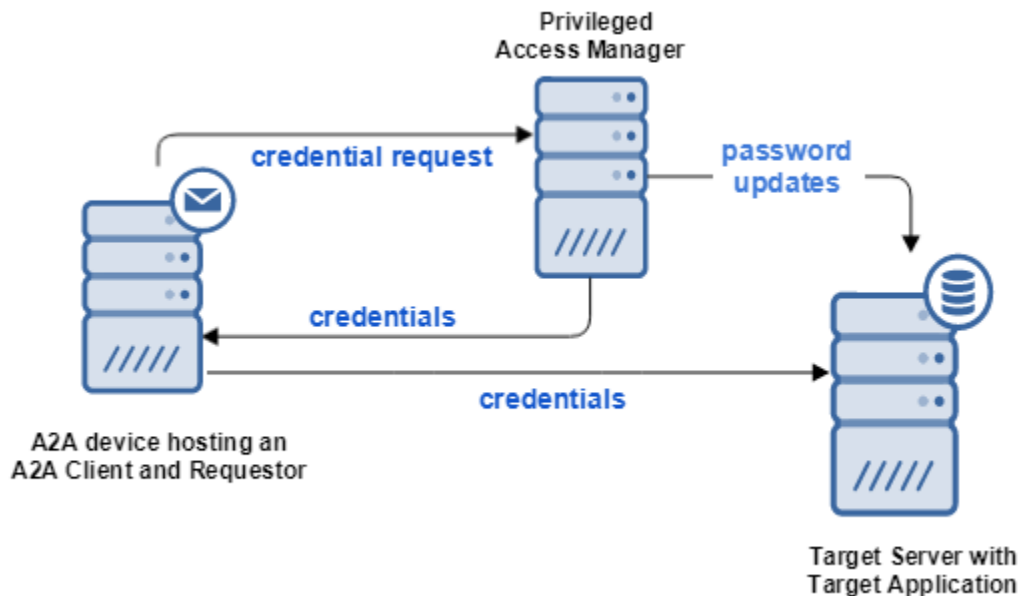

In this workflow, the user requires access to a privileged account. Using the GUI or CLI, the user requests the target account password.

**Figure 12: Privileged Account Access Flow**

## A2A Credential Requests

When an application requires target account credentials, the application sends the credential request at runtime to the appliance. The credential request includes the target alias that is associated with the account. If the requestor is authorized to access the target credentials, the appliance returns the credentials to the requestor. The requestor uses the account credentials to connect to the target application.

**Figure 13: A2A Credential Request Flow**

## Application-to-Application (A2A) Credential Management

Application-to-Application (A2A) credential management lets customer applications and scripts securely obtain credentials for target applications. A2A eliminates the need for customer applications and scripts to store credentials. The requesting applications and scripts are called *requestors*. The credentials are always encrypted and access is controlled and configurable. Also, the target account credentials can be changed at any time.

Review the following information to learn about A2A credential management:

### Benefits of A2A

A2A credential management offers the following advantages:

- Stores encrypted credentials. Credentials are not stored in plain text.
- Prevents unauthorized users from gaining access to credentials. An unauthorized user can access script source code or a configuration file containing the credential.
- A2A can determine whether unauthorized access occurs.

A requestor must obtain the credentials for a target application from PAM. To reduce the network traffic from the requester to the appliance, A2A provides a local secure cache on the request server. Based on configured password policies, PAM dynamically changes the credentials of a target account. These changes are pushed to the request servers to keep the local cache up-to-date. If credentials cannot be dynamically updated, the organization typically uses a fixed password or key on the target. The passwords or key are then hard-coded in the requestors. In such cases, there is significant overhead in coordinating changes to credentials simultaneously on the target application and all the related configuration

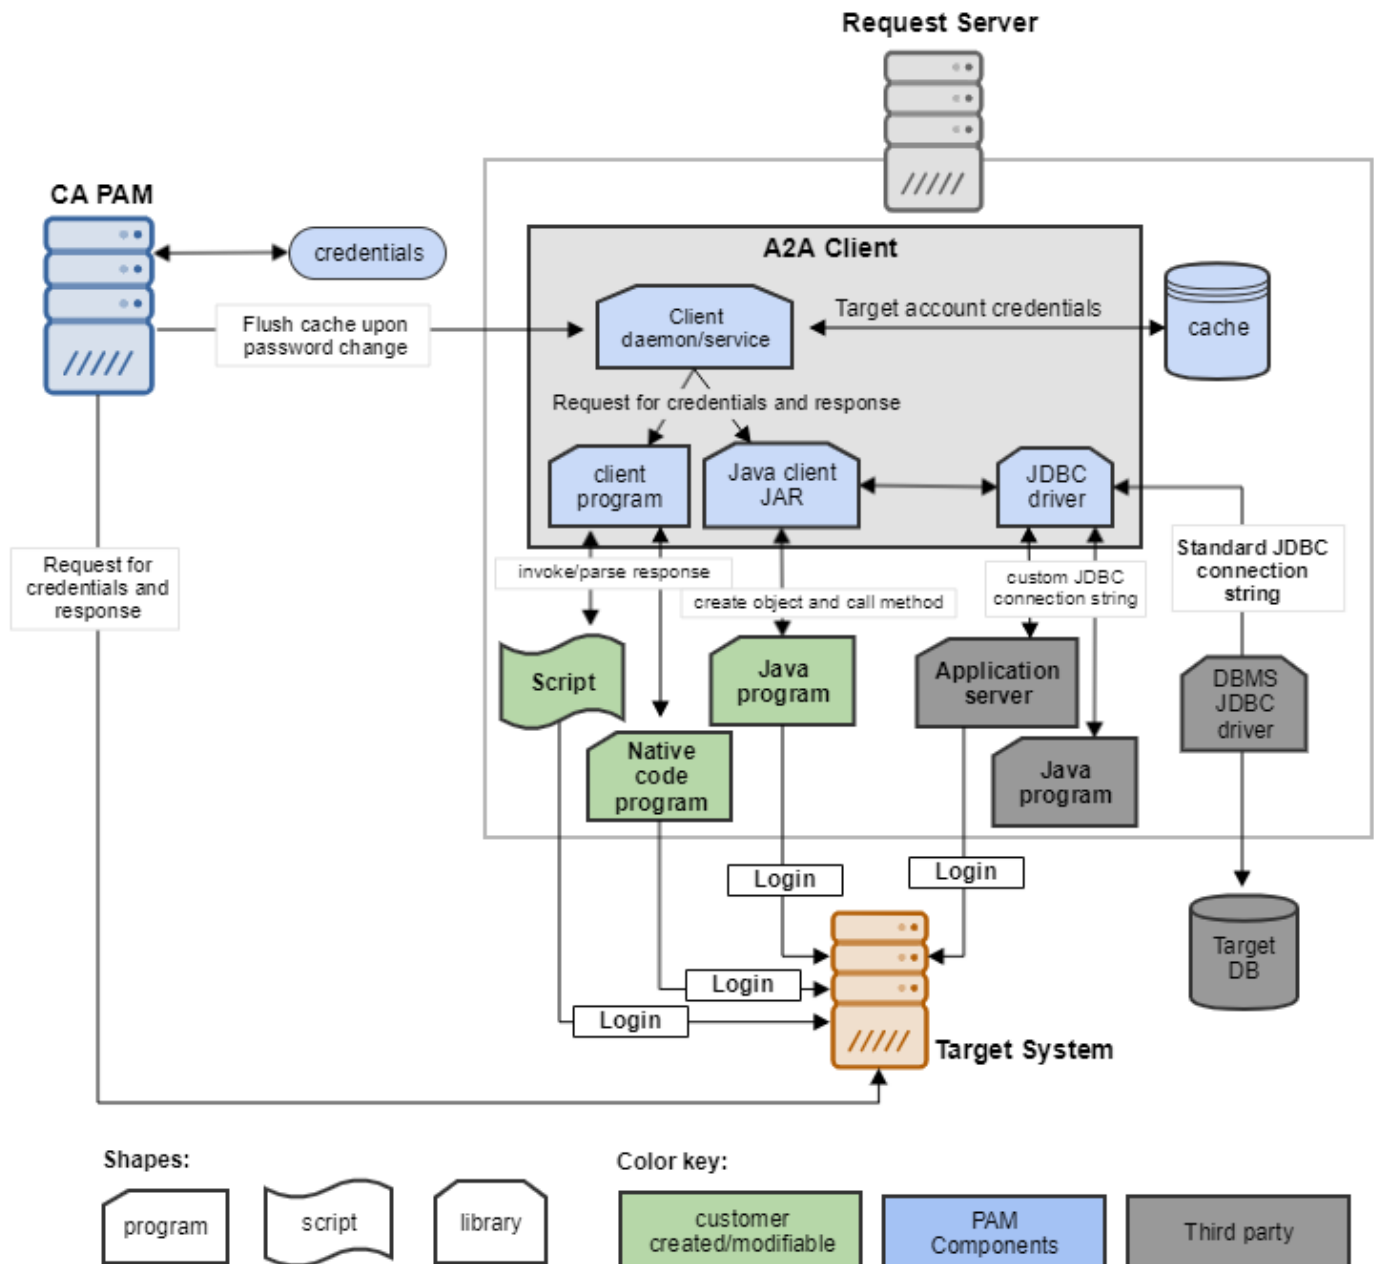

files and hard-coded scripts. The result is that credentials are not changed, which increases the potential for a data breach.

### A2A Components

The following diagram shows the components that are used to provide A2A credential management and how they interact.

**Figure 14: A2A Components**

The components are:

- **Requestor:** An application or a script that wants credentials to log in to a target application. For example, an OS, DBMS, or a customer-specific application.
- **A2A Client** which consists of a Client Program, a Java client JAR, a A2A JDBC driver, a Client Daemon or service, and runtime Cache:
  - The **Client Program** is an executable that is invoked from customer scripts and native code.
  - The **Java client JAR** interacts with a customer Java program. The Java client JAR contains a class with a method that is invoked to retrieve a password.
  - The **A2A JDBC driver** is a proxy JDBC driver that Java applications can use. A special connection string specifies the desired target alias and information for the DBMS-specific JDBC driver. The A2A JDBC driver forwards information to the DBMS-specific JDBC driver with the DB user ID and password that is obtained from Credential Manager.
  - The **Client daemon** (UNIX) or service (Windows) listens for requests from requesting applications or scripts. When a request arrives, the Client retrieves passwords. The Client also listens to the appliance for requests to flush the cache of account information when the account password is changed.
  - The **Runtime Cache** is a cache of account passwords and access information that is stored by the client daemon/service. This cache is stored locally to improve performance. The appliance notifies it when a password that it might contain has changed so that it can be removed from the cache.

The A2A Client is responsible for obtaining information about the program that invoked it, such as the program name, path, user executing the program, and hash.

- (Request) **Script:** A customer supplied script, in Perl, PHP, Python, UNIX shell (for example, sh, ksh, csh) that needs credentials for an account.
- **Native code program** or a **Java program:** An application that wants the credential for an account.

The following concepts also apply:

- Request Scripts are configured in the appliance by specifying the following information:
  - program request server
  - name
  - invocation path or the path on the file system and descriptors.

A registered Request Script specifies a Type. This field is optional.

- Request Scripts can be grouped to form a Requestor Group.
- A Target Account can be a Generic account an application-specific type such as UNIX, Oracle, Microsoft SQL Server. PAM cannot change the target password for Generic accounts but can change the target passwords of application-specific accounts. There might be multiple accounts with the same account name. The accounts might be on different servers or on the same server but with different target applications. PAM can effectively change the target password in these circumstances.

#### NOTE

For comprehensive information about the A2A feature, see [Manage Credentials Between Applications \(A2A\)](#).

## Secrets Management Overview

Use this section to understand Secrets Management in PAM.

Secrets management is access control for human users and programs to sensitive and privileged information. That information might include X509 certificates, connection strings, tokens, configuration parameters, encryption keys, credentials, and so on.

#### NOTE

Typically, credentials are used to authenticate an originating entity (such as a user or program) to a destination entity (such as a device or app). Credentials are a subset of secrets. However, credential management is handled separately. See [Credential Manager Overview](#) for more information on credentials.

PAM Secrets Management lets you control access to any information that your organization regards as secret, wants to protect, and wants to provide fine grained, auditable authorization. PAM gives Security Teams the ability to store, audit, and securely share this information with authorized recipients: people or processes.

PAM stores this information, or *secrets*, in a secure, encrypted vault.

PAM Secrets management provides the following general capabilities, among others:

- Administration
  - User Roles Management (granular roles for vault and secret management and access)
  - Vault Management (create, delete, update)
  - Secrets Management (create, delete, update)
- Access
- Process based, programmatic Authorization Mapping for Secrets (using A2A implementation)
- User-based Authorization Policies for Secrets (using the PAM UI/API)

See [Implementing Secrets Management](#) for instructions on configuring and using Secrets Management.

## PAM Server Control (Host-Based) Access Control Overview

This content introduces the functionality that is provided by the unified PAM Server Control Module and Utility Appliances.

By default, PAM provides network-based security by enabling centralized management of local and remote high-risk users over traditional physical hardware, virtual, and cloud environments. If enabled, *PAM Server Control* functionality adds the powerful *host-based security* capabilities previously provided by Privileged Identity Manager (PIM) and Privileged Access Manager Server Control (PAM SC).

Unified PAM SC provides host-based security for your most sensitive systems whether they are physical, virtual, or cloud-based. They provide active, comprehensive security software solution for open systems, tied dynamically to the operating system. Each time a user requests a security-sensitive operation, such as opening a file, substituting a user ID, or obtaining a network service, the product intercepts the event in real time and evaluates the validity of the operation before passing control to the native OS functions. Unifying this functionality with PAM adds powerful, fine-grained protection of operating system-level access and privileged user actions to its existing network-based security functionality.

For more information, see [Implementing PAM SC](#).

## Threat Analytics Overview

Threat Analytics is a powerful tool for identifying anomalies in PAM user behavior and implementing policies to dynamically mitigate potential insider threats or breaches by external threat actors.

Threat Analytics enables you to perform the following tasks:

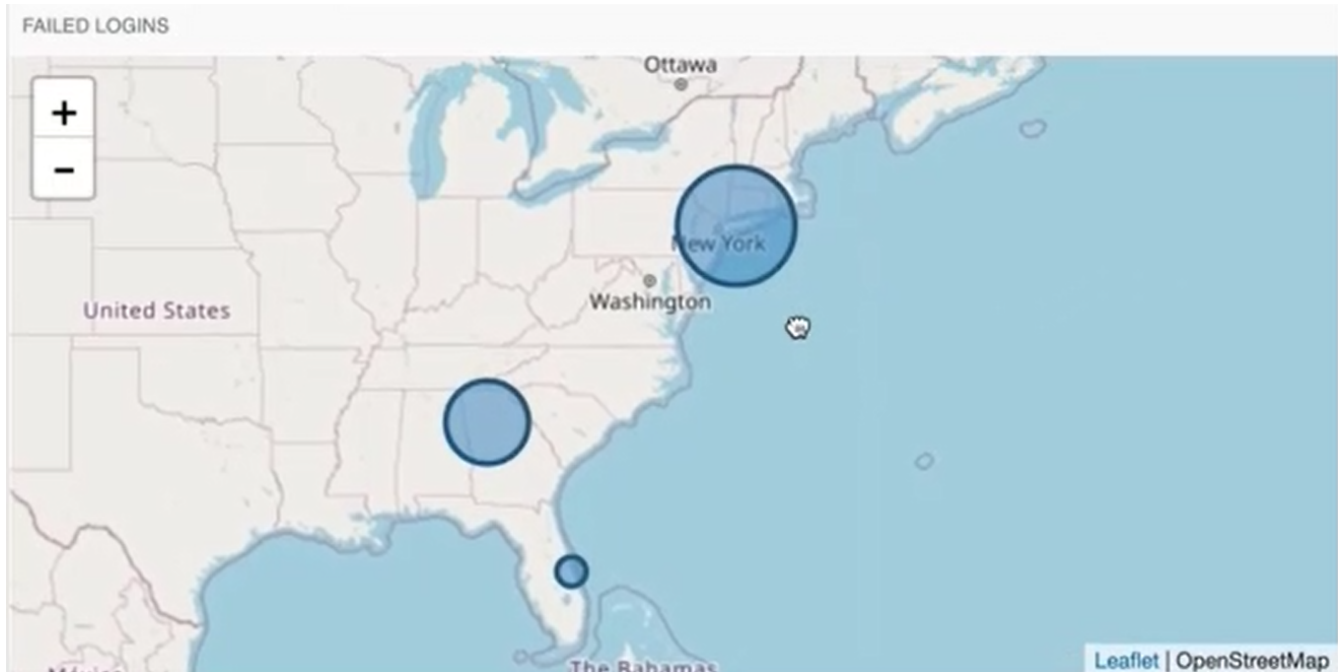

- Gather information on the threat landscape over time, from past events to the current moment.
- Configure policies and thresholds to dynamically mitigate against potential insider threats or breaches by external threat actors by triggering threat assessments for users or devices.
- Interpret, summarize, and filter network activity.
- Identify the threat landscape across an entire organization, from the overall threat snapshot down to the threat assessment for an individual user or device.

You interact with Threat Analytics using the *Threat Analytics Console*. The console provides graphs, maps, and other rich visualizations to help you analyze the threat data, as shown in the following examples:

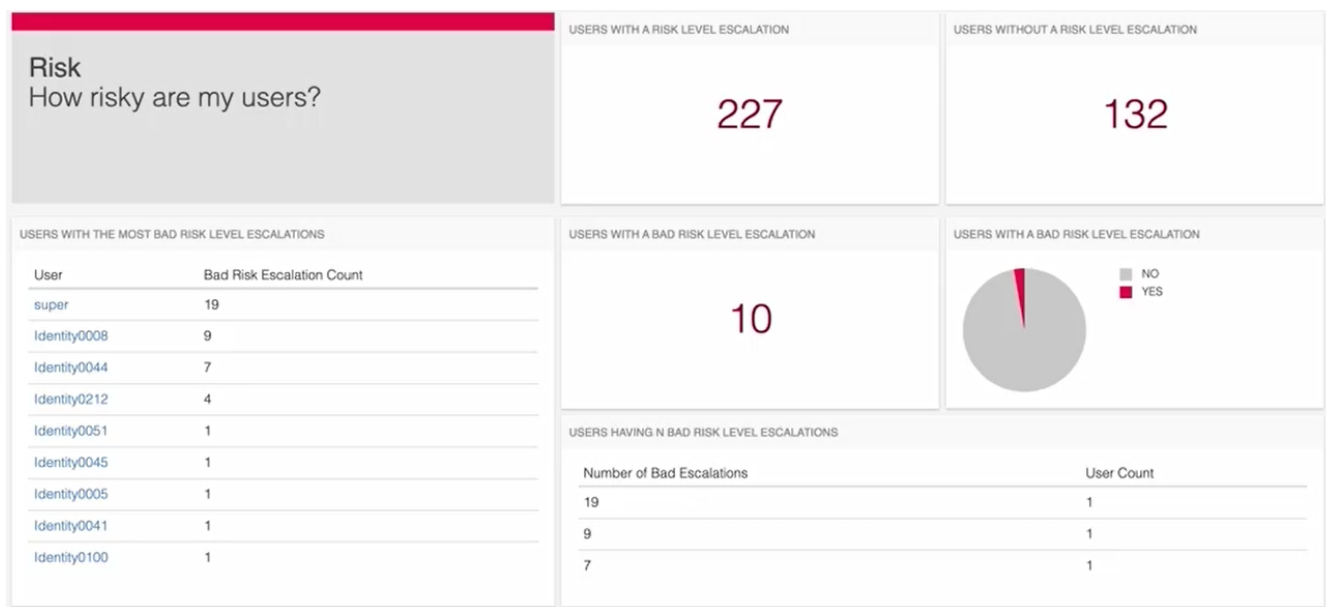

- View user and network threat activity at a glance:

- Use a geolocation view of the PAM network to see clusters of suspect users.

- Risk view shows counts of users with and without new risk level escalations and the number of users with Bad and Suspect risk-level escalations.

For detailed information, see [Implementing Threat Analytics](#).

# Deploying

---

You can deploy PAM as a hardware or software appliance. Learn how to deploy the product in different environments and how to set up clustering for high-availability deployments.

## Deploy Privileged Access Manager

The installation or deployment process varies according to which platform you use. The available options include:

- VMware OVA template
- Hardware appliance
- AWS AMI-based instance
- Microsoft Azure VHD

Members of a cluster must follow these rules:

- VMware OVA VM instances and the hardware appliance can be in the same cluster site. The AWS AMI instance can only be clustered with other AWS AMI instances in a cluster site. Similarly, a Microsoft Azure VHD instance can only be clustered with other Microsoft Azure VHD instances in a cluster site. Different sites in a multi-site cluster can run on different platforms.
- All cluster members must be running the same product release version. You can deploy the product in various ways to suit your existing security infrastructure.

## Product Deployment Infrastructure

- **Behind a Firewall**

Deploy the product in the DMZ directly behind a firewall to send high-risk users directly to Privileged Access Manager. This deployment protects devices against users that are authorized to perform upgrades, maintenance, development, and other administration activities.

**TIP**

For extra security in the DMZ, you can integrate the product with a RADIUS-based multifactor authentication solution like CA Advanced Authentication.

- **Behind an Existing VPN**

Deployment behind an existing VPN provides an extra level of control for high-risk users that are accessing resources through a standard VPN. In this scenario, Privileged Access Manager is connected to the existing internal network using independent, non-routed, non-bridged Gigabit network connections.

High-risk users who access the network through the standard VPN are routed to Privileged Access Manager for secondary authorization and device access. While the VPN keeps out unauthorized users, Privileged Access Manager keeps authorized users contained to only the devices they must access.

**NOTE**

SSL/VPN, which was supported in 2.x, is no longer supported in 3.x releases.

- **Parallel to an Existing VPN**

Deploy Privileged Access Manager in parallel to an existing VPN. High-risk users log in using an SSL connection. Privileged Access Manager authenticates these users and gives access to specific devices per a configured policy.

- **Between Virtual or Physical Networks**

Deploy the Privileged Access Manager between networks. The product provides access control and auditing of high-risk users that are granted access to a secure network segment. Access restricts users to only those devices and services necessary to perform their job.

- **In a Citrix XenApp Environment**

In a Citrix XenApp environment, Privileged Access Manager provides a complete entitlement management security framework. This framework enables companies to satisfy compliance and best practices for increasing numbers of high-risk users accessing the critical information technology infrastructure.

## IP Addresses and Ports for Network Connectivity

The ports that are listed in this topic are the default ports that Privileged Access Manager uses to establish network connectivity to target devices and managed services.

### Assign IP Addresses for the Appliance

Before you configure your network, assign and allocate IP addresses for the appliance. The hardware appliance has eight ports and the VMware OVA has 6.

### Review Port Assignments

The following table lists port assignment requirements for Privileged Access Manager or client workstations. Most connections use the TCP protocol, except for SNMP, NTP, and Syslog, which use UDP.

For AWS or Azure, ensure that the assigned ports are also open in the AWS or Azure network settings, and the OS instance firewall. Also, verify that the [AWS or Azure endpoints are open in the OS firewall](#).

For Credential Manager and the target connectors, you might have to open other ports. The target connector type determines the required port. For a detailed list of Credential Manager port requirements, see [Default Ports for Credential Manager](#)

#### NOTE

In the **Source** column, the term **Appliance** represents the Privileged Access Manager virtual or hardware appliance.

Port	Source	Destination	Notes
22	Appliance	SSH device targets	Required for target device access through a built-in SSH access method.
22	Administrator workstation	Appliance	Required for Remote PAM Debugging Services. This port is only available when the SSH Debug patch is installed and remote debugging is enabled.
23	Appliance	Telnet device targets	Required for target device access through built-in Telnet, TN3270, TN5250, or TN3270SSL access methods.
49	Appliance	TACACS server	Required for integration with a TACACS server.
123	Appliance	NTP servers	Optional for a standalone server, which is required for cluster nodes
135	Appliance	Windows target device	Required for Windows Remote connector use of WMI.

389	Appliance	LDAP server	Required for integration with an LDAP server
443	Client workstations	Appliance	Required for HTTPS access to Appliance.
443	PAM Client	Appliance	Users without installed Java can use the client instead of a browser.
443	PAM Access Agent	Appliance	Required for HTTPS access to Appliance.
443	Socket Filter Agent (SFA) on a target device	Appliance	Required for socket filter agent (SFA) use.
443	Appliance: cluster member	Appliance: cluster member	Required bi-directional communication between members of a cluster.
443	A2A Client	Appliance	Required for A2A Client use.
443	Windows Proxy	Appliance	Required for Windows Proxy use.
443	Management Console	Appliance	Required for the Management Console to open a client session with a managed cluster (VIP).
443	Primary Cluster Members	Management Console	Required for cluster to submit information to the Management Console.
443	SailPoint clientaz	Appliance	Use for SailPoint SCIM access to REST API.
445	Appliance	CIFS server	Required for integration with a CIFS server for session log storage.
445	Appliance	Windows target device	Required for Windows Proxy and Windows Remote connector use of SMB.
636	Appliance	Domain Controller	Required for Active Directory target application.
992	Appliance	TN5250 SSL targets	Required for target device access through a built-in TN5250 SSL access method.
1812	Appliance	RADIUS server	Required for integration with a RADIUS server.
2049	Appliance	NFS server	Required for integration with an NFS server for session log storage. The NFS server might also require port 111.
3306	Appliance	External MySQL log server	Required if external log server is configured.
3306	SailPoint	Appliance	SailPoint application uses STI to access PAM on this port.

3307	Appliance: cluster member	Other Appliance: cluster member	Required bi-directional between members of a cluster. This port is only open if the cluster is running, and only shows as open to port scans performed from another cluster member.
3389	Appliance	RDP target devices	Required for target device access through a built-in RDP access method.
5500	Appliance	RSA server	Required for integration with an RSA authentication server.
5900	Appliance	VNC target devices	Required for target device access using built-in VNC access methods.
5900	Appliance: cluster member	Other Appliance: cluster member	Required bi-directional between members of a cluster (Hazelcast). This port is only open if the cluster is running, and only shows as open to port scans performed from another cluster member.
8443	Appliance: cluster member	Other Appliance: cluster member	Required for internal HTTPS communication between cluster members.
8550	Appliance	Socket Filter Agent (SFA) on a target device	Required for socket filter agent (SFA) use.
13307	Appliance: cluster member	Other Appliance: cluster member	Required bi-directional between members of a cluster. This port is only open if the cluster is running, and only shows as open to port scans performed from another cluster member.
27077	Appliance	Windows Proxy	Required for Windows Proxy use.
28888	Appliance	A2A client	Required for A2A Client use.
TBD	Client workstations	Target devices	Any port to access configured services on target devices. The target devices are devices to which a PAM user is connecting using a local third-party application from the client.

### **Endpoint Addresses for AWS**

For AWS deployments, verify that the following endpoint addresses are also open in the OS instance firewall:

- **Commercial cloud:** iam.amazonaws.com
- **GovCloud:** iam.us-gov.amazonaws.com
- **AWS Policy:** sts.amazonaws.com

## Endpoint Addresses for Azure

For Azure deployments, verify that the following endpoint addresses are also open in the OS instance firewall:

- **Public Cloud:**
  - \*.azure.com
  - \*.microsoft.com
  - \*.microsoftonline.com
  - \*.core.windows.net
  - \*.graph.windows.net
  - \*.login.windows.net
- **US Government Cloud:**
  - \*.microsoft.us
  - \*.microsoftonline.us
  - \*.usgovcloudapi.net
- **China Government Cloud:**
  - \*.chinacloudapi.cn
- **German Cloud:**
  - \*.microsoftazure.de
  - \*.microsoftonline.de

## Download PAM Installation Media

This topic describes how to obtain the required installation media for PAM service pack (X.x.x) and major (X.x) releases.

### Download the Software for a Service Pack (X.x.x) Release

The software for service pack releases on the [Privileged Access Manager Solutions & Patches](#) page on the Broadcom Support site.

#### Follow these steps:

1. Open the [Privileged Access Manager Solutions & Patches](#) page in a new browser session. If you are prompted to log in, use your Broadcom Support credentials.  
A table containing all available component patches for each PAM service pack version opens.
2. Locate the **X.x.x Patches** section for your release.

The following table shows an example of the components available for a particular service pack:

Component	Description
CAPAM_X.x.x.p.zip	PAM Server update patch
remoteCLI-X.x.x.zip	RemoteCLI installer
AIXA2A-version.zip	A2A Client for AIX installer
WindowsA2A-version.zip	A2A Client for Windows installer
UNIXA2A-version.zip	A2A Client for UNIX installer
LinuxA2A-version-1.x86_64.rpm	A2A Client for RHEL RPM package
UNIXSFA-X.x.x.zip	UNIX SFA installer
WindowsProxy-X.x.x.zip	Windows Proxy installer
WindowsSFA-X.x.x.zip	Windows SFA installer

Component	Description
pam-utility-appliance-X.x.x.p.zip	Server Control Utility Appliance installer
PAMTA-X.x.x.vhd.zip	Threat Analytics VHD for Azure
PAMTA-X.x.x.ova.zip	Threat Analytics OVA for VMware

3. Select the link for the component software that you require and download the zip file to your local system.

**NOTE**

If you are running a service pack release but cannot find an entry for the component you require, download the version that is associated with the prior major release. For example, If you are running 4.0.3, download the 4.0 version. To locate the 4.0 version, follow the steps in [Download the Software for a Major \(X.x\) Release](#) and select the appropriate version in Step 6.

4. If necessary, copy the downloaded file or files to the systems where they are required.
5. If the download file is compressed, extract it to a local drive.

### **Download the Software for a Major (X.x) Release**

Download the installation media for a major PAM release from the Product section of the Broadcom Support Portal.

**Follow these steps:**

1. Open the [Broadcom Support Portal](#) in a new browser session. If you are prompted to log in, use your Broadcom Support credentials.
2. Select **Cyber Security Software** from the product selector (  ) drop-down list that is displayed to the left of your account name in the header.
3. Select **My Downloads** in the left pane.  
The **My Downloads - Cyber Security Software** page opens, listing your licensed products.
4. Select **PRIVILEGED ACCESS MANAGEMENT** from the list.
5. Filter the results to locate the required components:
  - For most components, filter the results to locate one of the following product entries
    - **PAM DEBIAN X.x** or **PAM with FIPS DEBIAN X.x** (as required)
    - **PAM Virtual Appliance DEBIAN X.x** or **PAM Virtual Appliance with FIPS DEBIAN X.x** (as required)

The following table shows an example of the major release components that are listed after selecting any of the previous product entries:

Component	Description
Privileged Access Manager rX.x.ova	PAM Server OVA for a hardware or VMware appliance
Privileged Access Manager rX.x with FIPS.ova	PAM Server OVA with FIPS for a hardware or VMware appliance
Privileged Access Manager rX.x for Azure.tgz	PAM Server VHD for Microsoft Azure
Privileged Access Manager rX.x for Azure with FIPS.tgz	PAM Server VHD with FIPS for Microsoft Azure
Privileged Access Manager Upgrade Patch rX.x.zip	PAM Server upgrade patch (for all appliance types)
Privileged Access Manager Utility Appliance rX.x.ova	PAM Utility Appliance OVA
RemoteCLI rX.x.zip	RemoteCLI installer

Component	Description
Unix Socket Filter Agent rX.x.zip	Unix Socket Filter Agent installer
Windows Proxy rX.x.zip	Windows Proxy installer
Custom Connector Framework rX.x JDK 8.zip	Custom Connector Framework JDK 8 installer
Custom Connector Framework rX.x JDK 11.zip	Custom Connector Framework JDK 11 installer
Privileged Access Manager SC Migration Utility rX.x.iso	PAM SC Migration Utility ISO image
Privileged Access Manager SAM Data Extraction rX.x.iso	SAM Data Extraction Utility ISO image

- For Credential Manager A2A Clients, filter the results to locate the **PAM App to App Manager** or **PAM App to App Manager with FIPS DEBIAN** (as required) software. The following table shows the major release components that are listed after selecting either of the previous product entries:

Component	Description
Windows A2A Manager (Client) rX.x.zip	Credential Manager A2A Client for Windows
Unix A2A Manager (Client) rX.x.zip	Credential Manager A2A Client for UNIX
AIX A2A Manager (Client) rX.x.zip	Credential Manager A2A Client for AIX

6. Select the required software component.
7. Select the required version from the **Release** column.  
The **Primary Downloads** page opens, listing all the available product downloads for the selected version, as shown in the following example:

← **PAM DEBIAN 4.1** ? Product Download Help

Primary Downloads Search 4.1 DEBIAN 0000 English

[Download Selected](#) ☒ Expand All

<b>Privileged Access Manager Utility Appliance r4.1.ova</b> 2.41 GB	Apr 27, 0022 12.00AM	8d18e808b8c05adcc7303e2aab3a c93cefddeb8835b52510f7bb3258d5 a729ab2	486fcc78759343e826327081752c 523a	<input type="checkbox"/>	<a href="#">Generate</a>

8. Use the available controls to download your required component file or files.

#### NOTE

For more information about how to use the controls and generic information about this procedure, select the **Product Download Help** button in the top-right (which is highlighted in the previous screenshot).

9. If necessary, copy the downloaded file or files to the systems where they are required.  
10. If the download file is compressed, extract it to a local drive.

## Deploy the VMware OVA Template

You can deploy Privileged Access Manager as a virtual appliance using a VMware OVA template.

First, deploy the VMware OVA template then configure the virtual appliance network settings. Before you can configure the network settings, the Privileged Access Manager license is required. After you upload the license, configure the network connection so that it can autoprovision (import) your virtual machine devices.

## **Download the Virtual Appliance OVA Software**

Download the software for this component from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

## **Deploy the OVA Template**

Deploy the Virtual Appliance OVA within a VMware ESX or ESXi environment.

### **Follow these steps:**

1. Log in to the vSphere Virtual Infrastructure Client or vSphere web client.
2. Select **File, Deploy OVA Template**. In the web client, select **Home, VMs and Templates**. Right-click the vCenter, and select **Deploy OVF Template**.
3. Browse to the location of the OVA file and select the file and select Open.  
The OVA template is imported. Continue with the rest of the configuration. Select Next to move through the configuration.
4. In the Name and Location settings:
  - a. Enter a new name for this appliance.
  - b. In the **Inventory Location**, select the data center location where you want to install PAM. Select **Next**.
5. For the **Host/Cluster** settings, specify the host or cluster location where you want to deploy the template.
6. For the Storage, select where you want to store all data files that are associated with the VM.
7. For the Disk Format, select **Thick Provision Eager Zeroed**. Thin Provisioning is not supported.
8. Accept the remaining default settings.
9. Review the settings. Verify that the **Power on after deployment** check box is **not** selected.  
If any setting is changed, failure to keep this box unchecked results in redeployment of the OVA template. Edit the settings before the first power-up cycle of the guest VM instance.
10. Select Next.  
The OVA template is imported into the VMware host, cluster, or data center location that you previously selected.

The VMware virtual appliance deployment is complete. Go to the next section to edit the virtual machine settings.

## **Edit the Virtual Machine Settings**

The tasks that are required to set up the virtual machine settings include:

- Add network adapters
- Modify virtual RAM and CPU settings

### ***Add Network Adapters***

The OVA template ships with one virtual network adapter out of the box. The virtual appliance supports a total of eight virtual network adapters per virtual machine.

You can add the additional virtual network adapters even if there are no immediate plans to use them. Doing so allows for expansion when redeploying a new virtual appliance.

### **WARNING**

Add the virtual network adapters *before* the first power-on cycle of the virtual appliance.

### **Follow these guidelines:**

- Add virtual network adapters two through eight.
- If you are deploying adapters on ESX/ESXi hosts, select the right VM network.
- Select the correct network adapter type (Host Only, Bridged, or NAT) when adding virtual network adapters.
- Optional: If the deployment only requires one virtual network adapter, set adapters two through eight so they do *not* connect when the virtual appliance powers on.
- Optional: Set all virtual network adapters with static MAC addresses. You can set a static MAC address that contains the VMware OUI prefix in compliance with the following format:

00:50:56:XX:YY:ZZ XX is a valid hexadecimal number between 00 and 3F

YY and ZZ are valid hexadecimal numbers between 00 and FF.

Do not set the value for XX greater than 3F. Otherwise, the address might conflict with MAC addresses that the vSphere vCenter Server generates, or addresses that are assigned to the adapters for infrastructure traffic. See the VMware vSphere documentation for more information about VMware OUI allocation. To generate MAC addresses that meet the requirements, third-party sites are available.

### ***Adjust Virtual RAM and CPU Settings***

See the Virtual Instances section of the [Installation Requirements](#) page for guidance on configuring RAM, CPU, and storage.

### **Clone and Launch the Virtual Machine Instance**

After the virtual appliance settings are complete, complete the following steps:

1. Take a snapshot of the instance and make a full clone. This newly cloned instance serves as the new template for future deployments in your environment.  
Any changes to the virtual machine settings require a new full clone.
2. Launch a new virtual appliance instance from the cloned VM.
3. Power on the virtual machine.  
After the boot process is complete, the Virtual Utility Console displays in the VMware Virtual Console.
4. Configure the network settings using the Virtual Utility Console.

### **Configure Network Settings**

For initial network configuration, configure a default gateway and one or more network interfaces. These first steps enable the virtual appliance to connect to a network.

#### ***Basic Network Setting***

From the Virtual Utility Console, configure the settings for the first IP address. For other interfaces, you can use the Privileged Access Manager user interface.

The Main Menu of the console shows which keys are used to navigate through each menu.

#### **Follow these steps:**

1. From the Main Menu of the utility console, select **Basic Network Settings**. The Network Setup screen appears.
2. For the Default Gateway field, enter an IP address of the virtual appliance.
3. Specify a name as the host name for the virtual appliance.
4. Set the Domain (if applicable)
5. Save your configuration. You return to the Main Menu.

#### ***Interface Network Settings***

Enable the required network interfaces for the virtual appliance.

#### **Follow these steps:**

1. From the Main Menu, select **Interface Network Settings**.

2. For each network enabled network interface, enter an IP address. At least one interface is required.
3. Set the subnet mask for each enabled network interface.
4. Save the configuration.
5. From the Main Menu, restart Networking.
6. Verify that the network configuration is valid by contacting (pinging) the configured IP address from another PC.

The remaining configuration steps can be completed from the Privileged Access Manager user interface or Workstation Client.

## Deploy on an AWS Amazon Machine Image (AMI)

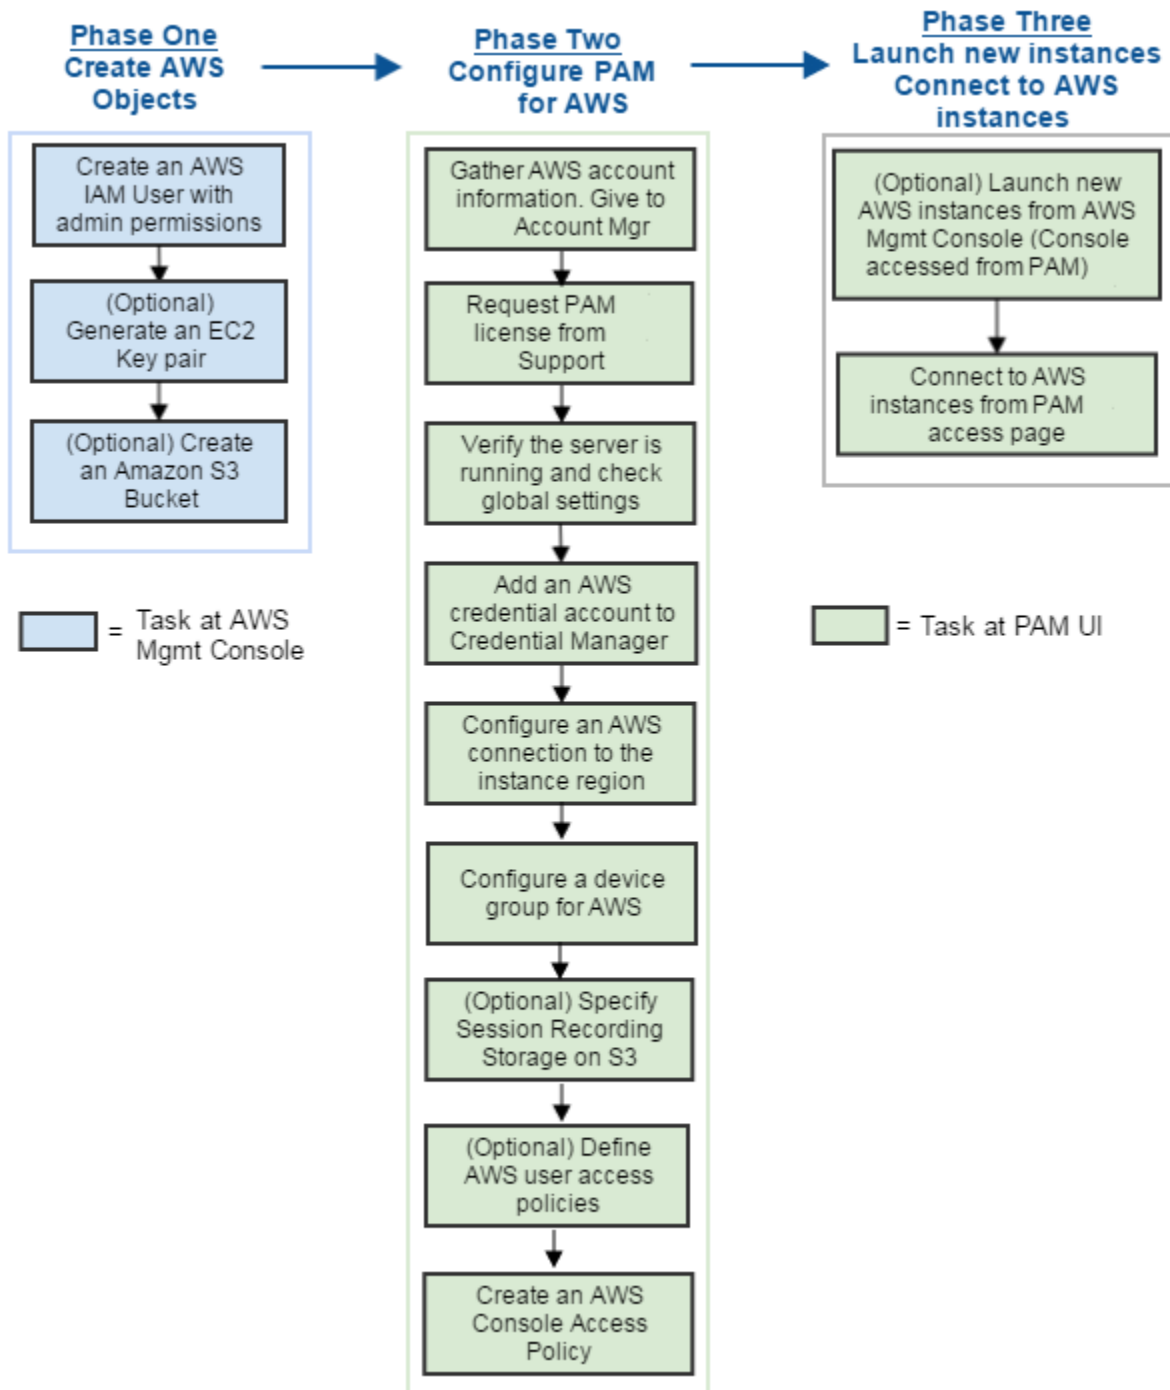

You can deploy PAM in the cloud on an AWS AMI virtual appliance. Privileged Access Manager can integrate with AWS in the following ways:

- Auto-discover AWS EC2 instances.
- Store access keys and use key pairs for auto-login.
- Use Amazon S3 buckets to store session recordings.
- Access the AWS Management Console through PAM, based on a policy.

The AMI acts as a template from which you can launch an instance.

Deployments tasks for an AWS AMI involve the following procedures:

**Figure 15: AWS AMI Deployment Task Flow**

The setup procedures are detailed in the following topics:

- [Create AWS Objects](#)
- [Configuring Privileged Access Manager for AWS](#)
- [Launch New Instances \(Optional\)](#)
- [Connect to AWS Instances](#)

## Create AWS Objects

Before you can integrate Privileged Access Manager with AWS, complete the AWS setup from the AWS Management Console.

These procedures explain how to create the following AWS objects:

- An IAM user with an Access Key ID and Secret Access Key pair. These procedures use the sample name **cademo-key-pair**.  
This key pair is assigned to the AWS instances that you can launch later.
- A uniquely named S3 bucket for storing PAM session recordings (optional).

Complete the following tasks at the AWS Management Console.

### Add an AWS IAM User with Administrator Permissions

Add an AWS IAM user with security credentials and permissions that allow integration between PAM and AWS.

1. Log in to the AWS Management Console.
2. Navigate to **IAM Dashboard, Users**, and select **Add User**.
3. Enter a user name. These procedures use **cademo** as an example.
4. For the Access type, select **Programmatic access**.  
If access to the Management Console is necessary, also select the **AWS Management Console Access** option.
5. Select **Next: Permissions**.

## Add user

Details

Permissions

Review

Complete

### Set user details

You can add multiple users at once with the same access type and permissions. [Learn more](#)

User name\*

[+ Add another user](#)

### Select AWS access type

Select how these users will access AWS. Access keys and autogenerated passwords are provided in the last step. [Learn more](#)

- Access type\* ☒ **Programmatic access**  
 Enables an **access key ID** and **secret access key** for the AWS API, CLI, SDK, and other development tools.
- ☐ **AWS Management Console access**  
 Enables a **password** that allows users to sign-in to the AWS Management Console.

\* Required

[Cancel](#)

[Next: Permissions](#)

6. In the Set Permissions screen, select **Create group**.
7. Select the **Show User Security Credentials** link.
8. Note the Access Key ID and the Secret Access Key values.
9. Select **Download Credentials** and download the **credentials.csv** file. Handle this file securely.
10. Select **Close** to return to the list of users.
11. From the list of users, select the entry for the cademo user to display the summary screen.
12. Select the **Permissions** tab then select **Attach Policy**.
13. Attach the following policies to the user. Use the search filter to narrow the list of policies.
  - **AdministratorAccess**. This policy permits federated access to the AWS Management Console.
  - **AmazonEC2ReadOnlyAccess**. This policy lets you import and discover AWS instances and import them into PAM.
  - **AmazonS3FullAccess** (optional). This policy is optional. Use the policy to read and write PAM session recordings to a mapped S3 bucket.
14. After selecting all relevant policies, select **Attach Policy** to return to the Summary page for the user. Review that all the permissions are set.

The following screen shows an example summary screen with only two policies:

Dashboard

Managed Policies

The following managed policies are attached to this user. You can attach up to 10 managed policies.

[Attach Policy](#)

Policy Name	Actions
AmazonS3FullAccess	<a href="#">Show Policy</a>   <a href="#">Detach Policy</a>   <a href="#">Simulate Policy</a>
AmazonEC2ReadOnlyAccess	<a href="#">Show Policy</a>   <a href="#">Detach Policy</a>   <a href="#">Simulate Policy</a>

### Generate an EC2 Key Pair (Optional)

Generating an EC2 key pair depends on the following conditions:

- If there are existing key pairs for existing target instances in your AWS account, you do not need to generate a key pair. However, you must add all existing key pairs to the Credential Manager target account. PAM must have the key pair to access these instances and can manage the key pairs. Adding key pairs is done using the PAM UI.
- If you have a new AWS account with no instances, you must generate an EC2 key pair.

To authenticate to an AWS instance, obtain an EC2 key pair. When you launch an AWS instance later, you must provide this key pair.

1. In the AWS Console, navigate to **EC2 Dashboard, NETWORK & SECURITY, Key Pairs**.
2. In the navigation bar, select any region available to you regardless of your location. You cannot share key pairs between regions.
3. Select **Create Key Pair**.  
You are prompted to enter a key pair name.
4. Enter a name then select **Create**. For this procedure, the example name is **cademo-key-pair**.  
The key pair file, such as **cademo-key-pair.pem**, automatically downloads.
5. Store the key file in a safe location.

#### TIP

Amazon EC2 stores the public key only, and you store the private key. Securely storing the private key pair is important because the AWS Administrator role is associated with the pair. To manage the keys securely, see AWS documentation.

### **Create an Amazon S3 Bucket (Optional)**

If you want to keep session recordings on premise and not in AWS, skip this procedure. To store session recordings in an S3 bucket, create an Amazon S3 bucket.

To store session recordings in an Amazon S3 bucket, follow these steps:

1. From the AWS Management Console, open the Amazon S3 Console.
2. Select **Create Bucket**.
3. Specify a **Bucket Name** and select a **Region**.
4. Select **Create** to see the new, empty bucket.

For more information, see [Amazon S3 documentation](#).

#### **NOTE**

[Configure Privileged Access Manager for AWS](#)

## **Configure Privileged Access Manager for AWS**

Configure Privileged Access Manager for AWS by completing the following procedures:

### **Gather AWS Account Information**

Gather the following information and provide it to your Broadcom account representative:

- Your AWS account number
- The regions where you plan to deploy the instance.  
The following regions are supported:
  - US East (Ohio)
  - US East (Virginia)
  - US West (N. California)
  - US West (Oregon)
  - US GovCloud (East) - Only for US government customers
  - US GovCloud (West) - Only for US government customers
  - Canada (Central)
  - EU (Frankfurt)
  - EU (London)
  - EU (Paris)
  - EU Central-2 (Zurich)
  - EU-South-1 (Milan)
  - EU-South-2 (Spain)
  - EU West (Ireland)
  - Asia Pacific (Mumbai)
  - Asia Pacific (Seoul)
  - Asia Pacific (Singapore)
  - Asia Pacific (Sydney)
  - Asia Pacific (Tokyo)
  - South America (Sao Paulo)
- Know the Privileged Access Manager version that you plan to use.
- Indicate whether you purchased the FIPS option.

Broadcom makes the appropriate AMI available to your account in the desired region, and sends you the AMI ID and Name.

### **Request a License from Broadcom Support**

A Privileged Access Manager license is required before you can connect with the AWS instance.

1. In the Privileged Access Manager UI, select **Configuration, Network**.  
The Network Configuration screen opens.
2. Open the **System Info** page and select **Hardware Identifiers**.
3. Copy the string in the **Hardware ID** field and provide it to the Broadcom licensing team to get a license.

### **Verify that the Appliance is Running and Check Global Settings**

Verify that the Privileged Access Manager appliance is running and that you can access it from the web UI or PAM Client.

This procedure assumes that the appliance is deployed in AWS, but that setup might not be the case. If Privileged Access Manager is deployed as a hardware appliance or as a VMware OVA, the appliance can still manage access for AWS instances.

#### **Follow these steps:**

1. From the UI, select **Settings, Global Settings**.
2. Confirm the values of the following settings.  
Basic Settings
  - **Login Timeout (Minutes):** 10
  - **Applet Timeout (Minutes):** 10
  - **Default Device Type:** Select **Access** and **Password Management**
 Warnings
  - **Show Recording Warning** is selected.
 These settings are not specific to AWS, but setting them globally is recommended.
3. Select **Save**.

### **Add AWS Account Credentials to Credential Manager**

To coordinate with AWS, store your AWS account credentials in a target account record in Credential Manager.

#### **Follow these steps:**

1. Log in to the UI and select **Credentials, Manage Targets, Accounts**.
2. Select **Add** to add an account.
3. In the **Application Name** field, select the magnifying glass and select **AWS Access Credential Accounts**.
4. Verify that the **AWS Credential Type** is set to **Access Key**.
5. Find and open the **credentials.csv** file that you downloaded.
6. From the values in the credentials.csv file, configure the following fields:
  - **Account Name**
  - **Access Key ID**
  - **Secret Access Key**
7. Select **Save**.  
The credentials are stored in PAM.
8. As a precaution, make a backup of the credential.csv file and securely store it off line. After securing the backup file, securely delete the credential.csv file from the users desktop.

### **Add an EC2 Private Key to Credential Manager (Linux Instances only)**

To auto-login to AWS Linux instances, add the EC2 private key file that you generated in AWS. By saving the key, you can log in to every AWS Linux instance that has **ec2-user** as a user name and the key-pair that is assigned at launch.

#### **NOTE**

All EC2 AWS Linux instances have the default account of ec2-user. If you launch another type of Linux instance, such as SuSE, Red Hat, or CentOS, the default accounts are different.

#### **Follow these steps:**

1. Log in to the UI and select **Credentials, Manage Targets, Accounts**.
2. Select **Add** to add an account.
3. In the **Application Name** field, select the magnifying glass and select **AWS Access Credential Accounts**.
4. For the **AWS Credential Type**, select **EC2 Private Key**, then enter values for the following settings:
  - **EC2 Instance User Name**
  - **EC2 Private Key**: Navigate to your **.pem** file and select **Upload**.
  - **Key Pair Name**: Name of the key pair you assigned in AWS Console, such as **cademo-key-pair**

### **Configure an AWS Connection to the Instance Region**

After you configure a credential account, add an AWS connection to the region in which your AWS instances are running.

#### **Follow these steps:**

1. From the UI, select **Configuration, 3rd Party, AWS**.
2. Select **Add**.  
The Add AWS Connection page opens.
3. Enter these values for the following fields:
  - **Access Key Alias**: cademo
  - **Region**: Select the region where your instances are running from the pull-down list.
  - **Active**: Select this checkbox to schedule this Alias/Region for import from AWS (at the frequency that is selected on the **Refresh Interval** tab).
4. Select **OK**.  
A confirmation window displays indicating that the AWS import is initiated.  
The Privileged Access Manager instance connects to the AWS Public API endpoint over port 443. Using the credentials in the vault, Privileged Access Manager tries to connect and start importing devices. If the connection is successful, a confirmation message displays.
5. Verify that the connection is listed in the Amazon Web Services (AWS) Configuration section.
6. (Optionally) Select **Test** to verify connectivity. After a successful test, the message "Connected successfully to AWS" displays.
7. (Optionally) To gain access to data centers in multiple regions where AWS is present, from the one connection panel, add other AWS regions. You then have access to these centers from the centralized single console.

### **Configure a Device Group for Access Policies**

Create a device group for use in an access policy for the AWS Management Console. These instructions are for AWS on Linux or Windows.

#### **Follow these steps:**

1. Log in to the Privileged Access Manager UI.
2. Select **Devices, Manage Device Groups**.
3. Select the Create Device Group link.
4. Set the following values:

**Group Name:** Enter a string. For example, AWSLinuxDevices or AWSWindowsDevices

This value must match the value that you specify for the Groups tag that you configure when launching an AWS instance later.

**Group Type:** AWS

**Access Methods:** SSH (Linux) or RDP (Windows)

5. Select **Save**.

### **Configure Session Recording Storage to Amazon S3 (Optional)**

You can store session recordings in an Amazon S3 bucket. If session recording is being done using CIFS/NFS, Amazon S3 is not necessary. This step is optional.

1. From the UI, select **Configuration, Logs, Session Recording**.
2. Select the **External Storage** tab.
3. In the **Primary Mount Settings** section, select Amazon S3 from the **Protocol** drop-down list.
4. Complete the remaining fields:
  - **Bucket** - Enter the AWS bucket to use.
  - **AWS Provision**- Select the appropriate entry from the drop-down list.
5. Select **SAVE SETTINGS**.
6. A confirmation message appears at the top of the screen.
7. **Select Mount.**  
A message appears at the top of the page indicating whether the mount is successful.  
If the share is mounted, **Mount Availability** displays the status of the mount: **available** or unavailable.
8. Go back to the **Session Recording** tab.
9. Specify the following types of sessions that you want to record:
  - **Text based recording to a NFS/CIFS/S3 mounted directory**
  - **Graphical session recording to a NFS/CIFS/S3 mounted directory**
 Each session recording option is unavailable until the required network mounts have been configured.
10. Select the **UPDATE** button to save your changes.  
If the configuration is successful, the message **Keystroke Logging configuration updated successfully** displays.

### **Define AWS User Access Policies (Optional)**

Privileged Access Manager provides two default AWS policies:

- IAMUserAccess
- PowerUserAccess

You can add your own user access policies. Select **Policy, Manage Policies, Create AWS Policy**.

### **Create an AWS Management Console Access Policy**

Create an access policy to the AWS Management Console. When an administrator accesses the AWS Management Console through Privileged Access Manager, the session is recorded, leaving an audit trail.

Configuring access eliminates the need for an AWS administrator to establish individual accounts with policies and permissions for each privileged user and associated applications. If you configure access for one account (cademo), you centralize access. However, logging and auditing is still tied to the user performing the action.

For auto-login, do not configure any AWS connections from the Configuration, 3rd Party menu. Simply load the access key and a secret access key into the Credential Manager account for each AWS instance that you want to manage.

**NOTE**

After you configure access to the AWS Console, only the permissions that are associated with the AWS IAM user are added for Privileged Access Manager. Earlier in this procedure, you assigned AmazonEC2ReadOnlyAccess policy to the IAM user so that user has read-only access to specific Amazon EC2 services and resources. For more information about AWS access permissions, see the AWS Directory Service user documentation.

**Follow these steps for access to the AWS console:**

1. From the UI, select **Policies, Manage Policies**.
2. Select **Add**.
3. In the User or User Group field, enter **super**.
4. In the Device or Device Group field, enter [xceedium.aws.amazon.com](https://xceedium.aws.amazon.com)
5. On the Services tab, select AWS Management Console SSO [AWS Access Credential Accounts – cademo – PowerUserAccess]
6. On the Recording tab, select **Web Portal** and **On Violation**.
7. Select **Save**.

**Create an Access Policy for the AWS Device Group**

For the Linux or Windows Device group, create an access policy that allows the super account access to the AWS instances. These procedures are similar to adding any access policy for an individual or group.

**Follow these steps:**

1. From the UI, select **Policies, Manage Policies**.
2. Select **Add**.
3. In the User or User Group field, enter **super**.
4. In the Device or Device Group field, enter the device group for your OS (AWSLinuxDevices or AWSWindowsDevices).
5. On the Access tab, select one of the following access methods:
  - **Linux:** SSH
  - **Windows:** RDP
6. On the Recording tab, select the relevant options:
  - **Linux:** Command Line, Bidirectional, On Violation
  - **Windows:** Graphical, On Violation
7. Select **Save**.

**Launch New AWS Instances (Optional)**

Typically, there are AWS instances that are already launched. If you want to launch any new instances, you access the AWS Management Console from the Privileged Access Manager Access page. From the Console, you can launch new instances. Accessing the Console using PAM lets you record and log the creation of the new AWS instances.

You created an AWS Management Console access policy in a previous procedure. Now, you can securely access the AWS Management Console.

**Follow these steps:**

1. Log in to the PAM UI.
2. Select **Access**.
3. Select the **AWS Management Console SSO** link. You are automatically signed in to the AWS Management Console.

Now you can launch new AWS instance. See the AWS documentation for how to [launch EC2 instances](#).

## Connect to AWS Instances

After all AWS instances are launched, connect to any instance from the Access page of the PAM UI.

### Import the AWS Instances

After you finish the AWS configuration, import the AWS instances.

#### **Follow these steps:**

1. From the PAM UI, select **Devices, Manage Devices**.
2. Select **Refresh AWS Devices** link.
3. Ensure that you see all your AWS instances.

### Connect to an AWS Linux Instance Using Auto-login

Follow these steps:

1. From the UI, select **Access**.
2. Select the **SSH** Access Method link for an AWS Linux instance.  
You are connected automatically and logged in as a valid user with the AWS EC2 Private Key.

### Connect to an AWS Windows Instance

To connect to an AWS Windows instance from the Access page, you need the Administrator password. Retrieve this password from the AWS Management Console then you can access the instance.

#### ***Retrieve the Administrator Password for the Windows Instance***

For Amazon EC2 Windows instances, AWS generates and encrypts a random Administrator password using the certificate (public key) of an Amazon EC2 key/certificate pair. Retrieve the Windows instance password by using the AWS Management Console and then by providing the corresponding Amazon EC2 private key to decrypt the password.

#### **Follow these steps in the PAM UI:**

1. Select **Access**.
2. Select the **AWS Management Console SSO** link. You are automatically signed in to the AWS Management Console.
3. Navigate to **EC2 Dashboard, Instances**.
4. Right-click on an instance entry
5. Select **Get Windows Password** from the pop-up menu.  
The window **Retrieve Default Windows Administrator Password** opens.
6. In the middle of the page, select **Choose File** and navigate to the file on your local system with the private key file.  
Example: cademo-key-pair.pem

## Retrieve Default Windows Administrator Password

To access this instance remotely (e.g. Remote Desktop Connection), you will need your Windows Administrator password. A default password was created when the instance was launched and is available encrypted in the system log.

To decrypt your password, you will need your key pair for this instance. Browse to your key pair, or copy and paste the contents of your private key file into the text area below, then click Decrypt Password.

The following Key Pair was associated with this instance when it was created.

**Key Name** cademo-key-pair

In order to retrieve your password you will need to specify the path of this Key Pair on your local machine:

**Key Pair Path**  cademo-key-pair.pem

Or you can copy and paste the contents of the Key Pair below:

```
-----BEGIN RSA PRIVATE KEY-----
MIIEowIBAAKCAQEAiZarbQsrOoe9heGmCw8Wh79jORmxxwQx9mMs4DdxdiUqULXSpY/ZCoj6i8Xe
Qy7me05pOezuMjfaX5b9VBwQ5aQogFZw3jmPiO278hFyWWaR8qsA/mx5ayQuYQYq2t6bjauA9uou
gjitpUsiB0bbMkw4J/JYZXqLHTxhlwKSkauVhMXH+JUXf5xfsPxJDYjWNQ8Ettino3hCy6cP+FYdt
ljAqutVLbyJMw5R+eObPLrctvYbZiireRDERGjW0FncfzQJE+2pzHywuixV+7Jw2rw5ShR99QPLn
```

Cancel

Decrypt Password

### 7. Select **Decrypt Password**.

A second page displays with the Administrator credentials, including the password.

### 8. Copy the information to your local system then log out from the AWS Console.

### 9. Return to the **PAM UI**.

## Connect to the Windows Instance

### Follow these steps:

1. From the UI, select **Access**.
2. Select the **RDP** Access Method link for an AWS Windows instance.  
You are prompted to accept the remote computers certificate.
3. Select the box **Do not ask me again** then **click OK**.  
The login page appears.
4. Enter the credentials and the domain that you copied from the AWS Console then select **Login**.

## Deploy a VHD on Microsoft Azure

Complete all the procedures in this topic to deploy a Privileged Access Manager instance on Microsoft Azure.

### Obtain Prerequisite Items

Obtain the following prerequisite items:

- A subscription to Azure.
- A Privileged Access Manager Azure VHD (Privileged Access Manager rX.x for Azure.tgz , which you download from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

### Create a Resource Group

In Azure, a Resource Group is a logical folder for all the resources you create, including Disks, Storage Accounts, VMs, and Network Security Groups. If your organization limits the ability to manage Resource Groups, reach out to your Azure Administration Team for assistance.

To create a Resource Group, follow these steps:

1. Log into Azure with an account with permission to create a Resource Group.
2. In the Azure UI, select **Resource Groups** from the **Azure services** menu at the top of the screen (as shown highlighted in the following screen capture):

Azure services

vhd

3. Select the **+ Create a resource** button in the top left of the **Resource Groups** screen.
4. Complete the fields on the **Create a resource group** screen that opens.
5. Select **Review and create**.
6. Verify that the resource group information is correct and select **Create**.

### Create a Storage Account

To create a Storage Account, follow these steps:

1. Return to the Azure home screen and select **Storage Accounts** from the **Azure services** menu at the top of the screen.
2. Select the **+ Create** button in the top left of the **Storage accounts** screen that opens.
3. On the **Create Storage Account** screen, provide the following information:
  - For **Resource group**, select the drop-down menu and select the resource group that you created in the previous procedure.

#### TIP

If you do not see your resource group, you can search for it by typing in the **Select existing** field at the top of the list of existing resource groups.

- The **Storage account name**, which must be 3 to 24 characters long and contain only lowercase letters and numbers.
  - {Optional} Specify the **Location** of the storage account, which can be different from the location of the resource group.
4. Select **Review and create**.
  5. Verify that the storage information is correct and select **Create**.
  6. The storage account is deployed and added to the list on the **Home, Storage Accounts** screen.
  7. Select your new storage account from the list. You must select the **Refresh** button.
  8. Select **Containers** from the **Data Storage** section in the navigation rail to the left. The **Containers** pane opens.

9. Select **+ Container** to create a storage container in the storage account. A **New Container** panel opens on the right of the screen.
10. In the **New Container** panel, enter a **Name** for the new container and select **Create**

**NOTE**  
The container name can only contain lowercase letters, numbers, and hyphens, and must begin with a letter or a number. Each hyphen must be preceded and followed by a non-hyphen character. The name must also be from 3 through 63 characters long.
11. On the **Containers** panel, locate your new container and select its name (not the checkbox to its left).
12. In the panel that opens, select the **Upload** icon in the upper left then select the Privileged Access Manager VHD image to upload it to Azure.

### **Create a Network Security Group**

Next, create a Network Security Group in Azure.

#### **Follow these steps:**

1. Enter "Network Security Group" in the search field at the top of the Azure portal.
2. Select **Network Security Group**.
3. On the **Network Security Group** page that opens, select the **+ Create** button to add a new Network Security Group.
4. For **Resource Group**, select your Resource Group.
5. Provide a **Name** for the Network Security Group.
6. For **Region**, select the same location as your storage account.
7. Select **Review + Create**.
8. Select **Create**.
9. Once the deployment is complete, select **Go to resource**.
10. Select **Inbound security rules** on the left panel.
11. Select the **+ Add** button.
12. On the **Add inbound security rule** page that opens, add rules for ports that you want to open. See [Default Ports for Credential Manager](#) for more information about which ports to open.
13. Select the **Add** button to commit the changes and create the Network Security Group.

### **Create a Virtual Network**

Next, create a virtual network in Azure.

#### **Follow these steps:**

1. Enter **Virtual Network** in the search field at the top of the Azure portal.
2. Select **Virtual Networks**.
3. On the **Virtual Network** page that opens, select the **+ Create** button to add a new Virtual Network.
4. For **Resource Group**, select your Resource Group.
5. Provide a **Name** for the Virtual Network.
6. For **Region**, select the same location as your Storage Account.
7. Select **Review + Create**.
8. Select **Create**.
9. Once the deployment is complete, Select **Go to resource**.
10. Select **Subnets** on the left panel.
11. Select the subnet "default" to show its properties
12. In the **Network security group dropdown**, find and select the new Network Security Group that you created earlier.

**NOTE**

Do *not* use the default value "None."

13. Select **Save** to commit the change.

### **Create a Managed Disk**

Next, create a disk in Azure.

#### **Follow these steps:**

1. Enter "disks" in the search field at the top of the Azure portal.
2. Select **Disks** from the search results.
3. On the **Disks** page, select the **+ Create** button to add a new disk.
4. Under **Project Details**, select an existing **Resource Group** from the drop-down menu.
5. Under **Disk Details**, provide the following information:
  - The **Disk Name**.
  - For **Region**, select the same location as your **Storage Account**. You must create a disk in the same location as the storage account where you uploaded your VHD.
  - To specify the disk source type and properties, follow these steps:
    - a. Select "Storage blob" from the **Source Type** drop-down menu. More context-sensitive controls appear.
    - b. In the **Source blob** field, use the **Browse** link to select the VHD. Select the Storage Account, then the Container, then the VHD, and finally select **Select**.
    - c. For **OS type**, select "Linux."
    - d. Verify that the value of the **VM generation** control (which appeared when you select Linux in the previous step) is "Gen 1."
  - To change the default **Size** (1024 GiB) of the disk, do the following steps:
    - a. Select the **Change Size** link. The **Select a disk size** page opens.
    - b. Verify that the value that is specified in the **Disk SKU** drop-down menu is "Premium SSD".
    - c. Select a listed disk size or specify a **Custom disk size** of at least 80 GiB.
    - d. Select **OK**
6. Select **Review and Create**.
7. Verify that your settings are correct and, if so, select **Create**. Otherwise, select the **Previous** button to go back and make any necessary changes.

### **Create the Virtual Machine**

To create a Privileged Access Manager VM in Azure, follow these steps:

1. Return to the **Disks** page and select your disk. A new pane appears with **+ Create VM**.
2. Select **+ Create VM**. The **Create Virtual Machine** panel appears.
3. In the **Basics** tab, enter a **Name** for your VM.
4. For **Resource Group**, select "Use Existing" and select your Resource Group.
5. **Location** is disabled because it is determined by the disk Storage Account location.
6. Select a size. See [Installation Requirements](#) for more information. Select the size and then the select the **Select** button at the bottom.
7. Select the **Networking** setting and do the following steps:
  - a. Select the Virtual Network that was created earlier. The "default" subnet is selected.
  - b. On the **Public IP** drop-down list, select **Create New**.
  - c. On the **Create public IP address** page that opens, set the **SKU** option to "Standard."
  - d. On the **NIC network security group**, select **Advanced**.
  - e. On the **Configure network security group**, select the name of the Network Security Group that you created earlier.
8. Select **Review + Create**.

9. Verify the settings on the **Summary** page, then select **Create** to commit your changes.  
Deployment begins. To monitor its progress, select the **Notifications** bell icon in the upper right.

### **License Your Azure PAM Instance**

Once the VM deployment is complete, log into and license the Privileged Access Manager instance.

#### **Follow these steps:**

1. Select **Virtual Machines** on the left rail.
2. Select the VM that you created. The **Public IP Address** is listed in the right column of the **Overview** tab.
3. Use the public IP address to access Privileged Access Manager UI. For more information, see [Accessing PAM](#).

#### **NOTE**

If your initial attempt to access the PAM UI fails, try rebooting the new PAM instance.

4. Select **Configuration, Licensing**
5. Copy the Hardware ID.
6. Contact Broadcom Support and request a license file with Azure support for the instance that is identified by the Hardware ID. For more information, see [this KB article](#).
7. Once you have the license file, Do the following tasks to install the license it:
  - a. Navigate to the **Configuration, Licensing** page and select the **Install New License** tab.
  - b. Choose the appropriate license file and select **Upload file**.
  - c. Verify the new license and select **Save New License**.

#### **NOTE**

The Azure LinuxDiagnostic extension is not available for Privileged Access Manager.

### **Set up CIFS Storage in Azure**

You can set up Azure to store your session recordings and database backups on an Azure CIFS share. Alternately, you can use an on-premises CIFS or NFS share, or create a separate Linux device with an NFS share in Azure. Azure does not support mounting an Azure file share in a different region than your Azure Privileged Access Manager VM. Once you have a share, follow the instructions in [Schedule a Backup of the Database](#).

To create a CIFS share in Azure, follow these steps:

1. In Azure, select the **Storage Accounts** menu on the left.
2. Select your Storage Account.
3. Under **Services** in the right pane, select **Files**.  
The File Service window appears.
4. Select the **+ File Share** button on the top left of the **File Service** panel.
5. Enter a Name in lowercase characters and numbers. Hyphens are allowed.
6. Enter a **Quota** (size limit) in **GB**.
7. Select the new File Share. In the resulting right pane, select **Connect** from the top menu.
8. Scroll down to the **Connecting from Linux** section.
9. Copy the command from the text box. We are only interested in the share path, user name, and password. The following example highlights those three elements:

```
sudo mount -t cifs //mystorage.file.core.windows.net/myshare
[mount point] -o vers=3.0,
username=mystorage,
password=7QX+bNjogEd7vvvJERIKzcqVVqzOV3CLuqqNE6FacZCtiK1F7ZAA4BT11I48EfbBmaMnNWQCz8XYizuNvjtrIQ4=,
dir_mode=0777,file_mode=0777,sec=ntlmssp
```

This share uses the CIFS Protocol, and SMB version 3.0.

10. Use this information to set up:

- a. Session Recording: See [Set up Session Recording](#).
- b. Database Backup: See [Schedule a Backup of the Database](#)

#### NOTE

**Next step:**

- [Configure an Azure Connection](#)

## Configure an Azure Connection

An Azure Connection enables clustering, importing of Azure Virtual Machines, and using Azure Active Directory as a SAML Identity Provider. You configure Azure as a Target Application and a Target Account in Privileged Access Manager, and then configure a connection. If you only want to manage Azure AD accounts, and not devices, see [Add an Azure AD Target Connector](#) instead.

### Azure as Target Application

#### *Create the Application in Azure*

The Azure Application allows Privileged Access Manager to access Azure Resource Groups, VMs (for Azure device import), network interfaces, and public IPs (for clustering).

#### NOTE

For clustering, configure the Azure Application on the first Primary Site member. See [Set Up a Cluster](#) and [Cluster Deployment Requirements for Azure](#) for more information.

Your configuration differs depending on whether you plan to manage accounts, devices, or both. If you are only managing devices, you can use public APIs or a web connection. For information about required privileges, see the Microsoft Azure document [Administrator roles by admin task in Azure Active Directory](#).

### *Application Registration*

To create an Application in Azure, follow these steps:

1. In Azure, select **Azure Active Directory** from the left menu.
2. Select **App Registrations** from the resulting service list.
3. Select **+New Registration** on the resulting pane.
4. Enter a **Name** of your choice. Do not include spaces in the name.
5. Select **Supported Account Types**: Accounts in this organizational directory only.
6. Select **Redirect URI**:
  - Select **Web** if you want to discover and manage devices but not accounts. This option does not require your Azure account name and password.
  - Select **Public client (mobile & desktop)** to be able to discover and manage accounts and devices. This option requires your Azure account name and password. You can also use this option to manage devices only.
7. Enter a **Sign-on URL** for the application. Enter your Azure Privileged Access Manager URL. For a cluster, select the IP address of the first node at the primary site. For example: `https://ip_address/cspm/home`
8. Select **Create**.
9. Open the App.
10. Copy the **Application ID** for use in creating a Privileged Access Manager Target Account.
11. Select **Certificates and secrets** in the **Manage** menu.
12. Under **Client secrets**, select **+New client secret**. Enter a **Description**, and an **Expires** Duration.
13. Select **Add**.

The **Value** of the Secret key appears. Copy the key value now. You cannot retrieve it after you leave this page. You must use it as the **Secret Access Key** when you create the Target Account.

If you are only managing devices, and using the **Web** option, skip to [Add Application to Resource Group](#). If you are managing devices using the public client, go to the following section. If you are managing accounts using the public client, go to [Account Management Using Public Client](#).

### ***Device Management Using Public Client***

1. Open the App that you created.
2. In the **Manage** menu, select **API Permissions**.
3. On the API Permissions panel, select **+Add a permission**.
4. On the Request API Permissions page, select **Azure Service Management**.
5. Select **Delegated permissions**.
6. Under **Select permissions**, type to search for "directory."
7. In the search results, select **user\_impersonation** (Access Azure Service Management as organization users (preview)).
8. Select **Add Permissions**.
9. Under **Grant consent**, select **Grant admin consent for [your directory]**.
10. Select **Yes**.
11. Close **API permissions**.
12. On the application **Manage** menu, select **Authentication**.
13. Scroll down to **Default client type**. Select **Yes**.
14. Select **Save**.
15. If you are not managing accounts, skip to [Add Application to Resource Group](#). If you are managing accounts, go to the following section.

### ***Account Management Using a Public Client***

1. Open the App that you created.
2. In the **Manage** menu, select **API Permissions**.
3. On the API Permissions panel, select **+Add a permission**.
4. On the Request API Permissions page, select **Microsoft Graph**.
5. Select **Delegated permissions**.
6. Under **Select permissions**, type to search for "directory."
7. In the search results, select **Directory.AccessAsUser.All** (Access directory as the signed in user).
8. Select **Add Permissions**.
9. Under **Grant consent**, select **Grant admin consent for [your directory]**.
10. Select **Yes**.
11. Close **API permissions**.
12. If you have not already set the Default client, go to the application **Manage** menu, and select **Authentication**.
13. Scroll down to **Default client type**. Select **Yes**.
14. Select **Save**.

### ***Add an Application to a Resource Group***

If you want to manage devices, you must associate your Application to your Resource Group:

1. Select **Resource Groups** from the Azure left menu.
2. Select your Resource Group.
3. Select **Access Control (IAM)**.
4. Select **+Add, Add role assignment**.
5. Select **Contributor** from the **Role** drop-down list. Leave **Assign Access to** as "Azure AD user, group, or service principal."
6. In the **Select** field, enter the name of your application. Select the application from the resulting list.

7. Select **Save**.

#### NOTE

If you have Virtual Machines in different Resource Groups (such as for clustering), repeat this association for each Resource Group.

### Create a Target Account

Clustering, Azure device import, and the Azure agent require a Target Account in Privileged Access Manager. Follow these steps in Privileged Access Manager:

1. Go to **Credentials, Manage Targets, Accounts**.
2. Select **Add**.
3. Use the **Application Name** magnifying glass icon to search and select **Azure Access Credential Accounts**. This action populates **Host Name** and **Device Name** with **ca.portal.azure.com**.
4. Select the **Access Credential** tab.
5. Select the required **Azure Application Type** and then provide the appropriate credentials in the context-sensitive fields immediately below:
  - **Web App/API**:
    - **Account Name**: The application name that you created in Azure.
    - **Secret Access Key**: The password key for your Azure Application.
  - **Native Client**:
    - **User Name**: Your Azure account user name.
    - **Password**: Your Azure account password.
6. Enter the **Application ID** from your Azure Application. If you did not copy it earlier, follow these steps:
  - a. In Azure, select **More Services** from the bottom of the left menu.
  - b. Enter “enterprise” in the filter field, and select **Enterprise Applications**.
  - c. Select **All Applications** from the menu.
  - d. Select your application from the application list.
  - e. Select **Properties**.
  - f. Copy the **Application ID** GUID from the property page.
7. Enter the directory ID. Get the **Directory ID** from Azure. Follow these steps:
  - a. In Azure, select **Azure Active Directory** from the left menu.
  - b. Select **Properties** from its menu.
  - c. Select the **Directory ID** GUID from its property page.
8. Select the Azure Cloud type Azure Commercial Cloud or Azure US Government. Azure US Government is used by all government agencies. Any PAM instance that is deployed on behalf of the US government requires the Azure US Government cloud type.
9. Accept or changes any other fields as appropriate.
10. Select **OK** to save the Target Account.

### Add an Azure Connection

After you configure your Target Account, configure Azure as a third-party connection in Privileged Access Manager. Follow these steps:

1. Go to **Configuration, 3rd Party, Azure**.
2. Select **Add** on the Azure Configured Connections tab.
3. For **Account**, select the Azure account you created, using the magnifying glass icon.
4. Select your **Subscription ID** from the drop-down list.
5. Select your **Resource Group** from the drop-down list.

6. Select **Sync Virtual Machines** to synchronize Azure Virtual Machines to Privileged Access Manager.
7. Select **Sync SAML Users** to synchronize Azure SAML users to Privileged Access Manager.
8. Select **OK** to save the Azure Connection.
9. Select your new connection from the list and select the **Test** button.

**NOTE**

The SAML **Test** button only works when the IDP has a SSL/TLS certificate that has been signed by a Certificate Authority. The **Test** button fails if the IDP only has a self-signed certificate.

A confirmation message or an error appears above the list.

10. (Optional) Select the **Refresh Interval** tab to set the frequency of the download of information from Azure. You set separate intervals for SAML Users and Virtual Machines. The intervals default to 60 minutes, but can also be set to 5, 15, or 30 minutes.  
To refresh Virtual Machines immediately, use the **Refresh Azure Devices** button on the **Devices, Manage Devices** page.  
To refresh SAML Users immediately, use the **Refresh Azure SAML Users** button on the **Users, Manage Users** page.

**NOTE**

The **Refresh Azure SAML Users** button only appears when [Azure AD as an Identity Provider \(IdP\)](#) is configured. Likewise, the **Sync SAML Users** checkbox has no effect until Azure is configured as an IdP.

**NOTE**

- [Cluster Deployment Requirements for Azure](#)
- [Azure AD as an Identity Provider \(IdP\)](#)
- [Add an Azure AD Target Connector](#)

## Clone a PAM Server Instance on VMware, AWS, or Azure

This content describes how to clone a PAM server instance. Failure to follow these procedures can cause conflicts between the clone and the original server upon which it was based.

### Clone a VMware PAM Server Instance

Use this procedure to clone a VMware PAM server instance.

#### **Follow these steps:**

1. If the donor server instance is part of a cluster, remove it from the cluster until all cloning operations are completed.

**NOTE**

Failure to remove the donor server instance from the cluster can cause the new clone to replicate on behalf of the original the first time it is started. This issue can result in clustering errors (for instance, when the original server instance is started back up again),

2. After the donor server instance has been removed from any cluster, shut down PAM on that server instance to avoid a live snapshot becoming the source of a clone. Leave the server shut down until new IP addresses have been assigned to the clone, so that they do not clash with each other.
3. Use the standard VMware procedure to clone the donor server instance to a new one. Assign *new* MAC addresses to the network interfaces in the process.
4. Verify that the donor server instance is still shut down then start the clone server instance.
5. Assign a new host name and IP addresses to the clone.
6. Once the clone server instance has been restarted with a new IP address, start the donor server instance back up and rejoin it to a cluster if desired.
7. Reset the database on the new clone.

## Clone an AWS PAM Server Instance

Use this procedure to clone an AWS PAM server instance.

### Follow these steps

1. If the donor server instance is part of a cluster, remove it from the cluster until all cloning operations are completed.  
**NOTE**  
 Failure to remove the donor server instance from the cluster can cause the new clone to replicate on behalf of the original the first time it is started. This problem can result in clustering errors (for instance, when the original server instance is started back up again),
2. After the donor server instance has been removed from any cluster, shut down PAM on that server instance to avoid a live snapshot becoming the source of a clone. Leave PAM shut down until new IP addresses have been assigned to the clone, so that they do not clash with each other.
3. Use the AWS Management Console to create an instance from the original donor server instance.
4. Once the cloned server instance is ready, start it up.
5. Restart the donor instance and rejoin it to a cluster, if appropriate.
6. Reset the database on the new clone.

## Clone an Azure PAM Server Instance

Azure does not support cloning as such. Instead, you convert an instance to a template and then use that template as the basis for new instances.

### NOTE

When you convert an instance to a template, verify that you first remove it from a cluster if it belongs to one.

## Deploy the Hardware Appliance

The following topics provide information about the Lanner 404L hardware appliance, and instructions on how to install it:

No software installation is required on the appliance.

### Unpack the Hardware Appliance from the Packaging

The hardware appliance package contains, at minimum, the items identified in the following table. If any of these items are missing, contact Broadcom Support.

Item		404L (Dual Power Supply model)	
No.	Name	Quantity	Illustrations / Notes
1.	L-shaped brackets	4	
2.	Sliding rail assemblies	2	Each sliding rail assembly can be separated into an inner frame and an outer frame assembly. 

2a.	Inner rail frame	1 per sliding rail assembly	The inner frame (or inner rail) has an outer safety lock (see step 2c.) for securing it to the appliance.
2b.	Outer rail frame assembly	1 per sliding rail assembly	The outer frame assembly consists of two heavy-gauge rail frames (center rail and outer rail) that incorporate a ball-bearing slide. One frame attaches and allows extension of the two frames. The other frame allows extension of the inner rail frame with the center rail. The rail assembly has an inner rail frame that, with two L-shaped brackets, is attached to the rack.
3.	Short flat-head screws	8	
4a.	Long flat-head screws	8	
4b.	Nuts for long flat-head screws	8	
5a.	Flat countersink screws	12	
5b.	Conical washers for flat countersink screws	12	
6a.	Front ear brackets	2	
6b.	Ear bracket screws	6	
7.	Appliance chassis	1	

8.	Power cords	2	
9a.	Console cable	1	
9b.	Ethernet patch cord	1	

### **Mount the Hardware Appliance in a Rack**

With the provided equipment, you can mount the appliance into a standard rack.

1. Remove the two rail assemblies from their packaging.

*Model 404L rail assembly, inner side up*

2. Separate the inner rail frame from the outer and center rail frames on each of the two assemblies:
  - a. Place one rail assembly as shown:

*Model 404L closed frame assembly, inner side up*

- b. Slide the inner rail frame all the way to the left. The frame stops at about half its length:

*Model 404L inner rail extended to left, inner side up*

- c. Turn the assembly upside down so that its outer side is visible as shown here:

*Model 404L inner rail that is extended to left, outer side up, with arrow*

- d. Press down the outer safety lock tab (indicated by the arrow), and – holding the tab down – pull the inner rail frame firmly to the left so that it is removed.

*Model 404L separation of inner and outer rail*

- e. Repeat this inner rail frame separation with the other rail assembly.
3. Attach the inner rail frames and ear brackets to the appliance chassis
  - a. Align the three indicated mounting holes of the inner rail to the screw holes on the chassis frame with the outer safety lock tab facing out and the notched end of the rail that is located at the rear of the unit. (These are connected by vertical dashed lines in the figure.) Attach it to the appliance using three of the short flat-head screws.
  - b. Attach one of the two front ear brackets to the chassis using the small black screws provided in the ear bracket package.  
The two attached parts should now appear as in this diagram:
  - c. Repeat these steps to attach the other inner rail and front ear bracket to the other side.

*Model 404L inner rail and Ear bracket attachment to appliance chassis*

*Model 404L ear bracket and inner rail frame mounted on the right side of appliance*

The L-shaped brackets secure the outer rail frame assembly to the rack. Attach these brackets to the outer rail assemblies first, before attaching the combination to the rack.

4. Attach two L-shaped brackets to each of the two outer frame assemblies:

a. On one outer rail assembly, attach an L-shaped bracket at each end:

**Front bracket:** Close the outer rail assembly so that the center rail frame is lined up or flush with the outer rail frame. Slide the inner ball bearing assembly all the way to the right to expose four oval holes on the left.

*Model 404L outer rail assembly closed, inner side facing up, with ball bearing assembly slid to right.*

Locate an L-shaped bracket so that the curved edge on the bracket wraps around the outer rail assembly outer frame (when held up on its side edge as shown), and the left end of the bracket points down toward you.

*Model 404L: Orientation of the L-shaped bracket against outer rail assembly*

Insert a long flat head screw (see Package Contents Table, Item 4a) through the first oval hole on the inner frame of the frame assembly, through to the outer frame, then through the L-shaped bracket long groove, and finally attach (but not tighten) a nut (see Package Contents Table, Item 4b) to the end of the screw. Repeat this with a second screw and nut through another pair of rail holes. (The third or fourth hole pair provides the best support. The additional two hole pairs are intended for alternative equipment that is not used here.)

Do not tighten the nuts yet because you need to adjust the location of the brackets when you mount the bracket-rail assembly to the rack.

*Model 404L: Front bracket onto outer rail assembly, inner side view, with screw and nut before attachment*

**Rear bracket:** Slide the outer rail away all the way to the right so that the inner safety lock snaps in place, exposing the screw holes on the outer rail:

*Model 404L: Outer rail assembly after sliding the outer rail (on the bottom side) to the right*

Attach the second L-shaped bracket to the other end of the outer rail with two long flat head screws, one through the first or second oval hole (Figure 176) from the center, and one through the third oval hole near the end.

*Model 404L: Rear bracket onto left outer rail assembly, inner side view, with screw and nut before attachment*

- b. Repeat these steps to attach the other two L-shaped brackets to the other outer rail assembly. When you turn the assembly around so that its outer edge faces you, it should appear with the brackets loosely mounted (for now):

*Model 404L: Outer and center rails with brackets (loosely) attached (Step 4), front at left, outer side view*

5. Mount each bracket-rail assembly to the rack in an appropriate rack bay:
  - a. Install the outer rail with the attached bracket to the front rack post by using two countersink screws and, if the rack holes are not pre-threaded (which might require clips), the conical washers provided. Note that the front end of the rail assembly has a black plastic H-shaped component.
  - b. Extend and adjust the rear bracket to meet the depth of the rack and secure it to the rack post with two countersink screws and conical washers.
  - c. Repeat steps (a) and (b) above to install the other rail to the other side of the rack.
  - d. You can now use a wrench to tighten the nuts and the screws that attach the L-shaped brackets to each of the rails.

*Model 404L: Right side rail, with the front bracket attached, mounted at the front right side of rack*

6. Place the appliance (with ear brackets and inner rails attached) in the rack, as shown here:

*Model 404L: Placing the appliance into the rack*

7. Slide the appliance into the frame. As you do, hold the tabs on the outer safety locks (as in 2.d.) on the left and right sides of the appliance, so that the appliance can slide all the way in, while the attached inner rails are prevented from sliding back out.
8. Attach the ear brackets to the frame through their remaining (center) holes.
9. Connect the Ethernet patch cable to an Ethernet port on the front panel (example: port **1**, which corresponds to **GB1** in the LCD and GUI interfaces), and to the network.
10. Connect the power cords to the two PSUs and to outlets.

### **Configure Network Connections for the Appliance**

After the appliance is installed and optionally, mounted in a rack, [Configure Network Connections for the Appliance](#).

### **Appliance Power Supply Units**

Each power supply is a modular unit that slides out of the appliance for offline replacement or repair. The power supplies are held in place by release levers that are easily accessible when facing the rear of the appliance. Each power supply unit (PSU) uses a standard detachable power cord.

If the power supplied to the appliance is interrupted (power fails or a supply unit is removed or unseated), the unit sounds a steady alarm tone. This alarm continues until the **silence switch** turns off the alarm.

The silence switch is a small button at the back of the unit, immediately to the left of the power supplies. Press the silence switch to turn off the alarm. After the switch is pressed, it is reset only after the power is restored and recycled back to each appliance. Power restoration means that each power supply is seated in the appliance, and that each power cord is plugged in to a live power outlet.

## Hardware Appliance Specifications

The Dual Power Supply Model 404L hardware appliance provides redundant modular power support to promote continuous uptime. The hardware appliance can host any supported PAM release and has the following specifications:

Item	Description
<b>System components</b>	
Chassis	1U IPC
Power Supply	Redundant dual hot-swappable 300-W Power Supply Units (PSUs)
System Board	Intel C236 Chipset (Skylake PCH)
CPU	Intel Xeon E3-1275v6 processor Quad core (8 threads)
Memory	64-GB DDR4 2400MHz DIMM with ECC support
Primary Storage	240-GB Solid-State Drive (SSD)
Secondary Storage (Backup)	240-GB Solid-State Drive (SSD)
Display	2 line x 20 character LCD
<b>Standard interfaces</b>	
Network	Eight (8) 1-Gigabit Ethernet Ports
LCD inputs	Four-button control
Serial	One RJ-45 Console Serial Port
USB ports	Not functional
<b>Physical specifications</b>	
Height	1.73" (44 mm)
Width	17.2" (438 mm)
Depth	18.4" (468 mm)
Unit Weight	15.4 lb (7 kg)
Enclosure	Fits standard 19" rack
<b>Environmental specifications</b>	
Storage Environment	-20 Celsius to 70 Celsius 5 - 95 percent RH, noncondensing
Operating Environment	0 Celsius to 40 Celsius 5 - 90 percent RH, noncondensing
Cooling	Processor: Passive heatsink System: 3x cooling fan

## Configure Network Connections for the Appliance

After you set up the hardware appliance, configure the IP network interfaces so the appliance can access a network. You can set up your network connections using the LCD panel, the PAM UI, or a Console port. The appliance is inaccessible to the network until its IP address is assigned.

### Use the LCD Panel to Configure Network Connections

The LCD panel on the front of the appliance provides the interfaces to complete the initial hardware setup and network configuration. The LCD panel is a two-line, 16-character-per-line LCD display.

**TIP**

To connect to a device that cannot auto-negotiate speed or the duplex mode such as older switches and hubs, use the UI.

**Using the LCD Panel Menu**

Familiarize yourself with the LCD Menu on the front of the hardware appliance. The menu allows for basic network configuration of the device.

The LCD Menu Control has four buttons under the LCD Menu Panel, from left to right: < ^ v >. These buttons function as follows:

Button	Functions
< (left arrow)	<ul style="list-style-type: none"> <li>Move Left</li> <li>Undo/Cancel</li> </ul>
> (right arrow)	<ul style="list-style-type: none"> <li>Move Right</li> <li>Enter/Confirm</li> </ul>
^ (up arrow)	<ul style="list-style-type: none"> <li>Move up</li> <li>Increase value</li> </ul>
v (down arrow)	<ul style="list-style-type: none"> <li>Move down</li> <li>Decrease value</li> </ul>

**NOTE**

Older hardware appliances have an ENTER and an ESC button instead of the left and right arrows. Use the ENTER button to move right or to confirm an entry. Use the ESC button to move left or undo an entry.

The LCD menu includes the following options to operate the appliance:

**Network Setup**

This option allows the installer to provide the required network configuration to get the appliance operational. Use the Up or the Down arrows to navigate through the menu.

Menu item 1:	Network Setup
--------------	---------------

**Reset Password**

This option resets the configuration password to the default password. Select the left arrow and the password is reset. A message displays after a successful reset.

Menu item 2:	Reset Password	After selecting >:	Password reset!	After about 30 seconds:	Reset Password
--------------	----------------	--------------------	-----------------	-------------------------	----------------

**Reboot**

This option reboots the appliance. After you power down and restart the appliance, the LCD displays the Network Setup screen.

Menu item 3:	Reboot	After selecting >:	Rebooting...	After about 60 seconds:	Shuts down, Boots up
--------------	--------	--------------------	--------------	-------------------------	----------------------

**Power Off**

This option turns off the power, displaying the following message:

Menu item 4:	Poweroff	After selecting >:	Powering off...	After about 30 seconds:	Shuts down
--------------	----------	--------------------	-----------------	-------------------------	------------

The power switch remains in the "on" position, but you can switch it off.

### Halt

The **Halt** command stops all processes. The power is still on, but the device is unusable because all processes are stopped. The LCD has the following display:

Menu item 5:	Halt	After selecting >:	Halted.	After about 15 seconds:	Shuts down
--------------	------	--------------------	---------	-------------------------	------------

Use the Halt command when the power must remain on. For example, if a monitoring system raises alarms due to power loss, use Halt.

### Turn On FIPS

This option turns on FIPS mode. FIPS mode is fully compatible with PKI smartcard use, including the US DoD CAC system.

The LCD Menu option turns on the FIPS flag and reboots the appliance when it switches to FIPS mode.

- Use FIPS mode only when applicable. After the FIPS mode is activated, the LCD is no longer available for configuration. Use the UI to make all subsequent changes.
- To operate with socket filters in FIPS mode, the monitored devices must have release 2.7 or later Socket Filter Agents (SFAs).
- If for any reason FIPS activation fails, the LCD displays: PATCH FAILED / UPGRADE ABORTED. If this failure happens, the appliance cannot be revalidated until after it is returned to CA Technologies.

Menu item 7 (if set):	Turn on FIPS	After selecting >:	[several process messages]	Reboot ->	in FIPS mode
-----------------------	--------------	--------------------	----------------------------	-----------	--------------

### Basic Network Configuration Using the LCD Panel

After the appliance powers up, perform the basic network configuration using the menu on the LCD panel. The following steps assume that you have installed the appliance.

#### Follow these steps:

1. Connect the desired number of Ethernet cable connections to ports 1 through 8 on the appliance. These ports correspond to GB1 through GB8 in the LCD and UI interfaces.
2. Connect the power cord, first to the appliance and then to an outlet.
3. Power up the appliance:
  - a. Turn on the power switch on the back of the appliance. Hold the switch until the unit powers on.
  - b. Verify that the LCD is lit, indicating power.

During power-up, the menu cycles through several message screens until boot is complete.
4. Navigate to the **Network Setup** menu item on the screen, and press the right arrow (>).

The first screen is the **Default Gateway**:

```
Default Gateway
000.000.000.000
```

5. To configure the Default Gateway IP address, set the value of a digit for each digit position in the address. Use the up and down arrows to go through and select an integer from 0 to 9. Move to the other positions in the IP address using the > (forward) or < (backward) arrows. Complete this process for each address you want to configure. Each octet is expressed on the display using three digits. For each octet that is less than 100, the first characters are zero. For example, the address 10.44.146.3 is expressed in the LCD as 010.044.146.003

#### NOTE

These settings are saved when the Save option later in the procedure. For the settings to take effect after saving, the appliance must first be rebooted.

6. After you have set the last position in the IP address, press > to go to the next screen Interface Setup. To cancel the Network Setup and return to the Network Setup menu, press the left arrow.
7. Press > to go to the **Pick Interface** screen. This screen shows the interface available for configuration.
  - a. Use the arrows to select the label GB1 through GB8 corresponding to the label of the desired Ethernet port (1 through 8).
  - b. Use the up and down arrows to go through and select an integer from 0 to 9
  - c. Press > to set the IP address for the selected interface.
8. After setting the interface, enter the netmask for the same interface, on the **Netmask for GBn** screen.
9. At the final Interface Setup screen, enter one of the following options. Use the up and down arrows to position the arrow on the option and press > to enter this selection.

```
Interface Setup
Cont/Sav/eXit C
```

- Select **Cont** (Continue) to repeat the procedure for another interface.
- Select **Sav** (Save) to save your configuration.
- Select **X** (exit) to discard all network settings that you configured after the last save and restore the previous settings.

The LCD returns to the Network Setup display.

10. From Network Setup, navigate to **Reboot**, and press the forward arrow (>).

The appliance reboots and it is ready for configuration.

### Use the UI to Configure the Network Connections

An alternative to the LCD panel for network setup is the PAM UI. If your device is unable to auto-negotiate speed or the duplex mode, use the UI to configure the network connection.

The following steps assume that you have installed the appliance.

#### Follow these steps:

1. Configure a PC with a static IP address of: 192.168.98.x, where x is not 100. The IP address of GB1 as shipped is 192.168.98.100.
2. Connect this PC directly to the **1** port on the front of the appliance. Port 1 corresponds to **GB1** in the UI. This port is auto-sensing, so you do not need a crossover if using a laptop with the same.
3. Open a Java-enabled browser and enter the following URL, including the slash at the end  
<https://192.168.98.100/config/>  
 The trailing address slash is required.
4. Log in to the UI:
  - a. Accept the license
  - b. In the Windows Security pop-up window which follows, enter the default configuration username/password (config/config)
 The **Configuration, Network Settings** page appears.
5. Set the appropriate values in the **Network Settings** and **Network Interfaces** sections.

6. (Optional) Speed autosensing does not work with all network appliances. If you experience connectivity issues, set the **Speed** and **Duplex** settings to static values for the network interfaces.
7. Click **Update** when you are finished configuring the settings.
8. Click **Restart Networking** to commit your changes. While the network is restarting, the appliance is temporarily unavailable.
9. After the browser refreshes, use the Toolbar: **Logout** button (in the upper-right corner) to end your session.
10. Confirm that your settings have been correctly configured by accessing the login page using your newly assigned address.

### **Use the Console Port to Configure Network Connections**

If you cannot use the LCD Panel or the UI, use the Console port. The Console port is above the nonfunctional USB ports. This port enables you to connect the appliance to a monitor. A console cable is supplied.

Note the following port specifications:

- Speed: **115200**
- Data bits: **8**
- Stop bits: **1**
- Parity: **none**
- Flow control: **XON/XOFF**

## **Deploy the PAM Client**

The PAM Client is a fully functional alternative to the Web browser UI. Use the Client to access Privileged Access Manager and perform administrator and end-user activities. The Client eliminates the need to keep browser configurations compatible with the product. The Client does not interfere with browser-based UI access – you can use both methods from the same workstation. See [Supported Environments](#) for information about where you can run the PAM Client.

Complete the following procedures to deploy the Client.

### **Download the Client Software**

Download a client version compatible with your workstation OS type from the browser-based UI login page. To install the PAM Client, the user needs the same user rights or permissions as any other application that you install.

#### **Follow these steps:**

1. From your client workstation, open a browser and navigate to the URL of a PAM server using *one* of the following formats:

`https://server_ip_address/`

`https://fqdn_of_server`

where `server_ip_address` or `fqdn_of_server` is the system where you installed the PAM server.

#### **NOTE**

If you enter an IPv6 address, make sure to enclose the address in brackets. For example:

`[2001:db8:3333:4444:5555:6666:7777:8888]`

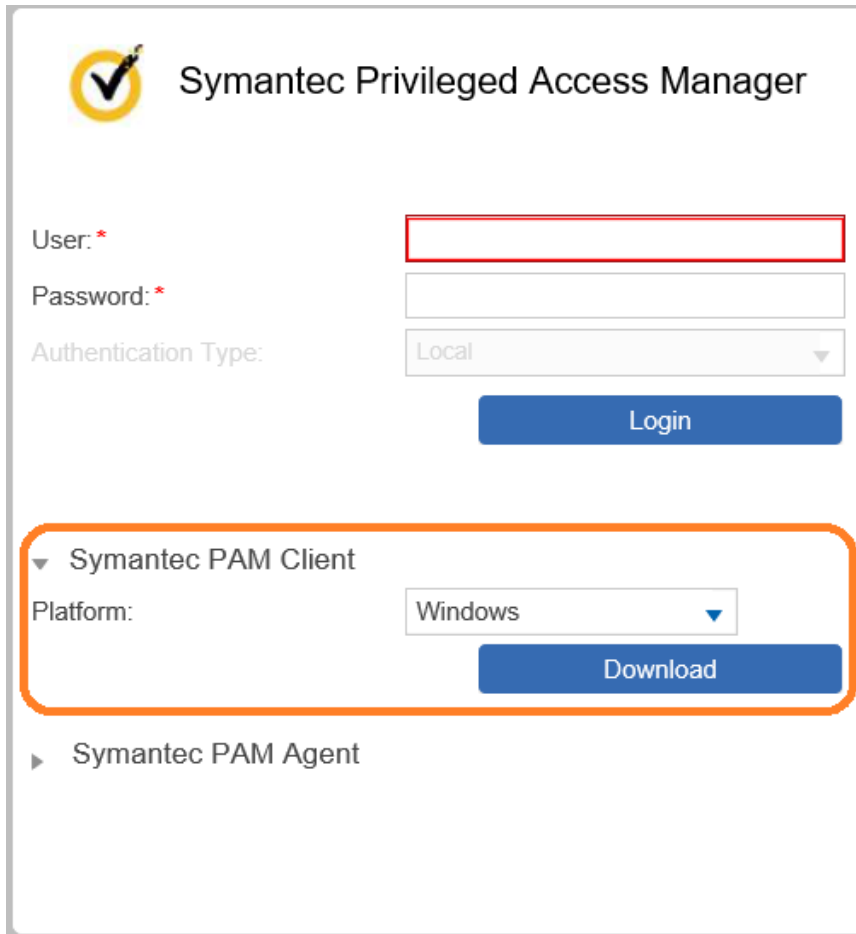

Examples:

– IPv4: `https://102.200.11.222/`

– IPv6: `https://[2001:db8:3333:4444:5555:6666:7777:8888]/`

– FQDN: `https://capam.forwardinc.com`

2. When the PAM UI login screen opens, select the arrow next to **Symantec PAM Client**. Context-sensitive controls open as highlighted in the following screen capture:

 Symantec Privileged Access Manager

User: \*

Password: \*

Authentication Type: Local

▼ Symantec PAM Client

Platform: Windows

► Symantec PAM Agent

3. In the **Platform** field, select the OS for your local workstation then select **Download**.
4. Save the installer file locally to your workstation.

### **Install the Client**

Refer to the appropriate instructions:

- [Specific macOS Instructions](#)
- [General Instructions](#)

### **Specific macOS Instructions**

After you download the installer file, extract the file and run the Client installer.

#### ***Use Sudo to Install***

For macOS, you can optionally use `sudo` to launch the installation. The installed files are then owned by `root`, preventing standard users from modifying the installed application files. With `root` ownership of the files, multiple users can concurrently use the same client installation. Use the following `sudo` command for `root` ownership:

```
sudo ./CAPAMClientInstall.app/Contents/MacOS/CAPAMClientInstall
```

The command "`sudo open CAPAMClientInstall.app`" does not give the ownership of the files to `root`.

If you install as `sudo`, the administrator password is only needed by during installation. However, if you do not install using `sudo`, you will only need the administrator password at run-time to use the SSH Proxy or SFTP Proxy. Everything other than the SSH Proxy or SFTP Proxy works without the administrator password.

#### NOTE

Sudo access is only necessary during installation. To distribute the PAM Client without user intervention, see the following:

- [Configure How the Client is Made Available](#)
- [PAM Client Silent Install](#)

PAM Client is a native macOS app with its own icon that appears in the dock.

#### NOTE

To log in to a PAM appliance from a macOS PAM Client, add the user certificate to the login keychain and system keychain. Adding the certificate prevents the user from being repeatedly prompted for login credentials.

### Multiple macOS Instances

To open multiple instances of the macOS PAM Client, invoke the binary `/Applications/CA PAM Client.app/Contents/MacOS/CAPAMClient` directly or use this command from terminal: `"open -n /Applications/CA\ PAM\ Client.app"`. Clicking the PAM Client app icon in Finder multiple times does not result in opening multiple instances.

### MacOS Subpixel Antialiasing

If you are using macOS Mojave with Subpixel Antialiasing disabled, the content in the Privileged Access Manager user interface may appear blurred. Re-enable Subpixel Antialiasing to fix this issue:

1. Open a Terminal.
2. Run the following command:

```
defaults write -g CGFontRenderingFontSmoothingDisabled -bool NO
```

3. Log out and log back in for the change to take effect.

### General Instructions

After you download the installer file, run the Client installer.

#### NOTE

If you install the Client in a UNIX environment, the UNIX system must have the necessary graphic libraries to show the PAM Client UI. Otherwise, when you run the Client, the Client exits without showing any error message in the log.

If the PAM Client starts, but the Dashboard Overview Tab is blank, the required libraries for the JxBrowser might be missing. To see which libraries are missing, go to the PAM Client installation folder and review the logs.log file. Install any missing libraries.

Follow the installation wizard, noting the following instructions:

- **License Agreement:** To accept the license agreement, scroll through the license text to the bottom of the panel.
- **Choose Install Set:** Select one of the following options:
  - **Typical:** Prompts you for an installation directory on your local workstation then installs the Client.
  - **Run:** Extracts the contents to a temporary location and runs the Client. The setup completes and the login screen appears.
- **Choose Install Folder:** Enter a path, or select the **Choose** button to find a folder. Consider the following options:

- If you use the default, ensure that the intended user has "Full control" of this folder. For example, a typical user might not have the required permissions to run the Client in the default folder.
- For a multi-user shared installation, select a directory where all users have write access. Another option is for each user to install the client separately in their own user folder, such as `c:\Users\<user>\`.
- For silent installation, see [PAM Client Silent Install](#).
- The PAM Client does not support installation in directories whose names include Japanese characters. If you install the PAM Client on a Japanese-language computer, enter a folder with no Japanese characters.

After the installation is complete, you can log in from the Client.

If you start the Client on a UNIX system and the UI Dashboard Overview Tab is blank, the libraries that the JxBrowser needs might be missing. To determine which libraries are missing, go to the Client installation folder and look at the `logs.log` file. This file lists the missing libraries are listed. Install those libraries.

### Log in from the Client

After the Client is installed, you can log in to the server. The initial client screen allows you to specify the address of a Privileged Access Manager appliance or appliance cluster VIP.

#### Follow these steps:

1. Open the client application.
2. Enter the following connection parameters for your server appliance.
  - **Address:** Enter the IP address in the form `address:port` or the assigned fully qualified domain name of the PAM server.

The PAM Client cannot use most well-known ports. See [Ports Not Allowed for the Client](#) for the full list.

#### NOTE

If you enter an IPv6 address, make sure to enclose the address in brackets. If you want to enter a port number with the IPv6 address, add a colon, followed by the port number. For example:

```
[2001:db8:3333:4444:5555:6666:7777:8888]:443
```

- **Connect Mode:** Select one of the following options:
  - **WEB:** Opens a connection to the server, and then opens a browser window to the UI. The console closes.
  - **CONNECT:** Opens a connection to the server, and displays a status connection console. The status connection console displays connection information and a **Launch Web Browser** and **Log Off** buttons.

You cannot switch between WEB and CONNECT, following your connection to the server. Select **Cancel** to return to the initial connection screen and restart the Client.
- 3. Select **Connect**.
- 4. If a client update is required, you are notified. Select **Update** to update automatically the installed client to the latest version. If necessary, restart the client.
- 5. If applet jars must be downloaded from the PAM server, you are notified. Select **Update** to install the appropriate applet jars automatically.
- 6. You may receive a **Verify Certificate** window before the login screen appears.
  - a. Select **View Certificate** to see the certificate details and evaluate its applicability.
  - b. If you approve of the certificate, select **Import** at the bottom of the dialog. Once it is trusted, you should not see the certificate warning any more.
- 7. When the login screen appears, enter the user name and password.
- 8. Select the **Authentication Type**.
- 9. Select **Login**.

Depending on the Connect Mode that you select, the browser window or the status connection window opens. If the status connection window opens, select **Launch Web Browser** to open the UI. The console window remains open. If you

close the browser window, you can Launch Web Browser later and can return to the same GUI location, as its state is preserved.

You can now use the product.

### **PAM Client Cache**

You can speed up the PAM Client connection to the Privileged Access Manager server by using the client cache. The cache saves reused files, much like any Web browser. The Client does not have a switch to turn the cache on or off. The cache works only if the Privileged Access Manager HTTPS certificate is configured properly. The certificate also must be trusted globally or in the local network or organization. The certificate cannot be trusted only by the client. Your whole system (OS) must trust the certificate. You can test whether your connection to the server is trusted by connecting with a Chrome browser. If you receive a Certificate warning such as "Your connection is not private," the cache is not used.

The PAM Client manages its own cache, but you may want to clear your PAM Client cache. To clear the PAM Client cache, delete this directory when all client processes have been terminated: `<client_root>\temp\web-cache`.

### **Modify Client Configuration Settings (Optional)**

The Client configuration settings specify operational behavior of the Client. Usually, the default Client configuration settings work for your environment. If necessary, you can modify the configuration settings.

#### **Follow these steps:**

1. From the Client login page, open the **Configuration Settings** window by selecting the gear icon in the lower-left corner
2. Select the relevant tab to change the following settings:

#### **Proxy**

##### **NOTE**

PAM only supports **Secure** (HTTPS) proxy.

Indicates whether the PAM Client is connecting to the PAM server through a proxy server. Select one of the following options for your deployment:

- No Proxy (default): The Client connects directly to the PAM server.
- Auto-detect proxy settings for this network: for a network-managed proxy
- Use system proxy settings: for workstation OS-managed proxy
- Manual system proxy configuration: for a custom target device as the proxy
- Automatic proxy configuration URL: for a web server-supplied proxy
- Ignore proxy certificate: This setting determines whether PAM trusts the proxy certificate. If the certificate is not trusted, the PAM Client cannot connect to the server. For security reasons, the setting is *unchecked* by default. If the Client keeps getting disconnected, it might be a result of a certificate mismatch. To avoid this problem, select this check box; however, this option is less secure.

#### **General**

Specifies memory for the Client.

- **Max memory size:** default (Windows, Linux x86): 1024 MB; (Mac, Linux x64): 2048 MB  
For Windows, 1200 is the maximum value. If the value is set to 1201 MB or greater, the client does not start again. If it does not restart, edit the **settings.properties** file at the installation root. Reset the **memory.max** parameter to 1200 or less and save the file.
- **Client language**  
By default, the Client automatically detects the language of the host computer OS and displays the user interface in that language, if available. To change the Client from the default to another language, clear the **Auto-detect** checkbox, and select a language from the **Client language** drop-down list.
- **Restore security prompts**

If you have previously selected a checkbox to ignore a security warning, selecting this **Restore** button causes the warnings to resume.

– **Use Host Address IP**

Set this option if PAM Client login attempts fail with "Unknown Error" messages.

**Cache**

Specifies the cache of previous PAM Client versions.

- **Enable Caching:** Stores previous versions for the PAM Client to revert to an earlier version. Default = On (checked).
- **Current Cache Size:** Specifies the total size of the cached versions of the PAM Client. Default: Total size of cached prior versions.
- **Clear Cache:** Specify to remove all cached versions. (You can remove individual versions by using the Manage button.)
- **Max Cache Size, MB (0 = unlimited):** Specify the maximum size of the cache by using the slider or the field.
- **Cached Versions:** Displays the number of cached versions.
- **Manage:** Displays details for all cached versions of the PAM Client. You can remove any or all versions.

**Certificate**

From a table list, specify a certificate authority (CA) certificate to be used. The PAM Client is provided with several preinstalled certificates. Add more if needed.

3. Select **OK** to save your settings.

**(Optional) Disable PAM Client Update Checking**

Use the following procedure to disable automatic update checking on PAM Clients that are experiencing startup issues.

**Follow these steps on each system on which a PAM Client is installed in your environment:**

1. Shut down any PAM Client instances that are running.
2. In the PAM Client installation folder, create a file called **update** with no file extension.
3. Open the **update** file with a text editor and entering the word `false`. Save and close the file.
4. Set permissions for the update file. For administrators, set full permissions. For users, set read-only permissions.
5. Launch the PAM Client and connect to the server.
6. If you see the message "Synchronization is Required," complete the following steps:
  - a. Select the gear icon in the left corner of the login dialog
  - b. Click Cache and select the following settings:
    - Enable Caching
    - Keep instances for reuse
  - c. Launch the PAM Client again and connect to the server.

**NOTE**

To re-enable update checking, delete the **update** file or edit it to remove the word `false`.

**Uninstall the Client**

**NOTE**

Starting from 4.1.3, the **CAPAMClient** binary and the **CAPAMClientInstaller** binaries are now 64-bit. The Java version for the PAM client has also been updated to use Java 17.

To use the latest PAM client, you as admin must either:

- Upgrade their existing PAM client to point to a 4.1.3 (or later) PAM instance,
- OR
- Use the installer to install the latest version of the PAM client.

If you choose to upgrade the existing PAM client to version 4.1.3, you cannot use the existing PAM client installer to uninstall this new version.

To uninstall the upgraded 4.1.3 PAM client, follow these steps:

1. Delete the PAM client installation folder.
2. Manually delete the registry key.

If you installed the PAM client as an administrator, delete the registry key in this location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\Symantec PAM Client
```

If you installed the PAM client with credentials OTHER than an administrator, delete the registry key in this location:

```
HKEY_CURRENT_USER\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\Symantec PAM Client
```

If you choose to install the 4.1.3 or later PAM client, use the installer to uninstall as needed. You do not have to manually clean up the installation.

Follow the instructions for your workstation type:

### **Windows**

Do one of the following tasks to remove the Client:

- Remove the Client from the Windows **Control Panel, Programs and Features**.
- Remove a PAM Client installation from its location in the file directory:
  - a. At the root level of the installation, locate the directory `_/CA PAM Client_installation.`
  - b. Open this directory and run the uninstallation wizard named **Change PAM Client Installation**.

### **Mac**

To remove a Mac installation, you need root privileges. Delete the installation directory and its entire contents.

### **Linux**

To remove a Linux installation, delete the installation directory and its entire contents. Do *not* use the uninstallation wizard that is provided.

#### **NOTE**

Use the table of contents to access the other topics in this section.

## **Configure How the Client is Made Available**

The Client configuration settings reside on the Privileged Access Manager server. These settings determine whether the PAM Client is enabled and how the installer software is made available. By default, the Client is enabled and the installer is available on a CA Delivery Network internet-based CA Delivery Network (CDN) location.

Any user role with the Global Settings permission can modify the Client settings. Preconfigured user roles with the necessary permission include Configuration Manager, Global Setter, and Operational Administrator.

#### **NOTE**

To use the client, access to the client must be enabled. Enabling the download button to appear on the main login page is not sufficient to use the client.

**Follow these steps:**

1. Log in to the UI.
2. Select **Settings, Global Settings**.
3. Select the **Client Settings** tab.
4. Configure the following settings:

**Client Settings:** Accept the default, **Enabled** to use the client. **Disabled** allows only applet use.

**Distribution Method:** Determines how the client installer is downloaded. Select one:

- **Internet (CA Delivery Network):** Delivers the client installer and modules from the internet-based CA Delivery Network (CDN) location.
- **Intranet:** Delivers the client installer and modules from a server at the designated URL. Use this option only when the CDN is unavailable. Provide the FQDN or IP address of the download server using the text box.

**Download Button on Login Page:** Select the checkbox to make the client download buttons appear on the web UI login page.

5. Continue with the setup by deploying the client software.

## Symantec PAM Client Silent Install

You can create a silent installation process for your Symantec Client users.

### Silent Installation for Windows

To install the Symantec Client in silent mode on Windows, add the command line argument “-i silent”.

**For example:** CAPAMClientInstall\_V3.4.5.exe -i silent

You can customize installation arguments in an installer properties file. Create the file `installer.properties` and add the following strings:

```
# Installation mode (Silent)
INSTALLER_UI=SILENT
# Installation directory - use "\\" to separate directories.
USER_INSTALL_DIR=C:\\CAPAMClient
# Installation set (Complete/Upgrade)
CHOSEN_INSTALL_SET=Complete
```

Then, execute using “-f <path to installer.properties file>”.

**For example:** CAPAMClientInstall\_V3.4.5.exe -f installer.properties

### Silent Installation for Linux

To install Symantec Client in silent mode on Linux, you need the command line argument “-i silent”.

**For example:** ./CAPAMClientInstall\_V3.4.5.bin -i silent

You can customize installation arguments in an installer properties file. Create the file `installer.properties` and add the following strings:

```
# Installation mode (Silent)
INSTALLER_UI=SILENT
# Installation directory
USER_INSTALL_DIR=/opt/CAPAMClient
# Installation set (Complete/Upgrade)
CHOSEN_INSTALL_SET=Complete
```

To use the installer properties file, add “-f <path to installer.properties file>”.

**For example:** ./CAPAMClientInstall\_V3.4.5.bin -f installer.properties

## **Silent Installation for macOS X**

### ***Remote Silent Installation***

To install the Symantec Client remotely in silent mode on macOS X, use this command:

```
sudo ./CAPAMClientInstall.app/Contents/MacOS/CAPAMClientInstall -i silent
```

## **Symantec PAM Client Silent Uninstall**

Learn how to uninstall the PAM Client on UNIX and Windows.

Use the following procedures to silently uninstall the PAM Client on UNIX and Windows.

### **Silently Uninstall a PAM Client on UNIX**

Use the following procedure to uninstall a PAM Client on UNIX without displaying any indication of the process or requiring a reboot.

**Follow these steps to silently uninstall the *PAM 4.0 version or later* of the client:**

#### **NOTE**

Version 4.0 rebranded the product to Symantec, resulting in a change in the path.

1. Enter the following command:

```
./<Installation location of PAM client>\_Symantec\ PAM\ Client_installation\Change\  
Symantec\ PAM\ Client Installation -i silent -DUSER_REQUESTED_RESTART=NO
```

**Follow these steps to silently uninstall versions of the client *previous to PAM 4.0*:**

1. Enter the following command:

```
./<Installation location of PAM client>\_CA\ PAM\ Client_installation\Change\ CA\ PAM  
\ Client Installation -i silent -DUSER_REQUESTED_RESTART=NO
```

### **Silently Uninstall a PAM Client on Windows**

Use the following procedure to uninstall a PAM Client on Windows without displaying any indication of the process or requiring a reboot.

#### **NOTE**

Starting from 4.1.3, the **CAPAMClient** binary and the **CAPAMClientInstaller** binaries are now 64-bit. The Java version for the PAM client has also been updated to use Java 17.

To use the latest PAM client, do one of the following operations:

- Upgrade your existing PAM client to point to a 4.1.3 (or later) PAM instance.
- Use the installer to install the latest version of the PAM client.

If you choose to upgrade the existing PAM client to version 4.1.3, you cannot use the existing PAM client installer to uninstall this new version.

To uninstall the upgraded 4.1.3 PAM client, follow these steps:

1. Delete the PAM client installation folder.
2. Manually delete the registry key.

If you installed the PAM client as an administrator, delete the registry key in this location:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\Symantec PAM Client
```

If you installed the PAM client using non-administrative credentials, delete the registry key in the following location:

```
HKEY_CURRENT_USER\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\Symantec PAM Client
```

If you choose to install the 4.1.3 or later PAM client, use the installer to uninstall as needed. You do not need to clean up the installation manually.

**Follow these steps to silently uninstall the PAM 4.0 version of the client:**

#### NOTE

Version 4.0 rebranded the product to Symantec, resulting in a change in the path.

1. Enter the following command:

```
"<Installation location of PAM client>\_Symantec PAM Client_installation\Change  
Symantec PAM Client Installation.exe" -i silent -DUSER_REQUESTED_RESTART=NO
```

**To silently uninstall versions of the client *earlier than PAM 4.0*:** enter the following command:

```
"<Installation location of PAM client>\_CA PAM Client_installation\Change CA PAM Client  
Installation.exe" -i silent -DUSER_REQUESTED_RESTART=NO
```

## Use a Private Content Delivery Network to Distribute the PAM Client Installer

When a user selects the PAM Client download option from the PAM UI logon screen, PAM attempts to retrieve the Client binaries from the Broadcom Public Content Delivery Network (CDN) over the Internet. However, If your site restricts Internet access or if PAM is deployed in a closed network, you must configure a Private CDN to support internal distribution of PAM Client binaries.

### Set Up a Private CDN Repository for PAM Client Binaries

Configure a server that is accessible to all user systems in the PAM environment as the Private CDN repository for the PAM Client binaries.

**Follow these steps:**

1. On the server that is designated as the Private CDN repository, create the following directory structure (exactly as shown) to store the PAM Client binaries:

```
ca-pam/  
+---install/  
    +---linux64    (one or more 64-bit Linux installers)  
    linux86        (one or more 32-bit Linux installers)  
    mac            (one or more macOS X installers)  
    Windows        (one or more Windows installers)
```

For example, you store Linux 32-bit installers in `ca-pam/install/linux86`.

2. From a system with Internet access, download the required PAM Client binaries from the following Broadcom Public CDN addresses each time that you upgrade your PAM environment:

- **Windows:** [https://d21oi5tjuccwe.cloudfront.net/ca-pam/install/win/CAPAMClientInstall\\_Vx.y.z.exe](https://d21oi5tjuccwe.cloudfront.net/ca-pam/install/win/CAPAMClientInstall_Vx.y.z.exe)
- **macOS:** [https://d21oi5tjuccwe.cloudfront.net/ca-pam/install/mac/CAPAMClientInstall\\_Vx.y.z.zip](https://d21oi5tjuccwe.cloudfront.net/ca-pam/install/mac/CAPAMClientInstall_Vx.y.z.zip)
- **UNIX:** [https://d21oi5tjuccwe.cloudfront.net/ca-pam/install/linux64/CAPAMClientInstall\\_Vx.y.z.bin](https://d21oi5tjuccwe.cloudfront.net/ca-pam/install/linux64/CAPAMClientInstall_Vx.y.z.bin)

The `x.y.z` represents the required PAM version number. For major releases, omit the `.z`. For example, to obtain the Windows binary for PAM 4.1.5 use the following address:

[https://d21oi5tjuccwe.cloudfront.net/ca-pam/install/win/CAPAMClientInstall\\_V4.1.5.exe](https://d21oi5tjuccwe.cloudfront.net/ca-pam/install/win/CAPAMClientInstall_V4.1.5.exe)

**NOTE**

If you cannot access the Broadcom public Internet CDN, contact Broadcom Support.

- Copy the downloaded binaries to the appropriate directories on the Private CDN repository. For example, copy Linux 32-bit installers into `ca-pam/install/linux86`

**NOTE**

If a PAM Client connects to a newer PAM server, it automatically upgrades to the new version upon connecting to an upgraded PAM server, using the binaries in the Private CDN.

**Configure PAM to Use the Private CDN**

Once the Private CDN repository is set up, configure PAM to use it by modifying the Client settings.

**Follow these steps:**

- Log in to the PAM UI using an account whose user role has the Global Settings permission (for example, Configuration Manager, Global Setter, or Operational Administrator).
- Go to **Settings, Global Settings, Client Settings**.
- For the Private CDN server in the intranet server (`https://`) field **Distribution Method**, select **Intranet** and enter the fully qualified domain name or IP address of the server of the Private CDN server in the **Intranet Server** field.  
For example, `myserver.example.com/`.  
If the server requires a specific port, add a colon (:) followed by the port number as shown in the following example:  
`myserver.example.com:8080`.
- Select **Save**.

The Private CDN is operational. When a user selects the PAM Client download option from the PAM UI logon screen, PAM retrieves the PAM Client binaries from the Private CDN.

**Ports Not Allowed for the Client**

The PAM Client and the PAM Access Agent cannot use the ports that are listed in this table. TCP and UDP ports are not permitted for incoming or outgoing communication. If you are having trouble connecting to the server through the Client or Agent, verify whether a proxy is configured using an invalid port.

You can see the port assignment in the Client or Agent configuration settings:

- From the Client login page, select the gear icon in the lower-left corner.  
The port setting is on the Proxy tab of the Configuration Settings window.
- For the Agent, select the Options menu, and Proxy.  
The port setting is available for the Manual Proxy Configuration option.

Invalid Ports			
1 tcpmux	53 domain	123 NTP	556 remotefs
7 echo	77 priv-rjs	135 loc-srv /epmap	563 nntp+ssl
9 discard	79 finger	139 netbios	587
11 systat	87 ttylink	143 imap2	601
13 daytime	95 supdup	179 BGP	636 ldap+ssl
15 netstat	101 hostriame	389 ldap	993 ldap+ssl
17 qotd	102 iso-tsap	465 smtp+ssl	995 pop3+ssl
19 chargen	103 gppitnp	512 print / exec	2049 nfs
20 ftp data	104 acr-nema	513 login	3659 apple-sasl / PasswordServer

21 ftp access	109 pop2	514 shell	4045 lockd
22 ssh	110 pop3	515 printer	6000 X11
23 telnet	111 sunrpc	526 tempo	6665 Alternate IRC [Apple addition]
25 smtp	113 auth	530 courier	6666 Alternate IRC [Apple addition]
37 time	115 sftp	531 chat	6667 Standard IRC [Apple addition]
42 name	117 uucp-path	532 netnews	6668 Alternate IRC [Apple addition]
43 nickname	119 nntp	540 uucp	6669 Alternate IRC [Apple addition]

## Deploy the PAM Access Agent for Windows

The PAM Access Agent is a lightweight Windows alternative to the PAM Client.

### PAM Access Agent Advantages

The PAM Access Agent has the following advantages:

- It does not use Java or applets.
- It tunnels through Privileged Access Manager to devices.
- It does not require the configuration of loopback addresses.
- It does not contain a browser, so it does not support Privileged Access Manager administration.
- It has a much smaller installer, storage footprint, and memory requirement.
- It uses Services instead of Access Methods
- It allows viewing of credentials

### PAM Access Agent Feature Support

Service	Network Redirection	Auto-Login	Session Recording	Command Filters	Socket Filters
SSH	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>
SSH Transparent Login	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	No	No
RDP	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	No	<b>Yes</b>
RDP Applications	No	No	No	No	No
RDP Applications with Transparent Login	No	No	No	No	No
Web Portal*	<b>Yes</b>	No	No	No	No
VNC	<b>Yes</b>	No	<b>Yes</b>	No	No
Telnet	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>
TN3270 / SSL	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>
TN5250 / SSL	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>

\*Web Portal does not support the PAM Browser.

Authentication Method	Support
Local	Yes
LDAP / AD	Yes
RADIUS / TACACS+	Yes
LDAP+RADIUS	Yes
LDAP+RSA	Yes
SAML	No
CA Single Sign-On	No
PIV/CAC / Smart Card	No

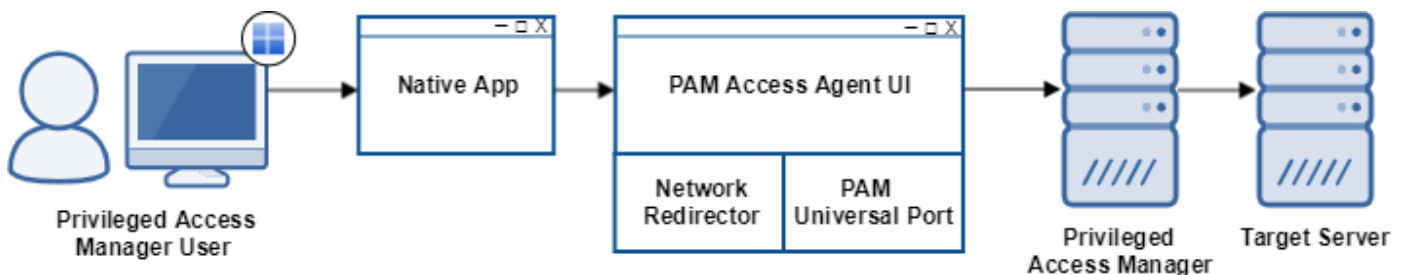

### ***Retrospective Approval Not Supported***

Retrospective Approval (Break Glass) for Password View Requests is a new feature that is not supported yet in the PAM Access Agent.

### **How the Agent Works**

You activate a service in the agent, then network traffic to the target device for that service is redirected and tunneled through PAM. The new agent Universal Port (UP) for Windows provides the service connection capability into PAM. For each activated service and target device, the UP generates the ephemeral port number on which the UP is listening for connections. Client applications (such as PuTTY) work seamlessly using the same public IP address and port they typically use for that connection. Once the service is deactivated, the client application is available for use with targets that are not protected by PAM.

**Figure 16: PAM Access Agent Architecture**

### **Download the Agent Software**

Download the PAM Access Agent for Windows from the browser-based UI login page. To install the PAM Access Agent for Windows, the user needs the same user rights or permissions as any other application that you install.

### **Follow these steps:**

1. From your client workstation, open a browser and navigate to the URL of a PAM server using *one* of the following formats:

`https://server_ip_address/`

`https://fqdn_of_server`

*server\_ip\_address* or *fqdn\_of\_server* is the system where you installed the PAM server.

Examples:

- <https://102.200.11.222/> (IPv4), [https://\[fd6d:8d64:af0c:1:0:242:22:233\]](https://[fd6d:8d64:af0c:1:0:242:22:233]) (IPv6)
  - <https://capam.forwardinc.com>
2. When the PAM UI login screen opens, select the arrow next to **Symantec PAM Agent**. Context-sensitive controls open as highlighted in the following screen capture:

The screenshot shows the Symantec Privileged Access Manager login interface. At the top, there is a logo and the title 'Symantec Privileged Access Manager'. Below this, there are input fields for 'User:' and 'Password:', both marked with an asterisk. An 'Authentication Type' dropdown menu is set to 'Local'. A blue 'Login' button is positioned below these fields. Further down, there is a section for 'Symantec PAM Client' and 'Symantec PAM Agent'. The 'Symantec PAM Agent' section is highlighted with an orange border and contains a 'Platform' dropdown menu set to 'Windows' and a blue 'Download' button.

3. Save the installer file locally to your workstation.

### Install the Agent

#### **NOTE**

**Installation Requirements:** Only 64-bit Windows 10 is supported in version 3.4.

After you download the installer file, run the agent installer. You need local administrator rights to install the agent, but not to run it. Follow the installation wizard, noting the following instructions:

- **License Agreement:** To accept the license agreement, scroll through the license text to the bottom of the panel.
- **Destination Folder:** Accept the default or select **Change** to find a folder.

#### **NOTE**

The PAM Access Agent does not support installation in directories whose names include Japanese characters. If you install the PAM Access Agent on a Japanese-language computer, enter a folder with no Japanese characters.

- When the installation is complete, a **Launch PAM Agent** checkbox appears. Select it and then Finish to close the installation and log in with the agent.

## Open the Agent

As a user, all you need is the Fully Qualified Domain Name (FQDN) or IP address of your Privileged Access Manager instance, and your user name and password.

### Follow these steps:

1. Open the PAM Access Agent.
2. Select the **Options** menu to set the log level, certificates, and proxy, if necessary. See [Optional Settings](#) for details.
3. In the **PAM Server/IP** field, enter the IP address or the assigned fully qualified domain name of the PAM Server or cluster VIP.
4. Select **Connect**.
5. You may receive a **Verify Certificate** window before the login screen appears. If you approve of the certificate, select the **Import this certificate permanently** checkbox. Select **Continue**.  
Once it is trusted, you should not see the certificate warning any more.
6. If an agent update is available, a dialog appears. If you select **Yes**, an installation dialog appears. Select **Yes** to upgrade the agent. Upgrading the agent is not mandatory.
7. When the login screen appears, enter the **User Name** and **Password**.
8. Select the **Authentication Type**.
9. Select **Login**.  
The Available Services tab appears, listing devices that you have permission to access. A Filter panel appears above the list allowing you to reduce the number of listed services.

## Optional Settings

An **Options** menu allows you to configure optional settings that might be required for your particular environment:

### Logging

Use this option to select the amount of application messaging:

- **Info:** Default setting, including error, and informational messages; medium amount of information
- **Debug:** All messages, including warnings, errors, informational messages; most information
- **Error:** Only log errors; least information

### Certificates

The Certificate Authorities (CA) window lists CAs that are trusted by the PAM Access Agent. You can perform the following actions:

- **Import:** Use this button to import your own certificates.
- **Export:** Use this button to export a certificate to a location on your local computer.
- **Remove:** Use this button to remove any certificates that you do not want.

### Proxy

Indicate whether the PAM Access Agent is connecting to the PAM server through a proxy server. Select one of the following options for your deployment:

- **No Proxy** (default): The agent connects directly to the PAM Server.
- **Auto-detect proxy settings for this network:** For a network-managed proxy. The agent executes the script that is retrieved from `http://wpad/wpad.dat` to determine which proxy server to use.
- **Use system proxy settings:** For workstation OS-managed proxy. On Windows, you can configure it using the `netsh winhttp set proxy` command.
- **Manual Proxy Configuration:** For a custom target device as the proxy
  - Enter the **Host** and **Port** of the Proxy server.

The agent cannot use most well-known ports. See [Ports Not Allowed for the Client](#) for the full list.

- Enter IP addresses to **Bypass**, such as 127.0.0.1 or 192.168.\* (for IPv4), or fe80:250:56ff:1111:2222:3333:\* (for IPv6)

To enter more than one address, separate each address with a comma, such as 127.0.0.1, 192.168.\*

- **Automatic proxy configuration URL:** for a web server-supplied proxy. The agent executes the Proxy Auto-Configuration (PAC) script that is retrieved from the URL to determine which proxy server to use.

### Timeouts

Specify timeout values for receiving a response to requests to the PAM Server:

- **Receive Timeout:** Specifies the timeout (in seconds) for receiving a response to requests to the PAM Server. The default value is 5 seconds.
- **3rd Party Authentication Timeout:** Specifies the timeout (in seconds) for receiving a response to requests to the PAM Server when third-party authentication (for example, Radius, RSA, and so on) is required. This value is used instead of **Receive Timeout** for such requests because third-party authentication generally takes longer. The default value is 90 seconds.

### Activate a Service and Connect to a Device

The PAM Access Agent uses Services instead of Access Methods. The agent ignores the **Client Application** field in a TCP/UDP Service configuration. The Agent does not open the client application for you.

The PAM Access Agent displays three tabs: Available Services, Activated Services, and Credentials.

**Available Services** lists devices that you have permission to access. You can select the column headings to sort the rows in ascending order by that field. Select a second time to sort in descending order.

- **Device Name:** The device name
- **Address:** The IP address of the device
- **Port** to connect to the service
- **Operating System** of the Device
- **Service:** The name of the service

Activated **Services** displays any service which is activated for use by a local application.

- **Device Name:** The device name
- **Address:** The IP address of the device
- **Port** to connect to the service
- **Operating System** of the Device
- **Service:** The name of the service
- **Credential:** The credential that you have selected to use with this service.

The **Credentials** tab lists the credentials available for you to view. There can be multiple credential rows for each device.

- **Account Name:** Target account for connecting to the listed device, and password viewing, if applicable.
- **Application Name:** Target application for connecting to the listed device, and password viewing, if applicable.
- **Device Name:** The device name
- **Address:** The IP address of the device
- **Status:** Dual-authentication status, such as Pending or Approved
- **Action:** Select **View Password** to view the password for this account.

### To connect to a device, follow these steps:

1. On the Available Services tab, double-click the Device row to activate the device connection. You can also enter or right-click to activate a service.
2. If there are multiple available credentials, the **Select Credential** window appears.

3. Select the **Credential** to use, and then **OK**.
4. Open the application that you use to connect to the device.
5. Enter the FQDN or IP Address of the device and port in the native application.  
The native application connects to the device.

**NOTE**

You might receive a security alert the first time that you try to connect using a native application with the agent activated. For example, PuTTY expects to connect to the target device, but the agent is redirecting traffic to Privileged Access Manager, where PuTTY obtains the key fingerprint. Therefore, it warns of a "potential security breach."

6. At the login prompt, hit Enter. The account name is automatically sent.  
If credentials are configured, they are also automatically sent.
7. When you are done using the PAM-managed device, right-click its row on the Activated Services tab and select **Deactivate Service**.
8. When you are done, **Log Out** from the PAM Access Agent.

**NOTE**

If a Service or Credential has become available since you logged on, select the **Refresh** button on the PAM Access Agent to display it.

**View Passwords**

Use the **Credentials** tab to select a credential to view. There can be multiple credential rows for each device.

Select **View Password** to view the password for an account.

**Silent Installation**

To install the PAM Access Agent in silent mode from a Command Prompt (as Administrator), use the following command:

```
CAPAMAgentInstall.exe /s /v"/qn"
```

To change the default installation directory, use this command:

```
CAPAMAgentInstall.exe /s /v"/qn INSTALLDIR=path_to_install_directory"
```

**Troubleshooting*****Network Error***

If you receive a "Network error" such as "Permission denied" or "Connection refused", you probably have a network redirection failure. You can resolve this error in several different ways:

- Run `CAPAMAgent.exe` as Administrator from a Command Prompt.
- Run the `CAPAMAgentCleanup` utility:
  - a. Log out from PAM Access Agent.
  - b. Run `CAPAMAgentCleanup.exe` (found in the installation folder) as Administrator from a Command Prompt.  
Any network redirectors are removed.

***DNS Resolution***

A Target Server Address can be defined in Privileged Access Manager using a DNS host name rather than an IP address. If the PAM Access Agent does not have access to an appropriate DNS server, it cannot resolve the host name.

***Language Mismatch***

PAM Access Agent does not support using a different language than the locale of the PAM Server. If the server is set to Japanese, and the agent computer is English, server communication tries to render in Japanese, but it shows non-Kanji

symbols. The agent user interface would be English, but dynamically generated drop-downs, such as password view reasons, and error messages, would be symbols. If both server and agent are the same language, whether English or Japanese, this problem does not occur.

### **Uninstall the Agent**

Use one of the following methods to remove the agent:

- Remove the PAM Access Agent from the **Windows Control Panel, Programs and Features**.
- Open the PAM Access Agent installer and select the **Remove** option.

## **How to Set Up a Cluster**

To protect your deployment from performance issues or failure, configure a *cluster*. A typical cluster consists of one or more sites (typically one per data center), each containing multiple PAM server instances (*nodes*). Server data is kept in sync between nodes in primary site or in a single site cluster using MySQL 8 Group Replication. Server data is kept in sync between the primary site and nodes at secondary sites using traditional MySQL 8 Replication.

Each site is then addressed by a single *virtual IP address (VIP)* that distributes requests between member nodes using [internal \(PAM software-based\)](#) or [external load-balancing](#). Each site in the cluster therefore operates as a single virtual system, providing support for the following benefits and capabilities to your PAM deployment:

- Improved throughput
- Expanded capacity
- Redundancy
- Disaster recovery

This article contains the following topics:

- [Single-and Multiple-Site Clusters](#)
- [Properties Of Single-Site Clusters and Primary Sites In Multi-Site Clusters](#)
- [Differences Between Primary and Secondary Sites and Their Members In a Multi-Site Cluster](#)
- [Internal and External Load-Balancing](#)

### **Single-and Multiple-Site Clusters**

Configure a *single-site cluster* or *multi-site cluster* using the following guidelines to help determine which best suits your requirements:

- **Separation of administrative and access tasks:** To designate specific PAM nodes to handle global administrative functions (such as policy maintenance and credential rotation) and others to handle user requests for access to privileged devices, configure a [multi-site cluster](#). Address all administrative requests to the VIP of the primary site and all access requests to the VIPs of secondary sites.
- **Geographical distribution of data centers:** If all your PAM nodes are deployed at a single geographical location and you do not need to separate them for administrative and access tasks, you only require a [single-site cluster](#). If your PAM servers are deployed over multiple geographically dispersed locations, configure a [multi-site cluster](#).

### **Single-Site Clusters**

If all your PAM infrastructure is deployed at a single geographical location and you do not require separate administrative and access tasks between nodes, you only require a *single-site cluster*. PAM replicates data across all the nodes so that they operate as a single virtual system addressed by a single VIP.

#### **NOTE**

Whenever you add another site to a single-site cluster, the first site you configured becomes the *primary site* for the new multi-site cluster. Once created, any site in the multi-site cluster can be promoted to become the primary site. For more information, see [Site Promotion Using Replication Analysis](#).

## Multi-Site Clusters

If your PAM environment is deployed over multiple geographically dispersed locations or you want to designate specific nodes to handle administrative activities (recommended), configure a *multi-site cluster*. The primary site in a multisite cluster must contain an odd number of members. Multi-site clusters have one *primary* site and one or more *secondary* sites. Each site is addressed by its own VIP.

- **Primary site** members are co-located and are typically designated for administrative activities (policy maintenance, credential rotation). If user requests for access to privileged devices must also be handled at the same data center, create and designate a secondary site at the same location for that purpose. Data that is saved on one member of the primary site is synchronously replicated across all primary site members. Only one primary site exists within a cluster at any time.

### NOTE

The primary site in a multi-site cluster behaves the same as a single-site cluster with the same properties. primary sites and single-site clusters both use group replication to keep themselves in sync.

- **Secondary site** are typically designated for access activities, that is, handling user requests for access to devices. Asynchronous replication is performed from the primary site to secondary sites. Replication allows secondary site members to recover gracefully and continue operating should a network issue exist between the sites, like a brown-out or DC outage.

### NOTE

A secondary site can also be promoted to primary site status, providing a warm backup if the primary site goes down. For more information, see [Cluster Synchronization, Promotion, and Recovery](#).

## Properties Of Single-Site Clusters and Primary Sites In Multi-Site Clusters

Single-site clusters and primary sites in multi-site clusters have the following properties:

- **Colocation:** All members of a single-site cluster should be colocated in the same data center. Group replication is best supported in geographical proximity. If you have remote data centers, create a multi-site cluster where each remote data center is a secondary site.
- **Primary leader:** The first cluster member that is listed in the primary site is designated as the *primary leader* and is the data synchronization source for all cluster members.
- **Cluster size:** A primary site is limited to nine member nodes. We recommend three and a maximum of five members. (See **Quorum**.) The more members that you add, the more communication work the cluster has to do. The total number of members in all sites is limited to 1,000.

### NOTE

If the entire cluster has only two members, do not put both members in the primary site. Instead, create a 1 x 1 configuration (one member at the primary site and one member at a secondary site). For more information, see [Primary Site Fault Tolerance](#).

- **Quorum:** In MySQL Group Replication, a "quorum" is the number of members that are required to make decisions for the cluster, such as whether a member has failed. The quorum is the majority of cluster members, or in this case the primary Site. For this reason, we recommend an odd number of members, such as 3 (whose quorum is 2), or 5 (whose quorum is 3). However, we do support fewer members.
- **Data replication:** Changes to administrative and Credential Management data can be made through any member and can propagate to the other members. When starting the cluster, the database from the first member is replicated to the other members, overwriting their data. Member-specific information, such as logs and some configuration data are not replicated.
- **Disaster recovery:** Add a secondary site (creating a multi-site cluster) to a single-location deployment to provide a warm backup for disaster recovery.

## Differences Between Primary and Secondary Sites and Their Members In a Multi-Site Cluster

Primary and secondary sites and their members in a multi-site cluster have the following important differences:

- There can only be one primary site, which is the source of data for all secondary sites.

#### **IMPORTANT**

If the primary site fails, you must *manually* promote a secondary site to be the primary site to restore cluster operation.

- Secondary site members are typically intended to support end-user access rather than global administrative functions, which are typically handled on the primary site. Some local administrative functions are available on secondary site members, including: managing sessions, logs, and recordings; managing password approvals, viewing credentials, and disaster recovery; some diagnostics; network, and security.
- Secondary sites, with few exceptions, do not support REST API or CLI operations. (The specific CLI command documentation mentions this, as in [checkInAccountPassword](#).) Use the VIP of the primary site for REST API and CLI commands.
- The best practice is to have each member of a particular secondary site in the same data center.
- Each secondary site has a leader which receives updates from the primary site. The secondary leader then replicates the data to the other site members and relays updates from secondary members to the primary site. This topology minimizes WAN traffic between the sites.
- If the secondary leader goes offline, the other site members communicate directly with the primary site.
- Secondary members can “self-heal” after being disconnected. See [Cluster Synchronization, Promotion, and Recovery](#) for details.
- Members can be added or removed from secondary sites without stopping the cluster. This process requires a VIP for the site you are subscribing to.
- Multi-site clustering uses MySQL 8 traditional asynchronous replication to communicate between primary and secondary sites. Almost all data changes start with data on a primary site node. When replication starts with data on a secondary site node, it first is replicated to the primary leader and the data is distributed normally from there.

### **Internal and External Load-Balancing**

PAM clustering supports internal and external load-balancing solutions which you configure at the *site level*. That is, multi-site clusters support individual sites that are configured with different load-balancing solutions. For example, in a three site cluster, the primary site and one secondary site can be configured to use an External Load Balancer. The third site can be configured to use PAM Floating IP load-balancing.

Specify the load-balancing solution for each site in your cluster by specifying one of the following **VIP Address Type** settings:

- **Floating IP:** (Default) Use the internal PAM software-based load-balancing solution in which requests addressed to the VIP are handled by the *site leader* (the first node added to the site) which redirects them to the least-loaded site member. If the site leader is down, the next node is automatically promoted to be the site leader, and so on, until the site leader is back online (This was the only load-balancing option before release 4.1).
- **External Load Balancer:** Use an external load-balancing solution to handle requests that are addressed to the VIP and redirect them to one of the cluster site members based on the external load balancer algorithm.

#### **NOTE**

For important guidelines for configuring external load balancers, see [External Load Balancer Configuration Guidelines](#)

### **Next Steps**

- [Cluster Deployment Requirements and Guidelines](#)
- [Configure a Cluster](#)
- [Cluster Synchronization, Promotion, and Recovery](#)
- [Configure Load Balancers to Determine the Availability of Cluster Nodes](#)

## **Cluster Deployment Requirements and Guidelines**

Before you configure a cluster, verify that your environment meets the following requirements:

## Network Requirements

Your environment must satisfy the following network requirements:

- **High Network Availability:** Clustering in the primary site uses synchronous SQL replication, which requires a high network uptime to avoid network loss. If the network is down, cluster members eventually time out and they are deactivated. A deactivated cluster member can cause synchronization problems.
- **DNS:** Note the following best practices:
  - Primary DNS uptime to avoid latency in the product UI and its subsystems. Maintain the primary DNS server to avoid failover to a secondary DNS.
  - Unique appliance host names: If host names are the same, logging, and other metrics are negatively impacted.
  - Register host names and IP addresses in the DNS for forward and reverse look-ups.
- **Internet Control Message Protocol (ICMP):** The internal active-active control uses ICMP ping to monitor network conditions.

### TIP

ICMP connectivity and LAN gateway require high uptime to reduce the cost of network loss.

Failed ICMP triggers a cluster member to enter isolation mode, implying that a communication failure between members is in progress. Restored ICMP during an isolated mode triggers an automated merge recovery. A merge recovery requires service download proportional to DB size and cluster size. The cluster automatically stops, then one database is copied and restored on all other appliances, and then the cluster restarts.

- **Network Time Protocol (NTP):** The product is pre-configured with default NTP servers, but these require internet access. If the cluster is not routed to the internet, use local LAN NTP servers to ensure that cluster members are set to the same time.
  - Configure the NTP in the GUI by selecting **Configuration, Date/Time**.
  - NTP server connectivity is checked during startup. If the times between appliances differ by 3 seconds or more, the cluster does not start. After a cluster starts, NTP server connectivity is not monitored so external monitoring is required.
- **TCP:** Do not permit TCP blocking, throttling, or traffic shaping on any part of the LAN, VLAN, or WAN for the following ports and protocols:
  - **Clustered appliance:** Within a site, these ports are required: TCP/443, 8443 (HTTPS); TCP/3307, 13307 (MySQL); TCP/5900 (Hazelcast). Between sites, only 443, 8443, and 3307 are required. For external user access, only 443 is required. (For a standalone appliance, only TCP/443 is necessary.)

### NOTE

TCP ports 3307 and 13307 must be set **Open**, not **Filtered**.

- **Socket Filter Agent (SFA) clients:** TCP/8550 (plus protocol-specific ports for RDP, SSH, and other access methods)
  - **A2A clients:** TCP/28888
  - **Windows Proxy:** TCP/27077
- See [IP Addresses and Ports for Network Connectivity](#) for more information.
- **Subnet:** The VIP and every member of a particular site must be in the same subnet.

## PAM Server Requirements

Before you implement a cluster, each member must have at least the following items configured:

- **Licensing:** Other than the Hardware ID, all cluster members need the same settings. See the [Licensing](#) configuration page for more information.
- **Network:** Some settings differ for each member. Ensure that the **Hostname** is different for each member. See the [Network configuration](#) page for more information.
- **Date/Time:** Ensure that the time server is specified correctly. See the [Date and Time configuration](#) page for more information.
- **Clustering:** Enter the same Shared Key on each member and save it there by selecting **Save Locally**. Once the cluster starts, the remaining cluster configuration is replicated to all members.
- **Use only IPv4 or IPv6 addresses.** Use only IPv4 or IPv6 addresses for addressing appliances in a cluster.
- **Ensure that all cluster members use the same software release.** Verify that each cluster member is running the same release of the product software. If not all members are at the same release (patch) version, upgrade all members to the latest release in the cluster.
- **All members of a Primary or Secondary site must be on the same platform.** A site can be on one platform: AWS, VMware, Azure, or hardware appliance
- **FIPS:** If any member of cluster is FIPS enabled, then all members must be FIPS enabled.

#### NOTE

You cannot change these values while the cluster is running.

### **External Load Balancer Configuration Requirements and Guidelines**

When using external load balancing, consider the following information when configuring the load balancers:

- All PAM servers in the cluster must be running PAM 4.1 or later.
- Deploy and configure a Layer 4 network load balancer for each site in the cluster that is configured to use external load balancing.
- Configure the load balancer to listen to port 443 on the VIP address configured in the PAM site definition.

#### NOTE

SSL connections do not terminate at the load balancer.

- Configure the load balancer to distribute incoming traffic to the local IP addresses of the members of the site.
- Enable Session Affinity and, if possible, configure the timeout value to be slightly longer than the login timeout value of the cluster members.
- Enable X-Forwarded-For header for A2A request servers (if applicable).

#### NOTE

If your load balancer does not support the X-Forwarded-For header, the following functionality may not work: auto-registration of request servers, auto-registration of Windows Proxy agents navigate navigate to work, and the creation of utility groups.

### **WAN Link Cluster Requirements**

You can use a WAN link between sites in a size cluster.

To use a WAN link, confirm the following requirements:

- Use only a public IPv4 address for the VIP (Virtual Management IP), as the cluster members are not on the same subnet.
- Be mindful that network packet loss is not excessive.
- Confirm that your NTP servers are running properly then turn on the cluster. Look the Date/Time page, NTP Status panel (`aactrl` output) to see that the following conditions are met:
  - "remote" column: At least one primary NTP server (denoted with a \*) is available
  - "offset" column: The absolute value of this field must be less than 3000
  - "when" column: This field must be less than 5 times the value in the poll column (the poll frequency)

Look for a summary message in the session logs, and then immediately address the NTP servers. An example log entry with an unacceptable value is shown:

```
NTP problem on member 10.0.0.21. NTP Server: *6.175.209.17: Offset: 1.1.51 (should be
< 3000), Poll: 64, When: undefined (when should be < poll *5)
```

- Assign a unique host name to each cluster member.

### **FIPS Certificate Requirements**

If you configure FIPS on your cluster, you must enable it before setting up the cluster. You must enable FIPS on each member of the cluster, including secondary sites. For more information about FIPS, see [Configure Enhanced Encryption for Stored Credentials](#).

### **AWS AMI Cluster Requirements**

To use AWS AMI instances in your cluster, set up your AWS environment correctly.

#### **Follow these steps:**

1. Create an AWS virtual private cloud (VPC) with at least one public subnet in which to locate your cluster. Assign an AWS Security Group that permits intra-subnet communication, inbound and outbound traffic through ports 3307, and 13307 (for MySQL).

#### **NOTE**

Ports 3307 and 13307 must be set **Open**, *not Filtered*

2. Configure the members of your AWS cluster and assign them to the VPC you created. Note the local subnet address for each.
3. Create an elastic IP address (EIP) for each member of your cluster and assign it to that member. Note which EIP is assigned to which instance.
4. Create an extra EIP to serve as the cluster VIP address, but do not assign this EIP to any instance.

#### **NOTE**

AWS Elastic Load Balancing (ELB) is incompatible with PAM internal (Floating VIP) load-balancing. However, you can configure an AWS ELB as the load-balancer for a site that is configured to use external load balancing.

To set up clusters on other AWS sites, AWS connections have to be configured in Privileged Access Manager. To configure the AWS connections, see [AWS Coordination](#).

### **Azure Cluster Requirements**

To build a cluster of Azure instances, follow these steps in your Azure environment. First set up your individual instances in Azure. See [Configure an Azure Connection](#). We recommend creating a separate virtual network for each Primary and Secondary site to avoid DHCP conflicts that might occur while the cluster is off.

Privileged Access Manager clustering uses Azure APIs which requires Azure credentials. In particular, the Azure VIP assignment requires Azure credentials. When you start the cluster, Privileged Access Manager creates an IP configuration for the VIP in the primary node Network Interface (NIC). If the primary node is unavailable, Privileged Access Manager deletes the VIP configuration from the primary node and creates it in the NIC of the next node.

#### **NOTE**

If you want to use an IPv6 cluster for PAM instances deployed in Azure, you cannot use a Floating IP as the IPv6 VIP address. You must use an external load balancer while configuring the IPv6 VIP address.

#### **Create a VIP for Each Azure Region**

1. On the Azure Portal, select **All Services**, and enter a "Public IP address."

2. Select **+Add** to create a public IP address.
  3. Enter a **Name**.
  4. Select **Static** for **IP Address Assignment**.
  5. For **Resource Group**, select **Use Existing** and select the Resource Group for your PAM instances.
  6. Select **Create**.
- This public IP address of your VIP is used in the PAM cluster configuration as the "VIP NAT Address."

### Create A Private IP Address for Your VIP

1. On the Azure Portal, select **Virtual Networks** from the left menu.
2. Select the Virtual Network for your PAM instance.
3. Select **Networking**.
4. Select your **Network Interface**.
5. Select **IP configurations** from the left menu.
6. Select **Add**.
7. Add a **Static IP Address** to the same subnet as the PAM server. This is the Private IP address for your VIP.
8. Associate the Public IP address with the Private IP address that you just added.
9. Record the Private IP address to use as the "VIP Address" in the PAM cluster configuration

## Configure a Cluster

Configure a cluster from the **Clustering** pane in the PAM UI. Configure each member in the cluster individually then activate the cluster by turning on synchronization. The exception to this rule is the configuration of third-party authentication, which is replicated.

### Follow these steps:

1. Log in to the UI on a PAM server that will be a member of the primary site.
2. Navigate to **Configuration, Clustering**.  
The **Clustering** page appears with the **Local Settings** tab selected.
3. Do the following steps on the **Local Settings** tab:
  - a. Use the controls in the **Shared Key** section to specify a 32-bit shared key for all members of all sites in the cluster to secure communications between them. (Do not use the same Specify shared key on separate clusters.)  
Use one of the following methods to generate the initial key:
    - Enter a **Passphrase** and select the **Generate Key** button. The **Key** field is populated with the generated value.
    - Use a third-party tool or the following OpenSSL command in Linux or Cygwin: `openssl rand -hex 16`. Enter the returned value in the **Key** field. (Required if operating in **FIPS Mode**, when the **Generate Key** button is disabled.)

Once the shared key is generated, use it to manually populate the **Key** field on all other instances in the cluster.
  - b. Specify network interfaces to use for IPv4 and IPv6 (or both, if applicable) communication between clustered appliances using the dropdown menus in the **Interfaces** section:

#### NOTE

To verify which network interfaces are configured with IPv4, IPv6, or both addresses, refer to the **Network Interfaces** section on the **Configuration, Network, Network Settings** panel.

#### NOTE

If AWS or Azure is being used, both **Interface** controls are dimmed and unavailable.

- **IPv4 Interface:** Select a network interface with an IPv4 address.
- **IPv6 Interface:** Select a network interface with an IPv6 address.

#### NOTE

Specify the same interface values on every member of the cluster.

- c. Select **Save Config Locally**. The same interface must be used by all the clustered members.
4. Select the **Global Settings** tab and do the following steps:
  - a. Under **Multi-Site**, determine the behavior of the secondary site when the primary site is unavailable. To change the behavior globally, first turn off the cluster. The options for the secondary site are:
    - **Operationally Safe**
      - Users can view passwords from the local PAM database.
      - Users can continue to access devices and can create sessions to devices.
      - All workflow functions are disabled. These functions are check-in/check-out, dual authorization, credential rotation, Service Desk integration, and reason to view credentials.
    - **Security Safe**
      - Users cannot create sessions to devices that are configured for auto-login using Credential Manager.
      - Users cannot view passwords.

Workflow functions are not available when the primary site is down.

- b. On Secondary sites, the **Disaster Recovery** tab defines the behavior of an *individual* secondary site member in case the primary site fails. For a secondary member to behave in Operationally Safe mode, keep the **Run Secondary Site in Operationally Safe Mode** checkbox selected. To run in Security Safe mode, clear this checkbox.
- c. Use the buttons under **Sites** on the **Global Settings** tab to add primary and secondary sites, add members to those sites, and administer them. Add a site manually or load the configuration from an existing cluster member. See [Add a Cluster Site](#) for instructions.
- d. To receive email notifications of the following types of cluster events, select the **Notification** tab then set the **Enable Email Notifications** option:
  - **Group Replication Quorum Failure**: Notifies the configured administrator when a MySQL group replication quorum failure has occurred.
  - **Group Replication Quorum Recovery**: Notifies the configured administrator when a MySQL group replication quorum failure has occurred and that PAM is going to reboot each member of the cluster.
  - **Member - Out of Sync**: Notifies the configured administrator when a cluster member has now been marked out of sync.
  - **Member - Timeout**: Notifies the configured administrator when a cluster member has timed out.
  - **Member - In Sync**: Notifies the configured administrator when a cluster member that was previously out of sync is now in sync again.

#### NOTE

Email notifications are sent to the **Admin Email** that is set at **Configuration, Monitor**. This setting is not replicated, so each primary member needs the email set separately. Each member should have the same monitor settings.

### Start the Cluster

When your cluster is configured, use this procedure to start it.

#### Follow these steps:

1. Open the PAM UI on any node in the primary site and login as an administrator with configuration privileges (for example, "config" or "super").
2. Navigate to **Configuration, Clustering**, and select the **Global Settings** tab.
3. Select the **Turn Cluster On** button at the bottom of the page.

### Stop the Cluster

Use this procedure to stop a cluster.

**Follow these steps:**

1. Open the PAM UI of any node in the primary site using its IP address or FQDN (do *not* use the site VIP address) and log in as an administrator with configuration privileges (for example, "config" or "super").
2. Navigate to **Configuration, Clustering**, and select the **Status** tab.
3. Select **Turn Cluster Off** button at the bottom of the page. Wait until a notification indicates that synchronization is off

**Next Steps**

- [Add a Cluster Site](#)
- [Add a Cluster Member](#)

**Add Sites to Your Cluster**

This content describes how to add sites to an [existing PAM cluster](#).

**IMPORTANT**

Each site member that you add must be configured with the same **Shared Key** and **Interface** values, as described in [Configure a Cluster](#).

**NOTE****IPv6 Addressing Prerequisites**

If you are configuring your cluster to use IPv6 addressing, verify that the following prerequisites are met:

- Verify that the PAM environment is IPv6-enabled and that at least one network interface with an IPv6 address is configured. For more information, see [Configure Network Settings](#).
- Verify that the **IPv6 Interface** menu on the **Configuration, Clustering** panel **Local Settings** tab specifies an interface with an IPv6 address

**Guidelines for migrating an existing IPv4 cluster to IPv6:**

- All the nodes in the cluster must be IPv6 enabled.
- Primary and Secondary node sites within a cluster must all use either IPv4 or IPv6 addresses. You cannot mix site address types.
- To support components that *are only addressable using IPv4* (such as A2A clients), configure at least one IPv4 VIP address for the cluster.

**Add a Cluster Site**

Follow this procedure to add a site to your cluster.

**To add a cluster site, follow these steps:**

1. Log in to the PAM UI on a primary site member.
2. Navigate to shared **Configuration, Clustering** page.
3. On the **Global Settings** tab, select the **Add** button.  
The **Add Cluster Site** page opens.

**NOTE**

The first site that you add is designated as the Primary Site. The first cluster member provides data for the initial sync. If that member fails, the next cluster member takes the primary role.

4. Enter a **Site Name**, which can be anything that helps you logically group the site members. For example: West coast, NYC, EMEA, or Primary.
5. Select the appropriate **PAM Appliance/Instance Platform**: one of **On-premises**, **AWS**, or **Azure**.  
For AWS or Azure instances, a drop-down list of your provisions appears:

- If you specified **AWS**, select the appropriate entry from the **AWS Provision** drop-down list that appears. The list includes only regions that you have configured in AWS connections. If you are using a cluster in AWS, see [AWS AMI Cluster Requirements](#).
- If you specified **Azure**, select the appropriate entry from the **Azure Provision** drop-down list that appears. The list includes only regions that you have configured in Azure connections. If you are using a cluster in Azure, see [Azure Cluster Requirements](#).

**NOTE**

If you want to use an IPv6 cluster for PAM instances deployed in Azure, you cannot use a Floating IP as the IPv6 VIP address. You must use an external load balancer while configuring the IPv6 VIP address.

6. Complete the following **Load Balancing** settings:

- **VIP Address Type:** Specify the load-balancing solution for each site in your cluster by specifying one of the following **VIP Address Type** setting options. For **important** guidelines for configuring external load balancers, see the [External Load Balancer Configuration Guidelines](#) section of the [Cluster Deployment Requirements and Guidelines](#) topic. When accessing a cluster, use the VIP address, NOT the Member address.
  - **Floating IP:** (Default) Use the internal PAM software-based load-balancing solution that uses the site leader (the first node that was added to the site) to handle requests that are addressed to the VIP. The site leader redirects these requests to the least-loaded node. If the site leader is down, the next node is automatically promoted to be the site leader, and so on, until the site leader is back online.
  - **External Load Balancer:** Use an external load-balancing solution to handle requests that are addressed to the VIP and redirect them to one of the cluster site members based on the external load balancer algorithm.
- **IPv4 and IPv6 VIP settings:** To configure VIPs to access the cluster using IPv4, IPv6, or both addressing, populate the following fields:

**NOTE**

We recommend always using a VIP. If a site has only one member, the VIP is not required. However, if the site has more members, or if you plan to add members later, then a VIP is required.

- **IPv4 VIP Address:** Enter a virtual address (VIP) to use to access the cluster using IPv4 addressing. Through a firewall, or for AWS, enter a mapped address in the form [local\_address or aws\_vpc\_ip], [NAT or aws\_eip]. For examples, see the following chart.

Local or AWS VPC IP	NAT or AWS EIP
10.0.0.59,	107.23.143.123
10.0.0.59,	capam1.example.com
10.0.0.59,	capam1.example.com:4443

**WARNING**

The cluster VIP and its members must be in the same subnet.

The cluster is always available for all users through this virtual IP address. The primary appliance uses its defined VIP, and redirects user requests to the least-loaded member of the cluster.

- **IPv4 VIP NAT Address:** If you are using NAT for the IPv4 VIP, add its IP address here.
- **IPv4 VIP Host Name:** Enter a DNS machine name that is used to access the cluster using an IPv4 VIP. Users adding a DNS name to their VIP settings should enable this configuration.
- **IPv6 VIP Address:** Enter a virtual address (VIP) to use to access the cluster using IPv6 addressing. Through a firewall, or for AWS, enter a mapped address in the form [local\_address or aws\_vpc\_ip], [NAT or aws\_eip]. For examples, see the following chart.

Local or AWS VPC IP	NAT or AWS EIP
fd6d:8d64:af0c:1:250:56ff: feb1:7a4a	2600:1f18:4c6e:9f00:56e1:a630:3a41:1b65
fd6d:8d64:af0c:1:250:56ff: feb1:7a4a	capam1.example.com

fd6d:8d64:af0c:1:250:56ff: feb1:7a4a

capam1.example.com:443

**WARNING**

The Cluster VIP and its members must be in the same subnet.

The cluster is always available for all users through this virtual IP address. The primary appliance uses its defined VIP, and redirects user requests to the least-loaded member of the cluster.

**NOTE**

We recommend always using a VIP. If a site has only one member, the VIP is not required. However, if the site has more members, or if you plan to add members later, then a VIP is required.

- **IPv6 VIP NAT Address:** If you are using NAT for the IPv6 VIP, add its IPv6 address here.
  - **IPv6 VIP Host Name:** Enter a DNS machine name that is used to access the cluster using an IPv6 VIP. Users adding a DNS name to their VIP settings should enable this configuration. Use this field to enter a Fully Qualified Domain Name and, if desired, a port number. Ports are only supported when entered with the FQDN. To enter a port number, enter the <FQDN>:<port number>.
  - **Internal Cluster Communication:** Specify whether to use IPv4 or IPv6 addressing for communication between cluster members:
    - **Use IPv4 VIP addressing requirements** (the default):
    - **Use IPv6 VIP:**
7. When [Cluster Tuning](#) mode is on, four **Database Replication** settings are available. Change these settings only if directed to do so by Broadcom Support:
- **Connection Timeout (seconds):** Set the time for a primary site member to wait to connect to a peer primary site database before failing. Timeouts can lead to deactivation of the member database.
  - **Socket Timeout (seconds):** Set the time for a primary site member to wait for a response from a peer primary site database before failing. Timeouts can lead to deactivation of the member database.
  - **Download Database From Secondary Site Leader:** Set this option (the default) To efficiently distribute the database, the initial startup mimics the replication pattern of sending data to the secondary site leaders. The secondary site members get their initial database from their site leader, using faster LAN speeds. This can speed up cluster startup, depending on your cluster size and WAN speeds. It also allows secondary sites to be available once their leader is ready, before the other site members are ready, if necessary.
  - **Secondary Site Leader Readiness Check Timeout (minutes):** The amount of time a secondary site member waits for its leader to be ready to download the database. After this amount of time, the secondary site member directly downloads the database from the primary site instead of through its site leader. The default setting is 30 minutes.
8. **Cluster Members:** List all the cluster member IP addresses.  
For guidance on cluster size, see the section about [Set Up a Cluster](#) page.
- **Member Address:** Enter the local IP address, AWS VPC IP, or FQDN.
  - **Member NAT Address/FQDN:** Enter mapped addresses in the form NAT, AWS EIP, or FQDN.
- All cluster members are synchronized automatically. The list is prioritized as follows:
- a. The first member is the source of data during the initial synchronization, and referred to as the "replication leader."
  - b. If the first member ever fails, the second member in the list becomes the new replication leader.
  - c. The up and down arrows move the selected IP address position in the order of the list. These buttons are visible only for the primary site.
  - d. The **X** immediately deletes the selected IP address.
9. Select **OK** to save the cluster site configuration.

## Other Steps

Once you have added a cluster site, follow these steps:

1. Select **Save Config Locally** to save the cluster configuration to the local appliance.
2. Select **Save To Cluster** to save the cluster configuration to all members in the cluster.

### NOTE

If you intend to enable cryptography for stored credentials, do so before turning on the cluster. See [Configure Enhanced Encryption for Stored Credentials](#) for instructions.

3. Select **Turn Cluster On**.

### WARNING

The *first time* that you turn on a cluster, start it at the first member in the primary site. The first member is the replication leader. Later, you can start the cluster from any member in the primary site. You can turn off a cluster from any member in the cluster, including secondary site members.

Any sessions from Secondary site members are logged off when the cluster starts. Sessions from Primary site members are interrupted but can be resumed after the cluster has completed its startup.

The **Cluster Startup Details** window appears with the following information:

- **Primary Site Members:** The number of primary site members appears in brackets, followed by a progress bar that advances as primary site members are synchronized.
- **Primary Site Leaders:** The number of secondary site leaders appears in brackets, followed by a progress bar that advances as secondary site leaders are synchronized.
- **All Members:** The total number of cluster members appears in brackets, followed by a progress bar that advances as cluster members are synchronized.
- **Countdown to Refresh:** Every 10 seconds the status refreshes. This counter lets you know that status is still being communicated.
- **Message Box:** The IP address and site name of each member appears. Status messages appear for each member as progress is updated.

When synchronization is complete for all primary members and each secondary leader, the cluster is ready to accept traffic. Other secondary members continue to synchronize while other members are available.

Once all cluster members are in sync, the Cluster Startup Details window disappears. The Status tab takes focus, displaying sites and the status of all site members.

### NOTE

In clusters, the blue globe icon on the title of a configuration panel signifies that the configuration is global, and replicated to all cluster members.

### NOTE

For more information see the following topics:

- [Add a Cluster Member](#)
- [Cluster Synchronization, Promotion, and Recovery](#)

## Add a Member to a Site While the Cluster is Up

This procedure describes how to add a member to the primary site or a secondary site of a cluster while it is up.

### NOTE

Adding a PAM instance to a cluster overwrites its data with cluster data, except for local configurations. Because credentials are included, you should log in as a user with the configuration management role that exists in both places, such as *super*. Keep in mind that the credentials overwrite and may be different.

**To add a cluster member, follow these steps:**

1. Ensure that the new PAM instance meets the requirements that are given in [Cluster Deployment Requirements](#).
2. On an existing cluster member, copy the **Shared Key** from the **Configuration, Clustering** page, **Local Settings** tab. If you know the **Passphrase**, you can enter it on the new member instead. **Note:** If you are in FIPS mode, the Passphrase is not used.
3. On the same page, see which **Interface** clustering is using (such as GB2).
4. On the new cluster member, go to the **Configuration, Clustering** page, **Local Settings** tab. Paste or **Generate** the **Key** and select the **Interface**. **Note:** If you are in FIPS mode, the **Generate Key** button is disabled.
5. Select **Save Config Locally**.
6. On the **Global Settings** tab, select **Load Configuration from Member**.
7. In the resulting window, enter the IP address of an existing member of the cluster, and select **OK**. The **Clustering** page gets information from the existing member and displays it.
8. Select a Primary or Secondary site and **Update**. To add a new site, see [Add a Cluster Site](#). The Update Cluster Site window appears.
9. Select **+** (Add a cluster member) to join it. Enter at least the first field value:
  - **Member Address:** Enter the local IP address, AWS VPC IP, or FQDN.
  - **Member NAT Address/FQDN:** Enter mapped addresses in the form NAT, AWS EIP, or FQDN.
  - **NAT Port:** Enter the NAT port, if applicable.
10. Select **OK**.
11. Select **Subscribe to Active Cluster**, and select **Yes** to join the active cluster when prompted. The new cluster member begins synchronization by pulling data from the cluster site leader. PAM restarts on the new cluster member. When the new cluster member finishes its sync with the Primary or Secondary leader, you can log in again.
12. On the **Configuration, Clustering** page, the Status tab displays information about the cluster:
  - Primary Site members display all sites and cluster members.
  - Secondary Site members list all sites but displays only their own member information.

**NOTE**

[Cluster Synchronization, Promotion, and Recovery](#)

**Change the IP Address of a Cluster Member**

If your network infrastructure changes, you might need to change the IP address of a cluster member. This procedure ensures proper operation of the cluster after a change to the IP address of a member.

**Follow these steps:**

1. Log in to the cluster member whose IP address you want to change.
2. Turn clustering off by selecting **Configuration, Clustering** and selecting **Turn Cluster Off**.
3. Navigate to **Configuration, Network, Network Settings**.
4. In the Network Interfaces list, select the interface that you want to modify and change the IP address.
5. Select **Update**.
6. Reboot the cluster member by selecting **Configuration, Power**, then selecting **Reboot Instance**.
7. After the cluster member reboots, log back in to the updated cluster member.

**NOTE**

If the cluster member has only one interface IP address, use the updated IP address in the URL to log back in to the instance.

8. Navigate to **Configure, Clustering, Global Settings**.
9. From the Sites list, select the entry for the site with the updated cluster member and select **Update**.
10. Change the IP address to the new address.

11. Select **Save Config Locally** followed by **Save to Cluster**.
12. Restart the cluster by selecting **Turn Cluster On**.

The cluster resumes operation with the updated address of the member.

## Tune a Cluster

Use cluster tuning *only* with the direction of Broadcom Support. To change configuration items that are not already visible on the Clustering page, follow these steps:

1. Verify that the Cluster is off.
2. Go to the **Configuration, Diagnostics, System** page.
3. Find **Cluster Tuning Mode**. Select the **On** button.
4. Go to the **Configuration, Clustering** page.
5. Select the **Tuning** tab.
6. Inspect and modify the following settings as directed by Broadcom Support:
  - **Enable Cluster Status Replication Timestamps:** When you select this option, two more columns appear for Site Members on the Status tab. A replication sample is sent from each member every minute. The column values are updated every five minutes. Select the **Refresh Replication Status** button to update the status immediately. These times will usually not differ between Primary Site members that are sending to and from each other, due to group replication.
    - **Last Replication Sample Received:** The elapsed time since this member last received a replication sample from the primary site or secondary leader.
    - **Last Replication Sample Sent:** The elapsed time since this member last sent a replication sample to the primary site or secondary leader.
  - **Duration to Preserve MySQL Binary Logs (hours):** Replication uses these logs to keep secondary sites in sync. If a secondary site goes further out of sync than logs are available, the entire database must be delivered to the site. The default value is 24 hours.
  - **Time of Day to Perform Log Trim and DB Dump:** The UTC time to perform this action.
  - **Primary Member Recovery Period (hours):** If a primary site member goes further out of sync than this period, the entire database must be delivered to the member. The default value is 24 hours.
  - **Cluster Database Consistency Check Period (minutes):** Configure how often, in minutes, the sync status is updated across the cluster. The default value is 5 minutes.
  - **Allowed Replication Lag Before Secondary Member Warning (minutes):** When a Secondary member loses connectivity with the primary site, it receives a warning after this duration.
  - **Allowed Replication Lag Before Secondary Member Out-of-Sync (minutes):** When a Secondary member loses connectivity with the primary site, it is marked Out-of-Sync after this duration.
  - **Allowed Replication Lag Before Secondary Member Deactivation (minutes):** When a Secondary member loses connectivity with the primary site, it is marked as Deactivated after this duration.
  - **Database Connection Timeout (minutes):** If the primary site cluster members detect quorum loss, wait for this duration before initiating quorum loss mode. If you set this value too low, you risk false alarms. Switching into quorum loss mode and back is time-consuming.

## Clustering Considerations for Appliances with Multiple Network Interfaces

If you have a clustered environment in which your PAM appliances have multiple network interfaces, configure you cluster as described in the previous pages then follow this procedure to avoid replication failures. These replication failures result from firewall rules that PAM creates to protect MySQL cluster replication traffic. If any cluster-to-cluster communication is sent using the wrong network interface (and therefore the wrong IP address), PAM replication fails because the proper firewall rules are not opened up.

## What to Check for Prior to Starting Your Cluster

To verify that your network interface controllers (NICs) are properly configured, first contact Broadcom Support to enable *Debug SSH*.

Once debug SSH is enabled, follow these steps:

1. SSH into every member of every site in your cluster.
2. From the SSH session for the primary leader, run the `ip route` command against *each* of the other members of that site:

```
ip route get intra-cluster-ip-address
```

3. From the SSH sessions of *each* of the other members of the primary site run the `ip route` command against the inter-cluster addresses of each member of the secondary sites:

```
ip route get secondary-site-member-inter-cluster-ip-address
```

4. From the SSH sessions of each of the members of the secondary sites, run the `ip route` command against each of the into cluster members of the primary site.

```
ip route get primary-site-member-inter-cluster-ip-address
```

Here is an example of an `ip route` command output, with the important content shown in bold:

```
# ip route get 10.242.2.160
10.242.2.160 via 10.236.12.1 dev eth0 src 10.236.12.241
cache
```

This IP address in bold indicates which of that IP addresses of that machine is used to initiate communication to the destination machine. If the significant IP address is the same as what is specified in your cluster configuration, then there is no problem. If the significant IP address is *not* the same as what is specified in your cluster configuration, then either your cluster configuration is in error or your additional routes are in incorrect.

## What To Do If Your Routes Are Incorrect

Additional routes are specified in the PAM configuration. If your routes are wrong, you can view the ones actually in effect using the `route` command. For example:

```
# route
Kernel IP routing table
Destination      Gateway          Genmask          Flags Metric Ref    Use Iface
default          10.236.12.1     0.0.0.0          UG    0      0      0 eth0
10.236.12.0      0.0.0.0         255.255.254.0    U      0      0      0 eth0
10.236.16.0      0.0.0.0         255.255.254.0    U      0      0      0 eth7
10.242.4.0       10.236.16.1     255.255.254.0    UG     1      0      0 eth7
localhost        0.0.0.0         255.255.255.255 UH     0      0      0 lo
```

This shows the routes actually in effect, the corresponding gateway, and the network interface that is be used. The network interfaces are described in linux terms. To correlate these to PAM terms, run the `/sbin/interfaceMappings.sh` command. For example:

```
# /sbin/interfaceMappings.sh
BOND1=bond0
BOND2=bond1
BOND3=bond2
BOND4=bond3
GB1=eth0
GB2=eth1
GB3=eth2
GB4=eth3
```

```
GB5=eth4
GB6=eth5
GB7=eth6
GB8=eth7
```

This example shows you that linux interface eth0 corresponds to PAM interface GB1 and that eth7 corresponds to GB8.

To see the IP addresses corresponding to each of these, run the `ipconfig` command. For example:

```
# ifconfig
eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 10.236.12.241 netmask 255.255.254.0 broadcast 10.236.13.255
    inet6 fe80::290:bff:fe43:1cf4 prefixlen 64 scopeid 0x20<link>
    ether 00:90:0b:43:1c:f4 txqueuelen 1000 (Ethernet)
    RX packets 234011558 bytes 291206046553 (271.2 GiB)
    RX errors 0 dropped 25393 overruns 0 frame 0
    TX packets 106480688 bytes 32363304465 (30.1 GiB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
    device memory 0xf7a00000-f7afffff

eth7: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 10.236.16.21 netmask 255.255.254.0 broadcast 10.236.17.255
    inet6 fe80::290:bff:fe43:1cfb prefixlen 64 scopeid 0x20<link>
    ether 00:90:0b:43:1c:fb txqueuelen 1000 (Ethernet)
    RX packets 12763590 bytes 5259011456 (4.8 GiB)
    RX errors 0 dropped 231 overruns 0 frame 0
    TX packets 12319523 bytes 5132833296 (4.7 GiB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
    device memory 0xf6500000-f65fffff

eth7:1: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 10.236.16.24 netmask 255.255.254.0 broadcast 10.236.17.255
    ether 00:90:0b:43:1c:fb txqueuelen 1000 (Ethernet)
    device memory 0xf6500000-f65fffff

lo: flags=73<UP,LOOPBACK,RUNNING> mtu 65536
    inet 127.0.0.1 netmask 255.0.0.0
    inet6 ::1 prefixlen 128 scopeid 0x10<host>
    loop txqueuelen 1000 (Local Loopback)
    RX packets 309661353 bytes 301153155953 (280.4 GiB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 309661353 bytes 301153155953 (280.4 GiB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
```

The previous example shows that eth0/GB1 has IP address 10.236.12.241, and that eth7/GB8 has address 10.236.16.2

Once you have established the correct routes, configure them using **Configuration, Network, Additional Routes** in the PAM UI.

For more information, see [Additional Routes](#)

## Cluster Synchronization, Promotion, and Recovery

After your cluster is configured and turned on, the **Status** tab on the **Configuration, Clustering** panel shows a list of cluster sites and members and details about each. The view of a cluster varies depending on whether you are logged in to a Primary site member or a secondary member.

From the **Status** tab, you can perform the tasks described in this topic.

### View Member Status

Each cluster member lists its status in the Site Members section of the clustering **Status** tab. On Primary site members, members of all sites are visible. On Secondary site members, only that member is visible. Primary site replication is evaluated every minute. Secondary replication status is evaluated every 5 minutes. Select **Refresh Replication Status** to update the status immediately. When a new member subscribes to a cluster, its database status is unknown. The status columns might appear out of alignment. Select the **Refresh Replication Status** button to update its status. Because the **Status** tab does not update automatically, you can use the **Refresh** button to update the UI.

### **Primary Site Members**

For the primary site, replication status updates every minute. If a member status is anything but "online" or "recovering", a warning indicator appears on the **Site Members** table, and an email notification is sent to the monitor. Monitor settings (**Configuration, Monitor**) are not replicated, so each primary member needs the email set separately. Each member should have the same monitor settings.

**Site Member Active:** Primary sites are always active.

**Replication Status:** A green checkmark indicates that the member is online and in sync. A yellow triangle with an exclamation mark means that the member is "recovering," is lagging, or communication has timed out. A red X indicates that the member status is offline, unreachable, error or missing, or out of sync. Hover over the icon to see a tooltip explaining the reason.

### **Replication Detail:**

- **Online:** The member is a fully functional group member, can connect and start executing transactions.
- **Recovering:** The member is going through the recovery process, receiving state information from a donor.
- **Offline:** MySQL exists on the member, but it does not belong to the group.
- **Unreachable:** The group suspects that the server is not reachable because it has crashed or disconnected involuntarily.
- **Error:** An error occurred on the recovery phase or while applying changes.
- **Missing:** Privileged Access Manager cannot find the member in the MySQL replication group.

**Log Files:** Every minute, sample data is replicated among primary site members. The cluster status log records the time that has elapsed since the last sample was sent and received (as mm:hh:ss). See [View Cluster Logs](#) for more information.

### **Secondary Site Members**

**Site Member Active:** A green checkmark indicates that the member is active. A red X indicates that the member has been deactivated. Secondary sites can be deactivated if they lag in replication more than 15 minutes behind the primary site. This threshold is configurable on the Tuning tab, but should only be done with the assistance of Broadcom Support. See [Cluster Tuning](#) for more information.

**Replication Status:** A green checkmark indicates that the member is online and in sync. A yellow triangle with an exclamation mark means that the member is lagging, or communication has timed out. A red X indicates that the member status is inactive or out of sync. Hover over the icon to see a tooltip explaining the reason.

**Replication Detail:** These thresholds are configurable on the Tuning tab, but should only be done with the assistance of Broadcom Support. See [Cluster Tuning](#) for more information.

- **In Sync:** Member is in sync with the primary site.
- **Timeout:** A yellow triangle with an exclamation mark means that the connection has timed out trying to contact this member. A warning appears on the Site Members table.
- **Lag Detected:** The member lags 5 minutes behind the Primary Site. A warning appears on the Site Members table.
- **Out of Sync:** The member lags 10 minutes behind the Primary Site. A warning appears on the Site Members table.
- **Inactive:** The member lags 15 minutes behind the Primary Site. When Inactive, a member no longer allows password views, auto-login, and so on. An email is sent to the Monitor. **Important:** When you change this value, you are changing how far out of sync a member can get before stopping it from functioning. However, if the Primary Site is unavailable and it is set to Operationally Safe mode, the Secondary Site can serve its own stale data. See step 5 in [Configure a Cluster](#).

**Log File:** Every minute, sample data is replicated from the primary site to secondary sites. Every 5 minutes, the cluster status log records the time that has elapsed since the last sample was received (as mm:hh:ss). Every minute, sample data is also replicated from the secondary site to primary site. Every 5 minutes, the cluster status log records the time that has elapsed since the last sample was sent (as mm:hh:ss). See [View Cluster Logs](#) for more information.

## **Remove Cluster Members**

### ***Primary Site***

From a Primary Site member, you can remove a member from any site without stopping the cluster. Select the member in the Site Members table on the **Status** tab and select **Eject Member**. This operation causes a dynamic reconfiguration of the cluster, and does not launch a recovery process.

#### **NOTE**

Ejecting a primary site member while jobs are running on that member terminates the jobs. To protect against such unintended consequences, put the member in Maintenance Mode and wait for it to quiesce before ejecting it.

### ***Secondary Site***

On a Secondary Site member, you can remove a member that you are viewing by using the **Leave Cluster** button. The **Leave Cluster** button lets you remove a secondary member from a cluster while the cluster remains on. This operation causes a dynamic reconfiguration of the cluster, and does not launch a recovery process. If it is the Secondary leader, the next member in the Secondary site becomes the site leader. However, you cannot remove the last remaining member of cluster. In that case, you must delete the site using the **Delete** button. You can also remove or add a Secondary Site without stopping the cluster.

## **Stop the Cluster**

To stop an entire cluster, select **Turn Cluster Off**. You can turn off a cluster from a primary or secondary member.

## **View Cluster Logs**

For troubleshooting purposes, review the cluster logs. Select **View Cluster Logs** from the primary or secondary members. On a secondary member, only the local site cluster logs are accessible.

The View Cluster Logs button is also available on the Global Settings tab when it is not enabled on the **Status** tab.

## **Cluster Synchronization**

Site members can get out of sync, particularly when a site member becomes unavailable. When you synchronize a cluster, databases across all members are updated.

**NOTE**

The re-sync process to a Secondary site or individual member downloads the entire database and terminates any active sessions on the Secondary site or member. Because re-syncing disrupts active user sessions on the member nodes that are involved, place the member nodes that are involved in the resync into maintenance mode for some time before the re-sync to prevent user logins to the affected nodes. For related information, see [Enable Maintenance Mode](#) under [Maintenance and Cluster Tuning Options](#).

**Synchronizing Sites**

The Sites section of the **Status** tab lists the Site Name, Type (primary or secondary), VIP IP address, and VIP FQDN.

The **Re-sync Site** button lets you synchronize all members at a given secondary site. You cannot re-sync a primary site. You cannot re-sync a secondary site unless it can contact the primary site.

**To re-sync a site:**

1. Select the checkbox next to the site you want to re-sync. Re-sync sites one at a time.
2. Select **Re-sync Site**.

**Synchronizing Site Members**

When clustering is on, the list of members differs depending on whether you are logged in to a member of a primary or secondary site:

- On a primary site member, the Site Members section shows the members for all sites.
- On a secondary site member, you can only see the secondary member that you are logged in to.

Individual secondary site members can be re-synced from any primary member. You can also re-sync a secondary member by directly logging in to that secondary site member.

**To re-sync a site member:**

1. Select the checkbox next to the member you want to re-sync.
2. Select **Re-sync Site Member**.

**Refresh Site Member Databases**

In the Site Members section, you can see the status of the member databases. To refresh the database status, use the **Refresh Replication Status** button. The elapsed time since the last sample replication was received, and the time since the last sample replication was sent is listed for secondary members.

**TIP**

On a primary site member, selecting the Refresh buttons updates the database status of all the members in the entire cluster.

**Secondary Member Rejoins the Cluster**

If an unreachable secondary site member comes back online, the member tries rejoining the cluster. First, the member asks the secondary leader for a copy of its database. The member performs an integrity check on the data, then uses it to overwrite its own data. After that check is complete, the database starts. Finally, the cluster recognizes this member, and user logins are forwarded to this member.

**Databases During Synchronization**

When a cluster starts, Privileged Access Manager takes a snapshot of the primary site database. The primary replication leader is the first one in the primary site member list. The replication process applies this snapshot to each of the cluster members, and reports site members as active. If the primary database is not active at the start, the database remains out of sync and you can lose data ([see this note about deactivated databases](#)).

Always start a cluster from a member with an in-sync database. To determine whether its replication status is in sync, look at the Site Members list.

If the primary database is not active, follow these steps:

1. Note the database status for each member.
2. Reorder the cluster members so that a primary member with an active database is reassigned to the top of the list.
3. Restart the cluster:
  - a. On the **Status** tab, select **Turn Cluster Off**.
  - b. On the Global Settings tab, select **Turn Cluster On**.

### **Primary Site Recovery**

Privileged Access Manager uses MySQL group replication for the cluster primary site, and traditional master-slave replication to and from secondary sites.

In MySQL group replication, a "quorum" is the number of members that are required to make decisions for the cluster, such as member health. The quorum is the majority of the members in a cluster, or in this case the Primary Site. The quorum for a three-member primary site is two, and for five members, the quorum is three. The quorum requirement prevents a "split-brain" scenario, where cluster members that are isolated (through network or power failure, for example) could continue operating separately.

If you remove a primary site cluster member voluntarily and gracefully, the cluster is dynamically reconfigured, producing a new quorum. A graceful (or orderly) shutdown is one of the following methods, rather than an abrupt shutdown:

- Use the **Configuration, Power, Stop Instance** control.
- On the **Configuration, Clustering** page in the UI, select the member in the Site Members table on the **Status** tab. Select **Eject Member**.
- On VMware, use the PAM Utility Console. Select **Power off PAM**.

For example, a four-member primary site cluster has a quorum of three. If you eject a member, the resulting three-member cluster has a quorum of two. See the [Fault Tolerance](#) chart for details.

### ***Quorum Loss Example***

Consider a primary site cluster with three members. One member becomes inaccessible because of a network failure. The cluster continues, and alerts administrators that one member is unavailable. If someone reboots a second member, a quorum cannot be achieved. Quorum loss requires PAM administrator intervention at this point, even if one of the members revives itself. See [Quorum Loss](#) for more information.

If the second member had been gracefully removed, as described in [Primary Site Recovery](#), the cluster would have dynamically reconfigured itself. No quorum loss would have been encountered.

### ***Quorum Loss Diagrams***

The following diagram illustrates a three-member Primary Site of a cluster in three different situations. Descriptions of the situations follow the illustrations.

The following diagram illustrates a five-member Primary Site of a cluster in three different situations. Descriptions of the situations follow the illustrations.

**Figure 17: Quorum by 5**

### **Healthy Primary Site**

In a healthy primary site, all members can communicate with each other. Replication proceeds uneventfully.

### **Quorum Rules**

If a primary site member cannot be reached by other members, the remaining members try to form a quorum. With a quorum, the remaining members continue to operate as a cluster. See the [Fault Tolerance](#) chart for details.

The preceding illustrations show three examples of a quorum continuing even though members have been lost. A power failure, network partition, or hardware failure could cause this disruption.

- In *Quorum Rules (A)*, one member is not reachable from the other two. Because two members can communicate, and they constitute a majority, they continue operating as cluster members. The odd member, if operational, cannot contact the others, therefore it ceases to operate as a cluster member. The instance then goes into [cluster recovery](#) mode.
- In *Quorum Rules (B)*, a network partition has divided the cluster members. Although two members can communicate with each other, they cannot form a quorum. The other three members make a quorum, and so continue as the cluster.
- In *Quorum Rules (C)*, a network partition has divided the cluster members. The primary replication leader can only contact one member, while three other members can communicate among themselves. Those three members make a quorum, and so continue as the cluster.

### **Cluster Recovery**

When one or more cluster members cannot join a quorum, the following actions are taken:

- Turn off clustering on the instance
- Back up its database
- Stop group replication
- Restart the application
- Send email notifications
- Standard login user interface is limited to configuration, including Clustering, Diagnostics, Upgrade, and Power
- If that member is managing the load-balancing VIP, the next available member in the list takes up that responsibility.

The cluster member attempts to heal itself in the following manner:

- Determine the replication leader by finding the member with the latest transaction
- Reboot itself if it is not the leader, up to five times

### **Quorum Loss**

Without a quorum, group replication cannot determine who has the latest complete data. A PAM administrator can log in to a primary site member to determine the next course of action:

- **Resume Cluster:** Reboot all cluster members for self-healing
- **Eject Member:** Remove an instance from the cluster. You can then diagnose and repair it apart from the cluster. Ejecting members from the Primary Site effectively reconfigures the number of members in the site. For example, in *Quorum Loss (B)*, if the cluster administrator ejects the unresponsive members, the remaining members make up the new cluster and can continue. This action risks losing data that could reside on the unresponsive members.

### **Member Rejoins the Cluster**

When a primary site member is unreachable, it no longer handles any load balancing. To remedy this problem, restart the cluster, but note the following caveat:

#### **WARNING**

If the first primary site member in the primary site list has an out-of-sync database, do not start the cluster. If you start a cluster from member with an out-of-sync database, you can lose data. To avoid this problem, reorder the primary site members in the list. Make the member with the first in-sync database (green checkmark) the first member in the list. Restart the cluster from this first member, which becomes the primary replication leader. If you have questions, contact Broadcom Support.

### **All Primary Members are Down**

For an active cluster (turned on), an event can occur to cause all members of the primary site to stop working. Events such as a power failure might cause the operating system of each site member to stop. When all the members come back online, the state of the cluster is unpredictable.

**To restore cluster stability, follow these steps:**

1. Turn off the cluster.
2. Determine which primary site member is the most trusted and up-to-date. See [Replication Analysis](#). That member might be the one that failed last relative to the other members.
3. Reorder the most trusted member to the first member in the primary site list.
4. Restart the cluster from this first member.

### **Site Promotion Using Replication Analysis**

In a multi-site cluster, if the Primary site is unavailable, you must promote a Secondary site to become the Primary site. Ideally, promote the Secondary site that has the most up-to-date information. For guidance on which Secondary site is the most up to date, use the replication analysis feature.

**NOTE**

Primary site replication IDs can be much higher than secondary site replication IDs because not all transactions are replicated to secondary sites. Replication IDs are also expected to vary slightly among primary site members as they continually update. This behavior is normal and should not affect secondary site promotion decisions. Replication Analysis is not intended to monitor ongoing replication activity.

**To promote a secondary site, follow these steps:**

1. Go to **Configuration, Clustering** page, **Status** tab and select **Turn Cluster Off**.  
A warning appears. Once you accept it, a "Turning Cluster Off" message appears.
2. Go to the **Global Settings** tab and select **Replication Analysis**.  
The Replication Analysis window opens. The page lists the site name, cluster member, and last replication ID for that member.
3. Determine the site and member with the highest replication ID, then close the page.
4. Select the site with the highest ID, then select **Set Primary Site**.
5. Move up the member in the new primary site to the first position in the list.
6. Select **Save Config Locally**.
7. Select **Save to Cluster**.  
When you promote a secondary site, saving the cluster might fail. To solve this problem, remove the site that is no longer reachable and save.
8. Select **Turn Cluster On**.
9. If you use the REST API or CLI Commands, ensure that they point to the VIP of the new primary site.

**NOTE**

The order of the sites Global Settings page remains the same even after you promote a site. The primary site is not always listed first. The first member in the newly promoted site is the new replication leader. Look at the Type column to determine primary and secondary sites.

**Unlock a Member When the Cluster Is Off**

When the cluster is turned off, the Credential Management services of each member are locked. No credentials can be viewed or used in auto-connect. An **Unlock Me** button is available on the **Status** tab. An unlocked member is independent of the cluster replication process, and can cause synchronization problems.

Before you unlock a member, note the following points:

- Unlocking permits scheduled jobs and processes to continue, which can trigger credential rotation.
- If the unlocked member is not the primary member of the cluster, any changes are lost after the cluster restarts.

**Application Distinct from Replication Leader**

The primary replication leader is elected by MySQL to be the source of data replication. The "application master", on the other hand, is elected by the Privileged Access Manager application. The application master is responsible for credential management jobs that rotate passwords. This member might not be the same as the primary replication leader.

If a standard user logs out from a secondary site member, a password rotation is handled by the application master in the primary site. If the application master shuts down, another primary site member is elected by PAM.

**NOTE**

- [Cluster Maintenance](#)
- [Cluster Backup and Disaster Recovery Process](#)

## Primary Site Fault Tolerance

In a PAM cluster, the Primary site makes fault tolerance decisions that are based on its quorum. For more information about the quorum, see [Primary Site Recovery](#). The size of the Primary site determines the quorum. The quorum determines its fault tolerance, or how many members the Primary site can lose and continue normal operations.

To ensure Primary site fault tolerance, we recommend at least three members at a Primary site. If the entire cluster has only two members, do not put both members in the Primary site. We recommend a 1 x 1 configuration (one member at the Primary site and one member at Secondary site).

Primary Site Size	Quorum	Member Failures Tolerated
1	1	0
2	2	0
3	2	1
4	3	1
5	3	2
6	4	2
7	4	3
8	5	3
9	5	4

## Configure Load Balancers to Determine the Availability of Cluster Nodes

Privileged Access Manager provides a health verification script ([https://PAM\\_server/health.php](https://PAM_server/health.php)) that load balancers can poll to determine the availability of nodes in your cluster. If the node is operating correctly, `health.php` returns HTTP status code 200 OK.

If any of the following problem conditions apply, the script returns HTTP status code 503 Service Unavailable:

- The node is in maintenance mode.
- Clustering is ON, the node is a secondary site member which is not active
- Clustering is ON, the node is a secondary site which is out of sync with the primary node
- The node is locked.

### NOTE

For information about unlocking nodes, see the section titled "Unlock a Member When the Cluster Is off" in the [Cluster Synchronization, Promotion, and Recovery](#) topic.

## Install and Configure a Socket Filter Agent

Privileged Access Manager Socket Filter Agents (SFAs) can restrict access to and from server-based devices. Socket filters provide a different kind of access control than devices with finite command sets, such as routers, for which command filtering is applied.

SFAs work with Socket Filter Lists (SFLs) configured on the PAM server. For details, see [Socket Filter Agent Support](#).

### Socket Filter Agent Installation Requirements

This section describes SFA requirements for installing a Socket Filter Agent.

- **Network Port Requirements:** SFAs have the following network port requirements:

- By default, port 8550 must be allowed between the target host containing the SFA and the appliance. You can configure the SFA to use a different port.
- Port 443 must also be open to allow communication back to the appliance, including messages for log entries.

**NOTE**

For AWS or Azure, ensure that these ports are also open in the AWS or Azure network settings, and the OS firewall of the instance.

- **Permissions:** SFA installation requires administration privileges, such as those provided by the Windows default Administrator account or the UNIX `root` account.
- **Supported Operating Systems:** See [Supported Environments](#) for operating systems that support the SFA.

Use the following optional procedure to monitor the status of SFA agents from the PAM UI.

**Download the Socket Filter Agent Software**

Download the software for this component from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

**Install and Configure a Socket Filter Agent on Windows**

Windows Socket Filter Agents are provided as MSI self-extracting packages. This section describes how to install and configure SFAs on a Windows target system.

**NOTE**

On Window targets, Socket Filter policies are not enforced against users who log in to targets directly, bypassing Privileged Access Manager.

***Install a Windows SFA Using the Installer UI***

Use this procedure to install a Windows SFA using the installer UI.

The account that is used to install the SFA impacts which accounts can uninstall the SFA. If one of the following accounts installs the SFA, no other account can uninstall the agent:

- A domain-based account with local Administrator privileges
- A local account with local Administrator privilege installs the SFA, but not the Administrator itself.
- A local Administrator account with local Administrator privileges

If the installing domain-based or local account becomes obsolete or invalid, you might not be able to uninstall the SFA. To uninstall the SFA product under these circumstances, contact Broadcom Support.

**Follow these steps:**

1. Ensure that all installation prerequisites are met.
2. Log in to the target Windows device as a local administrator.
3. Use the **Add/Remove Programs** window (or equivalent) to remove any existing Windows SFA from the target device.
4. Navigate to the directory where you uncompressed the SFA download.
5. Start the installer by double-clicking the `WinSFA.exe` file.
6. Follow the prompts.

After installation, the SFA starts and runs as a background Windows service with the default name "CA Technologies Socket Filter". Use the local Windows Services interface for service settings and control.

***Install an SFA Silently on Windows***

Use this procedure to install a Windows SFA silently with automatic startup.

The account that is used to install the SFA impacts which accounts can uninstall the SFA. If one of the following accounts installs the SFA, no other account can uninstall the agent:

- A domain-based account with local Administrator privileges
- A local account with local Administrator privilege installs the SFA, but not the Administrator itself.
- A local Administrator account with local Administrator privileges

If the installing domain-based or local account becomes obsolete or invalid, you might not be able to uninstall the SFA. To uninstall the SFA product under these circumstances, contact Broadcom Support.

#### Follow these steps:

1. Ensure that all installation prerequisites are met.
2. Log in to the target Windows device as a local administrator.
3. Use the **Add/Remove Programs** window (or equivalent) to remove any existing Windows SFA from the target device.
4. Navigate to the directory where you uncompressed the SFA download.
5. Open a Command Prompt window and navigate to the directory where you uncompressed the SFA download.

#### NOTE

On Windows Server 2008 and Windows Server 2012, right-click on the Command Prompt icon and select **Run as Administrator**.

6. Enter the following command:

```
path\WinSFA.exe /s /v"/qn /liwe c:\XCDM_SFA.log"
```

Where *path* is the path where the WinSFA.exe file is located.

The /q and /l options and parameters are recommended but not required.

After installation, the SFA starts and runs as a background Windows service (with the default name "CA Technologies Socket Filter"). Use the local Windows Services interface for service settings and control.

#### Change Basic Windows SFA Configuration Settings

Run the SFAConfig.exe configuration utility to change basic SFA settings.

#### Follow these steps:

1. Navigate to *SFA\_Install\_Dir*\Bin.  
*SFA\_Install\_Dir* is the SFA installation directory. Default: C:\Program Files (x86)\CATech\Socket Filter.
2. Execute *SFAConfig.exe*.
3. Change any of the following settings, as required:
  - **Port:** The port that the SFA uses to communicate with the appliance. Default: 8550
  - **Service Name:** The name of the SFA Windows service. Default: "CA Technologies Socket Filter."
  - **Service Description:** The description of the SFA Windows service Default: "CA Technologies Socket Filter."
  - **Run Agent in Verbose mode:** If enabled, the SFA produces detailed log messages for diagnostic purposes. Default: off.
  - **Enable IPv6 Protocol:** Set this option to enable the SFA to support IPv6. If not set (the default), the SFA supports only IPv4.
4. Select **Save and Restart Service**.  
The SFA restarts and the configuration changes are implemented.

#### Reconfigure a Windows SFA to Use Changes to the Target Device Network Configuration

The SFA reads and uses the target device network configuration during startup. It does not dynamically update if you make subsequent configuration changes (for example, adding a NIC or changing the IP address). You must therefore restart the SFA to reconfigure it to use target device network changes made *after* startup.

To restart the Windows SFA, use the local Windows Services interface. The default service name is "CA Technologies Socket Filter."

## Troubleshoot a Windows SFA

Turn on Verbose mode using the SFAConfig.exe configuration utility to generate detailed log messages.

Log messages are stored in the `log.txt` file that is located in the installation directory.

## Uninstall a Windows SFA

To uninstall a Windows SFA, do *one* of the following steps:

- Access the Windows Control Panel and use the **Add/Remove Programs** window (or equivalent).
- Open a Command Prompt window and enter the following text:

```
MsiExec.exe /X{5A2A2643-2BD6-4D09-9B03-E08098887B06} /norestart
```

## Install and Configure a Socket Filter Agent on UNIX

This section describes how to install and configure a Socket Filter Agent (SFAs) on a UNIX target.

### NOTE

On UNIX and Linux targets, the Socket Filter Agent only filters non-root users. A Socket Filter List in a policy becomes effective only for non-root users logging in to targets through PAM. Afterwards, the filter is in effect, even if the user logs in to the target directly. Socket filters for all users are reset after root restarts the socket agent (gksfd).

## Install a UNIX SFA

The UNIX SFA download package contains a separate installer script for each supported UNIX operating system. Each script has a descriptive filename of the following format:

```
gksfd_sfa-version_os-version[_64]_linux_install.sh
```

Where *sfa-version* is the SFA release version and *os-version* is the UNIX version.

For example:

- `gksfd_4.1.7_debian6_64_linux_install.sh` for a Release 4.1.7 SFA for Debian 6 (64-bit)
- `gksfd_4.1.7_rh6_linux_install.sh` for a Release 4.1.7 SFA for Red Hat EL 6 (32-bit)

### NOTE

You can use `gksfd_.xx_rh7_linux_64_install.sh` to install Red Hat Enterprise Linux 7, 8, and 9 systems.

Depending on the OS, there are different methods of deploying the SFAs. Because minimal configuration is required on the managed target device, an SFA can be deployed through preexisting software delivery mechanisms.

## Follow these steps:

1. Ensure that all installation prerequisites are met.
2. Log in to the target device as a local administrator.
3. Remove any existing UNIX SFA from the target device.
4. Open a terminal window.
5. Copy the appropriate installer script for your operating system to the directory where you want to install the SFA.
6. Run the installer script. For example, to install a 4.1.7 SFA on Red Hat Enterprise Linux (32-bit):

```
[root]# sh gksfd_4.1.7
_rh6_linux_install.sh
```

A terminal window opens, allowing you to interact with the installer script.

7. Follow the online directions. When requested, supply a destination directory to install the SFA. The default is `/usr/sbin`.

**NOTE**

Specifying a location different from the default installation location can cause unexpected behavior. We therefore recommend that you accept the default location.

The control script is installed.

**Configure and Operate a UNIX SFA**

A configuration file (`/etc/gksfd.cfg`) and a control script (`rc.gksfd`) control UNIX SFA operation

The following table describes key settings in the `gksfd.cfg` configuration file.

Name	Setting	Description
<b>Login control</b>	<code>SECURE_LOGIN=[ 0   1 ]</code>	0 : Allow login from outside of PAM 1 : Allow login only from a PAM connection.
<b>Secure user list</b>	<code>SECURE_USER= &lt;username_1&gt; , &lt;username_2&gt; , ... &lt;username_N&gt;</code>	Specifies every SFA superuser: every device login user that is not subjected to any socket filter policy.  Each username is delimited with comma, with no spaces permitted.
<b>IPv4 Support</b>	<code>IPv4=[ 0   1 ]</code>	0 : Disable SFA support for IPv4 addresses. 1 : Enable SFA support for IPv4 addresses. (Default)
<b>IPv6 Support</b>	<code>IPv6=[ 0   1 ]</code>	0 : Disable SFA support for IPv6 addresses. 1 : Enable SFA support for IPv6 addresses. (Default)

Use the control script to start, stop, restart, or reload the UNIX SFA process (`gksfd`).

**To run the control script, follow these steps:**

1. Change directory to the installed location of the script on your platform.  
The `rc.gksfd` control script is located in `/etc/init.d/` on all versions of UNIX *except* AIX, HP-UX, and Red Hat Enterprise Linux 9. On those platforms, the control script is installed in the following directories:
  - **AIX:** `/etc/rc.d/init.d/`
  - **HP-UX:** `/sbin/init.d/`
  - **Red Hat Enterprise Linux 9:** `/etc/rc.d/init.d`
2. Launch the control script using the following syntax:

```
rc.gksfd { start | stop | restart | reload }
```

To launch the SFA with options, launch `gksfd` directly using the following syntax:

```
gksfd [-options]
```

The following table describes the options:

Option	Default values when option is not set	Description
-4	N/A	Force the SFA to use only IPv4 addresses.
-6	N/A	Force the SFA to use only IPv6 addresses.

Option	Default values when option is not set	Description
-h		Display online help.
-l logfile	/var/log/gksfd.log	Specify the log file used.
-p port#	8550	Set the port to communicate with the appliance.
-v	info	Set log-level to Verbose mode. For example: /usr/sbin/gksfd -v >> /var/log/gksfdmessages Set this option only when extra logging is required.
-ver		Display the version number.

To apply persistent changes, set the UNIX SFA options in the `rc.gksfd` file.

#### NOTE

Some platforms, such as Red Hat Linux, might block port 8550 by default, which inhibits SFA operation. To determine whether the port is blocked, use the `netstat` command. If necessary, open port 8550 using the command `iptables -I INPUT 1 -p tcp --dport 8550 -j ACCEPT`, and restart the SFA.

### Reconfigure a UNIX SFA to Use Changes to the Target Device Network Configuration

The SFA reads and uses the target device network configuration during startup. The SFA does not dynamically update if you make subsequent configuration changes (for example, adding a NIC or changing the IP address). You must therefore restart the SFA to reconfigure it to use target device network changes made *after* startup.

To restart a UNIX SFA, run the SFA control script as follows:

```
rc.gksfd restart
```

### Troubleshoot a UNIX SFA

Use the `-v` option to turn on Verbose mode to generate detailed log messages.

The default location for log messages is `/var/log/gksfd.log`.

### Uninstall a UNIX SFA

#### Follow these steps:

1. Stop the `gksfd` daemon from the directory where the executable was installed. The following example is for Red Hat 6 Linux:  
[root]# `/etc/init.d/rc.gksfd stop`
2. Delete the following files:
  - The executable, typically located at `/usr/sbin/gksfd`
  - The control script, typically located at `/etc/init.d/rc.gksfd`

## Accessing PAM

Log in to the PAM UI to access the following role-based functionality:

- As a PAM *standard user*, to access and manage privileged network devices.  
For more information about using PAM to access privileged devices, see [Using PAM](#)
- As a PAM administrator, to do the following operations:
  - [Configure PAM servers](#)
  - [Implement PAM network-based access control](#)
  - [Implement Credential Manager to protect privileged account credentials](#)
  - [Implement PAM SC server-based access control](#)
  - [Administrate PAM](#)

### PAM UI Access Methods

End-users and administrators can access the PAM UI using the following methods:

- **PAM Client.** The [PAM Client](#) is an alternative to Internet Explorer that you install on your local workstation. The PAM Client does not interfere with browser-based UI access. Both methods can be used from the same workstation.
- **Web Browser.** Various browsers, such as Chrome, Safari, Edge and Firefox can be used with the following limitations:
  - Microsoft Edge running in Internet Explorer mode is the only browser that still supports NPAPI, which is required to use the RDP and SSH Java applets that are required to access resources. To use Microsoft Edge running in Internet Explorer mode, Java 8u-latest must be installed on the desktop. For more information, see [Internet Explorer mode in Microsoft Edge](#).
  - Microsoft Edge running in Internet Explorer mode does not support the [System Dashboard](#) or the [Management Console Cluster Dashboard](#).
- **PAM Access Agent (Windows only).** The [PAM Access Agent](#) is a lightweight alternative to the PAM Client that you install on your Windows workstation. The PAM Access Agent does not interfere with the browser-based UI access. Both methods can be used from the same workstation.

### Login to the PAM UI Using a Web Browser

To log in to the PAM UI using a supported web browser, follow these steps:

1. Open the browser and navigate to a server URL using *one* of the following formats:

```
https://server_ip_address/
```

```
https://fqdn_of_server
```

*server\_ip\_address* or *fqdn\_of\_server* is the system where you installed the PAM server.

Examples:

```
– https://102.200.11.222/
```

```
– https://capam.forwardinc.com
```

2. At the Login page, enter your credentials.

The credentials are specific to the server. The login experience can be different for the following reasons:

- Single sign-on provisioning might be set up.
- You might have to supply credentials at the point of login to a target system. Your server administrator can tell you if you require such credentials.
- The **Authentication Type** field on the login page has a value other than Local, such as RSA or RADIUS. As a result, specify which authentication domain to use.
- You are prompted to accept an organizational license.

**NOTE**

When a user with an Active Directory account attempts to log in following expiration or temporary replacement of a password, the **My Info** page appears. On this page, the user must change the password. The password is propagated to update to Active Directory.

**Access the PAM UI Using the PAM Client**

**Follow these steps to use the PAM Client:**

1. On a local workstation where you plan to use the PAM Client, open a web browser, and enter the URL of a PAM server
2. Download the PAM client installer executable.
3. Run the installer.
4. After the installation is complete, launch the PAM Client application and log in.

**NOTE**

For comprehensive information about installing and using the PAM Client, see [Deploy the PAM Client](#).

**Access the PAM UI Using the PAM Access Agent**

**Follow these steps to use the PAM Access Agent:**

1. On a local workstation where you plan to use the PAM Access Agent, open a web browser and enter the URL of a PAM server.
2. Download the PAM client installer executable.
3. Run the installer.
4. After the installation is complete, launch the PAM Access Agent and log in.

**NOTE**

For comprehensive information about installing and using the PAM Access Agent, see [Deploy the PAM Access Agent for Windows](#)

**Password Change on First Login**

When you log in the first time, you are prompted to change your password. Follow these password requirements:

- Differ from the previous password
- Be a length between the Global Settings values for **Min Length** (default: 6) and **Max Length** (default: 14)
- Have at least one (Latin) alphabet character
- Have at least one numerical digit character

## Account Information

You can also specify other account information. To modify these settings, select your account name in the top-right corner of the UI to view and modify your account information. Many of the fields are self-explanatory, but note the following settings.

Basic Info	
RDP Username	Used by the RDP applet as credentials for access to a remote Windows device. This field accepts a name with an embedded backslash to log in to a domain account.
Mainframe Display Name	Display Name that is used by the AS/400 applets TN3270, TN3270SSL, TN5250, TN5250SSL
Keyboard Layout	Conforms the keyboard input to native keyboard output. Select the pull-down arrow to display all available language options.
Administration	
Email self on login	Enables an email to be sent to the email address entered in the Basic Info page. Alerts you when the account is being used by someone else.
Email on Login	Enables an email to be sent to the email address of a specific user or administrator.
Terminal Customization	
SSH and Telnet CLI Terminal Customization	Select this box to display settings for configuring the command-line interface terminal.
RDP Resolution	Select the resolution for the RDP terminal.

## About the Landing Page Displayed After Login

After you log in to the server, the page you see depends on your user role.

- For *standard users* (users who use PAM to access and manage privileged network devices, not administrate PAM), the **Access** page displays. From the **Access** page, you can make connections to target devices and view passwords.
- If you have Global Administrator privileges, the **Dashboard Overview Tab** appears. Users with such privileges include the superuser, the Global Administrator, and the Operational Administrator or Server Control Administrator roles. More information about the **Dashboard** is available [here](#).

### NOTE

PAM also provides the following interfaces for configuring network settings and accessing PAM functionality programmatically:

- Network Interfaces**

PAM provides the following interfaces for configuring network settings on the PAM physical and VMware OVA appliances:

- LCD interface on the front panel of the hardware appliance. For more information, see [Configure Network Connections for the Appliance](#)
- VMware Console for the VMware OVA appliance. For more information, see [Deploy the VMware OVA Template](#).

- APIs**

PAM provides the following APIs for accessing its functionality programmatically.

- [PAM External REST API for Integrating Applications](#)
- [Credential Manager Remote CLI and Java API](#)

## Using PAM

---

The topics in this section describe procedures for *standard users* (end-users who use PAM to access and manage privileged network devices, not PAM administrators).

- [Establish Connection Sessions and View Target Account Passwords](#)
- [Configure Your Account Settings](#)
- [Display and Access Devices](#)
- [Filter Views](#)
- [View and Permit Views of Passwords](#)
- [Set Up Java for Internet Explorer](#)

### Establish Connection Sessions and View Target Account Passwords

The **Access** panel is displayed as the default landing page when a standard user logs in. Users with greater than standard user privileges open the panel by selecting the **Access** entry on the menu bar.

The **Access** panel provides a consolidated interface from which you can:

- Establish a **connection session** to target devices for which you have access permission.
- **View the password** of target accounts (of a target application maintained on a target device) for which you have permission.

#### NOTE

The functionality available on the **Access Devices** panel depends on the platform from which it is accessed. Use the following links to access content that describes the functionality available on the **Access Devices** panel on each platform:

- [PAM Client or a browser that supports applets \(IE 11\)](#): Full functionality
- [Other browsers](#) (for example, Chrome, Edge, Firefox, and Safari: Simplified interface with a subset of functionality
- [Mobile devices](#): Simplified interface with a subset of functionality.

### Review the Access Page

#### NOTE

Mobile users, see [Mobile User Access Page](#).

The **Access** page is available:

- As the unmarked landing page for a standard user
- By selecting the **Access** link on the Menu bar for any user with privileges beyond the Standard User role

The **Access** page provides a consolidated interface from which you can:

- Establish a **connection session** to any permitted Privileged Access Manager Device
- **View the password** of any permitted Target Account (of a Target Application maintained on a Privileged Access Manager Device)

After you log in, a page appears with the the following columns:

- Device Name
- Address
- OS
- Access Methods
- Web Portal
- RDP Applications
- Services
- Target Applications

If your administrator provisioned devices and assigned a policy to you (or your user group), you might have many rows. For example, you might have devices that are named "RH3," "Win2k," "WS2," and more. Each line item corresponds to access features available to you for that device.

For example, an access method named "RDP\_3389" might be available for your download and automatic connection to device "Win2k". Clicking "RDP\_3389" triggers an applet to be downloaded to your computer. The applet automatically executes a connection to the physical device labeled "Win2k". If single sign-on is configured, you might be prompted to enter a user name and password. You might be logged in automatically and land in the home directory.

In the column labeled "Target Applications", a drop-down list corresponds to Device "WS2". There might be a Target Application, such as "MSSQL" on that Device ("WS2"). Indented below that name might be a Target Account ("User1"). The items in this menu prompted Password Views. Thus if you select "User1" you invoke an overlay window that asks for your password viewing credentials. When you supply them, the password appears.

If the number of elements in the drop-down list exceeds thirty (target applications and target accounts combined), a pop-up list appears. The pop-up list shows the complete list of applications and accounts. You can then view the list of target accounts based on your target application. You can also directly search for the target application or the target account.

### **The SSH Access Method Behavior on the Access Page**

The SSH Access Method behavior for autologin using the SSH-2 Certificate Authentication protocol differs from autologin using the SSH-2 Password or SSH-2 Public Key protocols. After configuring the SSH-2 Certificate Authentication protocol, the SSH Access Method applet (MindTerm) connects an SSH Proxy Service in the PAM appliance that performs go-between, actions including SSH-2 certificate authentication. The SSH-2 Password or SSH-2 Public Key protocols do not require this additional layer of processing.

As a result, using the SSH-2 Certificate Authentication protocol reduces the number of simultaneous SSH Access Method applets per PAM Appliance. Additionally, the cryptography settings governing connections to Target Devices via the SSH-2 Certificate Authentication protocol will be configured on the **Configuration, Security, Cryptography** page under the **SSH Proxy** tab, versus the **SSH MindTerm** tab for the SSH-2 Password or SSH-2 Public Key protocols.

## **Use the Limited Functionality Access Devices Panel on Standard Web Browsers**

When you log in to the PAM UI from a standard browser (for example, Chrome, Edge, Firefox, or Safari; *not* Internet Explorer), a limited functionality version of the **Access Devices** panel is available.

The **Access Devices** panel is displayed as the default landing page when a standard user logs in. If you have greater than standard user privileges, select the **Access** entry on the menu bar open the panel.

This limited version of the **Access Devices** panel provides an interface from which you can:

- Obtain the credentials of any target account (of a target application maintained on a Privileged Access Manager device) for which you have privileges in the **Access Devices** table.
- View the details of any credentials that you are using the **Passwords currently in use** table.

The following screen capture shows an example of the limited **Access Devices**

**Symantec Privileged Access Manager**

Super System Info Logout

Dashboard Access Sessions Users Services Devices Credentials Policies Secrets

**Warning:** PAM-CMN-1018: Configuration Password is still the default value.  
PAM-CMN-3356: Remote CA PAM Debugging Services is ON.

(2) Passwords currently in use

Account	Applicati	Host	Device	Auto Contr	Timeou	Reques	Approve	Request Start Date	Request End Date	Status	Action
check...	app1	1.1.1.1	device1	All		super		2022/11/02 1...	2022/11/02 1...	Chec...	<a href="#">Check In</a>
dual...	app1	1.1.1.1	device1	All	10	super		2022/11/02 1...	2022/11/02 1...	Pending	

**Access Devices**

Column: Value: Filter Reset Add Filter My Views

Device Name	Address	Operating System	Target Applications
apikey.xceedium.com	apikey.xceedium.com	Other	Select
device1	1.1.1.1	Other	Select
JITDevice	10.17.41.105	Other	Select

### View the Credentials of Target Accounts for Which You Have Privileges

The **Access Devices** table lists the following information about target applications for which you have permission to obtain the login credentials:

- **Device Name**
- **Address**
- **Operating System**
- **Target Applications**

If your administrator has provisioned multiple devices and has assigned a policy to you (or your User Group), the **Access Devices** table has a corresponding row for each device. For example, you might have devices that are named "RH3", "Win2k", and "WS2". Each line item corresponds to access features available to you for that device.

In the Target Applications column, a drop-down list corresponds to Device "WS2". There might be a Target Application such as "MSSQL" on that Device ("WS2"). Indented below that name might be a Target Account ("User1"). The items in this menu prompt Password Views. If you select "User1", the **Show Credential** page appears.

### View the Details of Credentials That You Are Using

Select the **Password View Requests** to view the details of any credentials that you are using and, optionally, check them in.

**NOTE**

The **Passwords currently in use** table only appears (above the **Access Devices** table) if you are using at least one set of credentials.

**TIP**

To access the fully functional **Access Devices** panel from which you can establish connection sessions to permitted Privileged Access Manager devices, open the PAM UI using the PAM Client or Internet Explorer.

## Use the Access Devices Panel from a Mobile Device

When you log in to the PAM UI from a mobile device, a limited functionality version of the **Access Devices** panel is available.

The **Access Devices** panel is displayed as the default landing page when a standard user logs in. If you have greater than standard user privileges, select the **Access** entry on the menu bar to open the panel.

This mobile version of the **Access Devices** panel provides an interface from which you can:

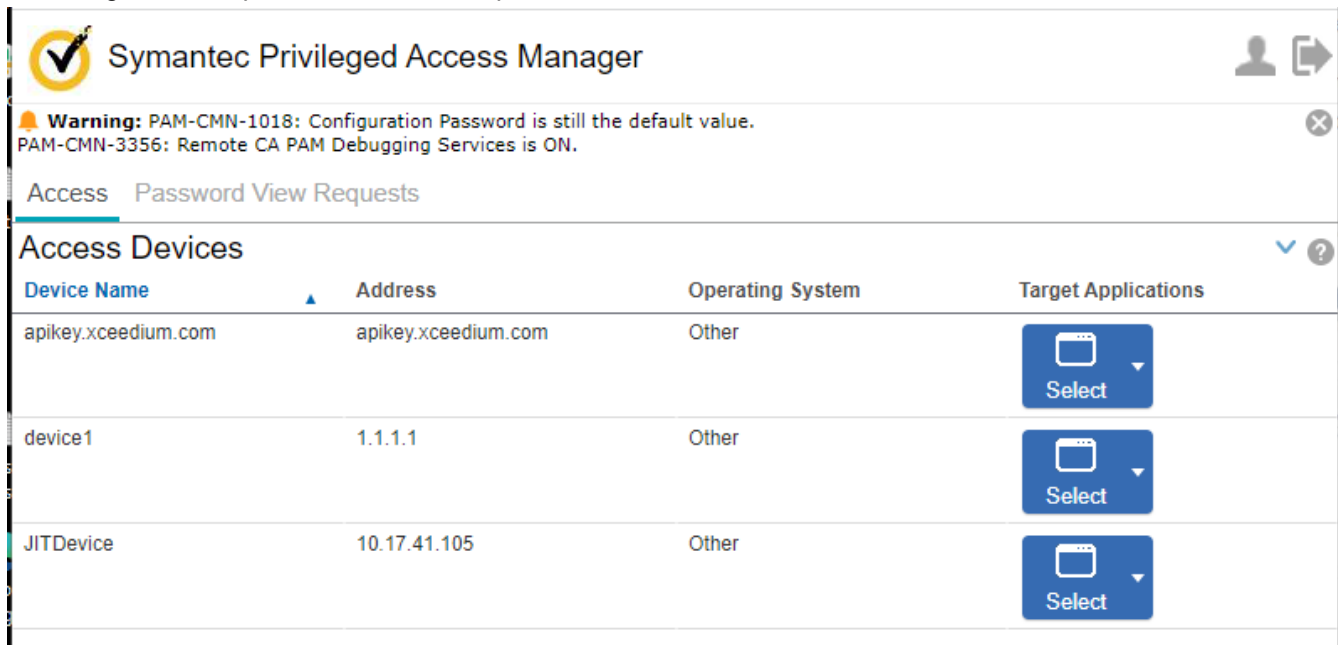

- View the credentials of any target account (of a target application maintained on a PAM device) for which you have privileges.
- View the details of any credentials that you are using.

### View the Credentials of Target Accounts for Which You Have Privileges

Select the **Access** tab to view the **Access Devices** table that lists the following information about target applications for which you have permission to obtain the login credentials:

- **Device Name**
- **Address**
- **Operating System**
- **Target Applications**

The following screen capture shows an example of the **Access**

The screenshot shows the Symantec Privileged Access Manager mobile interface. At the top, there is a header with the Symantec logo and the text "Symantec Privileged Access Manager". Below the header, there is a warning message: "Warning: PAM-CMN-1018: Configuration Password is still the default value. PAM-CMN-3356: Remote CA PAM Debugging Services is ON." Below the warning, there are two tabs: "Access" (selected) and "Password View Requests". The main content area is titled "Access Devices" and contains a table with the following columns: "Device Name", "Address", "Operating System", and "Target Applications". The table lists three devices: "apikey.xceedium.com", "device1", and "JITDevice". Each device row has a "Select" button in the "Target Applications" column.

Device Name	Address	Operating System	Target Applications
apikey.xceedium.com	apikey.xceedium.com	Other	Select
device1	1.1.1.1	Other	Select
JITDevice	10.17.41.105	Other	Select

tab.

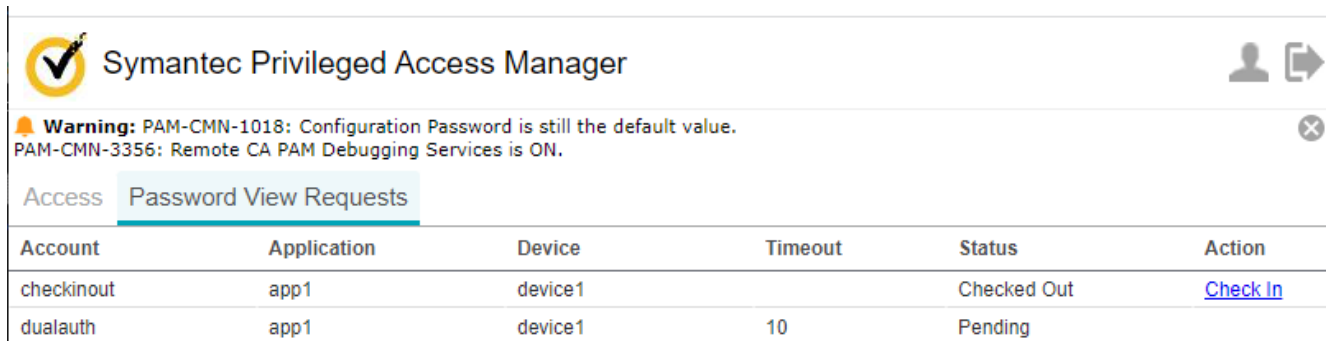

If your administrator has provisioned multiple devices and has assigned a policy to you (or your User Group), the **Access Devices** table has a corresponding row for each device. For example, you might have devices that are named "RH3", "Win2k", and "WS2". Each line item corresponds to access features available to you for that device.

In the Target Applications column, a drop-down list corresponds to Device "WS2". There might be a Target Application such as "MSSQL" on that Device ("WS2"). Indented below that name might be a Target Account ("User1"). The items in this menu prompt Password Views. If you select "User1", the **Show Credential** page appears.

### View the Details of Credentials That You Are Using

Select the **Password View Requests** tab to view the details of any credentials that you are using and, optionally, check them in.

The following screen capture shows an example of the **Password View Requests**

Account	Application	Device	Timeout	Status	Action
checkout	app1	device1		Checked Out	<a href="#">Check In</a>
dualauth	app1	device1	10	Pending	

tab.

#### NOTE

See also [Update Mobile User Password](#)

## Configure Your Account Settings

The first time that you log in, you are prompted to add or edit your name and email and to change your password. To update the information in the **User Information** panel later, select your name in the upper right of the page.

#### NOTE

Mobile users, see [Update Mobile User Password](#).

### Basic Info Tab

Use the following fields to configure basic account information:

#### NOTE

The **Mainframe Display Name** and **RDP User Name** options that were previously on this tab are now available on the [Extended Identities](#) tab.

- **User Name** cannot be edited.
- **First Name**, **Last Name**, and **Email** are required.
- Use **Old Password**, **New Password**, and **Confirm Password** to change your password.
- **Phone** and **Cell Phone** are optional.
- Select one of the following options from the **Keyboard Layout** drop-down list to specify your keyboard language.

#### NOTE

On Windows clients, you can leave the default **Auto** option to use the Windows OS setting for the virtual RDP keyboard. To use a different language for the virtual RDP keyboard, select that language from the list.

For any OS, select one of the following specific-language options:

- **DA** – Danish
- **DA-DK** – Danish (Denmark)
- **DE** – German
- **EN-GB** – English (UK)
- **EN-US** – English (US)
- **ES** – Spanish (Spain)
- **ES-419** – Spanish (Latin America)
- **FI** – Finnish
- **FR** – French
- **FR-BE** – French (Belgium)
- **FR-CA** – French (Canadian)
- **FR-CH** – French (Switzerland)
- **HU** – Hungarian
- **IT** – Italian
- **IW-IL** – Hebrew
- **JA-JP** – Japanese (Japan)
- **NO** – Norwegian
- **PL** – Polish
- **PT-BR** – Portuguese (Brazil)
- **PT-PT** – Portuguese (Portugal)
- **RU** – Russian
- **SV** – Swedish (International)
- **SV-SE** – Swedish (Sweden)

### **Administration Tab**

(Optional) Set the **Email Self on Login** option on the **Administration** tab to configure PAM to send you an email to each time that you log in.

### **Extended Identities Tab**

Configure alternate accounts to access RDP applets, mainframe applets, and Azure SQL Managed Instances on the **Extended Identities** tab.

To specify an alternate account, enter it in the corresponding **Value** field:

#### **NOTE**

The extended identities controls are not enabled until you log in with new credentials after a login session when you are *required* to change your password. That is, they are disabled the first time that you log in to an account and when you log in to make a required password change.

- **RPD User Name:** Enter an account name for use by the RDP Applet or the MSSQL JIT target connector.
- **Mainframe Display Name:** Specify an account name to use to access the AS/400 applets (TN5250 and TN5250SSL).
- **Azure Username:** Specify a valid Azure AD account name (an email address) to use to access an Azure SQL Managed Instance. The specified value must be an account that exists in Azure AD.

### **Terminal Customization Tab**

Use the controls on the **Terminal Customization** tab to customize settings for SSH, Telnet CLI, and RDP terminal settings.

To customize settings for SSH and Telnet CLI terminal sessions, set the **SSH and Telnet CLI Terminal Customization** option. Use the controls that appear to change font, color, character encoding, terminal dimensions, buffer, and scroll position.

To specify the default resolution for RDP terminal sessions, select an option from the **RDP Resolution** drop-down list.  
**Range:** 800 x 600 to Full Screen **Default:** 1024x768

## Preferences

Use the controls on the **Preferences** tab to optionally set the following options.

- Use the following options to optionally override the default date and time display preferences:

- Select a **Time Zone Region**, then a **Time Zone**.
- Select a **Date Format**, such as MM/DD/YYYY.
- Select a **Time Format**, such as 12 or 24 Hour.

### NOTE

The **Server Time** is always displayed in UTC. If you save any changes, they are reflected in the **User's Current Time**. Modifications do not take effect until the next login session.

- Set the **Enable Charts** option to enable graphical charts in the [Credential Manager Activities](#) reports.
- Set the **Application Color Scheme** option to override the global setting and specify whether to display the PAM UI in **Light** (the default) or **Dark** mode:

### NOTE

Dark mode is also not available on the PAM Agent or for all elements and components on other PAM UI platforms, including the following:

- PAM access methods (for example, RDP, SSH, and TELNET) launched from the **Access** page
- PAM LDAP Browser
- Session Recording Viewer
- Threat Analytics
- PAM Report output
- External API Documentation
- Online help
- Alternate Configuration Utility

## Update Mobile User Password

This topic only applies to users who log in from a mobile device.

The first time that you log in, you are prompted to change your password. **User Name** cannot be edited.

To update your password in the User Information window later, follow these steps:

- Select the User icon in the upper right of the Access page.
- Enter your current password in the **Old Password** field.
- Enter a new password in the **New Password** field and the **Confirm Password** field.
- Select **OK** to change your password.

### NOTE

See also [Mobile User Access Page](#).

## Display and Access Devices

Privileged Access Manager can identify and provide connections and passwords to remote devices, applications, and accounts to work on that device. An administrator role involves any type of management of the appliance and its managed objects. This page reviews end-user functions and provides additional information for the administrator.

### List the Devices Available

Your access policy, determining what Devices and passwords you can access, is dynamically applied during your login. This process results in the set of objects available on your Access page.

### Display Settings

To reset your graphical session (RDP, VNC) window size, select the **Display Settings** link to show a pop-up menu with the available size options (pixel width by height - for example, "1024x768"). The currently active option is marked in **bold**.

### Restart Session

Selecting **Restart Session** resets your session to your initial login state, without logging you out.

#### **WARNING**

Product behavior when restarting RDP Application sessions has changed in release 3.2.2. Previously, when you selected **Restart Session** on the **Access** page, the RDP Application applet remained connected to the target device and you could continue using it. Now when you restart a session, the RDP Application applet connection terminates and you must relaunch it to continue. Save your work before restarting a session!

### Filter Views

By default, you see an unfiltered view that shows all Devices and methods that you are permitted to use. You can filter this list by specifying the necessary field values so that it shows fewer Devices. See [Filter Views](#) for more information.

### Access the Devices

#### **WARNING**

**For users without a local account in Privileged Access Manager** (for example, if LDAP or RADIUS provisioned): On your first login, you might be required to go to the **User Information** page if you are not a local User. You then select **Save** before attempting to access a device. This step is necessary to propagate functionally required settings.

To access a device from its line-item listing, select a link on the Access list:

- **Access Methods** (VNC, Telnet, SSH, RDP), **Web Portals**, and your custom **Services** are launched by clicking their blue, named text buttons.
- **Applications** and Privileged Access Manager-defined **Services** appear in drop-down list.

When you hover your mouse over a Service or Web Portal, a pop-up hint window displays target address, port, and other information.

### **Access Method**

Selecting an Access Method downloads to your computer a Java applet customized to use the protocol (RDP, SSH, other). The applet has been specified to initiate a connection to the specified Device automatically.

To launch an Access Method:

From the list or drop-down list, select the desired Access Method button.

### **CLI Applet (Telnet, SSH)**

- If you have selected a CLI-based applet, a MindTerm terminal emulation applet with a control menu appears. **Note:** The MindTerm applet command line window has a 512-column by 512-row limit.
- If you have an SSO (single sign-on) configured (through **Policy, Manage Passwords**), they are applied and the prompt lands logged in.

You can configure terminal window characteristics (window size, font, colors, and other features) at several levels. Verify them with your Privileged Access Manager administrator:

- By an administrator using global default settings
- By an administrator using default settings for a specific Device
- By you for your specific use (overriding the Global Settings) in: **User Information, Terminal Customization, SSH and Telnet CLI Terminal Customization.**

### **SSH with X11 Forwarding**

For an SSH Access Method applet configured to forward X11:

1. From the Access page, launch the SSH applet.  
You are prompted for your **local** display coordinates (default is 0,0).
2. Enter your display coordinates.  
Your SSH session begins.
3. Invoke an xterm for a graphical application. If you are using **Cygwin**, use the "**x-terminal-emulator**" command (not "xterm").
4. You can now start X-Windows commands from the SSH applet.  
The session is then forwarded through the SSH tunnel to the X11 server running on the client host, and graphically displayed to the user.  
For example, using Cygwin:  
From within the SSH applet, invoke: xeyes  
The xeyes now displays on the users local X11 server.

See the settings table in Provisioning: Devices: Set up Devices: Create/Edit Devices for administrator setup of X11 forwarding.

### **Graphical Applet (RDP, VNC)**

Several seconds after you mouse over the applet link, you can select the applet window resolution. You can also select any of your local drives for mapping onto the RDP target.

If you select an RDP applet:

- The applet first displays a splash screen.
- Then, the interface emulation window of the applet appears.  
If credentials are not being passed (for example, through a single sign-on (SSO) configuration), you land at a credentials prompt. You can use the emulated interface as you would with native RDP – in other words, similar to as you would use your server locally.

### **Web Portal**

Selecting a Web Portal invokes a browser session on your computer with the web server on the specified Device. To focus interaction within the Web Portal, the browser controls (File menu bar, Back/Forward buttons, and others) are mostly disabled.

To launch a Web Portal:

- From the list, select the desired portal name.
- If credentials have been configured, they appear (in clear text) in the upper left. You can copy and paste them to fields in the portal interface.
- A new browser window or tab opens and attempts to land at the target website.

### **RDP Application**

Selecting an RDP Application connects to the specified Device and launches the specified RDP Application on the target device.

### **Notes**

- The connection method is either an Access Method or a Service; it is not identified on the Access page. (See the method descriptions elsewhere in this section.)
- If credentials are needed but not passed, connection progress stops at the credentials prompt.

To launch an RDP Application:

1. From the list or drop-down list, select the desired drop-down application name.  
The (hidden) connection method that is specified for this application is invoked.
2. Upon connection and credentials verification, the RDP Application is launched automatically.

### **Service**

Selecting a Service first creates a secure tunnel to the associated Device. This Service then invokes on your computer a communication application that automatically connects to the specified Device. The local path and executable file for the communication application is specified in advance by the Privileged Access Manager administrator. However, you can revise but them using the following procedure:

#### **NOTE**

Do not confuse the following terms:

- a *Service application* that is resident on a client computer
- an *RDP Application* that is resident on a Device
- a [*Target*] *Application* that is used with Credential Manager.

The first group of services is located in the Service column. The second group is in the RDP Application column. The third group is in the Target Application column.

To launch a Service:

1. From the list or drop-down list, select the desired Service button or drop-down selection.
2. The Service application is launched and a connection is attempted using this service.  
**Note:** If credentials are needed but not passed, connection progress waits at the credentials prompt.
3. Simultaneously, a pop-up acknowledgment window appears over the Access page.  
No interaction with this pop-up window is required to execute the Service using the default path.  
The Service name is not mentioned – only the device address and port are.

### **Change Service Local Path to Application**

Following the launch of a Service as described in the previous section, you can change the local path to the application.

If the specified local path to the application does not match the user setting for it, then from the acknowledgment pop-up window the user can:

1. Select Set or change local application to reset the path.  
The pop-up window expands to allow the user to create or revise the local **Path to Application**. This path is initially a copy of the Privileged Access Manager-stored path to the application.
2. Enter the actual path and application executable to be used, and select **Save**.  
This local path will then be substituted for the Privileged Access Manager-stored path the *next* time that you launch this Service.

## Filter Views

Pages in the PAM UI that have lists can be filtered, and those filters can be saved as Views. The Access page, Sessions, Users, Devices, Accounts, and so on, can all be filtered. You can add multiple filters, and can save them as a View, and can make a View the default View. The Reset button displays an Unfiltered list, or View. You can hide the Filter controls by clicking the "up" arrow to the right of the page heading, next to the Help question mark icon.

### Filter a List and Save a View

Every page with a list of objects or records has a row of filter controls above the list.

To filter a list, follow these steps:

1. Select a **Column** to filter on.
2. Enter a **Value**. Most columns accept free text. Some columns with a limited set of values, such as Operating System or Application Type, present a drop-down list or dialog for selection.

#### **NOTE**

Columns with limited values that are presented in a dialog allow multiple selections. For most columns, the filters treat these selections with "OR" logic. These column filters, such as Location, Operating System, and Device Type, display data for objects meeting any of the options that you select. However, the Tag column filter, available on the Access or Manage Devices pages, uses "AND" logic. Unlike unique attributes such as Operating System, a Device can possess multiple Tags. For example, if you filter on the Tag values of "AD" and "LDAP", you return only Devices possessing both tags, rather than Devices possessing either or both.

3. Select **Filter** to see the results.
4. To filter on multiple columns, select **Add Filter** and repeat the previous steps for each column you want to filter on. Select the **X** to remove a filter.
5. To undo the filter and restore the original unfiltered list, select **Reset**.
6. To save the filter results as a permanently stored View, select **My Views**, then **Save As**. The **Save As** window appears.
7. Enter a **Name**. Select **Set as Default View** if you want the view to appear whenever you view this page.
8. The **Columns** tab allows you to remove or add existing columns to the list display.
9. Select **OK** to save.  
The View can now be invoked from **My Views**. You can edit existing views from **My Views**, **Manage Views**.

### Text Filter Details

#### **Filtering on One or Two Characters**

If you filter a page list using a value of only one or two characters, the results return only entries that *start with* those characters. Characters can be single-byte, like English or multi-byte, like Japanese. The results do not include entries that *contain* those characters only in other parts of the string.

This behavior does not apply to Credentials page lists.

For example, if you filter on the Name column and you specify the characters "ca " the resulting list shows `capam` but not `tap.ca.com`.

#### **String Comparison**

The filter uses MySQL-style string comparison functions:

`%` matches any number of characters, including zero characters.

`_` matches exactly one character.

#### **Escape characters**

To filter on an otherwise reserved character, use "\" as the escape character. For example:

\% matches one "%" character.

\\_ matches one "\_" character.

\\ matches "\"

The final example could be used to filter on the File Path or Execution Path column of the A2A Scripts list.

## View and Permit Views of Passwords

### View a Password

Active Target Applications and their associated Target Accounts are listed on the Access Page. Every Target Application that is associated with a Device is identified in the drop-down list in the Target Applications column. Every Target Account that is associated with each application appears in a nested list. After selecting a Target Account from the drop-down list for a Device, a pop-up View Account Password Request window appears. After entering the Password (for the currently logged-in Privileged Access Manager user), the credentials are displayed in the pop-up.

### View a Password Requiring Dual Authorization

Dual Authorization requires access to the Credential Manager menu using the FirecallUser role. The menu is not available to a Standard User from the Access page.

### Check in a Password

You can monitor check-out status and can perform check-in from the Access page. If another administrator attempted to view this password, the message "This account is checked out by another user" appears in place of the View Account Password pop-up. For the second administrator to view (and also check out) the password, the first administrator clicks the **Check In** link for that account. The first administrator does not need to switch to the **Credentials Manager Target Accounts** panel.

## Set Up Java for Internet Explorer

The only browser Privileged Access Manager supports is Microsoft Internet Explorer 11. IE 11 is the only browser that still supports NPAPI, which RDP and SSH access Java applets use. If you use IE11, install the latest Java 8 version on the desktop. Ensure that Internet Explorer and Java are using the same 32-bit or 64-bit version. The 32-bit version of IE is used by default regardless of whether the Windows OS is 32-bit or 64-bit.

### Internet Explorer Version

You might not know which version of Internet Explorer 11 you are running. Regardless of whether Windows is running a 32-bit or 64-bit operating system, Internet Explorer is probably running a 32-bit version, which is the default. To determine which IE version you are using, follow these steps:

1. Open Internet Explorer 11.
2. Select the **Tools** gear icon.
3. Select **About Internet Explorer**.  
If the About window contains "64-bit Edition", then you are using the 64-bit version. Otherwise, it is 32-bit.
4. **Close** the About window.
5. To see if Java is enabled in Internet Explorer, select **Tools, Manage add-ons**. If the Add-ons chart shows a Java row, the Architecture column shows "32-bit", "64-bit", or "32-bit and 64-bit". If IE is 32-bit and the Add-ons window shows "32-bit" or "32-bit and 64-bit", it should work with PAM.

## Java Version

If you have installed Java on your computer, determine the version. Follow these steps:

1. In Windows, select **Settings**, then search for Control Panel.  
The All Control Panels window appears.
2. Select **Java**.  
The Java Control Panel appears.
3. Select the Java tab, then the **View** button.  
For each Java version, a row appears with an **Architecture** column. "x86" denotes 32-bit while "x86\_64" denotes 64-bit.  
The **Platform** column should show 1.8 or greater. If not, upgrade Java.  
The **Enabled** column should be checked.

If your IE and Java architectures match, the browser should work with PAM.

## Version Compatibility

If Internet Explorer and Java are not working together, you receive a dialog when you connect to Privileged Access Manager. The message states "The page you are viewing uses Java. More information about Java support is available from the Microsoft website." The solution is probably to install Java for the appropriate 32-bit or 64-bit architecture. If you install a new version of Java, you should close and open Internet Explorer before trying to use it.

See the Java website for more information about plug-in installation: [https://java.com/en/download/faq/java\\_win64bit.xml](https://java.com/en/download/faq/java_win64bit.xml)

For more information about further troubleshooting Java and Internet Explorer, see [https://www.java.com/en/download/help/ie\\_tips.xml](https://www.java.com/en/download/help/ie_tips.xml).

### NOTE

For instructions on downloading, installing, and using the PAM Client, see [Deploy the CA PAM Client](#).

---

## Configuring a PAM Server

---

Before you can use a PAM server, you must configure many required and optional configuration settings.

Appliance access and licensing settings depend on your appliance platform:

- **Hardware:** A pre-licensed physical appliance. For configuration information, see [Deploy the Hardware Appliance](#).
- **VMware OVA:** Provided by your account representative with a link to download the OVA to your vCenter location so that you can create a VM. You also receive a license to activate the instance.
- **AWS AMI:** Provided by your account representative with permission and an AMI number so that you can create an instance within your AWS account. You also receive a license to activate the instance.
- **Azure VHD:** Provided by your account representative with a link to download the VHD to your Azure location so that you can create a VM. You also receive a license to activate the instance.

Network context configuration:

- **Hardware:** Use the LCD display on the left side of the front panel of the appliance. See [Configure Network Connections for the Appliance](#).
- **VMware VM:** After you power on your VM, use the VMware Console to access the same controls as are provided by the LCD on a hardware device.

### NOTE

For clustered implementations, the blue globe icon on the title of a configuration panel signifies that the configuration is replicated to all cluster members. Configure changes to settings with the blue globe icon on the *primary* site of your cluster; they are not configurable on *secondary* sites.

### Required Configuration Settings

- [Date/Time](#) – Set up your appliance to synchronize with NTP time servers
- [Licensing](#) – Your appliance must be licensed for target Devices and feature use
- [Security](#) – Provide a certificate; optionally, set up PKI/CAC, specify CRL, sign applets, activate SAML use, activate API access

### Optional Configuration Settings

- Third Party – Configuration connection to these optional network resources:

- [AWS API Proxy](#)
- [VMware](#)
- [Vmware NSX API Proxy](#)
- [LDAP, RADIUS, or TACACS+](#), and [RSA](#) for [user authentication](#)
- [SafeNet or Entrust Hardware Security Modules](#) for Credential Management
- [Microsoft Office 365](#)
- [Splunk](#)
- [Network](#) – extra network interfaces as needed
- [Logs](#) – Configure log and session recording output to external storage
- [trap server](#)
- [Clustering](#)
- [Configuration and Database Backups](#)
- [Diagnostics and Troubleshooting](#)
- [Email Setup for Monitoring](#)
- [Power, Reboot, and FIPS Mode Controls](#)
- [Set Your Locale](#)
- [Master Provisioning Settings](#)

## Configure Global Settings

Use the **Global Settings** panel to set universal options for all users and devices.

### NOTE

Credential Manager-specific settings are configured in a separate location. See [Set Up Credential Manager Operation Settings](#) for more information.

Use the controls on the **Settings, Global Settings** panel to set universal options that apply for all users and devices. The controls are presented in the following tabs.

- [Basic Settings](#)
- [Passwords](#)
- [Accounts](#)
- [Alerts](#)
- [Applet Customization](#)
- [Client Settings](#)
- [SAML](#)
- [Threat Analytics](#)
- [Default Preferences](#)
- [Secrets Management](#)

To commit any settings changes that you make, select the **Save** button at the bottom of the panel. The screen refreshes to display the updated configuration and the "Global Settings Saved" text appears on the screen.

### **Basic Settings**

The basic settings include:

- **Default Auth Method** (Login Page): Specify the default authentication method that appears on the login page from the following values. At least one user must be created with that authentication method before this option becomes available. The options are:

- Local
- LDAP
- RSA
- RADIUS
- TACACS+
- PKI-CAC
- LDAP+RSA
- LDAP+RADIUS
- **Default Page Size:** Specifies the number of Device line items visible when a user initially hits the **Access** page after login.
- **Login Timeout:** Specifies the number of minutes of inactivity between a PAM user and the PAM UI (including connections to targets) before their session times out. This value is automatically extended when an active connection to a target device exists. The default value is 10. The maximum value is 2880 minutes (48 hours).
- **Connection Idle Timeout** (formerly **Applet Timeout**): Specifies the default number of minutes of inactivity before a connection (such as Telnet, SSH, Virtual Machine) with an external device times out. Users assigned policies with the [Extended Timeout](#) option enabled can override this value. The **Connection Idle Timeout** value cannot exceed the value of the **Maximum Connection Idle Timeout** setting.
- **Maximum Connection Idle Timeout:** Specifies the maximum **Connection Idle Timeout** value that a user can specify when initiating a connection with most external devices. The following device types do not support **Maximum Connection Idle Timeout**:
  - RDP Proxy Service
  - Web Portals
  - VNC devices

The absolute maximum value is 2880 minutes (48 hours).

#### NOTE

Verify that the **Maximum Connection Idle Timeout** value is long enough to accommodate the longest job that a user might run.

- **Table Refresh Interval:** Specifies the default refresh interval, in seconds, for the tables displayed in the following locations:
  - **Access** (from a browser other than Internet Explorer): **Passwords Currently In Use**
  - **Devices, Discovery:**
    - **Device Scan History** tab
    - **Discovery Jobs** tab
  - **Credentials, Discovery:**
    - **Scan Profile History** tab
    - **Discovered Accounts** tab
  - **Credentials, Manage Targets, Accounts**
  - **Credentials, Workflow, My Password View Requests**
  - **Credentials, Workflow, My Password View Approvals**
  - **Credentials, Workflow, All Password View Requests**
  - **Devices, Socket Filter Agent**
  - **Management Console: Staging Task Events**

The default interval is 60 seconds, the minimum interval is 30 seconds, and the maximum interval is 3600 seconds
- **Scan Purge Interval:** Specifies the number of days to keep Discovery scans.
- **Default Device Type:** Define the default template that is provided when a Device is added manually. The choices can be overridden on the template itself.

- **Access:** Default: Initially active and selected
- **Password Management:** Checkbox is active only with a Password Management license.
- **A2A:** Checkbox is active only with an A2A license.
- **External API Buttons**
  - **Enable:** Show and activate the **Try It Out** test button at the bottom of every API page in the **API Doc**. The **Try it Out** button enables external API calls from that page. This option is activated by default, but the Enable External REST API option in **Configuration, Security, Access** is not.  
To prevent external API calls from that page, clear the **Enable** checkbox for the Enable API Buttons setting.
- **Allow Bulk Network Scan:** When enabled, an Administrator can run a bulk scan of the network (Host/Port) to determine the status of ports (open/filtered). For information about how to run a Bulk Network Scan, see [Tools](#).

## **Passwords**

You can customize the password requirements for **Local** users by changing these fields. Other authentication method password policies are enforced by their infrastructure and PAM cannot control them. Unlike other accounts, the *super* account never expires. *Super* is not deactivated, even if the password failure limit is activated.

- **Security Level:** Specifies the level of password security that you require for User passwords:
  - **0 - New Password:** The new password must be different from the previous password.
  - **1 - 0+ Length Constraints:** Level 0 and password length must be between the Minimum Password Length and the Maximum Password Length, which are defined on this page
  - **2 - 1+ Require [a-zA-Z0-9]:** Level 0, 1 and password must have both an alphabet character and a digit.
  - **3 - 2+ Both Upper and Lower Case:** Level 0, 1, 2 and password must have both an Upper and Lower alphabet character.
  - **4 - 3+ Special Character:** Level 0, 1, 2, 3 and password must contain a special character such as: !, @, #, \$, %, ^
  - **5 - DoD strong password:** DoD requires a minimum of 15 characters. There must be *at least*:
    - Two uppercase letters
    - Two lowercase letters
    - Two integers
    - Two special characters, such as: !, @, #
- **Minimum Length:** If the Password Level is 1 or above, set the minimum password length.
- **Maximum Length:** If the Password Level is 1 or above, set the maximum password length.
- **Change Interval (Days):** Specifies the number of days between forced password changes for all users.
- **History:** Specifies the number of recent passwords that cannot be reused.
- **Failure Limit:** Specifies the number of failed login attempts before a user account is deactivated.
- **Failure Counter Reset (Minutes):** Specifies the number of minutes for which an account is deactivated after exceeding the **Failure Limit**.

## **Accounts**

- **Disable Inactive After (Days):** Specifies the number of days after which inactive user accounts are disabled. If the backup is older than the time limit, accounts are disabled when restoring a database from a backup.
- **Remove Disabled After (Days):** Specifies the number of days from when an account is disabled until it is deleted.
- **Forced Deactivation Alert:** Select an administrator to receive an alert when a user is deactivated. Monitoring must be configured for this feature to function. See [Set Up Email for Monitoring \(Legacy\)](#) for more information.
- **Email Deactivation Reminder:** Determines when to send an email to inactive users to remind them before their account gets deactivated. This option also specifies the subject line and body text for the email that is sent to users.

- **Remind Before Deactivation (Days):** Specifies the number of days when to send an email reminder to inactive users before their account gets deactivated.
- **Email Subject for Reminder:** Enter the text for the subject heading of the reminder email.
- **Email Body for Reminder:** Enter the body text for the reminder email.
- **Email After Deactivation:** Determines the subject line and body text for the email that is sent to users whose accounts have been deactivated due to inactivity.
  - **Email Subject for Deactivation:** Enter the text for the deactivation notice in the subject heading of the email.
  - **Email Body for Deactivation:** Enter the body text for the deactivation email.

**NOTE**

The Deactivation task runs every day at 2 AM, UTC time. The Deactivation reminder task runs every day at 2:15 AM, UTC time

The email reminder and deactivation email notifications require you to configure the SMTP email server. See the [Configure the Email Server](#) section the UI in the [Configure Email Preferences for Password View Policies](#) topic for more information.

**Alerts**

The options on the **Alerts** tab (formerly titled "Warnings") allow you to configure three optional messages to present to users. They can be customized to reflect individual company policies.

- **Show License Warning:** Set this option to display the specified warning text on the login page for all users. Double-byte characters such as those used for traditional Chinese are supported for warning messages. Select **User must accept license** to require each user to accept the license.

**NOTE**

The License Warning box scrolls to accommodate a long message. Upon setting either option, a text field in which you can customize the warning message appears.

- **Show Recording Warning:** Set this option to display the specified notification when a user opens a recorded applet or service session. For example, when a user opens an SSH console, the following warning appears in the window title bar and in the console: **"Warning you are being monitored."**

**NOTE**

The **Show Recording Warning** option is ignored for *applet* sessions that are made by users who are a member of any user group, deferring to the **Applet Recording Warning** setting specified for the group or groups. This global setting applies for *all* TCP/UDP and RDP service sessions.

**NOTE**

The specified message text is also used for applet recording warnings, even if the **Show Recording Warning** option is not set.

- **Show Informational User Message:** Set this option to display the specified information (for example, notice of planned maintenance) when a user logs in to PAM. For more information, see [Display a Message to Users at Login](#).

**Applet Customization**

The **Applet Customization** tab allows specification of the default terminal display characteristics for all users and all devices. These settings apply for Telnet and SSH applets, and include a switch to allow or disallow copy-and-paste text buffering.

- An administrator can override the defaults on a device basis by changing the **Terminal Type**, **Key Mapping**, and **Terminal Customization** settings for individual devices.
- A user can override the defaults by changing the **SSH and Telnet CLI Terminal Customization** on the **User Information** page.

Clicking the **Configure Terminal Settings** link button brings up a submenu with various terminal settings that you can define on a global basis. These settings are the systemwide default settings. Any terminal customization that is made at the user, user group, device, or device group level takes precedence.

#### NOTE

User terminal customization supersedes device terminal customization, which in turn supersedes global terminal customization.

- **Character Encoding:** *Default:* UTF-8
- **Font Family:** *Default:* Monospaced
- **Font Size:** *Default:* 12
- **Cursor Foreground:** *Default:* #33ff33
- **Foreground Color:** *Default:* #ffffff
- **Background Color:** *Default:* #000000
- **Terminal Size:** *Default:* [80,24]
- **Buffer Size:** *Default:* 100
- **Scroll Position:** *Default:* Left
- **RDP Keyframes Duration:** The keyframe duration determines how RDP is compressed. A small keyframe duration is equivalent to more frequent full frames of video data. The increased frequency results in a large file, but allows more a rapid seek in the RDP viewer. For sessions using RDP 6.1, file size can be reduced significantly by increasing the keyframe duration. Reductions to about half the size have been observed.
  - Small (Fast Seek/Large File): *Default*
  - Medium
  - Large
  - X Large (Slow Seek / Small File)
- **Web Recording Quality:** Specify the color depth and frame rate to use when recording a web portal session:
  - High: 24 BPP / 7 FPS (default)
  - Medium: 16 BPP / 5 FPS
  - Low: 8 bits per pixel / three frames per second
- **Applet Copy Paste:** Enable the use of copy and paste within any applet: This feature activates an Edit menu with Copy and Paste commands. When this option is disabled, the Edit tab is still visible but it is dimmed.
- **RDP Drive Mapping:** Configure RDP drive mapping to provide faster file sharing between the user workstation and the target server. Do the following steps to enable and configure this feature:
  - a. Set the **RDP Drive Mapping** option. A button Appears beside the pin icon in the upper toolbar. Hovering your cursor over the icon displays a tool tip that says "Add new device for mapping"
  - b. Click the **Add new device for mapping** button.
  - c. On the dialog that appears, select a folder on the local system to map to the target server.

#### NOTE

The name of the folder on the local system must only contain ASCII characters (that is, characters in non-English locales are not supported).

- **SSH Terminal File Transfer:** When "Enable SCP/SFTP" is selected, the MindTerm based SSH Access Method applet provides the menu items "**Plugins, SFTP File Transfer**" and "**Plugins, SCP File Transfer**". Each menu item invokes a new applet window to operate SFTP or SCP, which provides a file transfer interface. See [Display and Access Devices](#) for details on the controls.
- **Transparent Login Cache:** After using the Learn Tool and testing transparent login configurations, you can enable the Transparent Login Cache. This feature caches the Learn Tool, the Transparent Login Agent, and the Control Viewer on the RDP server. On subsequent connections to that Windows target, the load times for these applications are reduced.
- **Retrieve Public Address:** An administrator can enable or disable the Java applet Access Agent to retrieve the public address of the user. After a user logs in to PAM, the Java Applet Access Agent is downloaded to the user desktop. The applet retrieves the address of the gateway that is used for external access for auditing and for the VMware NSX

feature. In some environments, this behavior is not desirable. The Retrieve Public Address setting lets administrators disable this feature.

## **Client Settings**

Use these settings to control the distribution and use of the PAM Client.

- **Operating Mode:** Select **Enabled** to allow PAM Clients to log in to this appliance.
  - **Distribution Method:** Select one of the following options:
    - **Internet (Content Delivery Network)** : Allow PAM to engage a PAM to deliver client installers (following requests from the PAM UI login page).
    - **Intranet:** Use the CDN conforming server that you specify in the **Intranet Server** field to deliver installers
- NOTE**  
For more information, see [Use a Private Content Delivery Network to Distribute the Client Installer](#).
- **Download Button on Login Page:** Select **Enabled** to display and activate the **Download PAM Client** buttons. These buttons appear below the white panel on the login page.

## **SAML**

Use these settings to adjust SAML Web SSO authentication.

- **Require Inherited SAML Auth:** Select this option to force the inheritance of the user record **Authentication** setting on all members of a User Group. All group members inherit the settings regardless of whether individual authentication settings are set to "SAML". This setting is selected by default.
- **SAML Re-authentication Period:** Specifies the number of minutes of inactivity before a SAML session times out. The session is between the Service Provider and PAM as an Identity Provider. After a timeout, the next SSO request requires the user to log in again. Default: 60 minutes

## **Threat Analytics**

See the [Threat Analytics documentation](#) for information about the options on the **Threat Analytics** tab.

## **Default Preferences**

You can customize how Privileged Access Manager displays dates and times in the UI. Dates are stored in UTC, but can be displayed in the specified time zone for the user. Selecting a custom time zone can only be done through the GUI. This tab sets default references for all users, while [user information preferences](#) set preferences only for the logged on user.

- Select a **Time Zone Region**, then a **Time Zone**.
- Select a **Date Format**, such as MM/DD/YYYY.
- Select a **Time Format**, such as 12 or 24 Hour.

### **NOTE**

The **Server Time** is always displayed in UTC. If the user saves any changes, they are reflected in the **User's Current Time**. Modifications do not take effect until the next login session.

- **Enable Charts:** Set this option to enable graphical charts in the [Credential Manager Activities](#) reports.
- **Application Color Scheme:** Specify whether to display the PAM UI in **Light** (the default) or **Dark** mode by default. (Once they are logged in, users can change the color scheme in the local [account settings](#).)

### **NOTE**

Dark mode is also not available on the PAM Agent or for all locations on other PAM UI platforms, including the following elements and components:

- PAM access methods (for example, RDP, SSH, and TELNET) launched from the **Access** page
- PAM LDAP Browser
- Session Recording Viewer
- Threat Analytics
- PAM Report output
- External API Documentation
- Online help
- Alternate Configuration Utility

The global **Application Color Scheme** setting also controls the color scheme of the login panel when accessing the PAM UI from a web browser. (This setting cannot be overridden by local account settings.)

### **Secrets Management**

Use the **Maximum Secret Extension (Days)** option to set the maximum number of days that can be specified before secrets are expired or deleted, up to 365 days.

For more information, see [Managing Secrets](#)

## **Configure RDP Proxy Service Settings**

An RDP Proxy Service invokes a local third-party RDP application on a client to connect to a device. Native RDP Client support extends the Access controls to any native RDP client. To create an RDP proxy service, see [Create an RDP Proxy Service to Access a Device](#).

This content describes how to define configuration settings for your RDP Proxy Service.

**To enable and define settings for an RDP Proxy service, follow these steps:**

### **NOTE**

The target server is the server that you connect to using the RDP Proxy.

1. Select **Configuration, RDP Proxy, RDP Proxy Configuration**.
2. Select the following options, as appropriate:
  - Copy and Paste** - Enable copy and paste between the host machine and target server.
  - RDP Drive Mapping** - Enable file transfer between the host machine and the target server.
  - Transparent Login Cache** - After Using the Learn Tool and testing transparent login configurations, you can enable the Transparent Login Cache. This feature caches the Learn Tool, the Transparent Login Agent, and the Control Viewer on the RDP server. On subsequent connections to the Windows target, the load times for these applications are reduced.
  - Log Level** - Select Info or Verbose from the drop-down list. The verbose level provides detailed information about each event.
3. Select **Save** to commit your changes.
4. Optionally, to configure Kerberos Support for your RDP Proxy Service, see [Kerberos Authentication Support in RDP Proxy Service](#).

## **Default Administrator Accounts**

Privileged Access Manager provides two default administrative accounts to manage the product. The "super" account is for Global Administrators, and the "config" account is for configuration administrators. The super account is visible in the Manage Users list, while the configuration account is not.

## **Initial Administrator Login**

All User accounts other than "config" land initially at the **User Information** page, which provides basic User account settings that the user can manage. The user must enter a new password before leaving the page.

## **The Global Administrator (Super) Account**

Privileged Access Manager has a preconfigured global administrator account named **super**. The super account has global access to all configuration privileges for all functionality. The super account cannot be deleted. To change the password from the default, select the user name in the upper right corner. Change the Password in the Basic Info tab. You can change the Administrator login ID from "super" to something else using the [Configuration Utility](#).

When you initially log in to the product, you are logged in as super, with the password "super".

## **The Configuration Manager Account**

Use the configuration account for initial setup. To change the password from the default "config", select the user name in the upper right corner. Change the Password in the Basic Info tab.

Because the username "config" is commonly used, consider also changing the **Login ID** in addition to the **Password** using the **Change Password** page. The Change Password page is only visible from the [Configuration Utility](#).

## **Master Account Security**

After you set up user accounts, you can configure an account for access to the Configuration menu. If a user is granted permission to the Configuration menu, the **Configuration** button appears in the menu bar. When a Configuration menu item is accessed, the current user account credentials are used to log in automatically. Any changes are audited with an individual user ID.

The **Configuration** menu – presented to the configuration professional during initial "config" account access. Use it to configure the appliance before it is provisioned to users and devices.

We recommend that you change the password from its default value after the first logging in. When you log in as "super", you receive a warning message as long as the "config" password remains the default value, "config".

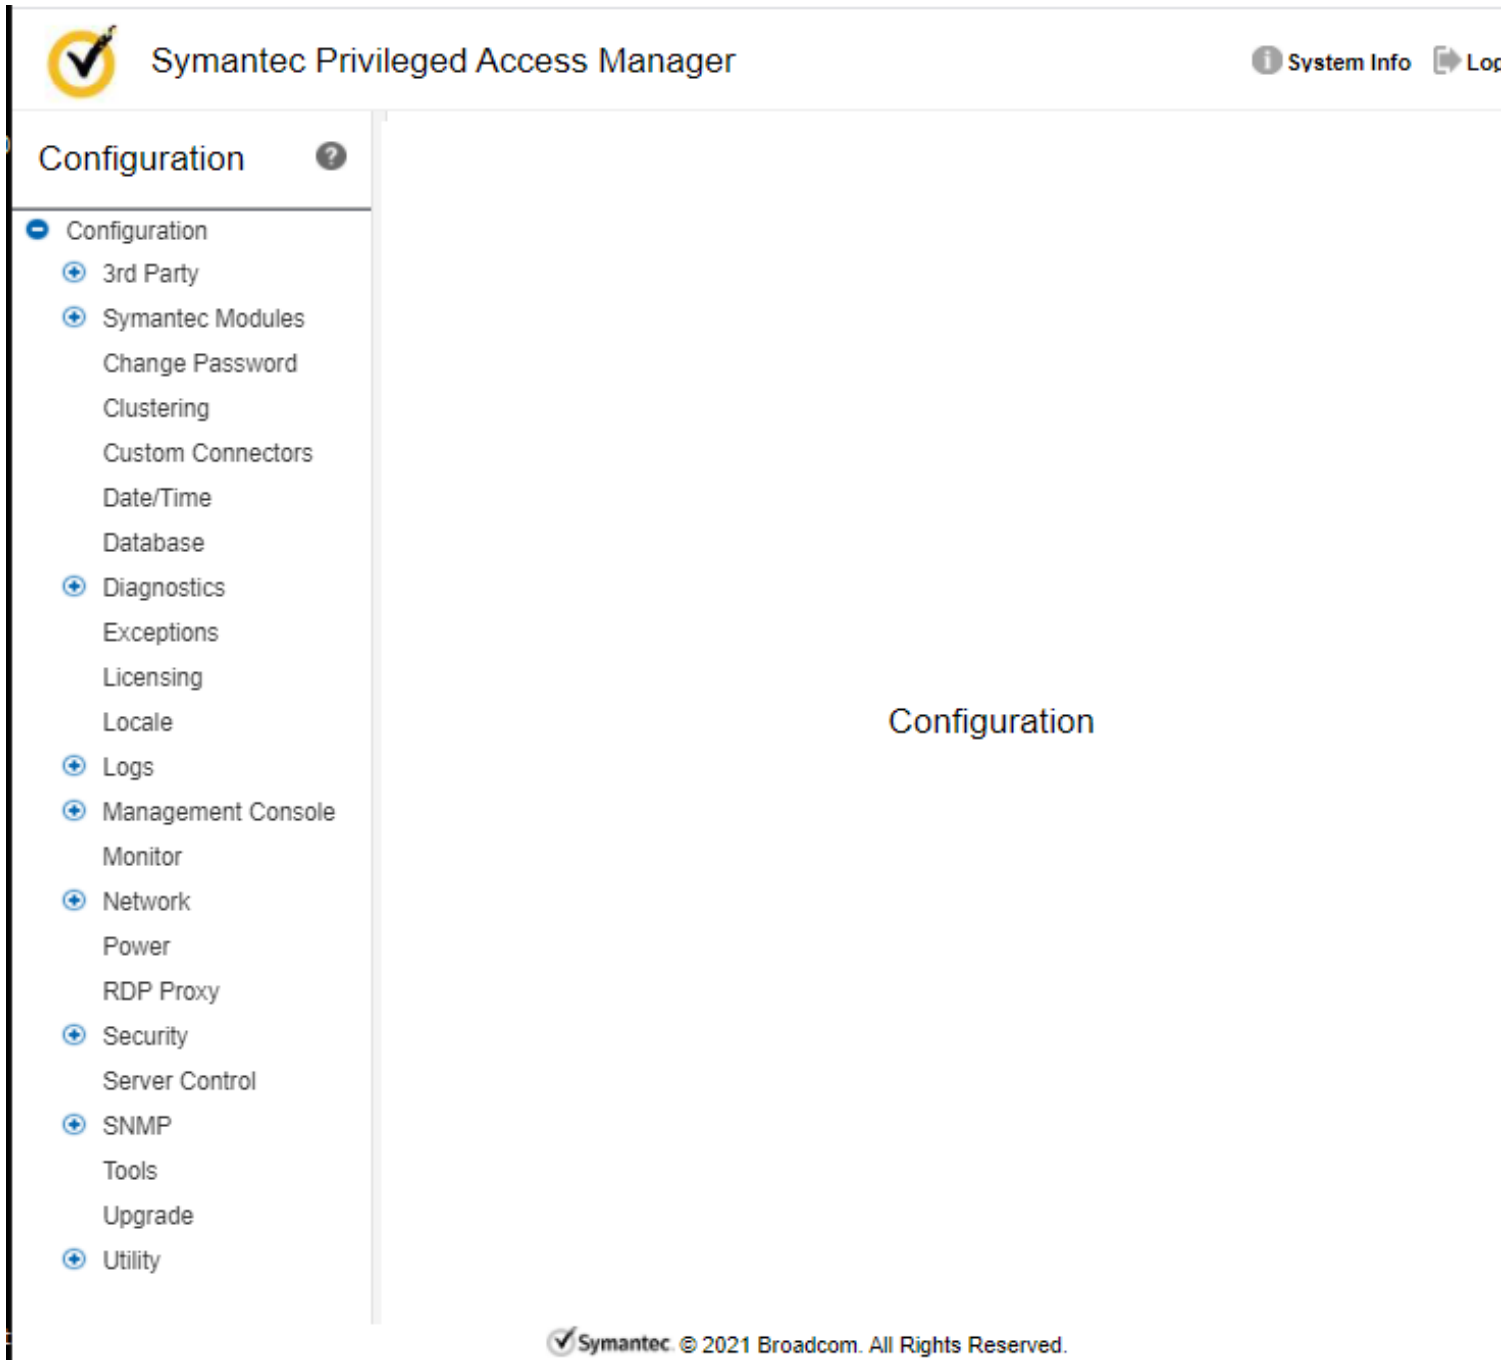

# **Alternate Configuration Utility**

If a bad patch or failed upgrade is applied to PAM, the Tomcat server that launches the regular UI might not start. If this problem occurs, use the Configuration utility. The Configuration utility is an alternate method to manage the configuration and upgrade tasks.

The Configuration utility provides the entire Configuration menu, including upgrade, but no provisioning options.

### **To access the utility:**

1. Open a browser. The Configuration Utility is available only from a browser.
2. Enter the same IP address or host name of the appliance but with **config** appended to the URL. For example:  
`https://11.12.33.123/config/` (IPv4) or `https://[fd6d:8d64:af0c:1:0:242:22:233]/config/` (IPv6)
3. When you are prompted to sign in, enter **config** for the username and password then select **Sign in**.  
The UI opens, displaying only the Configuration menu.

Unlike the standard Configuration menu, the utility has a Change Password option, which lets you:

- Change the login ID and password for the **config** user.
- Change the administrator login name from **super** to something else

For details, see [Change Login for Config or Super User](#).

## Change Login for Config or Super User

The Change Password page is only available in the [Alternate Configuration Utility](#).

### **Change Config User Login ID and Password**

To change the "config" user or password, follow these steps:

1. Log in to the Configuration site.
2. Select **Change Password** on the Configuration menu.
3. Under **Change Config User Login ID and Password**, you can change either the ID or the password or both.  
The replacement ID is still available here, even if it is not "config."
4. Enter a new Login ID if desired.
5. Enter a new password and confirm it.
6. If you change your mind before updating, select **Reset**. The Login ID reverts to its saved value, and the Password and Confirm fields revert to blank.

#### **NOTE**

When you select **Update**, you are logged out and you have to log in with your new "config" ID and password.

7. Select **Update** to save your changes.

### **Change Administrator Login Name**

To change the "super" administrator user name, follow these steps:

1. Log in to the Configuration site.
2. Select **Change Password** on the Configuration menu.  
You can change either the ID or the password or both.  
The replacement ID is still available here, even though it is not "config."
3. Enter a new Login ID.
4. Enter the existing password for "super".  
You need the password for "super" to change its login name.
5. If you change your mind before updating, select **Reset**. The Login ID reverts to its saved value.
6. Select **Update** to save your changes.

**Note:** You can change the password for "super" when logged in as "super" as any User would change their password. Use the User Information page, accessible by clicking the user name ("super") link in the upper right of the UI.

## **Licensing and Product Usage Reporting**

This content describes how to view your current licensed capabilities, install a new license, and configure product usage reporting (telemetry). You access licensing options from the **Licensing** page (**Configuration, Licensing**).

### **View Current License Capabilities**

The Current License tab lists the available capabilities:

- **Access Devices:** Maximum number that you can use
- **Password Devices:** Maximum number that you can use
- **A2A Devices:** Maximum number that you can use
- **Mainframe Capability:** Indicates whether enabled or disabled
- **AWS Capability:** Indicates whether an AWS connection is enabled or disabled
- **AWS API Proxy Users:** Maximum number that can be provisioned
- **VMware NSX API Proxy Users:** Maximum number that can be provisioned
- **VMware Capability:** Indicates whether the connection is enabled or disabled
- **External API Capability:** Indicates whether the API capability is enabled or disabled
- **Office365 Capability:** Specifies whether an Office365 administrative account is enabled or disabled
- **SafeNet HSM Capability:** Indicates whether SafeNet HSM is enabled or disabled. If SafeNet is enabled, Entrust cannot be enabled.
- **Entrust HSM Capability:** Indicates whether Entrust HSM is enabled or disabled. If Entrust is enabled, SafeNet cannot be enabled.
- **PAM Management Console Capability:** Specifies whether this capability is enabled or disabled.
- **SailPoint:** Indicates whether SailPoint is enabled or disabled.
- **Start Date:** Beginning date when the license takes effect.
- **End Date:** Date when your license expires. Applies only for PAM deployed on an AWS AMI instance.
- **Type:** Indicates whether the license is Perpetual (no end date), Temporary, or an Evaluation license. Evaluation licenses are also temporary.

### **Install a New License**

When you obtain a new or an updated license, you must install that license. For virtual machines, instructions for obtaining license files are included with the image download. For each hardware appliance, a license file is prepared by Broadcom and installed with the file.

#### **Follow these steps:**

1. Go to **Configuration, Licensing**.
2. Select the **Install New License** tab.
3. Use **Choose File** to locate the license file on your system. The license file is of type XCDLIC.
4. Select **Upload License File**.  
The **Verify New License** window appears.
5. Verify that the capabilities that are listed are expected and appropriate.
6. Select **Save New License**.

You have to log out and log back in for some options to appear in the interface, such as Entrust or SafeNet HSM.

#### **NOTE**

Licensing no longer detects NIC changes when generating the hardware identification string. This change allows you to add or remove NICs from running instances without breaking the licensing.

### ***Virtual Devices that Exceed License Limits***

A fixed number of device permits for each device type are created with each license. When you add a device rather than import one, a license permit must be available to save that device.

If an imported device exceeds the permit count, the appliance provides a device record, but the device is not provisioned. The device is a placeholder but not operational. The device has no Access or Password Management capability. If you attempt to assign and save the device, the attempt is rejected. When a permit becomes available or another permit is added, you cannot use the device.

## Configure Telemetry to Record Product Usage

Select the **Telemetry Data** tab on the **Licensing** page to enable collection of product usage data. For more information, see [Telemetry Data](#).

### NOTE

If you are licensed to use PAM under a Portfolio License Agreement (PLA) subscription, you must configure PAM to collect and send usage data.

## Configure Network Settings

Configure the network configuration settings for your PAM server on the **Configuration, Network, Network Settings** panel.

The basic network information is shown in the **Gateway** and **Network Interfaces** fields. These fields are the only required settings, except for an AWS AMI instance where a DNS server is the only required setting. If necessary, specify information necessary for DNS routing. For an AMI instance, the DNS setting is provided by the AMI instance and you must enter that value.

### Complete the following fields, as required:

- **Hostname:** Specify a unique hostname for the PAM server. Use this setting to distinguish the servers in a cluster. The IP address is not sufficient.
- **Domain Name:** Specify one or more (space- or tab-delimited) domain names using their top-level and second-level domains (for example: example.com) if you require them for any of the following use cases:
  - To provide the domain name for the mail system (`/etc/mailname`). For more information, see [the mailname man page](#).

### NOTE

Only a single domain name is required for this use case. If multiple domain names are specified, the first listed domain name list is used.

- To create an entry in the `/etc/hosts` file (in the form of `IP HOST.DOMAIN HOST`).

### NOTE

Only a single domain name is required for this use case. If multiple domain names are specified, the first listed domain name list is used.

- To append to unqualified (short) hostnames in DNS queries to create fully qualified hostnames. For example, if a short hostname is "host1" and the specified domain name is "example.com" then the resulting DNS query searches for "host1.example.com."

If multiple domain names are specified, PAM uses them in the specified order until the resulting DNS query returns a valid fully qualified hostname.

### IMPORTANT

Wildcards are not permitted in domain name definitions. Use spaces or tabs to delimit multiple domain names; commas are not valid delimiters.

- **Default IPv4 Gateway:** Use the corresponding field to specify the IPv4 address of the routing device where all packets are sent to destinations without an explicit route. The gateway is necessary when sending traffic to the Internet, to remotely managed devices, or for any other resource access. In a production environment, this value should not be "0.0.0.0" or empty.
- **Default IPv6 Gateway:** Use the corresponding field to specify the IPv6 address of the routing device where all packets are sent to destinations without an explicit route. The gateway is necessary when sending traffic to the Internet, to remotely managed devices, or for any other resource access. In a production environment, this value should not be empty.
- **DNS Servers:** Specify the name or IP address of one or more DNS servers (one per line to a maximum of three lines). The appliance only considers the first three entries due to restrictions on the underlying OS. For AWS and Azure deployments, the DNS servers of the hosting platform are displayed here, and cannot be changed.

**NOTE**

If you use a hostname for an NTP server, a DNS server is required here. If you remove all DNS servers, ensure that any configured NTP servers use IP addresses instead. See [Configure Date/Time Settings](#) for details.

- **MTU:** Enter a value, in bytes, for the maximum transmission unit (MTU) size, with a minimum value of 1000. The MTU value is updated instantly. You do **not** need to restart the network or reboot the appliance for the MTU value to take effect.

**NOTE**

Both the AWS and Azure platforms support updates to the MTU configuration. However, Microsoft states the preferred MTU is the default value of 1500. If the MTU is rejected by Azure network configuration, the MTU may reset to this default value.

- **IPv6 Enabled:** This option enables the IPv6 protocol in PAM. PAM can run on an IPv6 interface and can connect to target servers that are specified by IPv6 addresses for access or commercial management. Enabling or disabling this setting requires a reboot of your PAM device.
- **Network Interfaces:** This table defines network interfaces. The primary network interface is shown in the first row, named GB1. You use more network interfaces for specific features, such as [Additional Routes](#). To add another network interface, enter appropriate values in the **IPv4 Address**, **IPv6 Address**, **Netmask**, and **IPv6 CIDR** columns, in an available row, such as GB2. The following other columns are also present:
  - **Teaming:** Use this drop-down list to assign network interfaces to a Team. See [Network Teaming Interfaces](#) for more information.
  - **Speed:** Specifies the Ethernet capacity specification. Select **Auto** (negotiation), **1GB** (gigabit/sec), or **100** (100 megabit/sec). Default is Auto.
  - **Duplex:** Specifies the Ethernet transmission mode. Select **Auto** (negotiation), **Half** (half-duplex; alternating bidirectional), or **Full** (full-duplex; simultaneously bidirectional). Default is Auto.
  - **Enabled:** Specifies whether the interface is enabled.

**NOTE**

Licensing no longer includes the NIC to generate the hardware identification string. This change allows NICs to be added to running machines without breaking the licensing.

**Network Teaming Interfaces**

You can set up Network Teaming (also known as NIC teaming, bonding, or aggregation) to combine multiple network cards together for either enhanced performance or redundancy. A "bond" is set up among multiple network interfaces. This feature is available on the hardware appliance and VMware.

**NOTE**

NIC Teaming is available in VMware, configured in vSphere. Before you set up Network Teaming in Privileged Access Manager, ensure that no conflicts exist with the vSphere configuration.

**Modes**

Privileged Access Manager supports two Modes for Network Teaming:

- **Active Backup:** Use this mode for failover purposes. The first selected interface in the list (such as GB1) becomes the primary interface, and any others that are selected are "standby."
- **Adaptive Load Balancing:** Use this mode to increase throughput by sharing network traffic among several network interfaces.

## Configure Network Interface Bonds

Network interfaces are teamed together as a "bond." Privileged Access Manager supports up to four interfaces for teaming on a hardware appliance. On a VMware instance, you can use up to half of the existing teaming interfaces, or up to its maximum index. Assume that each VMware bond must have at least two interfaces. For example, if a VMware instance has seven network adapters, then the maximum allowed bond interfaces is three (BOND1, BOND2, and BOND3).

### Follow these steps:

1. Go to **Configuration, Network, Network Settings**.
2. Select a Network Teaming Interface bond, such as BOND1.
  - a. Enter an **IPv4** or **IPv6 Address** as a virtual network adapter for the bond.

#### NOTE

Each Bond should be configured to use a different subnet. Using the same subnet results in errors.

- b. For an IPv4 address, enter a **Netmask**, such as 255.255.255.0. For an IPv6 address, enter an **IPv6 CIDR** value.
  - c. Select a **Speed** from the drop-down list, or leave as "Auto."
  - d. Select a value for **Duplex** from the drop-down list, or leave as "Auto."
  - e. Select a **Mode** from the drop-down list, as described in [Modes](#).
3. In the list under Network Interfaces, select which interfaces should be teamed together with that bond.
  - a. For each interface, such as GB1 and GB2, select the bond from the **Teaming** drop-down list.
  - b. An Interface is automatically **Enabled** once it joins a team.
4. Select the **Update** button to save any changes. Select **Reset** to return the settings to their last saved state without saving. Select **Restart Networking** to start using the new settings immediately.

To see the status of a Network Team, select its row in the Network Teaming list, and select the **Status** button. The Network Team Status window opens. The following information appears:

- **Mode:** If mode is Active Backup, the Primary Interface (as opposed to the Backup interface) is listed. The Active Interface is the current active interface that sends and receives network traffic. If the Active Interface is not the same as Primary Interface, the Primary Interface is down and the failover has occurred.
- **Status:** A checkmark denoted that the team is operational.
- **Interfaces**
  - **Status:** A checkmark denoted that the interface is operational.
  - **Failure Count:** This number is a count of the failures of the member interface. This number is reset to zero when networking restarts or when the appliance reboots.

#### NOTE

- [Additional Routes](#)
- [Administrative Access Restriction](#)

## Restrict Administrative Access

By default, any user with administrator credentials can access the Configuration settings. To restrict access, explicitly specify which hosts have access by creating a white list.

### WARNING

When you add an IP address or CIDR block to the Access Restrictions settings, administrators on hosts that are not explicitly added are blocked from accessing the Configuration settings. For this reason, ensure that you add your own IP address.

You add an entry to the table, which functions as a whitelist.

**Follow these steps:**

1. Select **Configuration, Network, Access Restriction** to specify which networks or hosts can access the Configuration settings.
2. Select **Add**.  
The Add IP address / CIDR block window appears.
3. Enter an IP or CIDR block address to the text box. Examples: 192.168.1.1, 130.200.13.0/24
4. Select **OK**.  
The IP address or block of addresses is added to the list.  
Upon logging in again, only users having IP addresses included in the list can access the Configuration settings.

## Additional Routes

Select **Configuration, Network, Additional Routes** to configure routes to specific destinations. You can add routes for IPv4 and IPv6.

**Additional IPv4 Routes Tab**

- **Destination:** Specify the IP address or hostname for the destination of the route.
- **Netmask:** Enter a netmask, such as 255.255.255.0 . If **Netmask** is set to 255.255.255.255 , the target destination for the route is the network. Otherwise, the target destination for the route is host.
- **Gateway:** Specify the IP address of the routing device where all packets are sent to destinations without an explicit route.
- **Metric:** (optional) Lower values are preferred over higher
- **Device:** Assign an available Ethernet port, GB1 through GB3.

**Additional IPv6 Routes Tab**

- **Destination:** Specify the IP address or hostname for the destination of the route.
- **Gateway:** Specify the IP address of the routing device where all packets are sent to destinations without an explicit route.
- **Device:** Assign an available Ethernet port, GB1 through GB3.

## Configure Container Network Settings

**NOTE**

This topic was previously titled "Configure Docker Network Settings" because it described procedures that you performed on the **Docker Network Settings** panel. However, in this release (4.1.4) that screen has been renamed to **Container Network Settings** and this page has been renamed correspondingly.

Container technology allows applications and their dependencies to be packaged and run consistently across various computing environments. PAM uses this technology in the following components:

- PAM servers have an integrated *Local PAM Container* in which several PAM server components run.
- PAM SC Utility Appliances have an integrated *Utility Appliance Container* in which several Utility Appliance components run.

By default, all Local PAM Containers in the cluster use a virtual IPv4 network bridge to communicate with each other and their host PAM servers. By default, the IPv4 address range for the PAM server network bridge is 172.17.0.1/16 , so the container on each PAM server is assigned an IPv4 address in the 172.17.\*.\* range.

Alternatively, if you have configured a custom IPv6 subnet for Local PAM Containers, the default IPv6 CIDR value is f1b1:a:b:c::/64 .

Utility Appliance Containers use a separate IPv4 network bridge to communicate with each other and their host Utility Appliances. By default, the IPv4 address range for the Utility Appliance network bridge is `172.17.0.1/16`, so the container on each registered Utility Appliance is assigned an IPv4 address in the `172.17.*.*` range.

Use the following procedure to modify the default container bridge IP address ranges in case addressing conflicts occur. For example, using Classless Inter-Domain Routing (CIDR) for allocating IP addresses and routing in your environment can cause such conflicts.

**To modify the default container bridge IP ranges, follow these steps:**

1. Log into the PAM UI.
2. Navigate to **Configuration, Network, Container Network Settings**.
3. Update the value in the corresponding field:
  - **Local PAM Container IPv4 network bridge**: Enter an IPv4 address range. For example, `172.17.0.8/20`. The default value is `172.17.0.1/16`.
  - **Local PAM Container IPv6 Subnet CIDR**: Enter an IPv6 Subnet CIDR. For example, `f2b2:a:b:c::/64`. The default value is `f1b1:a:b:c::/64`.

#### NOTE

If you observe any issues with PAM or Utility Appliance operations after updating the Local PAM IPv6 Container CIDR, restart PAM networking. Specifically, restart PAM networking if any of the following conditions occur:

- Log forwarding to the splunk or syslog server is not functioning correctly.
- Target applications and accounts, especially the Active Directory SSH Key type are not functioning correctly
- An error appears while accessing the **Configuration, Utility, Status, Utility Group Status** page in the PAM UI.

**To restart PAM networking:** Navigate to **Configuration, Network, Network Settings** and select the **Restart Networking** button.

- **Utility Appliance Container IPv4 network bridge**: Enter an IPv4 address range. For example, `172.17.0.8/20`. The default value is `172.17.0.1/16`.
4. Select the **Update** button beside the value that you modified to apply the change.

The container configuration file is updated and the container daemon (`/etc/docker/daemon.json`) restarts.

#### NOTE

There may be temporary interruption in operation while the container daemon restarts. During this time, the **Update** button grays out. If you modified the Local PAM Container IPv4 or IPv6 values, the **local PAM container Daemon Status** informational field displays the condition of the Local PAM Container daemon.

## Custom Host File Entries

This feature enables users to update the PAM host file from the PAM user interface. In a clustered environment, host file entries are replicated across the cluster nodes and take 60 seconds at the most to replicate.

**Follow these steps:**

1. Select **Configuration, Network, Host File Entry**.
2. Select **Add**.  
The Add Host File Entry window appears.
3. Enter an IP address.

- IPv4 example: 10.11.12.13
  - IPv6 example: fd6d:8d64:af0c:1:0:242:22:233  
IPv6 addresses can be up to 40 characters.
4. Add one or more host names. Select the plus symbol to add additional hosts names. Select the x symbol to delete a host name.
  5. Add any optional comments about the host file entry.
  6. Select **OK**.  
A host file entry is added to the list.

## Authorize SNMP Polling

As a network administrator, you can authorize Simple Network Management Protocol (SNMP) polling of Privileged Access Manager.

### Follow these steps:

1. Go to **Configuration, SNMP, Poll Server**.
2. To respond only to SNMP version 3 requests, select the **SNMP V3 Only** checkbox.  
SNMP version 2c does not use encryption, and version 3 is required for **FIPS Mode**.
3. The **Read-Only Community** string is required only for SNMP version 2c, and is used for authentication.  
The current string is shown in this field, and you can edit it when the **SNMP V3 Only** checkbox is not selected.
4. Select **Start at Boot** to start a poll server when the appliance starts.
5. Select **Save** to save your settings.
6. Select **Start** to start the service immediately.  
The **Server Status** field reflects that it is running.  
You can select **Stop** to stop the service.

## Add SNMP V3 Users

As a network administrator, you can add polling user credentials to support SNMP v3 polling of Privileged Access Manager. To add an SNMP V3 user, follow these steps:

1. Go to **Configuration, SNMP, SNMP V3 Users**.
2. Select the **Add** button.  
The **Add SNMP User** window appears.
3. Enter the values for the user:
  - a. **Username** - Specify the user name to be authenticated with polling. Do not use the reserved user "xceedium".
  - b. **Authentication Passphrase** - Specify the public passphrase to be used with polling.
  - c. **Confirm Auth Passphrase** - Retype the public passphrase to confirm.
  - d. **Private Passphrase** - Specify the private passphrase to be used with polling.
  - e. **Confirm Private Passphrase** - Retype the private passphrase to confirm.
4. Select the **OK** button.

To edit an existing SNMP user, select the user from the list and select **Update**. To delete a user, select **Delete**.

## Enable SNMP Traps

As a network administrator, you can enable Simple Network Management Protocols (SNMP) traps on Privileged Access Manager. Configure access to an SNMP trap server using the Trap Server configuration page. Follow these steps:

1. Go to **Configuration, SNMP, Trap Server**.
2. Select the **Traps Enabled** checkbox.

3. Enter the **Trap Community** string that is used for authentication.

**NOTE**

The default **xcdgkpub** community retrieves the full MIB (Management Information Base). Starting with Privileged Access Manager 3.0, which is built on Debian 8, the "public" community retrieves only system information. In some earlier versions, the "public" community did retrieve the full MIB, but starting in Privileged Access Manager 3.0, use the **xcdgkpub** community to get the full MIB.

4. Specify the IP address or hostname of the **Traps Destination** server, also known as the Network Management Server.
5. Select **SNMP Version** 2c or 3.

**NOTE**

**FIPS Mode** does not support SNMP Version 2c. Use SNMP Version 3 with FIPS Mode.

6. For **SNMP V3**, enter these values:
  - a. **SNMPv3 Username**
  - b. **SNMPv3 Passphrase**
  - c. **SNMPv3 Private Passphrase**
7. Select the **Save Configuration** button.

### **Trap Server Internal Configuration**

**NOTE**

Privileged Access Manager uses SNMP **Inform**s rather than **Traps**.

- **Inform**s use acknowledgments for their notifications, whereas Traps do not.
- With **Inform**s in SNMPv3, the receiving application is authoritative, rather than the sending application (Privileged Access Manager).

When you configure an SNMPv3 Trap Server to receive traps from Privileged Access Manager, use the following values:

- authProtocol: SHA
- privProtocol: AES
- securityLevel: AuthPriv

## **Management Information Base (MIB) for SNMP Use**

A Management Information Base (MIB) describes the format of Simple Network Management Protocol (SNMP) messages for an organization. The attached MIB file contains the configuration for a network management program to receive Privileged Access Manager SNMP event notifications.

The following sections contain detailed lists of the Notifications, Object Types, MIB objects, and their Object Identifiers (OIDs). The final section describes some sample SNMP output.

The MIB text file contains most of this information. You can [view it](#) or you can [download it](#) by right-clicking and selecting the Save As option.

The Base OID for the Privileged Access Manager MIB is 1.3.6.1.4.1.10449.

### **Severity**

The `gkAlarmPerceivedSeverity` object (OID 406, as described in [Object Types](#)) in the SNMP notifications contains an integer denoting its severity:

Integer	Perceived Severity
0	indeterminate

1	critical
2	major
3	minor
4	warning
5	cleared

### Notification Types

The following table contains a list of notification types that are exposed as objects in the MIB. These objects are under `xceediumNotifications`.

Notification Type	Description	OID
<code>gkGenericNotification</code>	Generic type Xsuite Notification (unspecified)	100
<code>gkSysSMBServerStatus</code>	Remote Samba resource status	101
<code>gkSysNFSServerStatus</code>	Remote NFS resource status	102
<code>gkSysLDAPServerStatus</code>	LDAP server status	103
<code>gkSysSyslogServerStatus</code>	Remote syslog server status	104
<code>gkSysMailServerStatus</code>	Remote SMTP server (relay) status	105
<code>gkSysClusterStatus</code>	This notification is sent when the cluster status changes.	107
<code>gkSysDbBackupSMBServerStatus</code>	Remote Samba database backup resource status	108
<code>gkSysDbBackupNFSServerStatus</code>	Remote NFS database backup resource status	109
<code>gkSysDbBackupS3ServerStatus</code>	Remote S3 database backup resource status	110
<code>gkSysMultiSiteStatus</code>	Multisite cluster status changes	112
<code>gkSysS3ServerStatus</code>	Remote S3 resource status	113
<code>gkSessLoginFailed</code>	Login to Xsuite failed	200
<code>gkSessConnTerminated</code>	Xsuite connection session terminated	201
<code>gkSessLoginTerminated</code>	Xsuite Login session terminated	202
<code>gkSessConnExpired</code>	Xsuite connection session expired and is terminated	203
<code>gkSessLoginExpired</code>	Xsuite login session expired and is terminated	204
<code>gkSessSessRecAlert</code>	Xsuite session recording alert	205
<code>gkSessSessRecViolation</code>	Xsuite session recording violation	206
<code>gkSessSFAccDeactivated</code>	Account deactivated because of Xsuite socket filtering (leapfrog prevention) violation	207
<code>gkSessSFViolation</code>	Xsuite socket filtering (leapfrog prevention) violation	208

gkSessCFAlert	Xsuite command filtering alert	209
gkSessCFViolation	Xsuite command filtering violation	210
gkSessCFAccDeactivated	Account deactivated because of Xsuite command filtering violation	211
gkAppGKMonitorStatus	Xsuite monitor process started	300
gkAppLogwatchStatus	Logwatch process started	301
gkAppSNMPAgentStatus	Xsuite SNMP agent started	302
gkAppSNMPSubagentStatus	Status of the SNMP subagent, used to reply to polls of the Xceedium MIB OIDs	303
gkAppDBStatus	Xsuite database is up	304
gkAppFWDStatus	Xsuite secure forwarder started	305
gkAppSessManagerStatus	Xsuite session manager is started	306
gkAppAPWDStatus	Xsuite application watchdog daemon started	310
gkAppGKAuthDStatus	Xsuite application authentication daemon exception	311

### **Object Types**

The following table describes the properties that can be sent in the various notifications.

<b>Object Name</b>	<b>Syntax</b>	<b>Description</b>	<b>OID</b>
gkTrapUsername	DisplayString	Name of the user logged in at the time of the trap.	400
gkTrapDeviceIP	DisplayString	IP Address of the device on Xsuite where the trap occurred.	401
gkTrapDescription	DisplayString	Description of the trap.	402
gkAlarmEventTime	DateAndTime	This object represents the time of occurrence of the subject alarm. The time indication is in Xsuite local time.	403

gkAlarmId	Integer32	This object uniquely identifies an entry in the Alarm Table. It increases every time a new alarm occurs. Due to cleared alarms the index will not be contiguous. When the maximum is reached of Integer32 , the value of this object rolls over to 1. The actor must use 'alarmEventTime' to sort on chronological order. The gkAlarmId object is read-only even though it is used as index in the Alarm Table. The reason is that this facilitates a convenient way to extract the corresponding value from a notification where the object is included.	404
gkAlarmProbableCause	ProbableCause	This object represents the probable cause identification code (generic classification) for the subject alarm.	405
gkAlarmPerceivedSeverity	PerceivedSeverity	This object represents the perceived severity of the subject alarm.	406
gkAlarmName	DisplayString	The name of the event or alarm.	407
gkAlarmObject	DisplayString	The alarming object.	408
gkAlarmInformation	DisplayString	Additional information pin-pointing the problem.	409

## Status

The following table contains the subset of status properties that are exposed as objects in the MIB. These objects are under gkStatus for xceediumGateKeeper , and belong to the gkStatusGroup (group OID 4).

Object Identity	Syntax	Description	OID
gkSystemSerialNumber	DisplayString	Xsuite System Serial number, which is used to license the Xsuite and is tied to the security of the system	1
gkHardwareSerialNumber	DisplayString	Hardware Serial number of the Xsuite appliance, which is used to track the physical Xsuite hardware. The system Serial number may change in time, depending on the current circumstances, which in term will require a change in the license string.	2

gkVersion	DisplayString	Xsuite firmware version. This is the version number, which only shows which base firmware version is installed on the box. To determine what is the exact firmware configuration see the applied patches on the box.	3
gkAppliedPatches	DisplayString	All patches (hot-fixes, service packs or special patches) applied to the Xsuite appliance, showing as name with date and time	4
gkLicenseNodes	Integer32	Number of devices licensed for Access.	5
gkLicensesUtilized	Integer32	Number of Access licenses utilized out of the maximum issued.	6
gkTotalUsers	Integer32	Total number of users registered in the Xsuite database.	7
gkLoggedInUsers	Integer32	Displays the number of the currently logged in users	8
gkCurrentSessions	Integer32	Displays the number of the current sessions to remote hosts	9
gkTotalDBDiskUsage	Integer32	Disk space, occupied by the Xsuite database	10
gkLogDiskSize	Integer32	Current size of the logs on the disk	11
gkLogRecords	Integer32	Current number of the Xsuite log records	12
gkClusterStatus	DisplayString	Status of the GK if in cluster mode	13
gkMainframeStatus	DisplayString	Status of the Mainframe licensing.	15
gkAWSStatus	DisplayString	Status of the AWS licensing.	16
gkVMwareStatus	DisplayString	Status of the VMware licensing.	17
gkPassLicenseNodes	Integer32	Number of devices licensed for Password Authority.	18
gkPassLicensesUtilized	Integer32	Number of Password Authority licenses utilized out of the maximum issued.	19
gkA2ALicenseNodes	Integer32	Number of devices licensed for A2A.	20
gkA2ALicensesUtilized	Integer32	Number of A2A licenses utilized out of the maximum issued.	21
gkOffice365Status	DisplayString	Status of the Office365 licensing.	22

gkSafeNetHSMStatus	DisplayString	Status of the SafeNet HSM licensing.	23
gkThalesHSMStatus	DisplayString	Status of the Entrust HSM licensing.	24

## Alarms

The following table describes the basic alarm notifications that are sent by Privileged Access Manager.

Notification Type	Objects	Description	OID
gkAlarmStartup	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	Xsuite is starting up.	500
gkAlarmShutdown	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	Xsuite is shutting down.	501
gkAlarmReboot	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	Xsuite is rebooting.	502
gkAlarmLinkUP	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	Link on Xsuite has come up.	503
gkAlarmLinkDown	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	Link on Xsuite has gone down.	504

## Hardware Monitoring

The following table describes notifications specific to the Privileged Access Manager hardware appliance. These objects are from `xcd_hwmon`.

Notification Type	Objects	Description	OID
<code>gkCpuTempFailure</code>	<code>gkAlarmId,</code> <code>gkAlarmName,</code> <code>gkAlarmEventTime,</code> <code>gkAlarmPerceivedSeverity,</code> <code>gkAlarmObject,</code> <code>gkAlarmProbableCause,</code> <code>gkAlarmInformation</code>	The CPU temperature has gone above 135°F.	600
<code>gkCpuTempRecovery</code>	<code>gkAlarmId,</code> <code>gkAlarmName,</code> <code>gkAlarmEventTime,</code> <code>gkAlarmPerceivedSeverity,</code> <code>gkAlarmObject,</code> <code>gkAlarmProbableCause,</code> <code>gkAlarmInformation</code>	The CPU temperature has returned to below 135°F.	601
<code>gkChassisFanFailure</code>	<code>gkAlarmId,</code> <code>gkAlarmName,</code> <code>gkAlarmEventTime,</code> <code>gkAlarmPerceivedSeverity,</code> <code>gkAlarmObject,</code> <code>gkAlarmProbableCause,</code> <code>gkAlarmInformation</code>	One or more of the chassis fans have failed.	602
<code>gkChassisFanRecovery</code>	<code>gkAlarmId,</code> <code>gkAlarmName,</code> <code>gkAlarmEventTime,</code> <code>gkAlarmPerceivedSeverity,</code> <code>gkAlarmObject,</code> <code>gkAlarmProbableCause,</code> <code>gkAlarmInformation</code>	All of the chassis fans have recovered from their failure states.	603
<code>gkPrimaryDriveFailure</code>	<code>gkAlarmId,</code> <code>gkAlarmName,</code> <code>gkAlarmEventTime,</code> <code>gkAlarmPerceivedSeverity,</code> <code>gkAlarmObject,</code> <code>gkAlarmProbableCause,</code> <code>gkAlarmInformation</code>	The primary SSD has failed.	604
<code>gkPrimaryDriveRecovery</code>	<code>gkAlarmId,</code> <code>gkAlarmName,</code> <code>gkAlarmEventTime,</code> <code>gkAlarmPerceivedSeverity,</code> <code>gkAlarmObject,</code> <code>gkAlarmProbableCause,</code> <code>gkAlarmInformation</code>	The primary SSD has recovered from its failure.	605

gkSecondaryDriveFailure	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	The secondary SSD has failed.	606
gkSecondaryDriveRecovery	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	The secondary SSD has recovered from its failure.	607
gkPrimaryPsuFailure	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	The primary (leftmost) PSU has been removed or failed.	608
gkPrimaryPsuRecovery	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	The primary (leftmost) PSU has been re-inserted or recovered from its failure.	609
gkSecondaryPsuFailure	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	The secondary (rightmost) PSU has been removed or failed.	610
gkSecondaryPsuRecovery	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	The secondary (rightmost) PSU has been re-inserted or recovered from its failure.	611
gkTotalDiskUsageStatus	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	Total disk used status	700

gkTotalDBDiskUsageStatus	gkAlarmId, gkAlarmName, gkAlarmEventTime, gkAlarmPerceivedSeverity, gkAlarmObject, gkAlarmProbableCause, gkAlarmInformation	Total database disk used status	701
--------------------------	---	---------------------------------	-----

### Sample Notification

Line breaks have been added to this sample output. The service status section only appears when the service is started. The message body is divided into object-value pairs, such as OID 10449.0.403, `gkAlarmEventTime`, as described in the [Object Types](#) table. The date and time value is expressed as a hex string. The first two octets represent the year. In this case, `07E2` is 2018. The year is followed by month (`0C` is 12 for December), day, hour, minute, second, and deciseconds. The final OID, 10449.0.406, indicates the [Severity](#) as "critical."

## Configure Web Proxy Definitions

This content introduces web proxies and describes how to configure *web proxy definitions* to represent physical (or virtual) web proxies in your network. Use web proxy definitions when configuring [services to access web portals](#) if the network firewall would block a direct connection to the portal.

### NOTE

Web proxies are also referred to as web proxy servers and proxy servers.

### About Web Proxies

*Web proxies* act as an intermediary between devices inside your firewall and websites outside the firewall. A Network Administrator can configure one or more web proxies to allow controlled access to external websites that would otherwise be blocked by the firewall according to network security policy.

Web proxies can also be configured to provide the following security and performance benefits:

- Anonymize internal IP addresses to improve security.
- Caching content to improve data transfer speeds and reduce bandwidth usage.
- Filter content to prevent users from downloading content.

There are two methods to define web proxies in your environment:

- **Manual Configuration:** In a small environment, manually define proxy servers (by IP address and port).
- **Automatic Configuration:** In a large enterprise environment in which multiple web proxies are specified in a Proxy Auto-Configuraton (PAC) file, specify the URL of the PAC file.

### Configure a Web Proxy Definition

Use the following procedure to configure a web proxy definition to represent physical (or virtual) web proxies in your network.

#### Follow these steps:

1. Select **Configuration, Network, Web Proxies**.
2. Select the **Add** button.

3. Configure the following properties of the web proxy definition in the **Add Web Proxy** dialog that opens:
  - **Name:** A unique name for the web proxy definition.
  - **Description:** Optionally, a description of the web proxy definition.
  - **Proxy Type:** Specify the method to use to configure a proxy or multiple proxies, if they are defined in a PAC file. Select one of the following options:
    - **Use Manual Configuration:** Use this option to configure a single web proxy manually by specifying its host name or IP address and port in the **Address** and **Port** fields that appear.
    - **Use Automatic Configuration:** Use this option to configure multiple web proxies defined in a Proxy Auto-Configurator (PAC) file by specifying its URL in the **PAC URL** field. For example, `http://proxy1.company.com/proxy.pac`.
4. Select the **OK** button to save the web proxy definition.

**NOTE**

Specify a web proxy definition when configuring a service to access a web portal if the network firewall would otherwise block a direct connection to that portal. For more information, see [Configure a Service to Access a Web Portal](#).

## Configure Security Settings

This section describes how to configure security-related settings for your PAM environment, primarily using options under **Configuration**, **Security** in the PAM UI.

Use the table of contents to access the topics in this section.

### Server Access Options Configuration

As an administrator you specify the methods to use to access the server. You use the controls on **Configuration**, **Security**, **Access** to configure the server access methods.

#### Specify Access Options

Use the following controls on the **Access** tab to specify which methods to use to access the server.

**External REST API:** The External API provides programmatic control over most access functions. These functions include managing users, devices, and policies. This option also enables the API Doc interface. For more information, see [External API](#).

**Credential Management CLI:** The Credential Manager CLI provides administrative access to its password management functions. Management functions include adding, modifying, and deleting target and request data. The CLI also provides access to a limited set of maintenance operations. The Remote CLI is supported on UNIX, Linux, and Windows platforms. For more information, see [Use the Credential Manager CLI](#).

**VMware Console:** Access to the VMware console is enabled by default, and can be useful for emergency troubleshooting.

**Config User:** The product comes with a built-in Config user account, which you can disable. If you change the name of this account, you can still disable it.

**X-Forwarded-Host Check:** You can configure the appliance to deny any X-Forwarded-Host values that are not specified in a whitelist. Denying X-Forward host values protects against invalid host headers. To learn more about this option, see [Host Header Attack Mitigation](#).

**NOTE**

If your server is behind a proxy, load balancer, or router, verify that the device prevents against IP spoofing of the X-Forwarded-For HTTP header.

**Command String:** In addition to `sudo` and `pbrun` commands, you can enable command strings for Transparent Login to a managed device. Command strings are disabled by default as a security precaution. For more information, see [Device Setup, Transparent Login](#).

**TLS v1.0/1.1 Connection Allowed:** By default, the TLS 1.0, 1.1, and 1.2 communication protocols are enabled. To enhance security for inbound communication to PAM, such traffic from browsers, A2A clients, and the LDAP Browser, disable the **TLS v1.0/1.1 Connection Allowed** option. There may be existing connections using the TLS 1.0 or 1.1 protocol. Before you disable this setting, terminate any open connections TLS 1.0 or 1.1 connections by rebooting the appliance.

When FIPS mode is enabled, TLS 1.0 and TLS 1.1 protocols are automatically disabled. TLS 1.0 and TLS 1.1 are not permitted in FIPS mode.

#### NOTE

Applications running in the Java 6 runtime environment are limited to the TLS 1.0 protocol, such as version 2.8 A2A clients and Windows proxy agents. Update these components before disabling the **TLS v1.0/1.1 Communication Allowed** option. If your target server security upgrades allow only use of TLS 1.2 protocol, disable this setting.

**Concurrent Remote Connections:** By default, the appliance allows concurrent connections by the same user from different IP addresses. Your deployment might require concurrence. For example, a Citrix XenApp environment might have several jump boxes and a load balancer. An end user might run several sessions simultaneously, and the user sessions originate at different jump boxes.

To allow concurrent connections to a server, keep the default, **Enabled** for this option. To prevent concurrent connections to a server, set this option to **Disabled**.

#### IMPORTANT

In a clustered environment, setting **Concurrent Remote Connections** to **Disabled** does not prevent a user from having connections to other servers in the cluster. For example, if you have a cluster of five PAM servers, a user can have a single connection to all five of these servers, but cannot have multiple connections to any one of them.

### Specify PKI/Smart Card Options

To configure access options for smart card users, use the following controls on the **PKI/Smart Card Options** tab. For detailed configuration information, see [PKI Smart Card Authentication](#).

**PKI/Smart Card User Login:** With this option selected, the browser prompts for a client-side certificate upon locating the URL of the configured appliance.

**No Login Page without PKI/Smart Card:** When the Enabled checkbox is selected and a smart card is not present, users cannot to log in to the appliance. If the Disabled box is checked, users have the option of authenticating with Username and Password or other configured authentication methods. If users cannot authenticate with a smart card, the configuration page is always available with a known Username and Password.

**Policy Identifier:** Enter the PKI Policy Identifier here.

**Enable PKI/Smart Card Option on the Login Page:** If you use PKI smart cards to log in to PAM, this button adds a **PKI/Smart Card** option to the home page Authentication Type drop-down list.

## Secure Connections Using SSL Certificates

PAM uses TLS connections over HTTPS to secure communication between PAM servers and user sessions. You therefore require SSL certificates to enable these secure connections in your environment.

For a small test environment, you can create and use a self-signed SSL certificate.

For production environments including clusters, you require an SSL certificate from an in-house or third-party *Certificate Authority (CA)*.

You perform all certificate-related operations from the PAM UI **Configuration, Security, Certificates** page.

**See the following topics for detailed procedures for obtaining, applying, and managing SSL certificates:**

- [Create a Self-Signed SSL Certificate for Use in a Testing Environment](#)
- [Obtain and Apply SSL Certificates for a Single-Server Production Environment](#)
- [Obtain and Apply SSL Certificates for a Production Cluster](#)
- [Extract Required Certificates and CRLs from a Single SSL Certificate](#)
- [Certificate Revocation Update Options](#)
- [Sign Java Applets](#)
- [Delete a Certificate, CA Bundle, or CRL](#)

## Create a Self-Signed SSL Certificate for Use in a Testing Environment

As an administrator, you can create a self-signed SSL certificate, which is recommended as the minimal requirement to prevent security risk. This option is available at no cost, and useful for testing environments.

### NOTE

To obtain and install an SSL certificate for a single-server production environment, see [Obtain and Apply SSL Certificates for a Single-Server Production Environment](#).

To obtain and install an SSL certificate for a clustered production environment, see [Obtain and Apply SSL Certificates for a Production Cluster](#).

For production environments, [Secure Connections Using SSL Certificates](#). Generating a Certificate Signing Request (CSR) requires more steps and might involve a cost. A CSR is ordinarily used when organization policy requires it. To generate a CSR and certificates for a cluster, see [Obtain and Apply SSL Certificates for a Production Cluster](#).

### Video Overview

This short video provides an overview of the procedure to create a self-signed certificate.

### Create the Self-Signed Certificate

Use this procedure to create a self-signed certificate.

#### **Follow these steps:**

1. in the PAM UI, navigate to **Configuration, Security, Certificates** page.  
Stay on the **Create** tab which opens by default.
2. Select the **Self-Signed Certificate** option for **Type**.
3. Enter information in the following fields. Only the fields with a red asterisk are required. Do not use special characters.

- **Key Size:** We recommend 2048 bits. 4096 bits is more secure, but it slows down TLS handshakes and increases processor load during handshakes.
- **Common Name:** Enter the FQDN or IP address of Privileged Access Manager for the certificate request, such as `capam.ca.com` or `10.144.39.187`. This field maps to the CN field of the X.509 certificate.
- **Country:** Enter the two-letter country code, such as US, FR, or JP. This field maps to C value of the X.509 certificate.
- **State:** Enter the optional State or Province, such as Illinois, or Quebec. This field maps to ST value of the X.509 certificate.
- **City:** Enter the optional locality or city designation, such as Paris or Islandia. This field maps to L value of the X.509 certificate.
- **Organization:** Enter the organization, typically a company, for the certificate, such as "Acme Technologies." This field maps to O value of the X.509 certificate.
- **Org. Unit:** Set the optional organizational unit name, typically a subdivision, or location of the Organization, such as "Security BU". This field maps to the OU value/Organizational Unit designation of the X.509 certificate.
- **Days:** Set the validity time-period. The current appliance date becomes the "Not Valid Before" date for the certificate. The "Days" field is then used to determine the "Not Valid After" date.
- **Use Common Name for SAN:** Because some browsers require a value in the **Alternative Subject Names** field, the Common Name is repeated there by default. To add more names in that field, clear this checkbox. The Common Name should still be repeated in the **Alternative Subject Names** field.
- **Alternative Subject Names:** Some browsers require a value in this field. If no value is specified, the Common Name is repeated here. If more than one address is used to access the appliance, list FQDN and IP address aliases to the Common Name, one per line. This list must include the Common Name. Do not add a newline (line feed) after the last entry. Refer to the X.509 Subject Alternative Name.

**NOTE**

**For clusters (in internal test environments only):** Add the FQDN and IP address for the VIP and every member of the cluster. Any hostname or short VIP name that is used to access the cluster should also be added.

- **Filename:** Create a name for the certificate.

**TIP**

Include the creation or expiration date in the filename. For example, name it `capam_exp2019-07-19`.

4. Select **Create**.  
A confirmation message appears at the top of the page.
5. Do the following steps to stage the certificate for use:
  - a. On the **Set** tab, select the filename of the certificate that you created previously. The `.crt` extension is added to your filename.
  - b. Select **Verify** to confirm that this certificate is acceptable by Privileged Access Manager.
  - c. Select **Accept** to switch to the new certificate.
  - d. Reboot the appliance for the new certificate to take effect.
  - e. Install the certificate as a trusted root certificate in a browser.
  - f. When the **Security Alert** pop-up window appears, select **View Certificate**.
  - g. When the **Certificate** pop-up window appears, select **Install Certificate**.

**NOTE**

PAM Agents version 3.4 and later support connecting to a PAM server with an unexpired, untrusted certificate. If an older version of the PAM Agent cannot connect to the server to download the updates, replace that agent with a newer version.

- h. Select the **Yes** button.

**NOTE**

## Obtain and Apply SSL Certificates for a Single-Server Production Environment

This content describes how to obtain and apply SSL certificates from an in-house or third-party CA for a single-server production environment.

### NOTE

To obtain and install SSL certificates for a cluster, see [Obtain and Apply SSL Certificates for a Production Cluster](#).

To create and install a self-signed SSL certificate for a small development environment, see [Create a Self-Signed SSL Certificate for Use in a Testing Environment](#).

### Video Overview

The following video provides a brief overview of this procedure.

Do the following procedures in order to obtain a certificate from a Certificate Authority (CA) and apply it your PAM server:

### Request a Certificate from a Certificate Authority

To create a Certificate Signing Request (CSR) request for one appliance, follow these steps:

1. On the Create tab of the **Certificates** page, select the **CSR** option for **Type**. Enter information for the following fields. Do not use special characters.
  - **Key Size:** We recommend 2048 bits. 4096 bits is more secure, but it slows down TLS handshakes and increases processor load during handshakes.
  - **Common Name:** Enter the FQDN or IP address of Privileged Access Manager for the certificate request, such as `pam.ca.com`, `10.144.39.187` (IPv4), or `fd6d:8d64:af0c:1:0:242:22:233` (IPv6). This field maps to the CN field of the X.509 certificate.
    - **For Clusters:** Enter the FQDN of the cluster Virtual IP address.
  - **Country:** Enter the two-letter country code, such as US, FR, or JP. This field maps to C value of the X.509 certificate.
  - **State:** Enter the optional State or Province, such as Illinois, or Quebec. This field maps to ST value of the X.509 certificate.
  - **City:** Enter the optional locality or city designation, such as Paris or Islandia. This field maps to L value of the X.509 certificate.
  - **Organization:** Enter the organization, typically a company, for the certificate, such as "Acme Technologies." This field maps to O value of the X.509 certificate.
  - **Org. Unit:** Enter the optional organizational unit name, typically a subdivision, or location of the Organization, such as "Security BU". This field maps to the OU value/Organizational Unit designation of the X.509 certificate.
  - **Days:** Days are used only for self-signed certificates.
  - **Use Common Name for SAN:** Because some browsers require a value in the **Alternative Subject Names** field, the Common Name is repeated there by default. To add more names in that field, clear this checkbox. The Common Name should still be repeated in the **Alternative Subject Names** field.
  - **Alternative Subject Names:** Some browsers require a value in this field. If no value is specified, the Common Name is repeated here. If more than one address is used to access the appliance, list FQDN and IP address aliases to the Common Name, one per line. This list must include the Common Name. Do not add a newline (line feed) after the last entry. Refer to the X.509 Subject Alternative Name.

- **For Clusters:** Enter the FQDN and IP address for the VIP and every member of the cluster. Any hostname or short VIP name that is used to access the cluster should also be added.
- **Filename:** Create a name for the certificate. This file name is also the name of the private key that is generated. The name must exactly match the name of the certificate when uploaded.

#### TIP

Include the creation or expiration date in the filename. For example, name it `capam_exp2019-07-19`.

2. Select **Create**.
3. On the **Download** tab, select the **Filename** of the CSR you created, which has a PEM (Privacy Enhanced Mail) extension.
4. Select **Download**.  
Submit the downloaded PEM file to request a certificate from your CA. Users do not have to install root certificates because the third party validates the site.
5. For clusters, remain on the **Download** tab to download the private key:
  - a. On the **Download** tab, select the Private Key from the **Filename** drop-down list. It is under the **Private Keys** heading, with the same name as the CSR, but a KEY extension.
  - b. Enter a **Password** and **Confirm Password** for encrypting the private key. Record this password to use later when uploading certificates to cluster members.
  - c. Select **Download**. Save the **Private Key** to add it later to the received Certificate for the other cluster members.
6. Obtain a new certificate using the downloaded CSR. Follow the instructions from your Certificate Authority to receive a certificate.

#### IMPORTANT

If the Certificate Authority provides all the required certificates and certificate revocation information in a single certificate file, follow the procedure that is described in [Extract Required Certificates and CRLs from a Single SSL Certificate](#) to extract them.

### Upload the Third-Party Certificates and CRLs

Once you have the certificates and CRLs for their chain of trust, you upload them into the PAM server. You must upload them in the right order to avoid errors:

1. Root certificate (as CA Bundle)
2. Intermediate CRL
3. Intermediate certificate
4. Device CRL
5. Device certificate

#### **Upload the Root Certificate**

1. Go to the **Configuration, Security, Certificates** page. Select the **Upload** tab.
2. Select **CA Bundles** as **Type**.
3. For **Other Options**, select the applicable format (X509 or PKCS) for the certificate.
4. Select the root certificate by using the **Choose File** button to find the certificate **Filename**.
5. Select **Upload**.  
You should receive a success message.

#### **Upload the Intermediate CRL**

1. Select **Certificate Revocation List** as **Type**.
2. For **Other Options**, select the applicable format (X509 or PKCS) for the CRL.
3. Select the intermediate CRL by using the **Choose File** button to find the intermediate CRL **Filename**.
4. Select **Upload**.

You should receive a success message with details about the CRL source.

### ***Upload the Intermediate Certificate***

1. Select **Intermediate Certificate** as **Type**.
2. For **Other Options**, select the applicable format (X509 or PKCS) for the certificate.
3. Select the intermediate certificate by using the **Choose File** button to find the intermediate certificate **Filename**.
4. Select **Upload**.  
You should receive a success message.

### ***Upload the Device CRL***

1. Select **Certificate Revocation List** as **Type**.
2. For **Other Options**, select the applicable format (X509 or PKCS) for the CRL.
3. Select the device CRL by using the **Choose File** button to find the device CRL **Filename**.
4. Select **Upload**.  
You should receive a success message with details about the CRL source.

### ***Upload the Device Certificate***

1. If you generated the initial CSR on another appliance, you have to concatenate your private key with the certificate that you received. See [Install Certificates in a Cluster](#) for instructions. The resulting combination file would be uploaded as **Type of Certificate with Private Key**.
2. Otherwise, select **Certificate** as **Type**.
3. For **Other Options**, select the applicable format (X509 or PKCS) for the certificate.
4. Select the device certificate by using the **Choose File** button to find the certificate **Filename**.
5. Use **Destination Filename** to change the filename of the certificate. This field can be left blank if the name stays the same.  
If Privileged Access Manager generated the CSR, the "Destination Filename" must match the name of the CSR to match the private key properly. Rename the certificate that is received from the third party if necessary, so that:
  - a. Its base name is the same as the one that originally generated.
  - b. Its extension is ".crt".
 For example, if the original PEM name was abc.pem, the uploaded file must be named abc.crt.
6. If you are uploading a Certificate with a Private Key, enter the **Passphrase** that you used to create the Key, then re-enter it in **Confirm**.
7. Select **Upload**.  
You should receive a success message.

### **Verify and Set the Certificates**

Once all the required files have been uploaded, you inspect the files, verify them, and accept them. Once you accept the certificate chain, the appliance asks you to reboot. The certificate partially takes effect upon acceptance of the new certificate. We recommend applying certificates while the appliance is in maintenance mode, and to reboot the appliance before disabling maintenance mode.

#### **Follow these steps:**

1. On the **Download** tab of the **Security** page, select the **Filename** field and inspect the drop-down list of files. All the certificate and CRLs should be listed. Default files are also in the list.
2. On the **Set tab**, select the certificate that was generated by the third-party CA.
3. Select **Verify** to ensure that Privileged Access Manager accepts the certificate.  
Either a confirmation phrase or error message is provided at the top of the page.  
A success message means that the entire certification chain is valid.
4. After the verification, select **Accept** to apply the new certificate.  
The appliance asks you to reboot. The certificate does not take effect until the appliance is rebooted.

5. To activate the new certificate, select the **Reboot** button to reboot Privileged Access Manager.
6. After the reboot, logging in to the PAM server should not present an invalid certificate icon or message. On the **Set** tab of the **Configuration, Security, Certificates** page, the **System Certification** field shows the newly activated certificate name.

**NOTE**

For related information, see the following topics:

- [Secure Connections Using SSL Certificates](#)
- [Extract Required Certificates and CRLs from a Single SSL Certificate](#)
- [Certificate Revocation Update Options](#)
- [Sign Java Applets](#)
- [Delete a Certificate, CA Bundle, or CRL](#)

## Obtain and Apply SSL Certificates for a Production Cluster

This content describes how to obtain and apply SSL certificates from an in-house or third-party CA for a production cluster.

**NOTE**

To obtain and install SSL certificates for a single-server production environment, see [Obtain and Apply SSL Certificates for a Single-Server Production Environment](#).

To create and install a self-signed SSL certificate for a small development environment, see [Create a Self-Signed SSL Certificate for Use in a Testing Environment](#).

To secure communication between PAM servers and user sessions in a clustered environment, each node in the cluster requires the *same* SSL certificate that contains the FQDN and IP address of the VIP and every member of the cluster.

**IMPORTANT**

You do *not* need to stop the cluster to install certificates; install them one node at a time with the cluster up.

Do the following procedures in order to obtain a certificate from a Certificate Authority (CA) and apply it to all the nodes in your cluster:

### **Create a Certificate Signing Request (CSR) and Send it to the CA**

Designate any node in the Primary Site *other than the master* as the *CSR Originator* for the whole cluster and create the CSR from that server.

#### **Follow this procedure on the CSR Originator:**

1. On the **Create** tab of the **Certificates** page, select the **CSR** option for **Type**. Enter information for the following fields. Do not use special characters.

- **Key Size:** We recommend 2048 bits. 4096 bits is more secure, but it slows down TLS handshakes and increases processor load during handshakes.
- **Common Name:** Enter the FQDN of the cluster Virtual IP address, such as `pam.ca.com`. This field maps to the CN field of the X.509 certificate.
- **Country:** Enter the two-letter country code, such as US, FR, or JP. This field maps to C value of the X.509 certificate.
- **State:** Enter the optional State or Province, such as Illinois, or Quebec. This field maps to ST value of the X.509 certificate.
- **City:** Enter the optional locality or city designation, such as Paris or Islandia. This field maps to L value of the X.509 certificate.
- **Organization:** Enter the organization, typically a company, for the certificate, such as "Acme Technologies." This field maps to O value of the X.509 certificate.
- **Org. Unit:** Enter the optional organizational unit name, typically a subdivision, or location of the Organization, such as "Security BU". This field maps to the OU value/Organizational Unit designation of the X.509 certificate.
- **Days:** Days are used only for self-signed certificates.
- **Alternate Subject Names:** Enter the FQDN and IP address for the VIP and every member of the cluster. Any hostname or short VIP name that is used to access the cluster should also be added. Each FQDN, IP address, or alias should be on its own line. This list must include the **Common Name**. Do not add a newline (line feed) after the last entry. Refer to the X.509 Subject Alternative Name.
- **Filename:** Create a name for the certificate. This file name is also the name of the private key that is generated. The name must exactly match the name of the certificate when uploaded.

**TIP**

Include the creation or expiration date in the filename. For example, name it `PAM-Cluster_exp2019-07-19`.

2. Select **Create**.
3. On the **Download** tab, select the filename of the CSR you created, which has a PEM (Privacy Enhanced Mail) extension.
4. Select **Download**. Use this file to request a certificate from a Certificate Authority (CA) such as Entrust. Users do not have to install root certificates because the third party validates the site.
5. Select the Private Key (which has the same name as the CSR, but a .key extension) from the filename drop-down list. It is under the **Private Keys** heading,
6. Enter a **Password** and **Confirm Password** for encrypting the private key. Record this password for later use.
7. Select **Download**. Save the **Private Key** to add it later to the received Certificate for the other cluster members.
8. Follow the instructions provided by your CA to request the certificates using the downloaded CSR.

**IMPORTANT**

If the Certificate Authority provides all the required certificates and certificate revocation information in a single certificate file, follow the procedure described in [Extract Required Certificates and CRLs from a Single SSL Certificate](#) to extract them.

### Upload and Apply the Third-Party Certificates on the CSR Originator

Once you have the certificates and CRLs for their chain of trust, upload and apply them on the primary site node where you generated the CSR.

#### **Upload the certificates in the following order to avoid errors:**

1. **Upload the Root Certificate:**
  - a. Go to the **Configuration, Security, Certificates** page. Select the **Upload** tab.
  - b. Select **CA Bundles** as **Type**.
  - c. For **Other Options**, select the applicable format (X509 or PKCS) for the certificate.
  - d. Select the root certificate by using the **Choose File** button to find the certificate filename.

- e. Select **Upload**.  
If the operation completed, a success message appears at the top of the screen.
2. **Upload the Intermediate CRL:**
  - a. Select **Certificate Revocation List** as **Type**.
  - b. For **Other Options**, select the applicable format (X509 or PKCS) for the CRL.
  - c. Select the intermediate CRL by using the **Choose File** button to find the intermediate CRL filename.
  - d. Select **Upload**.  
If the operation was successful, a message appears at the top of the screen with details about the CRL source.
3. **Upload the Intermediate Certificate:**
  - a. Select **Intermediate Certificate** as the **Type**.
  - b. For **Other Options**, select the applicable format (X509 or PKCS) for the certificate.
  - c. Select the intermediate certificate by using the **Choose File** button to find the intermediate certificate filename.
  - d. Select **Upload**.  
If the operation was successful, a message appears at the top of the screen with details about the intermediate certificate.
4. **Upload the Device CRL:**
  - a. Select **Certificate Revocation List** as **Type**.
  - b. For **Other Options**, select the applicable format (X509 or PKCS) for the CRL.
  - c. Select the device CRL by using the **Choose File** button to find the device CRL filename.
  - d. Select **Upload**.  
If the operation was successful, a message appears at the top of the screen with details about the CRL source.
5. **Upload the Device Certificate:**
  - a. Select **Certificate** as **Type**.
  - b. For **Other Options**, select the applicable format (X509 or PKCS) for the certificate.
  - c. Select the device certificate by using the **Choose File** button to find the certificate filename.
  - d. Use **Destination Filename** to change the filename of the certificate. This field can be left blank if the name stays the same.  
If Privileged Access Manager generated the CSR, the "Destination Filename" must match the name of the CSR to match the private key properly. Rename the certificate that is received from the third party if necessary, so that:
    - a. Its base name is the same as the one that originally generated.
    - b. Its extension is ".crt".
For example, if the original PEM name was abc.pem, the uploaded file must be named abc.crt.
  - e. If you are uploading a Certificate with a Private Key, enter the **Passphrase** that you used to create the Key, then re-enter it in **Confirm**.
  - f. Select **Upload**.  
If the operation completed, a success message appears at the top of the screen.
  - g. Select **Verify** to ensure that Privileged Access Manager accepts the certificate.  
Either a confirmation or an error message is provided at the top of the page.
  - h. Do **not** accept the certificates until all the cluster members have uploaded their certificates. Setting the accepted certificates requires a reboot. Wait until you complete the next procedure for other cluster members before turning off the cluster and accepting certificates on each member.

### **Verify and Apply the Certificates on the CSR Originator**

Do the following procedure on the primary site node where you generated the CSR to verify and apply the certificates. **Follow these steps:**

#### **Follow these steps:**

1. Turn on Maintenance Mode to prevent new logins:
  - a. Navigate to **Configuration, Diagnostic, System**.

- b. Set the **Maintenance Mode** option to **On**.
  - c. (Optional) Monitor the server until all user sessions have ended to avoid abruptly terminating any active user sessions by stopping PAM prematurely.
2. Navigate to the **Configuration, Certificates** screen and select the **Download** tab.
3. Select the **Filename** field and inspect the drop-down list of files. All the certificate and CRLs should be listed. Default files are also in the list.
4. On the **Set** tab, select the certificate that was generated by the third-party CA.
5. Select **Verify** to ensure that Privileged Access Manager accepts the certificate. Either a confirmation or an error message is provided at the top of the page. A success message means that the entire certification chain is valid.
6. After verification, select **Accept** to apply the new certificate. A dialog appears stating that the system certificate has been changed and asking you to "stop the cluster and reboot the appliance to make the new certificate take effect." However, to maintain availability in a production environment, **you can proceed without stopping the cluster**. Select the **OK** button to dismiss the dialog. Do **not stop** the cluster.
7. Do the following steps to activate the new certificate by rebooting the server:
  - a. Navigate to **Configuration, Power**.
  - b. The **Power** screen displays a "Cluster Warning" stating that the PAM cluster must be turned off before powering down or rebooting any cluster member. However, since the cluster does not have to be stopped to install certificates, select the option acknowledging that you have read that guidance as shown in the following screen

I acknowledge that I have read the above guidance. (You will not be able to power off or reboot without first accepting this acknowledgment.)

capture:

- c. Select the **Reboot Instance** button. The server reboots.
8. After the reboot, do the following steps to verify that the certificate was installed correctly:
  - a. Log in to the PAM server. The PAM UI should not present an invalid certificate icon or message.
  - b. Navigate to the **Set** tab of the **Configuration, Security, Certificates** screen and verify that the **System Certification** field shows the newly activated certificate name.

### Prepare a Certificate File for Other Nodes

The certificate that is provided by the CA is only valid on the CSR Originator. For other nodes, you require a file that includes the contents of the following files that are located on the originating node:

- The private key (.key) file generated when creating the CSR.
- The certificate (.crt) file that is provided by the CA in response to the CSR.

The resulting privacy enhanced mail (.pem) file is valid for all other cluster nodes.

To combine (concatenate) the files, enter one of the following commands at a command prompt on the node where you generated the CSR:

- **Linux:** `cat private_key_file.key certificate_file.crt > combined_pem_file.pem`
- **Windows:** `type private_key_file.key certificate_file.crt > combined_pem_file.pem`

The contents of the resulting .pem file should resemble the following example:

```
-----BEGIN RSA PRIVATE KEY-----
Proc-Type: 4, ENCRYPTED
DEK-Info: AES-256-CBC, 58B125ACF0792928BA28D7BC53901D86

-----END CERTIFICATE-----

```

## **Apply the Certificates to All Other Cluster Nodes**

Follow these steps on every cluster member other than the CSR creator.

### **NOTE**

Upload the certificate files in the specified order. Failure to do so causes errors.

**Follow these steps to upload the certificates in the correct order:**

1. **Upload the Root Certificate:**
  - a. Go to the **Configuration, Security, Certificates** page. Select the **Upload** tab.
  - b. Select **CA Bundles** as **Type**.
  - c. For **Other Options**, select the applicable format (X509 or PKCS) for the certificate.
  - d. Select the root certificate by using the **Choose File** button to find the certificate filename.
  - e. Select **Upload**.  
If the operation completed, a success message appears at the top of the screen.
2. **Upload the Intermediate CRL:**
  - a. Select **Certificate Revocation List** as **Type**.
  - b. For **Other Options**, select the applicable format (X509 or PKCS) for the CRL.
  - c. Select the intermediate CRL by using the **Choose File** button to find the intermediate CRL filename.
  - d. Select **Upload**.  
If the operation was successful, a message appears at the top of the screen with details about the CRL source.
3. **Upload the Intermediate Certificate:**
  - a. Go to the **Configuration, Security, Certificates** page. Select the **Upload** tab.
  - b. Select **CA Bundles** as **Type**.
  - c. For **Other Options**, select the applicable format (X509 or PKCS) for the certificate.
  - d. Select the root certificate by using the **Choose File** button to find the certificate filename.
  - e. Select **Upload**.  
If the operation completed, a success message appears at the top of the screen.
4. **Upload the Device CRL:**
  - a. Select **Certificate Revocation List** as **Type**.
  - b. For **Other Options**, select the applicable format (X509 or PKCS) for the CRL.
  - c. Select the device CRL by using the **Choose File** button to find the device CRL filename.
  - d. Select **Upload**.  
If the operation was successful, a message appears at the top of the screen with details about the CRL source.
5. **Upload the Device Certificate with Private Key:**
  - a. Select **Certificate with Private Key** as **Type**.
  - b. For **Other Options**, select the applicable format (X509 or PKCS) for the certificate.
  - c. Select the device certificate by using the **Choose File** button to find the certificate filename.
  - d. Use **Destination Filename** to change the filename of the certificate. This field can be left blank if the name stays the same.
    - a. Its base name is the same as the one that originally generated.
    - b. Its extension is ".crt".  
For example, if the original PEM name was abc.pem, the uploaded file must be named abc.crt.
  - e. Enter the **Passphrase** that you used to create the Key, then re-enter it in **Confirm**. The Certificate with Private Key requires the password that you created when downloading the Key.
  - f. Select **Upload**.  
If the operation completed, a success message appears at the top of the screen.

### Verify and Apply the Certificates on the Other Nodes in the Cluster:

Once all the required files have been uploaded, inspect the files, verify them, and accept them. Once you accept the certificate chain, the appliance asks you to reboot. The certificate does not take effect until the appliance is rebooted.

**Follow these steps on every other node in the cluster, completing all steps before starting on the next node:**

1. Turn on Maintenance Mode to prevent new logins:
  - a. Navigate to **Configuration, Diagnostic, System**.
  - b. Set the **Maintenance Mode** option to **On**.
  - c. (Optional) Monitor the server until all user sessions have ended to avoid abruptly terminating any active user sessions by stopping PAM prematurely.
2. Navigate to the **Configuration, Certificates** screen and select the **Download** tab.
3. Select the **Filename** field and inspect the drop-down list of files. All the certificate and CRLs should be listed. Default files are also in the list.
4. On the **Set** tab, select the certificate that was generated by the third-party CA.
5. Select **Verify** to ensure that Privileged Access Manager accepts the certificate. Either a confirmation or an error message is provided at the top of the page. A success message means that the entire certification chain is valid.
6. After verification, select **Accept** to apply the new certificate. A dialog appears stating that the system certificate has been changed and asking you to "stop the cluster and reboot the appliance to make the new certificate take effect." However, to maintain availability in a production environment, **you can proceed without stopping the cluster**. Select the **OK** button to dismiss the dialog. Do **not stop** the cluster.
7. Do the following steps to activate the new certificate by rebooting the server:
  - a. Navigate to **Configuration, Power**.
  - b. The **Power** screen displays a "Cluster Warning" stating that the PAM cluster must be turned off before powering down or rebooting any cluster member. However, since you do not have to stop the cluster to install certificates, select the option acknowledging that you have read that guidance as shown in the following screen capture:
 

I acknowledge that I have read the above guidance. (You will not be able to power off or reboot without first accepting this acknowledgment).

  - c. Select the **Reboot Instance** button. The server reboots.
8. After the reboot, do the following steps to verify that the certificate was installed correctly:
  - a. Log in to the PAM server. The PAM UI should not present an invalid certificate icon or message.
  - b. Navigate to the **Set** tab of the **Configuration, Security, Certificates** screen and verify that the **System Certification** field shows the newly activated certificate name.

#### NOTE

For related information, see the following topics:

- [Secure Connections Using SSL Certificates](#)
- [Extract Required Certificates and CRLs from a Single SSL Certificate](#)
- [Certificate Revocation Update Options](#)
- [Sign Java Applets](#)
- [Delete a Certificate, CA Bundle, or CRL](#)

### Extract Required Certificates and CRLs from a Single SSL Certificate

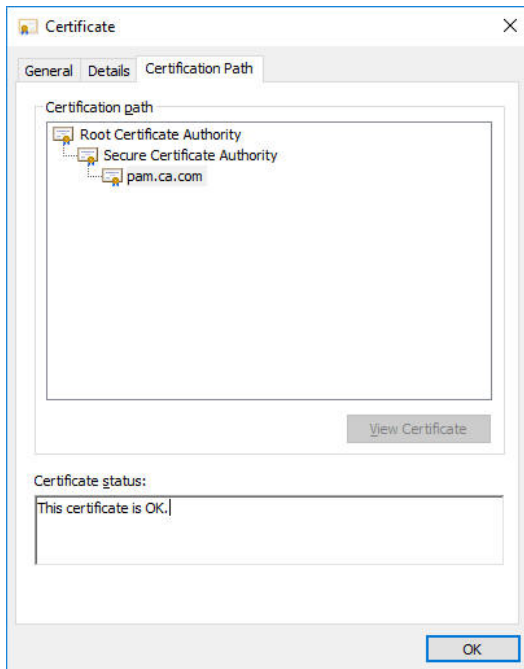

If the Certificate Authority provides all the required certificates and certificate revocation information in a single certificate file, use this procedure to extract those items from that certificate.

**Follow these steps:**

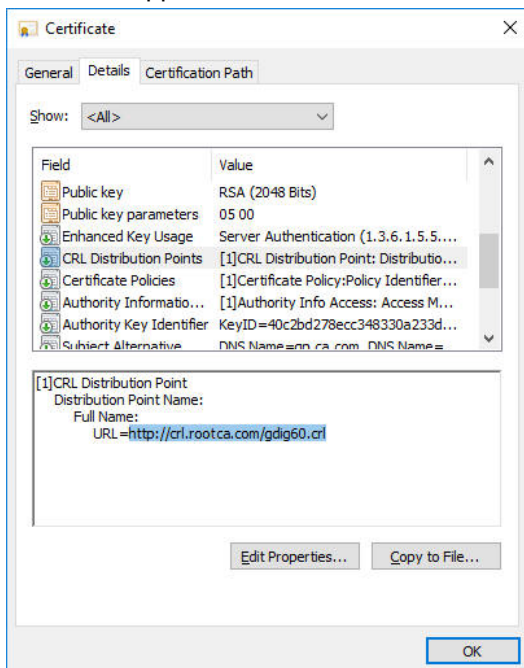

1. Copy the certificate to a convenient location on a local Windows computer.
2. In **Windows Explorer**, navigate to the location of the certificate file and open it.

A **Certificate** dialog opens.

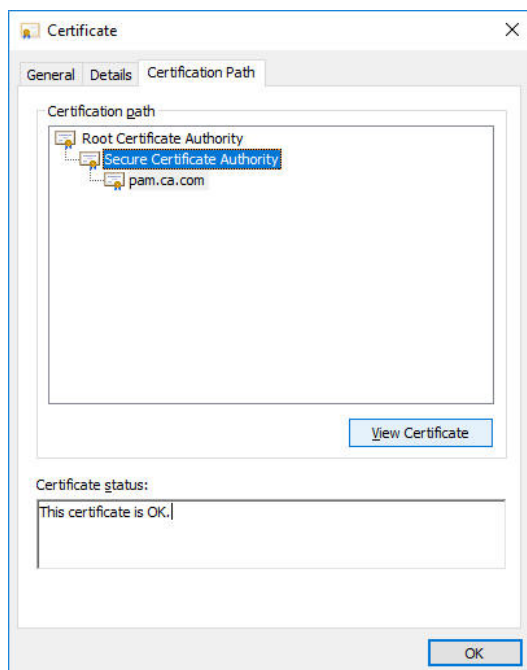

3. Select the **Certification Path** tab, where the trusted root CA is displayed at the top of the **Certification Path** pane, your device certificate at the bottom, and intermediate certificates in between.
4. Select the **Details** tab.
5. Scroll down and select the **CRL Distribution Points** field. The value appears in the window under the fields list.

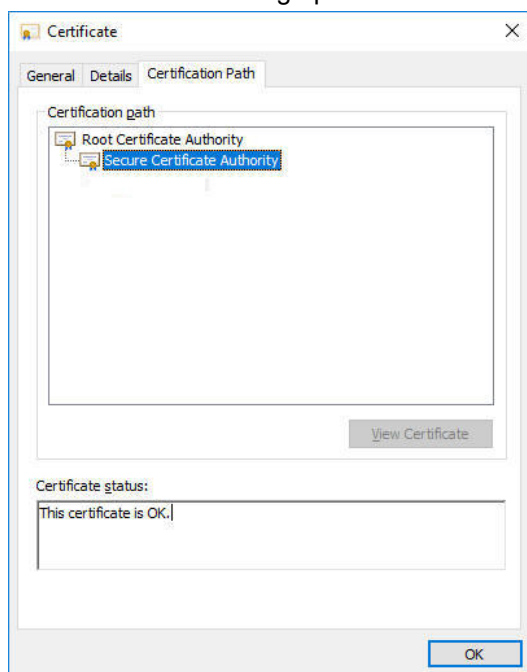

6. Select and copy the URL value.
7. Paste the URL into a browser. When prompted to open or save the CRL file, select **Save**. For convenience, save it to same location as the certificate.
8. On the **Certification Path** tab, select the intermediate certificate.

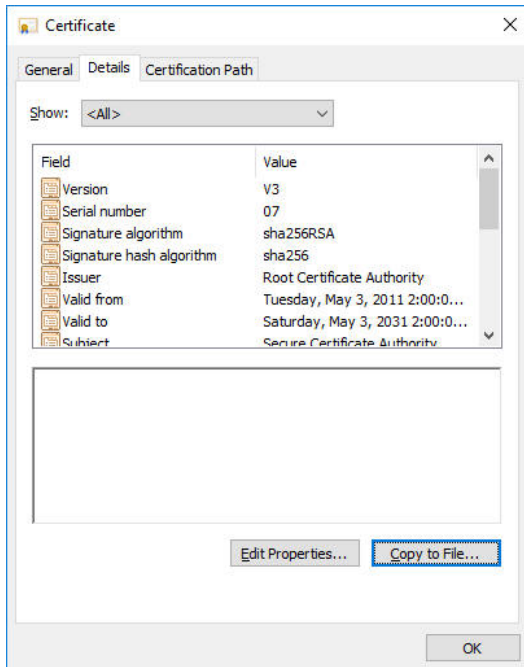

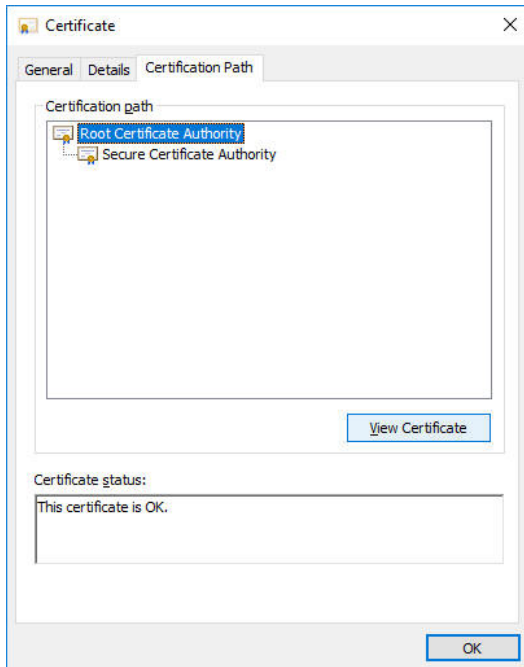

9. Select the **View Certificate** button.  
A new **Certificate** dialog opens for the intermediate certificate.

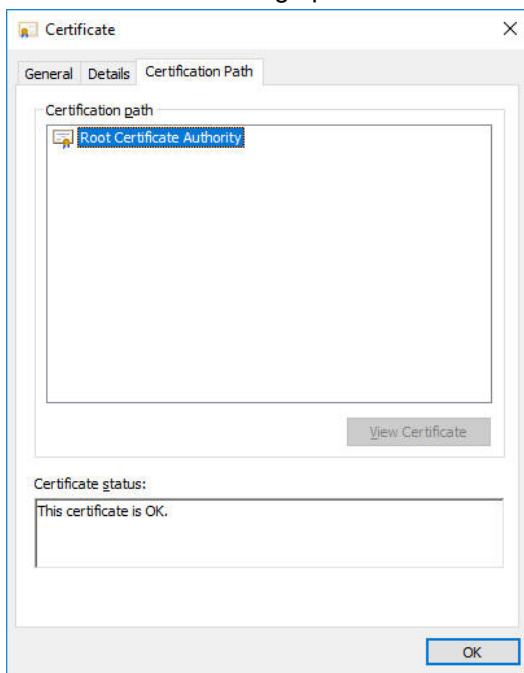

10. Select the **Details** tab on the **Certificate** dialog for the intermediate certificate.

11. Select the **Copy to File** button to save this certificate.  
The **Certificate Export Wizard** opens.
12. Follow the prompts in the wizard. For convenience, save the certificate to same location as the device certificate and CRL file.
13. Return to the open **Details** tab of the intermediate certificate dialog.
14. Scroll to the **CRL Distribution Point** field.
15. Copy the URL of the CRL Distribution Point as you did for the device certificate.
16. Paste the URL into a browser.  
When prompted to open or save the CRL file, select **Save**. For convenience, save the intermediate certificate to same location as the certificates and other CRL.
17. On the **Certification Path** tab, select the root certificate.

18. Select the **View Certificate** button.  
A new **Certificate** dialog opens for the root certificate.

19. Select the **Details** tab on the root certificate.  
20. Select the **Copy to File** button to save this certificate.  
The **Certificate Export Wizard** opens.  
21. Follow the prompts in the wizard. For convenience, save the root certificate to same location as the other certificates and CRL files.

**NOTE**

The root certificate does not have a CRL Distribution Point field.

You should now have certificate files for each level of the Certification Path, and CRLs for all but the root certificate.

- [Obtain and Apply SSL Certificates for a Production Cluster](#)

## Certificate Revocation Update Options

Certificate Authorities revoke SSL certificates when they detect an issue with the associated identity or that the certificate key has been compromised. The CA then publishes that information so that certificate users can stop using those revoked certificates.

This content describes how to configure PAM to regularly check that its security certificate is still valid using one of the following methods:

- **Regularly downloading the latest Certificate Revocation List (CRL):** Some CAs provide *CRL Distribution Points* from which you can periodically download CRL files that contain the latest list of revoked certificates.
- **Query an Online Certificate Status Protocol (OCSP) Server (or responder):** OCSP is a dynamic alternative to CRLs. OCSP enables an application or browser to query the Certificate Authority for the revocation status of a certificate each time a connection is established.

### NOTE

If your certificate is revoked, request a new certificate from the CA and apply it to all of your PAM servers.

Topics in this content:

- [Obtain CRL Distribution Point and OCSP Server Information From a Certificate](#)
- [Manually or Automatically Download CRLs](#)
- [Obtain Revoked Certificate Information from an OCSP Server](#)
- [Route OCSP Requests Through a Proxy Server](#)
- [Configure What to Do If Certificate Revocation Information Is Unavailable](#)
- [View CRL Information](#)

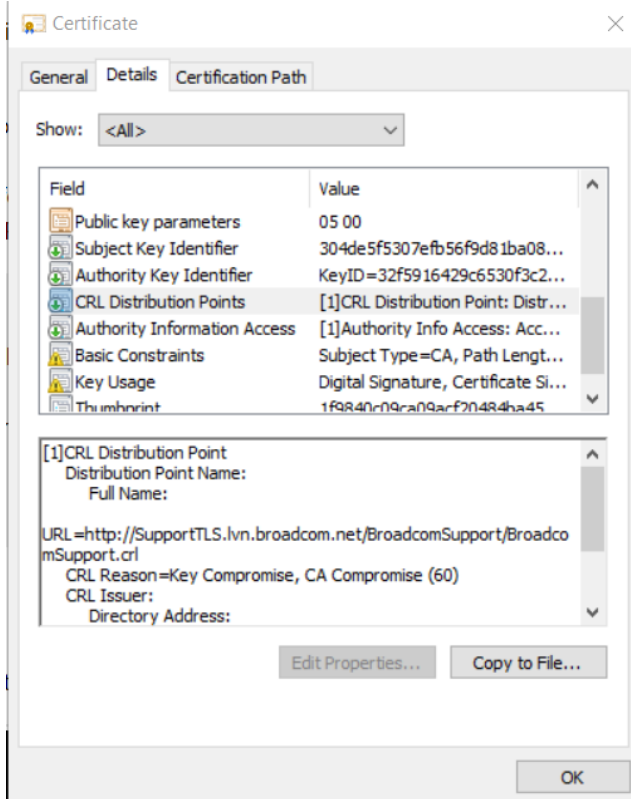

### Obtain CRL Distribution Point and OCSP Server Information From a Certificate

If necessary, use this procedure to obtain CRL Distribution Point or OCSP server information from the Certificate properties.

#### ***Obtain Information From a Certificate on Windows***

##### **Follow these steps:**

1. in Windows Explorer, navigate to the certificate file and open it.  
A **Certificate** dialog opens.
2. Select the **Details** tab.
3. To find details of available **CRL Distribution Points**, select the corresponding entry in the top list and take note of the URL or URLs in the lower panel.

4. To find out if the CA provides an OCSP server, do the following steps:
  - a. Select the **Authority Information Access** entry in the top panel.
  - b. Note whether a URL is provided in the lower panel. You do not need to copy the URL.

### Obtain Information From a Certificate on UNIX

To obtain information from a certificate on a UNIX system, enter the following command:

```
openssl x509 -in certificate_file.cer -text
```

### Manually or Automatically Download CRLs

Use one of the following procedures if your CA requires you to obtain revoked certificate information from CRLs that you download from a CRL Distribution Point.

#### Upload CRLs That You Manually Download from the CA

Use this procedure if your CA requires you to download CRLs from a CRL Distribution Point but your security protocols do not allow you to do so automatically.

#### Follow these steps:

1. Log in to the PAM UI.
2. Navigate to the **Configuration, Security, Certificates** pane and select the **CRL Options** tab.
3. For **Type**, select **Use CRL**.
4. For **CRL Type**, select **Manually Download CRLs**.
5. Download the CRL file from the CRL Distribution Point and, if necessary, copy it to the local drive of your PAM server.
6. Select the **Upload** tab and do the following steps:
  - a. Select **Certificate Revocation List** as **Type**.
  - b. For **Other Options**, select the applicable format (**X509** or **PKCS**) for the CRL.

- c. Select the device CRL by using the **Choose File** button to find the device CRL **Filename**.
- d. Select **Upload**.

You should receive a success message with details about the CRL source.

7. Return to the **CRL Options** tab.
8. Optionally, [change what action to take when revocation information is unavailable](#). The default action is **Allow User Access**.
9. Select the **Update** button.

### ***Automatically Download the Latest CRL***

Use this procedure to automatically download the latest CRL from a CRL Distribution Point.

#### **Follow these steps:**

1. Log in to the PAM UI.
2. On the **Configuration, Security, Certificates** page, select the **CRL Options** tab.
3. For **Type**, select **Use CRL**.
4. For **CRL Type**, select **Automatically Download CRLs**.
5. In the **URLs** text box, enter one or more URLs for CRL servers, one per line.
6. For **Time**, select a frequency for checking the CRL server. The default is five minutes.
7. Optionally, [change what action to take when revocation information is unavailable](#). The default action is **Allow User Access**.
8. Select the **Update** button.

### **Obtain Revoked Certificate Information from an OCSP Server**

Use this procedure if your CA requires you to query an OCSP server for revoked certificates.

#### **Follow these steps:**

1. Log in to the PAM UI.
2. On the **Configuration, Security, Certificates** page, select the **CRL Options** tab.
3. For **Type**, select **Use OCSP**.
4. Optionally, [change what action to take when revocation information is unavailable](#). The default action is **Allow User Access**.
5. [If necessary, configure the properties of a proxy server](#).
6. Optionally, specify a non-default timeout value for OCSP responses in the **OCSP Timeout** field. The default value is 10 seconds.

#### **IMPORTANT**

It is important to be aware of the following information when configuring the **OCSP Timeout** value for your environment:

- The preset timeout for most PAM UI operations (such as opening a pane or committing changes) is 60 seconds, after which a "Communication failure" error message occurs.
- The OCSP timeout applies to every certificate in your certificate chain, and the timeout value is cumulative, such that:

$$\text{Max OCSP Response Duration} = \text{Certificate Chain Length} * \text{OCSP Timeout}$$

Therefore, if your certificate chain length is four, setting the OCSP timeout to 20 seconds allows responses to OCSP queries to take up to 80 seconds. Since this duration is greater than the 60 seconds allowed for PAM UI operations, user operations may fail with a "Communication failure" error message.

7. Select the **Update** button.

The appliance automatically contacts the OCSP server regarding the specific certificate when it is used.

## Route OCSP Requests Through a Proxy Server

This procedure describes how to configure the information required if your environment requires a proxy Server to route OCSP requests and responses.

### Follow these steps:

1. Log in to the PAM UI.
2. Certificates pane **Configuration, Security, Certificates**, select the **CRL Options** tab.
3. For **Type**, select **Use OCSP**.
4. Configure the following properties of the OCSP proxy server:
  - **OCSP Proxy Server**: Specify the FQDN or IP address of the proxy server.
  - **OCSP Proxy Port**: Specify the port number to access the proxy server.

## Configure What to Do If Certificate Revocation Information Is Unavailable

The **When Revocation Information is Unavailable** option is available whether you download CRLs automatically, manually, or you use OCSP.

To use **When Revocation Information is Unavailable**, select an option from the drop-down list to determine whether a user with the certificate has access to PAM. The default is **Allow User Access**. With this mode, a user with the certificate is allowed access to PAM even though the revocation information that is related to that certificate is unavailable or not accessible. The other mode is **Deny User Access**. This mode denies access to PAM when revocation information is unavailable or not accessible.

The following table describes different conditions and the behavior that is associated with them when the **Allow User Access** or **Deny User Access** option is selected:

Condition	Deny User Access (Security Safe Mode)	Allow User Access (Operationally Safe Mode)	Co
Expired Certificate	N/A	N/A	Au
Self-Signed V3 X509 Certificate	N/A	N/A	Au
Expired CA	N/A	N/A	Au
Revoked CA	N/A	N/A	Au
CRL present, but the list is empty.	N/A	N/A	Au
No CRL present for the issuer of the certificate.	Certificate authentication fails. A CRL must be present and can be with an empty revocation list.	Certificate authentication succeeds.	
CRL expired for the issuer of the certificate.	Certificate authentication fails immediately. No checks are made to determine if the certificate is in the revocation list.	Certificate authentication proceeds and checks are made to determine if the certificate is in the revocation list. If found in the list, the certificate authentication fails or else succeeds.	
Automatic CRL download fails.	Certificate authentication fails for the URLs that failed to download as CRLs associated with the URL that failed are cleaned up. (Equivalent to <b>No CRL present for the issuer of the cert</b> condition.)	Certificate authentication succeeds or fails, depending on the existing CRL information. If the automatic download fails, no CRLs are cleaned up.	
No OCSP URI information available in the certificate	Certificate authentication fails. OCSP URI information must be present in the certificate and in all the certificates in the certificate chain.	Certificate authentication succeeds.	

Cannot connect to OCSP URI.	Certificate authentication fails.	Certificate authentication succeeds.	
-----------------------------	-----------------------------------	--------------------------------------	--

### View CRL Information

To view configured Certificate Revocation List (CRL) files and their associated status, select the **Certificate Revocation List** tab on the **Configuration, Security, Certificates** page.

#### NOTE

This option only appears if smartcard authentication is enabled for use with CRLs.

When populated with CRLs, the **Certificate Revocation List** tab displays the following fields for each certificate:

- **Issuer**
- **Next Update** (or note when it Expired)
- **Status**  
S = Stable, P = Processing, D = Downloading, I = Initial, F = Fail
- **File Name** (if applicable)
- **Distribution Point** (optional)
- **Fail Reason**  
If a CRL failure produces an error message, it is shown here.  
For example: `There is an invalid CRL file: filename`

#### NOTE

For related information, see the following topics:

- [Secure Connections Using SSL Certificates](#)
- [Create a Self-Signed SSL Certificate for Use in a Testing Environment](#)
- [Obtain and Apply SSL Certificates for a Single-Server Production Environment](#)
- [Obtain and Apply SSL Certificates for a Production Cluster](#)

## Sign Java Applets

Use the **Sign Applets** tab on the **Configuration, Security, Certificates** screen to sign Java Applet JARs with a certificate. For more information about signing Java applets, see [Managing Java on Your Client Workstation](#).

## Delete a Certificate, CA Bundle, or CRL

This content describes how to delete a certificate, CA bundle or CRL.

### Follow these steps:

1. On the **Configuration, Security, Certificates** page, select **Delete**.
2. Select the file name that you want to delete, and select **Delete**.

#### NOTE

For related information, see the following topics:

- [Secure Connections Using SSL Certificates](#)
- [Create a Self-Signed SSL Certificate for Use in a Testing Environment](#)
- [Obtain and Apply SSL Certificates for a Single-Server Production Environment](#)
- [Obtain and Apply SSL Certificates for a Production Cluster](#)

## Disable and Enable Cross-Site Scripting Attack Checking

- *Reflected* cross site scripting attacks when the browser fails to do so.
- *Persisted* cross site scripting attacks: a script is persisted in the database or logs and then played back to an unsuspecting user who later logs in to Privileged Access Manager.

If Privileged Access Manager is blocking excessive events that are known *not* to be XSS attacks, disable cross site scripting attack checking. Use the controls on **Configuration, Security, Cross Site**, and contact Broadcom Support.

To identify requests that are being blocked, search the session logs for the following message:

### Disable Cross Site Scripting Attack Checking

Use this procedure to disable cross site scripting checking.

#### **Follow these steps:**

1. Log in to the Privileged Access Manager.
2. Go to **Configuration, Security, Cross Site**.
3. Select the **Disabled** option.
4. Select **Submit**.
5. Reboot the server to implement the change.

### Enable Cross Site Scripting Attack Checking

Use this procedure to enable cross site scripting checking after it has been disabled.

#### **Follow these steps:**

1. Log in to the Privileged Access Manager.
2. Go to **Configuration, Security, Cross Site**.
3. Select the **Enabled** option.
4. Select **Submit**.
5. Reboot the server to implement the change.

## Configure Enhanced Encryption for Stored Credentials

The default software encryption module that Credential Manager uses to encrypt and decrypt stored credentials is the Wolfcrypt module from WolfSSL.

### **NOTE**

If you require hardware-based encryption for stored credentials, you can configure a [Hardware Security Module \(HSM\)](#).

### **Cryptography Options**

The following cryptography options apply to:

- Inbound TLS connections
- Symmetric keys that are used for encryption and decryption of sensitive data
- Credentials that are stored in the database
- Payloads sent to the A2A clients and Windows Proxy
- One-way hash generation, such as for User passwords (using SHA512)

To protect the symmetric keys, we generate a “key wrapping” key which is unique for each deployment. The key wrapping key is automatically generated using an initial entropy seed from hardware (RDRAND; see [Cryptography Passphrase](#)) when available. This key is propagated to all cluster members.

The default software Cryptographic Provider that Credential Manager uses to encrypt and decrypt stored credentials is the Wolfcrypt module from WolfSSL.

### ***FIPS Mode for PAM***

If you have licensed and implemented FIPS Mode for PAM, the Wolfcrypt module operates in FIPS mode according to its FIPS 140-2 validation (CMVP certificate #3389). FIPS Mode has to be activated only once, and does not need to be deactivated to upgrade your appliance. See [Power, Reboot and FIPS Mode Controls](#) for information about activating FIPS Mode.

### **Cryptography Passphrase**

You do not need to enter a “primary” passphrase “seed” for cryptography. If the RDRAND hardware random number generator is available, it generates the key encryption key. RDRAND is available for physical appliances, AWS instances, and most VMware virtual machines. VMware must use virtual hardware version 9 or above (ESX 5.1), and must use EVC Mode for Ivy Bridge (or later) Intel processors. See [System Information](#) to verify whether RDRAND is available.

If RDRAND is not available, the cryptographic provider creates the manual passphrase. WolfSSL produces the passphrase using a software algorithm.

## **Configure SSH Proxy, SSH MindTerm, and TLS Cryptography Options**

Use the options on the **Configuration, Security, Cryptography** pane to configure the SSH proxy, SSH MindTerm, and TLS ciphers that are used to secure connections for accessing devices.

### **Configure SSH Proxy and SSH MindTerm Cipher Options**

Default SSH algorithms that are shown on the SSH Proxy and SSH MindTerm tabs are listed in order of priority, balancing speed with security. However, to facilitate legacy target system management, not yet updated to secure encryption algorithms, the **Cryptography** panel provides options to configure older, vulnerable KEX/Ciphers/HMAC algorithms. The risk of downgrading PAM SSH encryption should be communicated to appropriate IT administrators in your organization. This risk is due to the impact on potential breach and non-compliance to standards and legislation such as PCI DSS, FISMA, etc.

#### **WARNING**

For FIPS mode PAM, the selection of algorithms is not automatically restricted for SSH. To maintain compliance, continue to use the default algorithms.

#### **NOTE**

You can only change SSH cipher options from a PAM server that is a member of the primary site in your cluster. (The **SSH Proxy** and **SSH MindTerm** tabs are hidden on members of secondary sites.) Changes may take one minute or longer to replicate, depending on network conditions. Additionally, making changes to a standalone node, then adding a new cluster member, does not replicate the changes.

When a policy is configured to use the sftpsftplib service, it needs one of the following Hash algorithms to be enabled in SSH Proxy: hmac-sha1,hmac-sha1-96,hmac-md5

### **Follow these steps:**

1. Navigate to **Configuration, Security, Cryptography**.
2. Do the following steps on the **SSH Proxy** and **SSH MindTerm** tabs, as required:
  - a. Determine the SSH security algorithms that are appropriate for your system. By default, the **Default** option is selected. The default algorithms in each category (Cipher, Hash, Key Exchange, Compression, and Server Host

Key) are considered to provide appropriate security for SSH connections. Depending on the devices you use, you may need to define other algorithms that are not as secure.

- b. To select algorithms other than the defaults, deselect the **Default** option, and select the eye icon to the right of each text box. A window appears showing all the supported algorithms for each category. You can copy and paste the appropriate algorithms into the text box.
3. Select **Update** when you have completed your selection.

### **Enable or Disable TLS Cipher Options**

The Super, Global Admin, or Configuration administrators can disable or enable cipher suites that are used by the PAM cryptography security settings. You choose the ciphers to use by selecting **Configuration, Security, Cryptography**, and then the **TLS v1.2 Ciphers** tab.

By default, the list of ciphers you can select is determined by which type of certificate is currently configured under **Configuration, Security, Certificates**, and then the **Set** tab. For example, if your certificate uses ECDSA, the **TLS v1.2 Ciphers** tab displays selected ECDSA ciphers. Likewise, if you selected an RSA certificate, the **TLS v1.2 Ciphers** tab displays selected RSA ciphers. As an Admin, you can only select the ciphers that are supported by the certificate.

For more information on setting a certificate, see [Obtain and Apply SSL Certificates for a Single-Server Production Environment](#).

#### **NOTE**

All the cipher settings are local, and have to be set per node.

#### **Follow these steps:**

1. Select **Configuration, Security, Cryptography**, and then the **TLS v1.2 Ciphers** tab.  
The tab displays the list of ciphers. Unavailable ciphers appear grayed out. By default, the list of ciphers depends on which certificate is currently configured under **Configuration, Security, Certificates**, and then the **Set** tab.  
The **FIPS Mode** informational status field shows you whether your default filename in the **Certificates** page is in FIPS and NON FIPS mode. By default, the only cipher that is enabled in FIPS mode is **TLS\_ECDHE\_ECDSA\_WITH\_AES\_256\_GCM\_SHA384**. If you require additional ciphers, you can enable them manually.
2. Select the desired ciphers.
3. Use the **Enabled Inbound TLS Ciphers** check box to select all ciphers.
4. Select **Update** to confirm and exit the **TLS v1.2 Ciphers** page.
5. After changing the cipher list, a message appears that a reboot is needed. Reboot the node. This message displays until the node is rebooted.

## **Authenticate Users Logging in to the Server**

When a user logs in to Privileged Access Manager, the server can authenticate each user locally or remotely with a third-party source.

To authenticate users locally:

1. Navigate to **Settings, Global Settings**.
2. In the **Default Auth Method** field, select **Local**.
3. Add users for local authentication from the **Users, Manage Users** page.

To authenticate users remotely using a third-party, you must configure the server to use that third-party. PAM works with the following third-party directories and devices.

- [LDAP directories](#): Compatible LDAP directory services include Microsoft Active Directory (AD), OpenLDAP, and other LDAP-compliant repositories. You can also configure [Kerberos authentication with PIV/CAC](#) for an LDAP domain.
- [LDAP+RADIUS](#): Sequential authentication from an LDAP directory and a RADIUS server
- [PKI Smart Card Authentication](#): Smart cards or a browser that is loaded with certificates for authentication.
- [RADIUS](#) and [TACACS+](#): Authentication against a RADIUS or TACACS+ server
- [RSA](#): Authentication using an RSA SecurID server
- [LDAP+RSA](#): Sequential authentication from an LDAP directory and an RSA SecurID server
- [SAML](#): SAML authentication using PAM as one or both of the following providers:
  - Identity Provider
  - Service Provider

For configuration instructions, select the authentication method you want to use from this list of supported third-party methods.

## How to Set Up LDAP Servers for User Authentication

This topic describes how to enable PAM to communicate with an LDAP server.

### Add an LDAP Device

Add a device that represents the target LDAP server, where an administrator account exists. This account must have read access to the tree from which PAM can pull administrators.

#### Follow these steps:

1. Navigate to **Devices, Manage Devices**, and select **Add**.
2. Complete the following required settings:
  - **Name**: Enter the name of the LDAP server. If Access is configured, this name is displayed on the Access page.
  - **Address**: Enter the LDAP Server IP address or fully qualified domain name. DNS must be configured on the Network Settings page for FQDN to work.
  - **Device Type**: Select Password Management. Other types can also be selected.
 Optionally, for details about other tabs on the Add Device page, see [Device Setup](#).

3. Select **Save and Add Target Applications**. The Add Target Application page opens.

4. Complete the following fields:
  - **Application Name**: Specify an application of your selection.
  - **Application Type**: Select the applicable application.
    - For Active Directory, select Active Directory or Windows Proxy. To use the Windows Proxy type, a Windows Proxy must already be set up. For instructions, see [Configure the Windows Proxy Connector](#).
    - For other LDAP servers, select LDAP.

Depending on the type, different tabs become available at the top of the Add Target Application window

5. Fill in the fields for your application type:
  - Active Directory: Enter the **Domain Name**, such as ca.com. Alter the default **Domain Controller Port** if necessary.
  - Windows Proxy: Select the Proxy from the **Available Proxies** list. Alter any other information as necessary.
  - LDAP: Select a **Server Type** of either OpenLDAP or Other. Alter the **Protocol** and **Port** if necessary. For more information about application settings, see the relevant topic:
    - [Add an LDAP Target Connector](#)
    - [Add an Active Directory Target Connector](#)
    - [Add a Windows Proxy Connector](#)
6. Select **OK** to save the application.

## Create a Target Account for the LDAP Server

Specify an application for bind requests between PAM and the LDAP server.

### Follow these steps:

1. Navigate to **Credentials, Manage Targets, Accounts**, and select **Add**. The **Add Target account** pane opens.
2. Begin at the **Application Name** field. Select the LDAP application that you created previously.  
The **Host Name** and **Device Name** automatically populate.
3. In the **Account Name** field, specify an account to use for connecting to the LDAP server.
4. Enter the **Password** for this account.
5. Enter the information that is required for the application type in use:
  - Active Directory: Enter the Distinguished Name (DN). For example:  
CN=Lookup,CN=Users,DC=security,DC=com
  - Windows Proxy: Accept the default entry.
  - LDAP: Enter the DN. For example: CN=Lookup,CN=Users,DC=security,DC=com
 If necessary, alter the default **Change Process**. For more information about optional account settings, see [Add Target Accounts to Target Applications](#).
6. Select **OK** to save the account.

## Identify the LDAP Servers in Your Environment

Identify the remote LDAP server account that the appliance contacts to authenticate users. As an Administrator, you must have an account on the LDAP or Active Directory Server. This account must have read access to the tree from which you want to pull Administrators.

### Follow these steps:

1. Navigate to **Configuration, 3rd Party, LDAP**.
2. Select **Add** on the **LDAP Domains** tab.
3. Complete the following fields by searching and selecting the appropriate entries:
  - **Bind Server**
  - **Bind Application**
  - **Bind Account**
 If you have only one LDAP account, complete the Bind Account field first, then the **Bind Server** and **Bind Application** fields automatically populate.
4. For a Windows Proxy, complete the **Bind Credentials** field. For example: admin@domain.local
5. Select the appropriate **SSL Usage** value.
6. (Optional) To prevent regular synchronization updates between PAM and the LDAP directory, set the **Disable Periodic Update** option. Options related to periodic updates are disabled and you can proceed to Step 9.

#### NOTE

To perform manual updates, navigate to **Users, Manage User Groups**, and select **Refresh LDAP Groups**.

7. Set the **Sync Scope** option to specify whether to synchronize **Groups and Users** or just **Groups**.
8. Specify the **Sync Methodology** that PAM uses to synchronize with the LDAP server: **Interval** or **Schedule** then use the context-sensitive fields as described in the following procedures:
  - **Interval** (Default): Synchronize with the LDAP server at a regular interval that you specify in the **Update Interval (minutes)** field. The default value is 1440.

#### NOTE

If you set a small Update Interval value, such as 10 minutes, the high LDAP update traffic might interfere with, or disable, operation of the cluster operation. To avoid this problem, you can

manage synchronization on-demand. Navigate to **Users, Manage User Groups**, and select **Refresh LDAP Groups**.

- **Schedule:** Synchronize with the LDAP server according to a specified schedule. Scheduling allows you to avoid running the update during peak periods when PAM servers are experiencing heavy loads. In environments with multiple LDAP instances, you can also use scheduling to stagger the order and timing of refreshes for each instance.

**To configure the details of your update schedule, follow these steps**

- a. Select the **Sync Schedule** tab.
  - b. Specify how often updates should occur from the **Frequency** drop-down menu:
    - **Not Scheduled** (the default)
    - **Once**
    - **Minutes**
    - **Hourly**
    - **Daily**
    - **Weekly**
    - **Monthly**
  - c. Use the context-sensitive controls that appear to specify the schedule details:
    - **Start Time:** The start time of the refresh in hours:minutes:seconds
    - **Begin Date:** The date the refresh cycle begins
    - **End Date:** The date the refresh cycle ends (this field is optional)
    - **Reoccurs every:** The number of units specified in the Frequency attribute that should occur before the next refresh.
    - **Days** (Weekly frequency only): Select one or more days of the week on which the update should occur.
    - **Days** (Monthly frequency only): Select one or more days of the month (1 through 31) on which the update should occur.
9. To filter the LDAP members from this connection, use the fields in the **Attributes** tab.
  10. If Kerberos network authentication is set up on the LDAP server, enter the KDC server and port on the **Kerberos** tab.
  11. On the **Browse Points** tab, optionally enter one or more DN's to serve as starting points to browse the LDAP directory. A browse point becomes the root from which to start browsing the tree.
  12. To map specific fields from a PIV/CAC smart card to fields in Active Directory for authentication, use the **Custom Field Mapping** tab. We normally compare the smart card Subject Name to the DN (`distinguishedName`) AD attribute, and the Subject Alt Name on the card to the UPN (`userPrincipalName`) attribute. Use the **Subject Name** and **Subject AltName** drop-down lists to alter these mappings. For example, you might want to map **Subject AltName** to `altSecurityIdentities`.
  13. Select **OK** to save.

The newly added LDAP domain appears in the **LDAP Domains** list. Once the connection to the LDAP server has been configured, navigate to **Users, Manage User Groups**, and select **Refresh LDAP Groups** to import users.

#### **Modify the Check Down LDAP Servers Interval (Optional)**

LDAP servers can shut down or can become unavailable for other reasons. The **Check Down LDAP Servers Interval** setting specifies the interval, in minutes, when PAM checks whether a previously unavailable LDAP server has become available. The LDAP servers must be in the LDAP domains list.

#### **Follow these steps:**

1. Navigate to **Configuration, 3rd Party, LDAP**.
2. Select the **Check Down LDAP Servers Interval** tab.
3. In the **Interval (minutes)** field, set the frequency that the LDAP servers are polled. The default is 30 minutes.
4. Select **Update** to save the setting.

You can also select **Check Now** to poll all servers immediately.

### ***View Detailed Information about LDAP Activity (Optional)***

Use the **LDAP Sync History** tab to obtain detailed information about all LDAP activity, including domains and addresses, source types used (Scheduled or Manual), the exact queued times, start times, and end times, and the status of each job.

### ***Configure Multiple LDAP Servers***

You can add multiple LDAP servers for the same or different domains. Users select the correct domain during authentication. If the primary server is unavailable, the appliance connects to any backups if listed. All **Associations** and user policies will be maintained after connection to the new server.

### **Import LDAP Groups**

To import LDAP groups, use the Privileged Access Manager LDAP Browser, which launches automatically when you select an **Import LDAP Groups** button in the UI.

#### **NOTE**

You cannot import individual devices or users. To import individual objects, use the LDAP Browser to import the groups containing those objects.

When you import an LDAP group, the TLS 1.0/1.1 Connection Allowed configuration option is enforced.

To import LDAP device groups or user groups, see the following topics.

- [Import LDAP Device Groups](#)
- [Import LDAP User Group](#)

#### **NOTE**

[How to Configure Active Directory for User Authentication](#)

## **How to Configure Active Directory for User Authentication**

Active Directory is one of the LDAP directories that are used to authenticate users who attempt to access Privileged Access Manager.

### **View Records Through Cross-Domain Trusts**

If Active Directory Servers are in a cross-domain trust, you can view the user DN for a record in one Active Directory domain from a different domain. Active Directory domain trusts allow administrators to share accounts across domains. This relationship allows a domain to contain users, devices, user groups, and device groups that are *foreign* to it. The term foreign means that the directory is authoritatively maintained by a separate domain.

For each Active Directory domain that supplies users or devices, configure each domain in the UI. Navigate to configure each directory. You can then view and import these records using the PAM LDAP Browser.

#### **Follow these steps:**

1. Log in to the PAM UI as an administrator with User management privileges.
2. Navigate to **Configuration, 3rd Party, LDAP**, and configure each directory that supplies users or devices.
3. Configure the product for access to each Active Directory domain in the relevant cross-domain trust.
4. Navigate to **Users, Manage User Groups**.
5. Select **Import LDAP Groups** to launch the LDAP Browser. The LDAP Browser has a choice of cross-domain participants and any other configured LDAP directories.
6. Select one of these domains from the **Select LDAP Domain** drop-down list.
7. From the LDAP browser, select a group that contains members in this domain. Initially, the browser displays Security Identifier (SID) numbers corresponding to the entities, with no SID resolution at this point. Members that are contained

in the foreign domain are not resolved for the external domain. Members are presented relative to the current local domain.

8. To enable the cross-domain SID resolution as fully qualified DN, select **Options, Enable Group Member SID Resolution**. You can switch this setting on or off at any time.
9. Select a different browser tree item. After it has settled, return back to the previous group. The browser now builds its tree and Entry Attributes display by resolving the SIDs. This process might take a while before the Browser displays the resolved DNs for each record.
10. Select the updated menu item, **Options, Disable Group Member SID Resolution**. Move back and forth between tree items. You can see that the resolved members are cached. This cache persists while you are logged in, whether you are using the LDAP browser.

SID resolution does not affect how groups are imported into the appliance. Whether the SIDs are resolved in the LDAP browser, foreign members are resolved by the LDAP browser to create users.

### **Active Directory Password Updates**

When an Active Directory user logs in to PAM using LDAP as the authentication type, the user might be prompted to update the password. A password update is triggered when one of the following events occurs on the Active Directory Server:

- The Active Directory administrator sets the user password to a temporary value using one of the following Active Directory options:
  - New Object - User
  - Reset Password, User must change password at next login
- The user password expires

For either event, the appliance displays a User Information page with a message that the user must change the password. After the user changes the password, the old and new values are passed on to the Active Directory Server. The user is authenticated and the user record is updated. The user then gains access to the appropriate target.

The appliance updates the session logs to include password update requests. The confirmation of the record update on the Active Directory Server is also logged.

### **Configure Required LDAP Password Updates**

Configure PAM LDAP connection to use an SSL protocol.

#### **Follow these steps:**

1. Select **Configuration, 3rd Party, LDAP**.
2. Add or update an LDAP entry.
3. Enter the appropriate information for each tab.

#### **On the Add LDAP Domain tab, enter the following information:**

- Set the **SSL Usage** field to STARTTLS or LDAP

#### **NOTE**

Use a target account with sufficient privileges to reset other Active Directory users passwords.

The target account that is associated with the Active Directory Administrator must have sufficient privileges to reset the passwords of imported Active Directory users. Otherwise, the imported user cannot change a password that becomes invalid.

On the Active Directory Server, grant the minimal privileges to the account to reset passwords by issuing the following command or its UI equivalent:

```
dsacl "DN%" /I:S /G "%user_domain%\xsuiteLookup:CA;Reset Password;user"
```

- *DN* is the Distinguished Name for the domain, for example: `DC=exampledomain,DC=com`
- *user\_domain* is the short name for the Windows domain
- *xsuiteLookup* is the account Username
- Select **Disable Periodic Updates** if you do not want to update changes from the LDAP server.
- Select the **Sync Method**.
  - **Groups and Users:** Users within a group are imported as part of the group import. If Periodic Updates is enabled, LDAP changes related to Users and Groups are updated.
  - **Groups Only:** Users within a group are not imported as part of the group import. Users are provisioned the first time they login. At login time, users are assigned groups based on an LDAP lookup and the imported groups in PAM. If Periodic Updates is enabled, LDAP changes related to groups are updated. When device groups are imported, devices within the groups are also imported automatically.

**NOTE**

The following authentication types are supported for Groups Only: LDAP, LDAP + RADIUS, LDAP + RSA. When the Sync Method is Groups Only, the external API must be enabled.

- Set the **Update Interval** in minutes. Specify how often you want to update changes from the LDAP server. The Active Directory user is granted reset- password permissions and read-only permissions.

**On the Attributes tab, enter the following information:**

- Specify the **Unique Attribute**. This is the unique field in the LDAP directory that represents the user. Typically, this points to the `userName` field of the user. Example: In Active Directory, this maps to `sAMAccountName`.
- Specify the **User Group Object Class**. For Non-AD Directories, it is possible to have a custom LDAP Schema. In this schema, a non-standard objectClass is used to signify what defines a Group in the directory.
- Specify the **Group Member Attribute**. In LDAP directories, it is possible to have a nonstandard field in which the members are defined. Commonly, this is "members," but if you have a custom schema, your field may be different.
- Specify the **Group Search Filter**. If you have a large LDAP directory with many groups, you can speed up the LDAP queries by looking for groups that have a specific naming convention. Example: In the case of `PAMGroup-Admins`, refine the search to only query for "PAMGroup-".

**On the Browse Points tab, enter the following information:** If you have a large directory, set specific browse points to look for a user or group instead of traversing from the root of the directory. The browse points help to expedite the LDAP queries.

**On the Domain Trust tab, enter the following information:** Select one or more Domain Trusts from the **Available Domain Trust** list. Using the arrows, add or delete them from the **Selected Domain Trust** list.

**Configure Required LDAP Password Updates**

The **Custom Field Mapping** tab (**PIV/CAC Field**, **Subject Name**, **AltName**): Custom field mapping is used when aligning PIV/CAC authenticated users back to an LDAP Directory, such as a CA Directory or Active Directory. When looking up a CAC user, PAM uses the Subject or Subject Alternative Name (SAN) on the certificate back to the directory. In your directory, this value is stored in an Attribute on the user record within the directory. Example: The SAN of the certificate is `first.last@company.com`. This value is stored in the email field of an Active Directory user object.

**Configure LDAP and RADIUS in Combination to Authenticate Users**

Privileged Access Manager can use a combination of an LDAP server and RADIUS server to authenticate users.

**Follow these steps:**

1. Set up the LDAP server and the RADIUS server. As an example, the RADIUS server has a record for a user named **user1**.
2. Configure the appliance to use the LDAP and RADIUS servers. Servers must be available for each type.

- **RADIUS server:** See the instructions for [setting up RADIUS or TACACS+](#)
- **LDAP server:** See the instructions for [setting up LDAP](#).

When you specify the LDAP server for the appliance, set the **Unique Attribute** field to an attribute in the LDAP user record that identifies the user. The LDAP attribute that you enter must have the same value as the user name of a RADIUS user record. This common value enables the two servers to authenticate a user.

#### NOTE

For Active Directory, the LDAP attribute is typically the **sAMAccountName** or **userPrincipalName**. For other LDAP servers, it is typically **uid**. Regardless, you can use any LDAP attribute.

For example:

- RADIUS user-name: **user1**
- LDAP user record: **sAMAccountName=user1**
- Unique Attribute: **sAMAccountName**

The LDAP+RADIUS configuration is configured.

At the UI login screen, the user experience is reflected by the following steps:

1. The user enters user1 and the password.
2. For the Authentication Type field, they select **LDAP+RADIUS**.  
The **Domain** and **RADIUS Password** fields display.
3. Select the applicable LDAP Domain from the drop-down list.
4. Enter the RADIUS password for user1.

User1 is authenticated against the LDAP server. If the first authentication is successful, user1 is authenticated against the RADIUS server. If authentication is successful, user1 gets logged in to Privileged Access Manager.

## How to Configure PKI Smart Card Authentication

Privileged Access Manager can authenticate users who log in with a PKI smart card. The appliance authenticates each by the user certificate that is loaded on the smart card.

#### NOTE

FIPS mode is fully compatible with PKI smart card use, including the US DOD CAC system.

Complete the following tasks to enable smart card authentication for users logging in to PAM.

#### Watch a Video

Watch this video for a demonstration on setting up PKI smart cards:

#### Set Up OCSP or CRLs for Certificate Validation

To authenticate a user who logs in with a smart card, the appliance has to determine the revocation status of the user certificate. Configuring certificate validation is a prerequisite for enabling smart card authentication.

To validate a user certificate, set up one of the following methods:

- [Use OCSP Validation](#)
- [Use CRL Validation](#)

Each procedure explains how to upload the required certificates and then enable the user certificate validation option.

**TIP**

We recommend using certificate bundles to simplify the set-up process. If you use a certificate bundle, you do not have to upload individual certificates.

**Use OCSP Validation**

You can use Online Certificate Status Protocol (OCSP) to validate the status of a user certificate. PAM sends an OCSP request to the OCSP server to validate user certificates. The OCSP server returns the required information in the user certificate.

**To use OCSP, follow these steps:**

1. Obtain the certificate bundle or the individual certificates from the Certificate Authority (CA). If you plan to use intermediate certificates, also obtain the CRL and the intermediate certificates.
2. Navigate to **Configuration, Security, Certificates** page.
3. Select the **Upload** tab.
4. Upload the root certificate or certificate bundle for each chain to be used. The root certificate must be in the certification path of the user certificate.  
Complete the following fields then select **Upload**.
  - **Type:** Select CA Bundles (recommended) or Certificate  
To create a CA Bundle on a Windows system, use Microsoft Certificate Manager. To access the Certificate Manager, select the **Start** button. In the search field, enter **certmgr.msc**. The Certificate Manager (certmgr) opens.
  - **Other Options:** Select the format (X509 or PKCS) of the certificate you are uploading.
  - **Filename:** Browse to the root certificate or bundle on your local system that you want to upload.
  - **Destination Filename:** Optionally, change the filename of the certificate. Otherwise, leave this field blank.
  - **Passphrase:** If necessary, enter the password for the certificate.
5. Optionally, upload the CRL and any intermediate certificates. Depending on the PKI in the environment, intermediate certificates might be necessary. The certificate must be in the certification path of the user certificate.  
Complete the following settings and select **Upload**.
  - **Type:** Select Intermediate Certificate
  - **Other Options:** Select the format (X509 or PKCS) of the certificates you are uploading.
  - **Filename:** Browse to the certificate on your local system that you want to upload.
  - **Destination Filename:** Optionally, change the filename of the certificate. Otherwise, leave this field blank.
  - **Passphrase:** If necessary, enter the password for the certificate.

**TIP**

If you upload the root certificate or certificate bundle, there is no need to upload a CRL.

6. Go to the **CRL Options** tab.
7. For the **Type** setting, select **Use OCSP** then select **Update**.

**NOTE**

Next step: [Enable Smart Card Authentication](#).

**Use CRL Validation**

You can use a CRL to validate the status of a user certificate.

**To use a CRL, follow these steps:**

1. Obtain the certificate bundle or the individual certificates from the Certificate Authority (CA). If you plan to use intermediate certificates, also obtain the CRL and the intermediate certificates.
2. Navigate to **Configuration, Security, Certificates** page.
3. Select the **Upload** tab.

4. Upload the root certificate or certificate bundle for each chain to be used. The root certificate must be in the certification path of the user certificate.

Complete the following fields then select **Upload**.

- **Type:** Select CA Bundles (recommended) or Certificate  
To create a CA Bundle on a Windows system, use Microsoft Certificate Manager. To access the Certificate Manager, select the **Start** button. In the search field, enter **certmgr.msc**. The Certificate Manager (certmgr) opens.
- **Other Options:** Select the format (X509 or PKCS) of the certificates you are uploading.
- **Filename:** Browse to the root certificate or bundle on your local system that you want to upload.
- **Destination Filename:** Optionally, change the filename of the certificate. Otherwise, leave this field blank.
- **Passphrase:** If necessary, enter the password for the certificate.

5. Upload the CRL. Complete the following fields then select **Upload**:

#### TIP

If you upload the root certificate or certificate bundle, there is no need to upload a CRL.

- **Type:** Select Certificate Revocation List
  - **Other Options:** Ignore this field. The field does not apply to the CRL.
  - **Filename:** Browse to the CRL on your local system that you want to upload.
  - **Destination Filename:** Optionally, change the filename of the CRL. Otherwise, leave this field blank.
  - **Passphrase:** If necessary, enter the password for the CRL. Passwords are not typically required for CRLs.
6. Optionally, upload the intermediate certificates. Depending on the PKI in the environment, intermediate certificates might be necessary. Certificates must be in the certification path of the user certificates.

Fill out fields then select **Upload**.

- **Intermediate Certificate:** Select the intermediate certificate.
- **Other Options:** Select the format (X509 or PKCS) for the certificates.
- **Filename:** Browse to the certificate on your local system that you want to upload.
- **Destination Filename:** Optionally, change the filename of the certificate. Otherwise, leave this field blank.
- **Passphrase:** If necessary, enter the password for the certificate.

7. Go to the **CRL Options** tab.
8. For the **Type** setting, select **Use CRL**. Accept the default, Manually Upload CRLs, for the **CRL Type** setting.
9. Select **Update**.

#### NOTE

Next step: [Enable Smart Card Authentication](#).

### Enable Smart Card Authentication

After you set up certificate validation, enable smart card authentication.

#### NOTE

Linux desktops cannot use the PKI/Smart Card option. Use a Windows or Macintosh desktop.

#### Follow these steps:

1. Navigate to **Configuration, Security, Access**.
2. Select the **PKI/Smart Card Options** tab.
3. Select **Enabled** for the following options:
  - **PKI/Smart Card User Login.** This option enables smart card login. With this setting enabled, the appliance requests a user certificate during login.
  - **Enable PKI/Smart Card Option on the Login Page.** This option adds a PKI login button on the login page.

4. Optionally, you can enable the following settings:
  - **No Login Page without PKI/Smart Card** checkbox: If you select Enabled, users must have a smart card to log in. If you select Disabled, users can authenticate using a username and password or other configured authentication methods. For most situations, you can leave this option disabled. If users are unable to authenticate using smart card, the configuration page is always available using a known username and password.
  - **Policy Identifier**: Optionally, enter the identifier to the PKI policy for the certificate.
5. Select **Save**.

### **Approve Smart Card Users to Allow Logins**

The first time that a smart card user logs in to PAM, the administrator must approve the user. This requirement does not apply to preapproved users. Preapproved users are users who are added to the appliance by means, such as CSV imports, LDAP imports, or APIs. At login, an unapproved user sees an error message indicating that the certificate registration is in process. The message reflects normal operation. After an administrator approves the user, the user can reattempt to log in.

#### **NOTE**

A user might have to notify the PAM administrator to grant approval.

#### **Follow these steps to approve a smart card user:**

1. Log in to PAM as a User/Group Manager, Operational Administrator, or Global Administrator
2. Select **Users, Approve Smart Card Users**.
3. Select Approve for each smart card user. To deny the user, select Delete.
4. Select **Save**.

The user is approved.

After a successful login, the appliance displays a message requesting a certificate to validate the user identity. From a list of certificates, the user must select the certificate that is designated for smart cards use then log in. A user can determine whether the certificate is for smart card use by viewing the certificate details. From the Details tab, the **Key Usage** or **Enhanced Key Usage** field indicates whether the certificate is for smartcard login. After the user selects the correct certificate, the appliance validates it against the certificate chain. If the validation is successful, the user is prompted to enter the smart card PIN.

## **How to Configure RADIUS or TACACS+ for Authentication**

As an administrator, you can authenticate users against RADIUS and TACACS+ servers.

RADIUS and TACACS+ users are imported as user groups. When a RADIUS server is used to identify users for a User Group, the appliance first attempts to match the User Group: Groupname to the designated Attribute 25.

The users can be refreshed manually through a link that appears on the User Group page.

Complete the following tasks:

### **Prerequisites**

#### ***TACACS+ Server Support***

The appliance can work with the following software:

- tac\_plus
- Cisco Secure Access Control Server (ACS) version 4 or 5

**NOTE**

When configuring device access to Cisco, you cannot configure a unique enabled password for each Cisco device user with TACACS.

**RADIUS Server Support**

The appliance supports the PAP and CHAP authentication for RADIUS.

**WARNING**

During RADIUS authentication, if multiple user records are found with the same RADIUS login name, the login process is blocked and is deactivates all those users. An administrator explicitly enables *one* of these users.

When importing LDAP users with RADIUS authentication, all these LDAP RADIUS users are deactivated when either of the following conditions exists:

- If multiple LDAP users have the same RADIUS login name
- If any of the LDAP user login names match an existing RADIUS user in the appliance.

**Configure a Device and Target Information**

Before you configure authentication with RADIUS or TACACS+, add the server, create a target application, and set up the target account.

**Follow these steps:**

1. Navigate to **Devices, Manage Devices**, and select **Add**.
  - a. Enter a **Name**. If Access is configured, this name is displayed on the Access page.
  - b. Enter the RADIUS or TACACS+ Server IP **Address** or FQDN. DNS must be configured on the Network Settings page for FQDN to work.
  - c. Select at least the Password Management **Device Type**.
  - d. See [Device Setup](#) for details about other Device settings (optional).
2. Select **Save and Add Target Applications**.  
The Add Target Application window appears. **Host Name** and **Device Name** are populated with your Device data.
3. Specify an **Application Name**.
4. Select RADIUS/TACACS+ Secret as the **Application Type**.  
A second tab, named RADIUS/TACACS+ Secret, appears in the Add Target Application window.
  - a. Select **Type** of either RADIUS or TACACS+.
  - b. Alter the **Port** if necessary.
  - c. For more information about optional Application settings, see [Add Target Applications](#).
  - d. Select **OK**.
5. Navigate to **Credentials, Manage Targets, Accounts**, and select **Add**.
  - a. Use the Select magnifying glass icon to select the **Application Name** you created for RADIUS or TACACS+. The **Host Name** and **Device Name** are populated.
  - b. Specify an **Account Name**.
  - c. Enter the **Secret** for this account.
  - d. For more information about optional Account settings, see [Add Target Accounts and Aliases](#).
  - e. Select **OK** to save the Account.

**Add RADIUS and TACACS+ as Third-Party Servers**

After you configure the target application and target accounts for RADIUS and TACACS+, complete the setup by adding these servers as third-party servers.

Follow these steps:

1. Navigate to **Configuration, 3rd Party, RADIUS and TACACS+**.
2. Select **Add** on the **RADIUS and TACACS+ Servers** tab and do the following steps:
  - a. Use the Select magnifying glass icon for **Account** to find the RADIUS or TACACS+ account and select it. **Server** and **Application** automatically populate.
  - b. You can also start by selecting the **Server**, then **Application**, then **Account**.
3. Optionally, select the **Timeout** tab and adjust the following settings to modify RADIUS timeout parameters:
  - **Login Timeout (secs)**: Specifies the login timeout for all RADIUS server login attempts
  - **RADIUS Timeout**: Specifies the maximum time to wait for a reply from the RADIUS server
  - **RADIUS Retries**: Specifies the number of times a request will be sent before trying the next server
4. Select **OK** to save.  
The RADIUS or TACACS+ domain appears in the **RADIUS and TACACS+ Accounts** list.
5. To enable creating a User Group for RADIUS or TACACS+, log out of the appliance and log back in.
6. Navigate to **Users, Manage User Groups**, to import users from RADIUS or TACACS+.
  - a. Select **Create RADIUS Group** or **Create TACACS+ Group**.  
To locate users in a RADIUS or TACACS+ group, each group name you specify must match a corresponding group name or ID on the RADIUS or TACACS+ server. The appliance uses the configured grouping to manage users.
  - b. Enter a corresponding RADIUS or TACACS+ group name or ID as the **Group Name**.
    - All the privileges that users maintain are derived from their group. Only users with a local account or whose group matches the group name in the UI is granted access. Contact the RADIUS or TACACS+ server administrator for the group name.
    - If a RADIUS group is provisioned but the user does not exist, a shadow RADIUS user is created. The shadow user is not visible in the user management screen or the user list.

For more information about User Groups, see [Configure User Groups](#).
7. Select **OK** to save the Group.

## Configure PAM to Support RSA SecurID Authentication

You can configure PAM to work with RSA SecurID servers and enable a user to authenticate with LDAP credentials and an RSA PIN and tokencode.

### Prerequisites

PAM 4.1.5 replaced the old RSA authentication plug-in with the new RSA authentication plugin. Because the new plug-in is REST-based, the **RSA SecurID Authentication API** must be enabled on the **SecurID Authentication Manager**. For details about how to enable the **RSA SecurID Authentication API**, search for "Configure the RSA SecurID Authentication API for Authentication Agents" in the [RSA Community documentation](#).

### Register PAM as an Authenticating Device on the RSA SecureID Authentication Manager Server

Before starting with the following configuration, make sure that the RSA SecurID Authentication API is enabled on the RSA SecurID Authentication Manager. See the previous **Prerequisites** section.

After enabling **RSA SecurID Authentication API**, copy the following items from the **RSA SecurID Authentication Manager**:

- The Access ID
- The Access Key
- The configured Communication Port

To configure RSA SecurID authentication, first register PAM as an authenticating device on the RSA SecureID Authentication Manager Server.

**Follow these steps:**

1. Verify that the **Hostname** specified on the **Configuration, Network, Network Settings** screen in the PAM UI matches the Hostname that is specified in the RSA Authentication Agent entry for the PAM instance.
2. Ask the RSA SecurID administrator to register PAM as an authenticating device on the RSA SecureID Authentication Manager Server, and to provide you with `sdconf.rec` and `sdopts.rec` files. The RSA SecurID administrator generates a `sdconf.rec` file and provides it to you.
3. Do the following steps to create and configure an `sdopts.rec` file for your environment: (If you already have an `sdopts.rec` file, simply open the file and add the new lines):

**NOTE**

Make sure the `sdopts.rec` file has UNIX-style line endings. It does not support Windows line endings.

- a. Open a text editor and add the following line:

```
USESERVER=Primary_RSA_IP:Communication_Port,10
```

For example, `USESERVER=USESERVER=203.0.113:5555,10`

**NOTE**

If IPv6 has been enabled on both PAM and the RSA Authentication Manager server, use of the authentication server's IPv6 address is supported. For example,

```
USESERVER=[fd6d:8d64:af0c:1::cafe]:5555,10
```

- b. If your environment includes replicated RSA servers, add a `USESERVER` entry for each replica server, as shown in the following example code:

```
USESERVER=Replication_RSA_IP_1:Communication_Port,10
```

```
USESERVER=Replication_RSA_IP_2:Communication_Port,10
```

```
...
```

```
USESERVER=Replication_RSA_IP_n:Communication_Port,10
```

- c. Add the Access ID and Access Key collected from the RSA SecurID Authentication Manager after enabling the **RSA SecurID Authentication API**, as shown in the following text:

```
ACCESSID=64_Bit_AccessID
```

```
ACCESSKEY=64_Bit_Access_Key
```

The contents of a sample `sdopts.rec` file appears similar to the following text:

```
# RSA Servers
```

```
USESERVER=rsa-authmgr-primary.domain.com:5555,10
```

```
USESERVER=rsa-authmgr-replica-1.domain.com:5555,1
```

```
USESERVER=rsa-authmgr-replica-2.domain.com:5555,1
```

```
# Config
```

```
ACCESSID=2ba0uc767851d204v8gt7tax7sre9n2756q19d1t56210j85253h4948fhlt7o33
```

```
ACCESSKEY=z9xcd934fg4809499a1ge5m53f7srda2vv8406pr9a59s67ard22q94tsymuc4h
```

- d. Save the file as `sdopts.rec` and close the editor.
4. Do the following steps to upload the `sdconf.rec` and `sdopts.rec` files to the appliance:
  - a. Go to **Configuration, 3rd Party, RSA**.
  - b. Select the **Upload File** tab.
  - c. Select **Choose File**, locate the `sdconf.rec` file, then select **Upload**.
  - d. Select **Choose File**, locate the `sdopts.rec` file, then select **Upload**.

**NOTE**

The **Node secret** on the **RSA Files** tab is populated after the first successful user authentication.

## **Configure the RSA SecurID 800 Hybrid Authenticator**

Configure the product to allow authentication using an RSA USB token.

RSA SecurID 800 authentication requires advance preparation by the RSA SecurID administrator. Indicated in Preparation / Authentication.

## **Configure LDAP+RSA Authentication**

The product allows a user to authenticate with LDAP credentials and an RSA PIN and tokencode readout from an RSA SecurID authenticator.

### **Follow these steps:**

1. Set up the LDAP server and the RSA SecurID server. As an example, the RSA server has a record for a user named **user1**.
2. Configure the appliance to use the LDAP and RSA servers.
  - **RSA server:** See the previous instructions in this topic.
  - **LDAP server:** See the instructions for [setting up LDAP](#).

For the LDAP configuration, set the **Unique Attribute** field to an attribute in the LDAP user record that identifies the user. The LDAP attribute that you enter must have the same value as the user name of an RSA SecurID user record. This common value enables the two servers to authenticate a user.

### **NOTE**

For Active Directory, the LDAP attribute is typically the **sAMAccountName** or **userPrincipalName**. For other LDAP servers, it is typically **uid**. Regardless, you can use any LDAP attribute.

For example:

- RSA SecurID username: **user1**
  - LDAP user record: **uid=user1**
  - Unique Attribute: **uid**
3. For LDAP, use the PAM LDAP Browser to import and register the LDAP user group which contains user1. After the import, users in that group are now provisioned to apply both authentication types when logging in.

### **User Experience Example:**

1. At the UI login screen, user1 enters the user name and password
2. User 1 selects **LDAP+RSA** for the Authentication type.  
More fields appear for the LDAP and RSA servers.
3. User1 enters the following credentials:
  - LDAP Password and Domain
  - RSA Passcode (PIN+Tokencode)

User1 is authenticated against the time-sensitive RSA server. If the first authentication is successful, user1 is authenticated against the LDAP server. If authentication is successful, user1 logs in to PAM.

## **Using SAML 2.0 to Authenticate Users**

Learn how to configure PAM to use Security Assertion Markup Language (SAML) 2.0 to authenticate users.

PAM supports SAML 2.0, an XML-based open standard data format for exchanging authentication and authorization data between two entities, as an authentication option.

PAM can operate as either of the following SAML 2.0 entities for a web portal SSO connection:

- Identity Provider (**IdP**) – Authenticates a user identity and generates an assertion
- Service Provider (**SP**) – Consumes the assertion (user identity) and provides access to a service or resource.

Depending on whether PAM is the IdP or SP, SAML-compliant partners can assume the complementary role:

- **Privileged Access Manager** as an IdP handles transactions accordingly:
  - **IdP-initiated connections** – The user is provided direct access to Privileged Access Manager. During a user login, PAM authenticates the user. After login, the user is able to launch a Web Portal to the SP (AWS Management Console) without requiring authentication. The user then has access to the SP (AWS) facilities.
  - **SP-initiated connections**: The user accesses the SP directly and the SP redirects the user to Privileged Access Manager for authentication. After the user is successfully authenticated, the user is redirected back to the SP post-login landing page.
- **Privileged Access Manager** as an SP: If communication is initiated at Privileged Access Manager, any other entity can be the remote IdP, including another PAM server.

### **Next Step**

- [Configure PAM as a SAML Identity Provider \(IdP\)](#)
- [Configure PAM as a SAML Service Provider \(SP\)](#)

## **Configure PAM as a SAML Identity Provider (IdP)**

You can configure Privileged Access Manager as an Identity Provider (IdP) to provide authentication services to a SAML 2.0 Service Provider (SP). The PAM IdP supports the HTTP POST binding for sending messages.

This topic contains the instructions to configure PAM as an IdP:

### **Prerequisites for SAML Configuration**

Before you configure the appliance as an IdP, complete the following tasks:

- [Provision user accounts](#)
- [Configure SAML global settings in the PAM UI](#)
- [Obtain a certificate for signing responses](#)

### ***Provision User Accounts at Each Side***

The IdP and SP must have user accounts with matching user names. Users must have permission to access resources at the SP.

### ***Configure SAML Global Settings in the UI***

Before you configure the IdP configuration, confirm the default SAML settings.

#### **Follow these steps:**

1. Select **Settings, Global Settings**.
2. Select the **SAML** tab.
3. Verify the following two settings:
  - **Require Inherited SAML Auth**: When the authentication method for a user group is set to SAML, this option applies SAML authentication to all user group members. The appliance disregards the authentication method for each individual group member. This setting is selected by default.
  - **SAML Re-authentication Period (Minutes)**  
This setting applies only when PAM is the IdP. This setting specifies the minutes of inactivity before a session with a PAM IdP expires. A subsequent SSO request requires the user to log in again. Default: 60 minutes

### ***Obtain a Certificate to Sign Authentication Responses***

To sign and encrypt SAML responses for an SP, the PAM IdP must have a signed certificate from a Certificate Authority.

**To obtain an SSL certificate, follow these steps:**

**NOTE**

These steps apply for a single instance of PAM and for a cluster. In a cluster, complete the following procedure *only* on the first member of the primary site.

1. In the UI, navigate to **Configuration, Security, Certificates**.
2. On the **Create** page, select **CSR** (Certificate Signing Request). When you create a CSR, the appliance creates the CSR and a private key file.  
For information about completing the CSR form, see [Create a Self-Signed Certificate or a CSR](#).
3. Download the CSR and send it to the Certificate Authority.  
The Certificate Authority returns a certificate file and a CRL.
4. After you have the certificate file, go to **Configuration, Security, Certificates**.
5. Select the **Upload** page and configure the following options:
  - **Type:** Certificate
  - **Other Options:** X509
6. Select **Upload**. The certificate is now available to the appliance.  
For a cluster, you must copy the certificate and the private key to all other cluster members. For instructions, continue to the next procedure.

**Upload Key/Certificates In a Clustered environment**

In a cluster, the IdP configuration is automatically replicated across all cluster members. The certificate is not replicated. You must copy the certificate and private key from the first member of the primary site to every other cluster member.

On the first member of the primary site, **follow these steps**

1. Go to **Configuration, Security, Certificates**.
2. Go to the **Download** page and download the private key file to your local system.
3. Create a file using a text editor.
4. Into this file, copy the contents of the private key file and the certificate file from the Certificate Authority. The private key file was generated when you created the CSR.
5. Save the new file.

On *every other member* of the cluster (excluding the first member of the primary site), **follow these steps**:

1. Log in to the UI and select **Configuration, Security, Certificates**.
2. Select the **Upload** tab and set the following fields:
  - Type: Certificate with Private Key
  - Other options: PKCS
3. Select **Choose file** and select the new, combined file.
4. Select **Upload**.

**Configure PAM as an IdP**

A SAML SSO partnership is between an SP and IdP. The SP has the resources that users request while the IdP has the information to authenticate users who make the requests. The IdP returns an assertion that contains information about the user. The SP uses this information to determine whether to grant access to a user.

In a clustered environment, the appliance replicates the IdP configuration from the first member of the primary site to other members across the cluster. The exception is the key/certificate file that encrypts responses. You manually copied the key/certificate file to each member of a cluster in the [previous procedure](#).

**To configure PAM as an IdP, follow these steps:**

1. **For clustered environments only:** At the first member of the primary site, turn off the cluster. If the cluster is active, you cannot enable the IdP settings.
2. Go to **Configuration, Security, SAML, IdP Configuration** tab.

3. Complete the following settings listed:
  - **Status:** Indicates whether the IdP is enabled. Enable this setting to complete the IdP configuration.
  - **Entity ID:** Enter a unique test string to identify this IdP.
  - **Fully Qualified Hostname:** Enter *one* of the following values. Ensure you specify the fully qualified host name.
    - For a single instance, enter the value of the IdP host name, such as capam.example.com.
    - For a primary cluster member, enter the VIP address or VIP host name.

**TIP**

Inform your federation partners to use the fully qualified host name when accessing the PAM IdP.

- **Signature Algorithm:** Select the encryption algorithm to sign certificates.
  - **IdP Certificate:** Select a certificate to sign assertions. Use the default certificate, gkcert.crt, installed with PAM or a certificate that you uploaded in the [previous procedure](#).
4. Optionally, select **Download IdP metadata** to generate an XML file and send it to the remote SP.

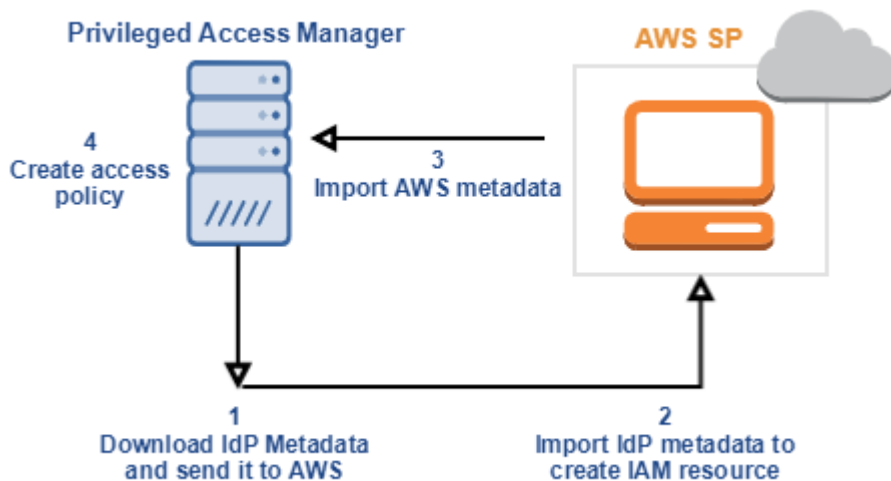

The configuration is complete. If you change any of these settings, select **Update IdP Configuration**.

For details about SAML metadata, see the [SAML specifications](#).

**Example: Configure SAML SSO to an AWS SP**

The following example shows how to set up federated SSO between a PAM IdP and Amazon Web Services (AWS) as the SP. In this example, the configuration relies on metadata. The process is reflected in the following figure:

**Figure 18: saml sso with AWS SP**

**Download IdP Metadata and Send it to the AWS SP** To establish trusted communication between the IdP and AWS SP, first configure and download the IdP metadata file. The downloaded file, named idp-metadata.xml, describes the IdP-supported SAML services. The file contains:

- Information about how an SP can send authentication requests to the IdP
- Certificate (public key) for verifying the signed assertions
- FQDN or IP address of the PAM server

**NOTE**

If you change the FQDN or the certificate changes, update the IdP metadata and resend the file to the SP.

**Follow these steps:** This procedure assumes that the IdP is already enabled.

1. Log in to the PAM UI as a Configuration Administrator.
2. Navigate to **Configuration, Security, SAML**. Select the **IdP Configuration** tab.
3. Enter values for the following fields:
  - **Entity ID:** Assign a name that identifies this IdP.  
This ID is included in the metadata file and in assertions.
  - **Fully Qualified Hostname:** Enter the fully qualified name of the IdP host. The default example is `idp.example.com`.
  - **Signature Algorithm:** Select the encryption algorithm that is used to sign the IdP certificate
  - **IdP Certificate:** Select the certificate and key you are currently using for the appliance.
4. Select **Update IdP Configuration** to apply the current certificate, host name, and your assigned ID.  
You receive a confirmation message at the top of the page.
5. Select **Download IdP Metadata** to save the `idp-metadata.xml` file locally.
6. At AWS, import the IdP metadata file, as instructed in the next procedure.

**Import IdP Metadata to Create an AWS IAM Resource** A PAM administrator sends the IdP metadata to AWS. An AWS Administrator must import the metadata file to its SP endpoint. The file provides the necessary information for AWS to make authentication requests to PAM.

#### WARNING

**CAUTION!** The following procedure describes a product that is independent of PAM.  
The procedure is provided only as an example. You might encounter different features or different appearance.

**An AWS administrator must follow these steps:**

1. Log in to the AWS Management Console and navigate to **Services, IAM, Identity Providers**.
2. Select **Create Provider** and complete the following settings:
  - **Provider Type:** Select SAML.
  - **Provider Name:** Enter a name to identify the PAM IdP.
  - **Metadata Document:** Locate the IdP metadata sent by the PAM Administrator.
3. Select **Next Step** then confirm the configuration by selecting **Create**.
4. In the left pane, select **Roles, Create New Role**.
5. Enter a **Role Name**, and select **Next Step**.
6. On the Select Role Type page:
  - a. Select **Role for Identity Provider Access**
  - b. Select **Grant Web Single Sign-On (WebSSO) access to SAML providers**
7. In the next panel, select the SAML provider that you created in the previous steps. Select **Next Step**.
8. Continue past the **Verify Role Trust** page. In this example, you do not need to edit the Verify Role Trust: Policy Document.
9. On the **Attach Policy** page, we recommend that you use select one of the pre-built policy templates, such as **Amazon EC2 Read Only Access**. If you are testing on a public EC2 instance, do not let others log in to your box. Select **Next Step**.
10. Review the confirmation then select **Create Role**. Your new role appears in the roles list.

Your AWS account is now configured to communicate with the PAM IdP. **Import AWS SP Metadata at the IdP** AWS uses the concept of roles for authentication. When the IdP generates the authentication response, the assertion must contain role data for the user being authenticated. The role definition and other information are in the AWS SP metadata. The file also includes the attributes the SP expects in the IdP

authentication response. The AWS SAML metadata file is available at: <https://signin.aws.amazon.com/static/saml-metadata.xml>. After you obtain the file, import it into PAM. **Follow these steps:**

1. Log in to the PAM UI as a Configuration Administrator.
2. Select **Services, Import SAML 2 SP Metadata**.
3. Select **Choose file** and browse to the AWS SP metadata file.
4. Select **Import SAML 2.0 SP Metadata**. A message confirms the import.  
After the import, the appliance creates two objects:
  - A web portal service. The name of the service matches the SP Entity ID in the metadata file. In this example, the service is called **AWS Management Console Single Sign-On**.
  - A device with an address of the Assertion Consumer Service at the SP.
5. Navigate to **Services, TCP/UDP Services** and select the new web portal service and update it.
6. Ensure that the Auto Login Method field is set to SAML2.0 SSO POST.
7. Select the **SAML SSO Info** tab and configure the following fields:
  - **Initiating Party**: Select **IdP-Initiated**
  - **Require Signed Authn Requests**: Clear the checkbox. The AWS SP does not send signed authentication requests.

For information about the other fields on this page, see [Configure Automatic Login to Web Portals](#).

After you complete the procedures, PAM can provide an assertion to AWS. Based on the assertion, AWS can permit access to the requested resource. **Create a Policy for Users to Access to AWS Resources** For a user to gain access to an AWS resource, set up a policy for that user at the appliance. The policy is made up of a TCP/UDP service and a device that the appliance automatically creates when you imported the SP metadata. The policy also includes selected attributes that the AWS SP accepts in the assertion response.

**Follow these steps:**

1. Log in to the PAM UI.
2. Select **Policy, Manage Policies, Add**.
3. On the **Association** panel, select a user and the device **signin.aws.amazon.com**. This device is the one automatically generated based on the SP metadata.
4. On the **Services** panel, select the **AWS Management Console Single Sign-On** service.
5. On the **SAML** panel, add the following attributes under the **Requested Attributes** column:
  - **Subject Name Identifier**: The available name identifier format is associated with the TCP/UDP service
  - **RoleSessionName**: Assign a label in the **Attribute** column. Use any identifier.
  - **RoleEntitlement**: Select Constant in the **Attribute** column. In the **Value** column, enter the concatenated AWS ARNs for the IAM role and the Identity Provider, separated by a comma. For example:

```
arn:aws:iam::123456789012:role/
MyAWSroleForMyIDP,arn:aws:iam::123456789012:saml-provider/
AWSstoredMetadataForMyIDP
```

The following picture shows an example:

Update Policy samluser - signin.aws.amazon.com

Access Services **SAML** Password Filters Recording CA PAM Server Control Transparent Login

AWS Management Console Single Sign-On

Select entries from the Requested Attribute combo box to configure additional SAML attributes. Requested Attributes in bold are required.

**+**

Requested Attribute	Name Identifier Format	Provision Type	Attribute	Value
Subject Name Identifier	urn:oasis:names:tc:SAML:1.1:nameid-format:unspecified	LOCAL	User Name	
RoleEntitlement		LOCAL	Constant	arn:aws:iam:...
RoleSessionName		LOCAL	Email	

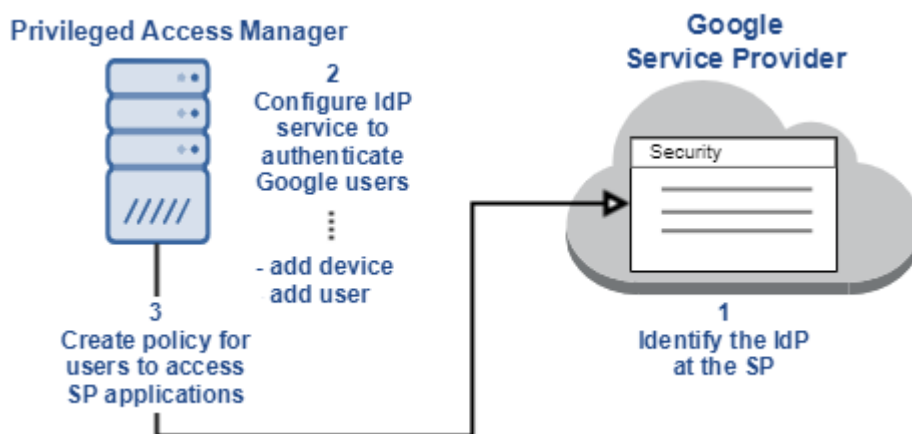

6. Select **OK** to save the policy.

The user can now access the AWS federated resource without having to log in.

### Example: Configure SAML SSO to a Google SP

You can work with an SP that does not provide metadata. In this example, PAM IdP is configured for SSO with a Google SP. Google does not use metadata to exchange information to or from its partners. The process is reflected in the following picture:

**Figure 19: SAML SSO Google Example**

**Identify the IdP at Google** At Google, the PAM IdP must be configured so it can authenticate Google accounts.

#### NOTE

The following procedure describes a product that is independent of PAM. The procedure is provided only as an example. You might encounter different features or appearance.

#### Follow these steps:

1. Log in to the Google Admin Console (<https://admin.google.com>).
2. From the main menu at the top left, select the Security, then scroll down the page and select **Set up single sign-on (SSO)**.
3. Scroll down the page and select the checkbox **Setup SSO with third party identity provider**.
4. Enter values for the following fields:

- **Sign-in page URL:** `https://capam_IP_or_hostname /idp/profile/SAML2/Redirect/SSO`
  - **Sign-out page URL:** PAM does not support single sign-out. Enter `https://capam_ip or hostname /` as a placeholder.
  - **Change password URL:** PAM does not support password changes. Enter `https://capam_ip or hostname/` as a placeholder.
  - **Verification certificate:** Upload the certificate from PAM IdP. This certificate works with the private key that is used to sign the SAML response. To obtain this certificate, take *one* of the following actions:
    - Copy the certificate from the IdP metadata file.
    - Download the certificate from the appliance. Select **PAM Configuration, Security, Certificates**, and go to the **Download** tab.
5. Select **Use a domain-specific issuer**.
  6. Optionally, to allow a specific set of users access to the application, specify entries in the **Network masks** field.
  7. Continue to the next procedure.

**Configure a Service to Authenticate Google Users** Set up a service at the IdP that represents the Google SP. No metadata is available to set up this service. Obtain the necessary information from the SP. **Follow these steps:**

1. Log in to the PAM UI.
2. Navigate to **Services, Manage TCP/UDP Services, Add**.
3. On the **Basic Info** panel, configure the settings with the following values:
  - **Service Name:** Entity ID of the Google SP. For this example, GoogleApps.
  - **Local IP:** Address of the end-user local host, such as the user laptop, in the format 127.0.0.5 (IPv4) or ::1 (IPv6). Do not use an address of an existing service.
  - **Ports:** Enter the ports of the local host, such as 443:4430.
  - **Protocol:** TCP
  - **Application Protocol:** Web Portal.
  - **Auto Login Method:** SAML2.0 SSO POST
  - **Launch URL:** URL for the ACS, using the format: `https://<Local IP>:<First Port>/a/google_domain/acs`. Enter the literal string `<Local IP>:<First Port>`. *These entries are not placeholders. Replace `google_domain` with the domain of your Google services, such as calendar or email. This domain is the location consuming SAML assertions.*
4. In the **SAML SSO Info** panel, configure the fields with the following values
  - **SAML Entity ID:** `google.com/a/google_domain`
  - **Initiating Party:** SP-initiated
  - **Require Signed Authn Requests:** Clear the checkbox.
  - **Encryption:** Select None. Google applications do not support encrypted assertions. If the SP does support encryption, you can select the **Name ID** or **Assertion** option. Then, copy the certificate from the SP in the **PEM Encryption Certificate** field.
5. On the **SAML SSO Attributes page**, select the name identifier format `urn:oasis:names:tc:SAML:1.1:nameid-format:unspecified`
6. Select **OK**.

**Create a Device Representing Google** Add a device that identifies the Google SP. **Follow these steps:**

1. Select **Devices, Manage Devices, Add**.
2. Most of the fields are self-explanatory, but note the following entries:

- **Address:** Enter the fully qualified domain name of the server hosting the ACS. You can extract the address from the ACS URL, for example: [https://www.google.com/a/your\\_google\\_domain/acs](https://www.google.com/a/your_google_domain/acs). The device address that is provisioned in PAM is [www.google.com](http://www.google.com).
  - **Device Type:** Access
  - **Services** tab: Select the TCP/UDP service that you configured for the SP in the previous procedure.
3. Select **OK** to save the device entry.

**Create an IdP User Matching the SP User** Create a user with a user name matching a Google user account that can log in to applications. **Follow these steps:**

1. Select **Users, Manage Users, Add**.
2. Most of the fields on the tabs are self-explanatory.
3. In the Roles panel, select the applicable user role for the user logging in to PAM simply to access the SP.
4. Select **OK** to save the user entry.

**Create a Policy for Users to Access to Google Applications** For a user to gain access to a Google application, set up a policy for that user at the appliance. The policy is made up of a TCP/UDP service, the device, and the user entry you created in the previous procedures. **Follow these steps:**

1. Log in to the PAM UI.
2. Select **Policy, Manage Policies, Add**.
3. On the **Association** panel, select a user and the device with the name **www.google.com**.
4. On the **Services** panel, select the **GoogleApps**.
5. On the **SAML** panel, add the following attribute entry: Attribute entry with the following values:
  - **Requested Attribute:** Subject Name Identifier. This attribute is always required.
  - **Name Identifier Format:** urn:oasis:names:tc:SAML:1.1:nameid-format:unspecified
  - **Attribute:** Email
6. Select **OK** to save the policy.

The user can now single sign-on to the Google application.

## **SAML SSO User Experience**

When a user makes a request, there are two types of communication flows:

- IdP-initiated: The user starts at the IdP and gets redirected to the SP.
- SP-initiated: The user begins at the SP and the SP sends an authentication request to the IdP. The IdP responds with an assertion, which identifies the user.

The two SAML SSO configuration examples illustrate each type of flow.

### ***IdP-initiated SSO to the AWS Management Console***

In the AWS example, the service you configured to the AWS Management Console is for IdP-initiated SSO.

**The SSO flow follows these steps:**

1. The user logs in to PAM and the Access page in the UI is displayed.
2. On the Access page is a link to AWS Management Console Single Sign-On.
3. The user selects the link and gains access to the Console directly without entering credentials.

### ***SP-Initiated SSO to Google Apps***

For SP-initiated communication, initiate the connection at the Google. Typically, the user has the access URL to the SP.

**WARNING**

The following procedure describes a product that is independent of PAM. The procedure is provided only as an example. You might encounter different features or appearance.

**The SSO flow follows these steps:**

1. In a browser, the user enters the URL to Google: <https://accounts.google.com/>
2. At the login, the user enters their user name.
3. The SP redirects the user to the PAM IdP.
4. If the user has not authenticated, PAM presents the login page. The user logs in and the IdP authenticates that user.
5. Following authentication, the IdP redirects the user back to Google with the assertion. The user is logged in automatically to Google.

**Configure PAM as a SAML Service Provider (SP)**

The following sections explain how to configure a PAM SP:

**Prerequisites for SAML Configuration**

Before you configure PAM to act as an SP, there are some initial tasks to complete:

- Provision user accounts
- Configure SAML Global Settings
- Obtain a Certificate to Sign Authentication Requests

These prerequisite steps are described in the next few sections.

***Provision User Accounts at Each Side***

The SP and IdP must have user accounts with matching user names. Users must have permission to access resources at the SP.

***Configure SAML Global Settings***

Before you configure the SP configuration, confirm the default SAML settings.

Follow these steps:

1. Select **Settings, Global Settings**.
2. Select the **SAML** tab.
3. Verify the following two settings:
  - **Require Inherited SAML Auth:** When the authentication method for a user group is set to SAML, selecting this option applies SAML to all user group members. The individual authentication method is disregarded. This setting is selected by default.
  - **SAML Re-authentication Period (Minutes)**  
This setting applies only when Privileged Access Manager is the IdP. This setting specifies the minutes of inactivity before a session with a PAM IdP expires. A subsequent SSO request requires the user to log in again. Default: 60 minutes

***Obtain a Certificate to Sign Authentication Requests***

A certificate for the SP is necessary to encrypt such items as an authentication request. Obtain an SSL certificate for your PAM fully qualified domain.

**Follow these steps:**

1. Navigate to **Configuration, Security, Certificates**.

2. On the **Create** tab, select **CSR (Certificate Signing Request)**. For more information, see [Create a Self-Signed Certificate or a Certificate Signing Request](#).  
Use the CSR to obtain a certificate, CA chain, and CRL from your applicable Certificate Authority.
3. After you obtain these files, upload them. Go to **Configuration, Security**, and select the **Upload** tab. Select and upload the appropriate files.
4. Go to the **Set** tab to accept the certificate.

### Example: Configuring SAML SSO with PAM

The following example illustrates how to establish SAML single sign-on between two PAM servers acting as SAML partners. In the procedures that follow:

- The SP and the IdP are both PAM appliances.
- Metadata files are used to define each partner to one another.

**Import IdP Metadata to the SP** The IdP metadata file is an XML file that describes the SAML services that the IdP provides. The document contains information about how an SP can send authentication requests to the IdP. The file contains the certificate (public key) that the IdP uses to sign all assertions. Finally, the file includes the fully qualified domain name (or IP address) of the IdP. Therefore, anytime the FQDN or the certificate changes, update the IdP metadata and upload the file to the SPs. **Download the metadata file:**

1. Log in to the PAM IdP as a Configuration Administrator.
2. Navigate to **Configuration, Security, SAML**, and select the **IdP Configuration** tab.
3. Following a change in the appliance hostname or the default certificate, update the IdP settings as follows:
  - a. In **Entity ID**, assign a unique name to identify this IdP.  
This ID gets included in the IdP metadata file and in the assertions the IdP generates.
  - b. In **Fully Qualified Hostname**, enter the value that is used for this SP, such as: mypam.example.com
  - c. From the drop-down list for **IdP Certificate**, select the certificate and private key pair.
  - d. Select **Update IdP Configuration** to apply the current certificate, hostname, and your assigned ID.
  - e. Upon changing your hostname, select **Accept IdP Certificate** in that panel.
4. Select **Download IdP Metadata** to save the metadata file locally.
5. Upload the metadata to the SP

### Upload the metadata to the SP:

1. Log in to the SP as a Configuration Administrator.
2. Navigate to **Configuration, Security, SAML, SP Configuration** tab.
3. At the minimum, complete the required fields.
4. Select **Save Configuration**.
5. Select the **Configured Remote SAML IdP** subtab.
6. Identify at least one corresponding IdP by clicking **Upload An Identity Provider Metadata**. Browse to the metadata file from the IdP and select **Upload**.
7. Move to the **Set** tab and accept the file.

The IdP is now identified by its **Friendly Name**, if available, and its **Entity ID**. **Import the SP Metadata to the IdP** This PAM SP is now aware of the IdP by way of the imported IdP metadata file. Use an SP metadata file to identify itself to the IdP. The SP and IdP now can then communicate with each other. **Download the SP metadata:**

1. If you are not already there, navigate to **Configuration, Security, SAML**, and select the **SP Configuration, Configured Remote SAML IdP** subtab.
2. Identify the line item for the IdP that you are looking for.
3. Select the **Download Metadata** link for this IdP and select it to save this SP metadata file locally.

**Upload the SP metadata to the IdP:**

1. Log in to the IdP as a Configuration Administrator.
2. Select **Services, Import SAML 2 SP Metadata** to open the import page.
  - a. **Choose File** to locate the XML file that you obtained from the SP.
  - b. Select the **Import SAML 2 SP Metadata** button to upload it to IdP.  
After you do so, you will see several acknowledgment messages. If there are errors, they are noted in red.

Uploading the SP metadata results in identification of the SP authorization function as a Service, and the SP server as a Device.
3. Confirm that a Service record has been created under **Services, Manage TCP/UDP Services**, with a **Service Name** matching the IdP SAML Entity ID. Select the **Update** button to see the details. The record has the following information:
  - Typical specifications for a Web Portal, with **Auto Login Method**="SAML2.0 SSO POST"
  - Launch URL, which is the Assertion Consumer Service URL
  - **SAML SSO Info** tab with the SAML Entity ID
  - **SAML SSO Attributes** tab with SAML SSO Subject Name Identifier Formats and SAML SSO Attributes
4. In **Devices, Manage Devices**, verify that a Device record has been created with **Name** and **Address** matching the IdP SAML-applicable FQDN.

**Provision SSO Access Policy** The SP and IdP have been configured to trust each other. Now you can provision the IdP to permit its users to access the SP services. When you open a policy for the SP (for a particular user or user group), select the corresponding SP service. The service is identified by Entity ID. This action opens the SAML tab so that its attributes can be specified.

**NOTE**

If the SAML attributes are not sufficiently identified, revise them as necessary. The SAML Name Identifier Format is initially not specified. If this value is missing, select one of the available options so that the **xAttribute** becomes available.

**SAML SSO User Experience** After you set up SAML SSO, a **Single Sign On** option becomes available on the login screen of the PAM UI. The following process assumes an SP-initiated connection:

1. The user requests a resource at the SP by selecting **Single Sign On** at the login screen.
2. The user is alerted that the login proceeds with authentication at a different target, the IdP. If there are multiple IdP targets, the user must select one from the drop-down list, then select **ENTER**.
3. The User is then brought to the login page for the IdP. No **Single Sign On** option is available at the IdP.
4. The User enters the required credentials.
5. The IdP has authenticated the user, its task is complete. Control is handed back to the SP, where the user is granted access to the application.

**JIT Provisioning**

Just-in-time (JIT) SAML provisioning in PAM enables the provisioning of new user accounts from SAML assertions.

For JIT Provisioning to work effectively, follow these guidelines:

- Create PAM user groups that match user groups that are used in the SAML assertion.
- Use the **userGroup** attribute in the assertion for these user groups.
- The user must belong to an existing user group to which the user is not provisioned, and authentication fails. The user is redirected to the login page.
- The user can belong to multiple user groups.
- If a user later logs in with a different set of user groups, the user moves to those user groups.
- Entitlements for users are defined by the user groups.
- As an administrator, you cannot manage user group membership inside the appliance. You can manage membership only using assertions.
- This user group behavior only works for users that are provisioned using JIT provisioning.

### ***JIT Provisioning User Groups Examples***

The following examples illustrate how the SAML **userGroup** attribute interacts with user groups. For these examples, the following user groups are configured in PAM: Group A, Group B, Group C, Group D.

- The SAML assertion contains Group A and Group C. The user is provisioned in those user groups
- If the assertion contains only Group E, the JIT provisioning and authentication fail. The user is redirected to the login page.
- A user belongs to Group A and Group C and the assertion contains Group B and Group D. The user account moves from Group A and Group C to Group B and Group D.

### ***Configure JIT Provisioning***

Follow the same instructions that are found in [Configure PAM as the SP](#). When you get to the **Configured Remote SAML IdP** step on the SP Configuration page, either **Upload** or **Add** the IdP information as instructed.

- If you select **Add** and you manually create an Identity Provider (IdP) record, select the **Allow Just In Time Provisioning** checkbox.
- If you select **Upload An Identity Provider Metadata** and you create an IdP record from the imported IdP metadata document, select **Update** afterwards. Select the **Allow Just In Time Provisioning** checkbox.

Select **Save Configuration**.

## **Azure AD as an Identity Provider (IdP)**

You can configure Privileged Access Manager to use Active Directory on Microsoft Azure as its Identity Provider using SAML. You can configure Azure as IdP whether Privileged Access Manager is [deployed on Azure](#) or not.

### **Set up the Azure Application**

To create an application in Azure, follow these steps:

1. Log into Azure with an account with permission to grant admin consent for API permissions.
2. In the Azure UI, select **Azure Active Directory** from the **Azure services** menu at the top of the screen (as shown highlighted in the following screen capture):

## Azure services

3. Select **App Registrations** from the **Manage** section that appears in the left rail.
4. Select **New Registration** from the menu bar on the **App registrations** pane.
5. Enter a **Name** of your choice. Do not include spaces in the name.
6. At the **Who can use this application or access this API** prompt, select one of the following options, as appropriate:
  - **Accounts in this organizational directory only (pamdev only - Single tenant)**
  - **Accounts in any organizational directory (Any Azure AD directory - Multitenant)**
7. For **Redirect URI**, select **Web** (the default) and enter the URL of your Privileged Access Manager UI in the following format: `https://ip_address/cspm/home` . For a cluster, select the IP address of the first node at the primary site.
8. Select **Register**. The application is created.
9. Select **API permissions** from the **Manage** section in the left rail.
10. On the **Configured permissions** pane that opens, select **Add a permission**.

### NOTE

The **User.Read** delegated permission, which appears in the list of permissions is configured by default.

11. On the **Request API permissions** wizard that opens, select **Microsoft Graph**.
12. On the next page, select **Delegated permissions**.
13. Locate and open the **Directory** entry in the list of permissions then select the **Directory.AccessAsUser.All** entry.
14. Select **Add Permissions** at the bottom of the page.  
You are returned to the **Configured permissions** pane where **Directory.AccessAsUser.All** has been added to the list of configured permissions.
15. Select **Application permissions**.
16. Locate and open the **Directory** entry in the list of permissions then select the **Directory.Read.All** entry.
17. Select **Add Permissions** at the bottom of the page.  
You are returned to the **Configured permissions** pane where **Directory.Read.All** has been added to the list of configured permissions all. The **Configured permissions** list should now be complete with all three permissions:

- Directory.AccessAsUser.All
- Directory.Read.All
- User.Read

18. Select **Overview** at the top of the left rail and select **Endpoints** at the top of the page.
19. Copy the **Federation Metadata Document** URL. Paste the URL into another browser window to download the metadata. Save the XML as "federationmetadata.xml".
20. Open the hamburger menu in the top left of the screen and select **Azure Active Directory**.
21. On the **Overview** screen that opens, select **Enterprise Applications** from the left rail.
22. Select **All Applications** from the **Application Type** drop-down and select **Apply**.
23. Locate and open your new application.
24. Select **Properties** from the **Manage** section in the left rail.
25. Select **Yes** for **User assignment required**.
26. Select **Yes** for **Visible to users**.
27. Select **Save**.

## Configure SAML in PAM

1. Log in to your PAM instance. If you are setting up a cluster, ensure that the cluster is on. Use the first node in the primary site.
2. Navigate to **Configuration, Security, SAML, RP Configuration**.
3. Complete the following fields:
  - **Entity ID:** Your App ID URL, for example: `https://ip_address`
  - **Friendly Name:** CAPAM
  - **Fully Qualified Hostname:** Your PAM IP address  
For a cluster, each member uses its own IP address.
  - **Certificate Key Pair:** select `gkcert.crt` from the drop-down list.
  - **SAML IdP Metadata Refresh Mode** (optional): To specify a schedule for refreshing Azure federation metadata, specify **Hourly** or **Daily**. (The document from which to read Azure federation metadata must be specified in the **Metadata Refresh Source URL** field on the **Configured Remote SAML IdP** tab.)
4. Select **Save Configuration**.
5. If you are using a cluster, repeat this procedure for each instance, but only entering the IP address in the **Fully Qualified Hostname** field.
6. Select **Configure Remote SAML IdP**.
7. Select **Upload an Identity Provider Metadata**. Select **Choose File** to find "federationmetadata.xml" and **Upload** it.
8. Select the new remote SAML IdP entry on the Configured Remote SAML IdP page, and select **Update**.
9. Edit the **Friendly Name** field to be friendlier, to "Azure IdP," for example.
10. Select the **Allow Just In Time Provisioning** checkbox.
11. Optionally, specify the URL of an Azure federation metadata document from which to periodically refresh Identity Provider data in the **Metadata Refresh Source URL** field. (Only used if the **SAML IdP Metadata Refresh Mode** option on the **RP Configuration** tab is set to Hourly or Daily).
12. Select **OK** to save.
13. Select the **Download Metadata** button. "XsuiteMetadataFor\_*Friendly\_Name*.xml" is saved to your Downloads folder.
14. Open the metadata file and copy each Location field URL. For clusters, there are multiple Locations. For example, in this line, copy the entire URL between the quotes:  
**IPv4**  
 Location="https://12.34.56.78/samlsp/module.php/saml/sp/saml2-acs.php/xsuite-default-sp"  
**IPv6**  
 Location="https://https://https:[fd6d:8d64:af0c:1:0:242:22:233]/samlsp/module.php/saml/sp/saml2-acs.php/xsuite-default-sp"

## Configure SAML in Azure

Now we configure the SAML IdP settings in Azure using the information from Privileged Access Manager.

1. Navigate to **Azure Active Directory, App Registrations**. Open your Azure IdP Application.
2. Select **Authentication** from the **Manage** section in the left rail.
3. In the **Web** section of the **Authentication** screen that opens, remove the existing default **Redirect URI**.
4. Use the **Add URI** control to enter each location that you copied from the PAM metadata file.
5. Select **Save**.
6. Select **Manifest** from the **Manage** section in the left rail.
7. Line 8 on the **Edit Manifest** window shows this text: `"app roles": [],`
8. Enter the following text between the square brackets:

```
{
  "allowedMemberTypes": [
    "User"
```

```

    ],
    "displayName": "Global Administrator",
    "id": "b1d7feb5-d688-4187-b257-42df5b621bfd",
    "isEnabled": true,
    "description": "Allows access to and configuration of all PAM functionality",
    "value": "GlobalAdministrator"
  },
  {
    "allowedMemberTypes": [
      "User"
    ],
    "displayName": "Standard User",
    "id": "86456979-e617-41e3-be5f-243ec00d6113",
    "isEnabled": true,
    "description": "Allows users to access and manage remote devices",
    "value": "StandardUser"
  }
}

```

9. Select **Save**.

10. Navigate to **Azure Active Directory, Enterprise Applications**. On the **All Applications** page that opens, select your Azure IdP Application from the list that is displayed.

11. Select **Assign User and Groups**.

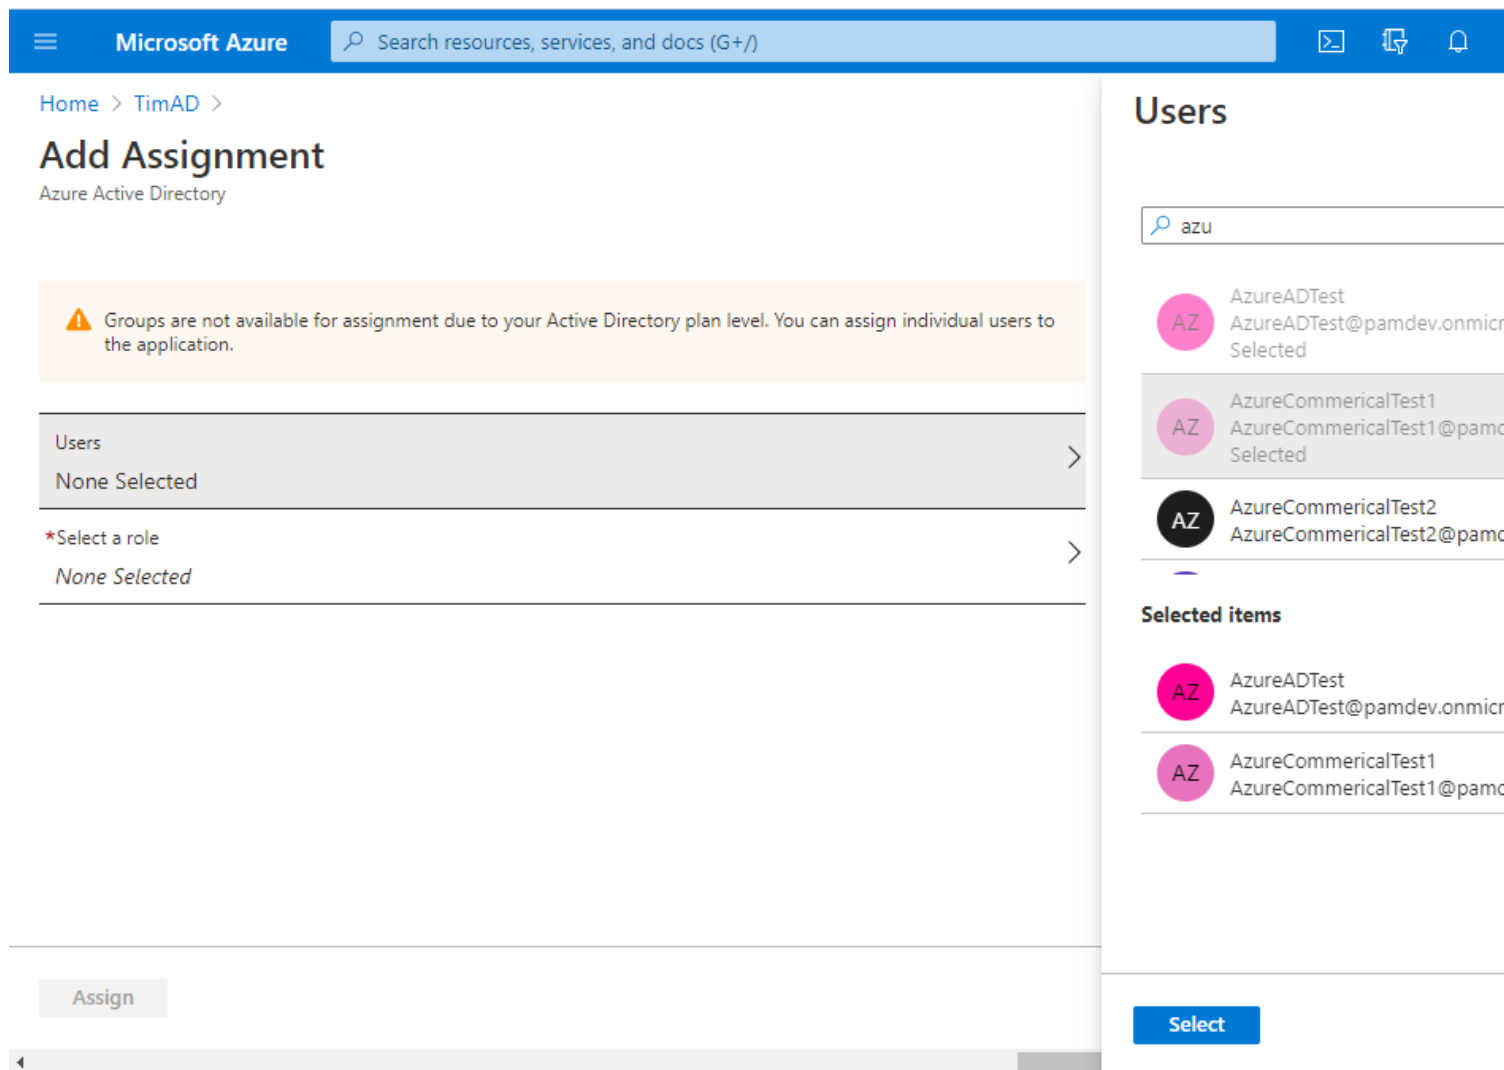

12. Select **+ Add User**.

13. On the **Add Assignment** page that opens, select the **Users** entry, then **select** a user or users from the **Users** list that appears and click **Select**.

**Figure 20: Screenshot showing user selection**

The screenshot shows the Microsoft Azure portal interface. The main heading is "Add Assignment" under "Azure Active Directory". A warning message states: "Groups are not available for assignment due to your Active Directory plan level. You can assign individual users to the application." Below this, the "Users" section shows "2 users selected." and a role selection dropdown set to "Standard User". The "Assign" button is visible at the bottom left. On the right, the "Users" panel lists three users: "Avishek Sarkar" (as665283@pamdev.onmicrosoft.com), "AzureADTest" (AzureADTest@pamdev.onmicrosoft.com, Selected), and "AzureCommericalTest1" (AzureCommericalTest1@pamdev.onmicrosoft.com, Selected). The "Selected items" section lists "AzureADTest" and "AzureCommericalTest1". A "Select" button is at the bottom right of the Users panel.

14. Select **Select a Role** for the selected user or users, then select a role or roles and click **Select**.

**Figure 21: Screenshot showing role assignment for selected users**

15. Select **Assign**.

### **Create Azure SAML User Group in PAM**

1. In Privileged Access Manager, go to **Users, Manage User Groups**, and select **Add**.
2. Enter the **Group Name** as `AzureSAMLUsers` exactly.
3. Select **OK** to save the group.

### **Create an Azure Target Account and Connection in PAM**

If you have not already configured an Azure Target Account and an Azure Connection, follow the instructions at [Configure an Azure Connection](#).

The Target Account and Connection for Azure in Privileged Access Manager enable these processes:

- Remove active sessions at the next user refresh. This process enhances security because a user could have an active session after their access is revoked.
- Remove and clean up the User in Privileged Access Manager. This process prevents orphaned Azure accounts in Privileged Access Manager.

### **Use Single Sign-On to log in to PAM**

1. Log out from Privileged Access Manager.
2. The login page now has a Single Sign-On link below the Login button.
3. Select the Single Sign-On link.
4. You log in with your Azure AD credentials.

## **Hardware Security Modules (HSMs) for Credential Manager**

By default, Credential Manager uses a software encryption module that is validated to FIPS 140-2 Level 1 (CMVP certificate #3389) to encrypt and decrypt stored credentials. Additionally, a Java encryption module that is validated to FIPS 140-2 (CMVP certificate #3514) is also [implemented](#).

To provide hardware-based encryption to encrypt and decrypt stored credentials, configure one of the following Hardware Security Modules.

- [SafeNet HSM](#)
- [Entrust nShield Connect HSM Appliance](#)
- [Common HSM Features](#)

### **Configure PAM to use a Safenet HSM**

Learn how to configure PAM to use a SafeNet HSM to encrypt and decrypt its stored credentials in place of its built-in cryptographic engine

Configure PAM to use a SafeNet HSM to encrypt and decrypt its stored credentials in place of its built-in cryptographic engine

#### **Configure the SafeNet HSM**

Refer to the Safenet documentation to learn how to configure the Safenet HSM .

#### **Configure Privileged Access Manager**

Although not required, it is recommended that you configure Safenet appliances in Privileged Access Manager only during Privileged Access Manager downtime. If your Privileged Access Manager is a production appliance, plan a maintenance window.

#### **NOTE**

When tested for Privileged Access Manager 2.3, 5000 target account records took approximately 10 minutes to process.

Once Safenet HSM can receive communication, you can configure Privileged Access Manager to use up to three Safenet appliances of the same release level.

#### **Back Up the Database**

Before configuring Privileged Access Manager to engage with the Safenet appliance, back up the Privileged Access Manager database.

**Follow these steps:**

1. Log in to Privileged Access Manager as an administrator (for example, as "super").
2. Navigate to **Configuration, Database**.
3. On the **Database** tab, select **Save Database and Configuration**.  
The page updates with a confirmation of the backup creation with the database (and configuration) filenames. Note the database filename, which should be similar to: gkdatabase20130714124622.gz
4. Click the database filename to select it, and click **Download**.  
The database is saved to your local workstation (or other location).
5. Use this file if you must recover your Privileged Access Manager database.

**Configure the HSM**

The following procedure assumes configuration to one Safenet appliance, and Safenet HSM licensing for Privileged Access Manager. See the section on "Scaling" later in this content for information about changing the number of HSM or Privileged Access Manager appliances.

**Follow these steps:**

1. Log in to Privileged Access Manager as an administrator (for example, as "super").
2. Navigate to **Configuration, 3rd Party, Safenet HSM**.
3. On the **Safenet HSM Configuration** tab, enter the Safenet credentials that you established when setting up the device.
  - a. Enter the **Security Principal Username** you set when configuring the Safenet administrative account.
  - b. Enter the **Security Principal Password** you set when configuring the Safenet administrative account.
  - c. Enter the **Partition Name** as specified during Safenet (5.2 or later) configuration.
  - d. Enter the **Partition Password** you set in the "Create Storage" step during your Safenet configuration procedure earlier.
  - e. Enter the **Address** (IP address or FQDN) assigned to the Safenet appliance.
4. Click **Add** to initiate the configuration.  
After successful account access to the Safenet appliance, the page refreshes, returning with a confirmation message. The **Network Attached HSMs** tab updates with the address (labeled **HSM**), **Status**(showing as *PartitionName: ConnectionStatus*), and permitted **Action** (**Remove** button is available).
5. Reboot Privileged Access Manager.
6. Log back in to Privileged Access Manager, and navigate to the **3rd Party** page.

**NOTE**

Reencryption occurs immediately following a password request from an A2A Client, if that occurs earlier.

Once Safenet Safenet is active, this status is displayed on the [View System Information](#) page.

**Scaling**

Although not required, we recommend that you configure Safenet appliances in Privileged Access Manager only during Privileged Access Manager downtime. If your Privileged Access Manager is a production appliance, plan a maintenance window.

**NOTE**

When tested for Privileged Access Manager 2.3, 5000 target account records took approximately 10 minutes to process.

**Add a Safenet Appliance**

You can add a second and a third Safenet appliance to the Privileged Access Manager configuration. When doing so, repeat the procedures in "Configure Safenet" and "ConfigurePrivileged Access Manager."

**Requirement:** Use the same password for the storage element that you assigned in the **Create Storage** procedure for each Safenet appliance.

### ***Remove a Safenet Appliance***

You can remove a Safenet appliance from an existing Privileged Access Manager configuration.

#### **Follow these steps:**

1. Log in to Privileged Access Manager as an administrator (for example, as "super").
2. Navigate to **Configuration, 3rd Party, Safenet HSM**.
3. On the **Network Attached HSM** tab, click the remove button of a Safenet appliance you want to remove.  
The page refreshes to show removal of the selected appliance.
4. If you have removed the only (remaining) appliance, reboot Privileged Access Manager.
5. Log back in to Privileged Access Manager, and navigate to the **3rd Party** page.

#### **NOTE**

Reencryption occurs immediately following a password request from an A2A Client, if that occurs earlier.

6. Privileged Access Manager does not remove the authorized client from Safenet. Issue the following command on the Safenet HSM:

```
[Safenet] Safenetsh:> client delete -c <hostname> -f
```

Otherwise, if the authorized client is registered on the HSM, and you want to add to HSM again later, you receive an error message: This client is already registered on the HSM.

### ***Share a Safenet (Group) Among Multiple Appliances***

A Safenet HSM appliance or appliance group that has been configured on one Privileged Access Manager appliance may then be configured on more appliances. Follow the procedure in "Privileged Access Manager Configuration" earlier in this content.

**Requirements:** Each Privileged Access Manager appliance must use the same encryption/decryption key.

### ***Share a Safenet Group Within a Cluster***

A Safenet appliance group may be configured for use in an existing Privileged Access Manager synchronized cluster by configuring the devices in the following sequence.

#### **WARNING**

Each member of a Privileged Access Manager cluster must use the same HSM installations – that is, an identical set of **Address** and **Partition Name** combinations should be configured on each Privileged Access Manager.

Assumptions:

- An existing Privileged Access Manager cluster:
  - Primary Privileged Access Manager member (Call this device X1)
  - First Secondary Privileged Access Manager member (X2)
  - Second Secondary Privileged Access Manager member (X3)
- Three Safenet HSM appliances (of the same release level):
  - First HSM (H1)
  - Second HSM (H2)
  - Third HSM (H3)

#### **Follow these steps:**

1. If the Privileged Access Manager cluster is active, stop it. Per the following steps, do **not** restart the cluster again until after all HSMs have been configured on each Privileged Access Manager device.
2. Navigate to **Configuration, 3rd Party, Safenet HSM**.

3. On the **Safenet HSM Configuration** tab on X1, fill in and Add H1.
  - Do **not** reboot (until after all HSMs – H1, H2, and H3 – have been configured on X1).
  - The encryption key must be generated *one time only* on H1, and then must be copied to H2 and H3.
4. After Privileged Access Manager X1 has successfully connected to H1, fill in and Add H2. Do not reboot.
5. After Privileged Access Manager X1 has successfully connected to H2, fill in and Add H3. Do not reboot.
6. Now, reboot (primary cluster member) X1.
7. For (secondary cluster member) X2, repeat steps 2 through 5.
8. For (secondary cluster member) X3, repeat steps 2 through 5.
9. Restart the Privileged Access Manager cluster.

## Configure PAM to use an Entrust nShield Connect or Connect XC HSM

This content describes how to configure PAM to use an Entrust nShield Connect or nShield Connect XC HSM to encrypt and decrypt stored credentials in place of its built-in cryptographic engine

### Prerequisites

Configuring Privileged Access Manager to work with the Entrust HSM requires one of the following the following appliances:

- nShield Connect
- nShield Connect XC hardware appliance

### Deployment Guidelines

Privileged Access Manager can operate with Entrust nShield HSMs according to the following guidelines:

- Entrust nShield Connect 1500 running client software Security World Software version 11.62.00. This client can be used with nShield Connect versions: 500, 6000, and 6000+
- Entrust nShield Connect XC running client software Security World Software, version 12.40.2. This client can be used with the following nShield Connect XC versions: XC Base, XC Mid, and XC High

### Configure Entrust nShield Connect or nShield Connect XC

Before you can configure communication with the nShield HSM, prepare the HSM to recognize Privileged Access Manager.

#### **NOTE**

The following procedures describe a third-party environment (Entrust nShield Connect 7.1) that is outside Broadcom control. The procedures are representative examples of the interface. For installation instructions, see the manufacturer documentation for your nShield product.

For Entrust Security World Software 11.62.00, refer to these following documents that come with the Entrust product:

- nShield\_Connect\_Quick\_Start\_Guide.pdf, referred to as INSTALL GUIDE in the following procedure
- nShield\_Connect\_and\_nethSM\_User\_Guide.pdf, referred to as the USER GUIDE in the following procedure

For Entrust Security World Software 12.40.2, refer to these following documents that come with the Entrust product:

- nShield\_Connect\_Installation\_Guide.pdf, referred to as the INSTALL GUIDE in the following procedure
- nShield\_Connect\_User\_Guide\_Unix.pdf, referred to as the USER GUIDE in the following procedure
- nShield\_Connect\_User\_Guide\_Windows.pdf, referred to as the USER GUIDE in the following procedure

**Follow these steps:**

1. Install and configure the nShield appliance. You must follow the INSTALL GUIDE to install and configure the HSM on the network.
2. Note the nShield appliance Ethernet interface IP address. This address is entered in later when setting up PAM. You *cannot* use an FQDN or other DNS name.
3. Create a Security World: You must create a security world as described in Chapter 7 of the USER GUIDE.
4. Create an Operator Card Set.  
An Operator Card Set (OCS) contains one or more smart cards that are used by the nShield Security World. These cards protect all cryptographic secrets that PAM can create. You must create an Operator card Set as described in Chapter 8 of the USER GUIDE document.
5. Make note of the **OCS name** and **passphrase**. The PAM setup uses these values.  
This OCS must be a "1 of N" set, where N is at least the number of HSMs. N can be greater than that number, but the OCS must be 1 of N.

**WARNING**

When creating an operator card set with more than one card, each card must have the same OCS name and password. Both the name and password are user selectable.

Using the same name and password allow PAM to use multiple nShield HSMs as a failover group. Also, PAM searches the nShield device for the operator card based on its name, so the name on each card in a set must be the same.

The standard OCS is non-persistent, means you can only use the keys protected by that OCS while the required card remains loaded in the smart card reader of the nShield device. The keys protected by this card are removed from the memory of the hardware security device as soon as the card is removed from the smart card reader. Although this feature provides added security, it means that only a single user can load keys at any given time.

**NOTE**

If the required card cannot remain loaded in the smart card reader, you must create a **persistent** Operator card set. This is described in Chapter 8, in the "Persistent Operator Card Sets" section of the USER GUIDE document.

6. Create the Remote File System (RFS): You must create a "Remote File System" as described in Chapter 6 of the USER GUIDE document. The RFS stores configuration data and shared secrets for clustered clients (PAM instances) that share a single HSM or a group of HSMs.  
Note of the client computer IP address on which you set up the RFS. This address is entered when you set up PAM. Do *not* enter an FQDN.
7. Register the PAM IP address on the nShield.  
You must register the PAM IP address as a client onto the nShield device. **This is done on the front panel of the nShield device**, and is described in Chapter 6, in the "Configuring the unit to use the client" or "Configuring the nShield Connect to use the client" section of the USER GUIDE document.  
During the process, configure PAM as a "**non-privileged**" client and does **NOT** use an nToken device.  
To add PAM IP address as a client remotely on the Remote File System (avoid the need to access the nShield device), see the "Remote configuration of additional clients" section in Chapter 6 of the USER GUIDE document.
8. PAM IP address registration on the RFS.  
You must register the PAM IP address on the Remote File System to allow for PAM clustering where multiple PAM in a cluster could share an nShield device. **This is done on the computer that acts as the RFS** and is described in the section entitled "Setting up client cooperation" in Chapter 6 of the USER GUIDE document.

**TIP**

For PAM clustering (multiple PAM instances) to work, it must have 'gang-client' argument in the rfs-setup command.

Depending on your environment, you can use either Method 1 or Method 2:

**Method 1:**

For every unauthenticated client (with write access but without **KNETI** authorization) that needs to be a client of this remote file system, run the command on the RFS machine:

```
rfs-setup --gang-client --write-noauth PAM_IP_address
```

#### NOTE

The **--write-noauth** option should only be used if you believe your network is secure. This option allows the client you are configuring to access the RFS without KNETI authorization.

#### Method 2:

For every authenticated client (with write access and KNETI authorization) that needs to be a client of this remote file system, run the command on the RFS machine:

```
rfs-setup --gang-client PAM_IP_address EEEE-SSSS-NNNN keyhash
```

- **EEEE-SSSS-NNNN** is the ESN of the unit
- **keyhash** is the hash of the KNETI key on the unit.

#### TIP

To retrieve the unit's **ESN** and **KNETI**, run the following command:

```
anonkneti nShield_device_IP_address
```

### Configure PAM to Use the HSM

After a Entrust nShield Connect HSM is set up, configure PAM. The configuration enables PAM to establish communication with up to three nShield HSMs of the same release.

To identify the Entrust HSM to PAM, complete the following steps:

1. Install the license.
2. Back up the database.
3. Identify the HSM to PAM

#### WARNING

We recommended that you configure PAM to use nShield HSMs only during downtime. For a PAM appliance in production, plan a maintenance window.

#### Install the License

Before you configure communication with the HSMs, install the Privileged Access Manager license for HSM use.

#### Back Up the Database

Adding an HSM configuration triggers reencryption of all passwords in the database. Before configuring Privileged Access Manager to engage with the nShield appliance, back up the database.

1. Log in to the UI as an administrator (for example, as "super").
2. Navigate to **Configuration, Database**.
3. On the **Database** tab, click **Save Database and Configuration**.  
The page updates and displays the backup file names. Note the database filename, such as gkdatabase20130714124622.gz
4. Select the database filename from the file list, and click **Download**.  
The database is saved to your local workstation (or other location).

Use this backup file to recover your database if necessary.

#### Configure the HSM Settings in

**WARNING**

Before you reboot PAM or restart a cluster, verify that the OCS smart card is inserted into the Entrust nShield HSM. After PAM is successfully communicating with the HSM, you can remove the card. If PAM loses network connectivity to the HSM, the card might also be required to re-establish the connection.

The following procedure assumes configuration to one nShield HSM appliance.

1. Log in to the UI as an administrator (for example, as "super").
2. Navigate to **Configuration, 3rd Party, Entrust HSM**.
3. On the **Entrust HSM Configuration** tab, enter the nShield credentials that are used to configure the nShield HSM.
  - a. In the **Token Label** field, enter the name of the OCS.
  - b. Enter the IP address (not a DNS name) of the client computer on which you set up the Remote File System.

**NOTE**

The default port for the two nShield address parameters is 9004. If you are not using the default port, specify the alternate port number in a full socket declaration. For example: 192.168.0.2:9999

- c. In the **Token Password** field, enter the password of the OCS.
  - d. In the **Address** field, enter the IP address (not a DNS name) assigned to the nShield appliance.
4. Click **Add** to initiate the configuration.
  - If you are configuring a *first* HSM, all passwords in the database are reencrypted. A dialog appears, warning you of this effect and allowing you to cancel.
  - If you are configuring a second or third HSM, no reencryption or dialog occurs.

During the process of changing from native Privileged Access Manager to nShield encryption, the Credential Manager database is copied to the nShield appliance. While the database is copied, the existing Credential Manager database is still available for use for other purposes.

After successful account access to the nShield appliance, the page refreshes with a confirmation message. An updated Networked Attached HSMs tab appears with the address and status of the appliance.

5. Reboot Privileged Access Manager.
6. Log back in to Privileged Access Manager and navigate back to the **3rd Party** page.
7. Confirm the required reencryption of passwords.

This reencryption also occurs immediately following a password request from an A2A Client, if that occurs earlier.

Once Entrust nShield is active, this status is displayed on the [View System Information](#) page.

**Add or Remove HSMs**

You can change the Privileged Access Manager configuration of HSMs to add or remove one or more HSMs, or update the stored OCS password.

We strongly recommend that you configure nShield appliances in Privileged Access Manager only during downtime. If your Privileged Access Manager is a production appliance, plan a maintenance window.

**WARNING**

Before you reboot PAM or restart a cluster, verify that the OCS smart card is inserted into the Entrust nShield HSM. After PAM is successfully communicating with the HSM, you can remove the card. If PAM loses network connectivity to the HSM, the card might also be required to re-establish the connection.

**Add HSMs**

You can add one or two more HSMs for Privileged Access Manager. A maximum of three HSMs is allowed.

**Follow these steps:**

1. Log in to the UI as an administrator (for example, as "super").
2. Navigate to **Configuration, 3rd Party**, and expand it.

3. On the **Entrust HSM Configuration** tab, enter the nShield credentials that are used to configure the nShield HSM.
  - a. In the **Token Label** field, enter the name of the OCS.
  - b. Enter the IP address (not a DNS name) of the client computer on which you set up the Remote File System.

#### NOTE

The default port for the two nShield address parameters is 9004. If you are not using the default port, specify the alternate port number in a full socket declaration. For example: 192.168.0.2:9999

- c. In the **Token Password** field, enter the password of the OCS.
  - d. In the **Address** field, enter the IP address (not a DNS name) assigned to the nShield appliance.
4. Click **Add** to initiate the configuration.  
After successful account access to the nShield appliance, the page refreshes with a confirmation message. The **Network Attached HSMs** tab is updated.
5. Reboot Privileged Access Manager.
6. Log back in to Privileged Access Manager, and navigate to the **3rd Party** page.
7. Initiate the required re-encryption of passwords.

This re-encryption also occurs immediately following a password request from an A2A Client, if that occurs earlier.

The Token Password value must be the same one that you used for the first HSM. Otherwise, you must reconfigure your other HSM OCS.

#### ***Remove HSMs to Revert Encryption***

To revert the encryption mechanism back to Credential Manager, remove HSMs.

#### **Follow these steps:**

1. Log in to the UI as an administrator (for example, as "super").
2. Navigate to **Configuration, 3rd Party**.  
The **Networked Attached HSMs** tab shows one or more HSMs.
3. Confirm that the HSM or HSMs are online.
4. Next to the HSM you want to remove, click **Remove**.  
If only one HSM is configured, a message indicates that the removal triggers re-encryption of all passwords in the database. The passwords are reassigned to Credential Manager. Following the re-encryption process, you see a Success or an Error message.
5. Reboot Privileged Access Manager.
6. Log back in to the UI, and navigate back to the **3rd Party** page.  
The HSM is no longer being used.
7. Confirm the required re-encryption of passwords.  
This reencryption also occurs immediately following a password request from an A2A Client, if that occurs earlier.

#### **Configure a Cluster to Work with an nShield Group**

An nShield HSM or HSM group can be configured for use in an existing Privileged Access Manager synchronized cluster.

The following procedure assumes the following setup:

- An existing *n*-member cluster is configured.
- Up to three nShield HSM appliances (of the same release level) are installed in the network.

#### **Follow these steps:**

1. On the primary PAMcluster member:
  - a. Complete all preliminary procedures (license installation, database backup), if needed.
  - b. For every HSM in the network, [Configure the HSM Settings in PAM](#).
2. For each additional cluster member, [Configure the HSM Settings in PAM](#).

All members of the cluster can now use the Entrust HSM.

## Common HSM Features

The following features apply to all brands of HSMs.

### Updating Passwords

You can update the Token Password of an installed Entrust nShield HSM, or the Partition Password of an installed SafeNet Luna SA HSM, without taking the HSM offline.

1. On the HSM appliance or appliances, change the relevant HSM password. (See the manufacturer documentation.)
2. In Privileged Access Manager web UI or Client, navigate to **Configuration, 3rd Party**, and your HSM module (Entrust or SafeNet).
3. On the **Network Attached HSMs** tab, confirm that the HSM Status field shows "online."  
For example, for an Entrust HSM:  
In the Entrust HSM Configuration staging panel, enter the new password in the second Token Password field at the bottom of the panel. This field is next to the Update and Activate button.

#### NOTE

Because the password field characters are hidden, you can copy and paste the password instead of typing the password to avoid data entry errors. If you have multiple HSMs, the Token Password is the same on each, so you do not have to identify the specific appliance.

4. Click **Update & Activate**.

A response is presented at the top of the **3rd Party** page:

- If the password is correct, you the following response appears:  
"Success updating the HSM password."
- If the password is *not* correct, or if there was a problem communicating with the HSM, the following response appears:  
"Error the HSM password is incorrect."

## AWS Coordination

As a Privileged Access Manager Administrator, you can configure access to one or more regions in one or more Amazon Web Services accounts. You can then import AWS instances as Privileged Access Manager Devices and provide controlled, account-obfuscated end-user access to the AWS Management Console. Credentials for a particular AWS account are stored as an individual target account in Credential Manager. Using an enhanced configuration interface, you can provision combinations of AWS accounts and regions for concurrent connection.

Configuration allows these types of coordination:

- Configuration of restricted access to the AWS Management Console website for any policy-enabled Privileged Access Manager user
- Import, and regular refresh, of all active AWS devices (in the configured AWS region) as Privileged Access Manager devices

Follow these procedures:

1. [Obtain an AWS account](#) with at least the following privileges:
  - ec2:DescribeInstances
  - ec2:DescribeTags
2. [Store AWS Account Credentials in a Privileged Access Manager CM.](#)
3. (Optional) [Configure AWS Connection](#)
4. (Optional) [Configure AWS Settings](#)

5. (Optional) [Provision AWS Management Console Access](#)
6. (Optional) [Apply AWS Policy Settings](#)
7. (Optional) [More Account/Region Specific Configuration](#)
8. (Optional) [Clustering](#)

#### NOTE

To use Privileged Access Manager with AWS, you apply a license with AWS Capability Enabled. You can verify the license on the **Configuration, Licensing** page.

### **Obtain an AWS Account**

You identify an accessible AWS account before configuring Privileged Access Manager to communicate with it. Your organization might already have such an account, or you can set one up at <https://aws.amazon.com>.

#### NOTE

The AWS account must have at least the following privileges:

- ec2:DescribeInstances
- ec2:DescribeTags

Note the character strings for these AWS objects:

- Access Key ID
- Secret Access Key

Select and note the following AWS view:

- AWS (geographical) region - for example, **US East (N. Virginia)**

### **Store AWS Account Credentials in Privileged Access Manager**

So that Privileged Access Manager can coordinate with AWS, first store your AWS account credentials in a target account record in Privileged Access Manager Credential Manager.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**. The Target Accounts page opens.
2. Select **Add**.
3. Begin typing AWS in the **Application Name** field, and select **AWS Access Credential Accounts** from the drop-down list. Alternatively, select the magnifying glass icon to open a modal window to select this application. The **Host Name** and **Device Name** are populated with the AWS-specific names.
4. In the **Access Key** field, assign a user-friendly unique label for your AWS account.
5. Fill in the **Access Key ID** and **Secret Access Key** you collected from AWS.
6. (Optional) If applicable, assign an **Access Role Name**.
7. (Optional) If you use AWS GovCloud, in **AWS Cloud Type** select **Government**.
8. Do not populate any other fields or change any other settings.
9. Select **OK**.

Privileged Access Manager can now use your AWS access credentials for auto-connection in multiple scenarios.

### **Configure AWS Connection**

After you have stored your account credentials, you point to them in your Privileged Access Manager-to-AWS configuration settings and activate a connection.

**Follow these steps:**

1. Select **Configuration, 3rd Party, AWS**.  
The Amazon Web Services (AWS) panel appears.
2. Select the **Add** button.  
The **Add AWS Connection** window appears.
3. Select your previously set user-friendly Account Name from the **Access Key** drop-down list.
4. In the **Region** field, select your applicable geographical region.
5. (Optional) Select the **Active** checkbox to prompt importing devices with (AWS) State="running" (without an AWS "Xsuitelgnore" tag). Otherwise, only the validity of your stored account-region pair is tested.

**NOTE**

For clustered environments, to avoid importing devices multiple times, causing duplicate device conflicts and exceeding your license, only set the primary member of the primary site as "Active."

6. Select **OK** to confirm the connection, and if activated, perform the initial account-region device import from AWS. You receive a confirmation at the top of the page that the connection has been validated. The **AWS Configured Configurations** tab displays an account-region line item.

Your Privileged Access Manager connection to this AWS account is now activated for the selected region. The connection is available for access to AWS Management Console and is used for importing devices. The imported devices are visible and available for use on the **Devices, Manage Devices** page, where you can edit the Privileged Access Manager-applied (not the imported) fields.

**Configure AWS Settings**

Use these steps to set the refresh rate as well as the how to display the **Access Key** field in the UI.

**NOTE**

Upon upgrade to version 3.4.4 or later, the **Use ID** becomes the default: this setting makes the **Access Key ID** the default display name.

**Follow these steps:**

1. Select **Configuration, 3rd Party, AWS**.  
The Amazon Web Services (AWS) panel appears.
2. Select the **AWS Settings**. See the following Configure AWS Settings:
  - a. In the **Refresh Interval** field, enter the frequency of the download of device information from Amazon. Interval defaults to 60 minutes, but can also be set to 15, 30, or 45 minutes. You can also
  - b. Select how to display the **Access Key** field in the UI:
    - Select the **Use Alias** radio button to display the more user-friendly value, Access Key Alias, in the UI.
    - Select the **Use ID** radio button to display the AWS-generated Access Key ID in the UI.
3. Select **OK**.

**NOTE**

All other currently-open pages that have the AWS credentials loaded must be refreshed for this change to take place.

**Provision AWS Management Console Access**

After you store your account credentials, set a user policy with a controlled-access web portal that opens the AWS Management Console.

**Follow these steps:**

1. Select **Policies, Manage Policies**.

The Manage Policies page opens.

2. Select the **Add** button.

The Add Policy window appears.

3. In the **User** or **User Group** field, start typing the User or User Group you want the policy to apply to. Select the matching full name from a filtered drop-down list.
4. In the **Device** field, select **http://xceedium.aws.amazon.com** from the drop-down filtered list.
5. Set up the policy link:
  - a. Select the **Services** tab, and select **AWS Management Console SSO**. Select the arrow to move the service to Selected Services.
  - b. In the Target Account files next to the service, select **AWS Access Credential Accounts - Access Key**.
  - c. Select in the field marked **AWS Policy**, and select an available setting, such as **IAMUserAccess**.
6. Select **OK**.  
On their **Access** page, provisioned users and user group members should now have a web portal type link **AWS Management Console SSO** for device **http://xceedium.aws.amazon.com**.
7. Log into PAM using an AWS-provisioned user or user group member and select the **AWS Management Console SSO** link.
8. On the **Available Credentials** dialog that appears, select the **userID-govcloud** entry. If you cannot access the AWS GovCloud, ask the AWS GovCloud administrator to assign, at minimum, the following policy to the **userID-govcloud** account:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:GetFederationToken",
      "Resource": [
        "arn:aws-us-gov:sts::*:federated-user/*"
      ]
    }
  ]
}
```

For more information about AWS policies and permissions, see [https://docs.aws.amazon.com/IAM/latest/UserGuide/access\\_policies.html](https://docs.aws.amazon.com/IAM/latest/UserGuide/access_policies.html).

### **Apply AWS Policy Settings**

To ensure transparent login access to this site from Privileged Access Manager, the AWS Management Console requires a current, appropriate AWS policy. The default settings and any custom settings require communication with AWS. See [http://docs.aws.amazon.com/IAM/latest/UserGuide/access\\_policies\\_inline-using.html](http://docs.aws.amazon.com/IAM/latest/UserGuide/access_policies_inline-using.html) for more information.

#### **Follow these steps:**

1. In **Policies, Manage Policies**, Select the **AWS Policies** link.
2. Select an existing, or create a new, AWS Policy.
3. Apply the following AWS IAM policy settings to its **Policy** field, and Select **OK**:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:GetFederationToken",
```

```

        "Resource": "*"
    }
}
]
}

```

4. Be sure to use this revised AWS Policy in the Services policy template for an applicable User with "http://xceedium.aws.amazon.com".

### **More Account/Region Specific Configuration**

#### ***S3 Mounts***

Amazon S3 mounts can no longer be assumed in the (sole) AWS Account and Region that are specified in release 2.2.0. On the **Configuration, Logs, Session Recording** page, **NFS/CIFS/S3 Settings**, you must explicitly identify which **AWS Provision** (Account and Region) to use.

#### **WARNING**

**Warning:** If there is an active S3 mount using a particular **Configuration, Logs, Session Recording, NFS/CIFS/S3 Settings, Amazon S3** provision setting at the time you attempt to remove its corresponding connection from **Configuration, 3rd Party, Amazon Web Services (AWS) Configuration**, the connection is not dropped. The mount remains intact, and an error message is displayed on the **3rd Party** page.

#### **Clustering**

The members of a Privileged Access Manager synchronization cluster that is created within AWS must be located within the same AWS VPC subnet.

Synchronization can no longer be assumed in the (sole) AWS Account and Region that are specified in release 2.2.0. On the **Configuration, 3rd Party, Clustering** page, you must explicitly identify which **AWS Provision** (Account and Region) is being used.

When configuring your AWS connections (see [Configure AWS Connection](#)), set only the primary member of the primary site as "Active." This restriction helps you avoid importing devices multiple times, causing duplicate device conflicts, and exceeding your license.

#### **NOTE**

- [Integrating an AWS API Proxy \(Optional\)](#)

## **Configure and Manage Session Recording**

Configure session recording to enable PAM to create and store recordings of supported (CLI, RDP, VNC, and Web Portal) connection sessions.

### **Session Recording Overview**

Each session recording is stored or referenced within PAM using the following elements:

- The recording itself, in a media file (with associated file extension) corresponding to the nature of the session:
  - **RDP session:** `.gsr` graphical session recording file.
  - **VNC session:** `.vsr` graphical session recording file.
  - **SSH session:** `.txt` CLI (text-based) session recording file.
- A *metadata file* that contains information about the session recording. These metadata files are created by session recording reconciliation, which is described in the following section.

**IMPORTANT**

Metadata files have the *same name* as the session recording with which they are associated but with a **.inf** extension. For example, the metadata file that is associated with `session_recording_filename_1.gsr` is `session_recording_filename_1.inf`

**NOTE**

There are also other session recording file types that are used internally. You can ignore these, but *do not delete* them.

- An entry in the *session recording database* that references the session recording media file and information about the recording from the metadata file. The session recording database is used to populate the **Session Recording Viewer**.

**Session Recording Reconciliation**

PAM runs the following *session recording reconciliation processes* that identify session recordings that do not have a corresponding metadata file or database entry and, if so, creates the missing element:

- **Most Recent Recordings:** Reconciles recent session recordings. Runs hourly.
- **All Other Recordings:** Reconciles other session recordings. Runs daily.
- **Restored Recordings:** Reconciles session recordings [recovered from archives](#). Runs hourly.

**TIP**

You can check the status of the session recording reconciliation processes on the [System Info pane](#) **System Activity** tab.

**NOTE**

Session recording reconciliation processes do not run while a PAM server is in maintenance mode.

**Mount an NFS, CIFS, or S3 Network Share for Session Recordings**

Text-based recordings can be stored on a remote syslog server, a mounted network share, or both. Graphical recordings must be stored on a mounted NFS, CIFS, or S3 network share.

This procedure describes how to mount an NFS, CIFS, or S3 network share to enable recording for graphical or text-based session recordings.

**NOTE**

For information about syslog servers, see [Remote Syslog Server Configuration](#)

**NOTE**

When mounting an NFS or CIFS share for session recordings, configure appropriate privileges for the specified directory on the host system. For an NFS share, grant read, write, and execute permissions (`rwx`) to everybody. For a CIFS share, grant **Full Control** to **Everyone**.

**Follow these steps:**

1. Navigate to **Configuration, Logs, Session Recording**.
2. Select the **External Storage** tab.
3. In the **Primary Mount Settings** section, select one of the following network share protocols from the **Protocol** drop-down list:
  - NFS (version 3 and 4 are supported)
  - CIFS
  - Amazon S3
  - NFS (Verify Certificate)
 Option fields relating to the selected protocol are displayed below the **Protocol** drop-down list.
4. Complete the option fields that are associated with the selected protocol:
  - **NFS:**

- **Share Path:** Enter the directory path name of the NFS mount point.

**IMPORTANT**

In a multi-cluster environment, you must configure a separate NFS mount point for each cluster.

**WARNING**

Do not use the same NFS mount point that you are using for [scheduled database backups](#). The session recording and scheduled database backup processes create and delete a file with the same name to check the remote storage status. If you specify the same NFS mount point, file locking can occur as both processes attempt to create or delete the same file.

- **Hostname:** Enter the IP address or hostname of the server with the share.
- **Request Timeout:** Optionally, enter a non-default timeout value (in tenths of a second) for NFS requests. If no value is specified, the default is determined by the NFS server, typically 600.

**NOTE**

We recommend that if the NFS server does not respond quickly enough that you accept the default **Request Timeout** to avoid latency. However, if NFS storage is down, you can set a lower value to receive early notification.

- **Encrypt in Transit:** Allows PAM to send session recording data over a secure (TLS) channel. No remote server certificate verification is performed. If remote server certificate verification is required, select NFS (Verify Certificate) protocol.

– **CIFS:**

- **Share Path:** Specify the mount point using the format `\\hostname\share` . (You can also use forward slashes.)
- **Username:** Specify a user who has read and write access to the remote share.
- **Password:** Specify the password for that user.
- **Domain:** Specify the CIFS domain.
- **SMB Version:** Select the version of Server Message Block that is used by the target system. Newer versions of SMB are more secure. If you no longer support older file shares (like Windows 2003), we recommend using SMB2 or SMB3, provided the CIFS system supports it.

**NOTE**

Azure does not support mounting an Azure file share in a different region than your Azure Privileged Access Manager VM.

– **Amazon S3:**

- **Bucket:** Enter the AWS bucket to use.
- **AWS Provision:** Select the appropriate entry from the drop-down list.

**NFS (Verify Certificate):**

- **Encrypt in Transit:** Allows PAM to send session recording over a secure (TLS) channel.
- **Verify Certificate Chain:** Allows PAM to verify the remote server certificate and the complete chain of the remote server certificate.
- **Verify Hostname(s):** Specifying one or more hostnames allows PAM to check if the certificate Subject Alternative Name (SAN) or Subject Common Name (CN) matches the specific host names.

**NOTE**

The **Verify Certificate Chain** and **Verify Hostname(s)** options involve verification of a remote server certificate. The CA bundle, including the public key of the remote server certificate, must be uploaded into PAM. Select **Configuration, Security, Certificate, CA Bundles**.

5. Select **Save Settings**.

A confirmation message appears at the top of the screen.

6. Select **Mount**.

A success or an error message appears at the top of the page.

**IMPORTANT**

If you must unmount a configured NFS share and restart the NFS server, wait at least 2 minutes for the NFS share to become available before attempting to remount that share.

**Network Mount Point Subdirectories**

PAM stores session recordings in the following subdirectories that it creates under the configured mount point::

- On each day that sessions are recorded, a correspondingly named *daily subdirectory* (*YYYYMMDDPAM*) to store those recordings. For example, if the mount point share path is `/var/nfsshare`, the session recordings for Jun 7, 2022, are stored in `/var/nfsshare/20220607PAM`.

**NOTE**

The daily subfolders are transparent to session viewers; the physical location of files is not shown on the **View Session Recordings** panel.

- A `recoverPAM` subdirectory that is used when restoring archived files. For example, if the mount point share path is `/var/cifsshare`, the `recoverPAM` subdirectory is located at `/var/cifsshare/recoverPAM`. For more information, see [Archive and Recover Session Recording Files](#).

**Verify the Status of a Mount**

The **Mount Status** field displays whether the share is mounted or unmounted. If the share is mounted, **Mount Status** displays the status of the mount: **available** or **unavailable**

If **Mount Status** shows **unavailable**, the share is still mounted but not currently accessible (for example, due to network problems or share permissions). In this case, there is no need to remount the share. When the issue causing the share to be inaccessible is resolved, the status changes back to **available**

**WARNING**

By default, an access policy can specify that a session is to be recorded. If the configured network share becomes unavailable, users cannot establish a connection to the share. To allow such sessions to connect anyway, change the [session recording access policy](#) to **Connect anyway. (Operationally Safe)** For optimal security, we recommend that you keep the default access policy and configure [session recording failover](#).

**(Optional) Set Up Session Recording Failover**

To avoid losing session recording ability due to a storage failure, mount a secondary share to provide failover. Session recording failover dynamically switches over to the secondary share without any loss of data. While the secondary share is in use, you cannot view session recordings on the secondary or the primary share until the primary is restored. To restore session recording on the primary share, the primary share must be back online. When the primary share comes back online, recordings that were split across the two shares are automatically recombined. You can then view the recordings seamlessly.

To configure failover mount settings, navigate to **Configuration, Logs, Session Recording, External Storage**. The configuration for the failover mount settings is identical to the configuration for [Primary Mount Settings](#).

**Activate Session Recording**

To active session recording, specify one or more of the types of sessions that you want to record.

**Follow these steps:**

- Navigate to **Configuration, Logs, Session Recording**.
- Select the **Session Recording** tab.
- Specify the types of sessions that you want to record. Set one or more of the following options on the **Configuration, Logs, Session Recording** screen:

- **Text-based recording to the syslog server**
- **Text-based recording to a NFS/CIFS/S3 mounted directory**
- **Graphical session recording to a NFS/CIFS/S3 mounted directory**

These recording options are unavailable until you configure the required [syslog server](#) or network mounts.

4. **Allow External Storage for Large Session Recording Decryption:** If storage on your appliance becomes limited, large session recording files might become unviewable. Select this option to allow the decryption of large session recordings on the external storage. We attempt to use appliance storage first, and only use external storage when necessary. The decrypted files are deleted from external storage periodically. If you never want decrypted session recording files on your own storage, leave this option in its default cleared state.
5. Select the **UPDATE** button to save your changes.

#### NOTE

To prevent failures, unset the appropriate option if a share is nearing capacity.

### Specify Which Sessions to Record

Use one of the following mechanisms to record sessions:

- **Automatically, by policy** – When provisioning a policy in each **Policies, Manage Policies**, User/Device record, you can elect to activate recording based on the following criteria:
  - Media type: graphical, command line, bidirectional command line, web portal
  - On violation: socket filter or command filter violation
 For more information, see [Set Up a Policy](#).
- **Manual** – Privileged Access Manager administrators can activate session recording while a session is taking place using controls on the **Sessions, Manage Sessions** screen. Each session line item has a recording stop/start switch. For more information, see [Session Management](#).

#### TIP

View recorded sessions from the **Sessions, Session Recording** panel. For more information, see [View Session Recordings](#).

### Change the Session Recording Access Policy

By default, if the configured network mount becomes unavailable, users cannot establish a connection if their session should be recorded. Use the controls on the **Access Policy** tab to change the access policy to allow such sessions to connect anyway.

#### NOTE

For optimal security, we recommend that you keep the default setting and configure [session recording failover](#), described in this topic.

#### Follow these steps:

1. Navigate to **Configuration, Logs, Session Recording**.
2. Select the **Access Policy** tab.
3. Select one of the following options to dictate how the product responds if the session recording mount is unavailable:
  - **Present an error and do not connect. (Security Safe):** This option is the default. If a User is configured for session recording and the mount point is unavailable, do not allow the User to connect to the target device. The **Error Message** entered in the text box is presented to the User. If the mount point is lost during a previous session, the User connection is terminated.
  - **Connect anyway. (Operationally Safe):** If a user is configured for session recording and the mount point is unavailable, allow the user to connect to the target device anyway. Users are not inhibited from accessing the device, but no session recording is created for this session. If the mount point is lost during a previously started session, the user is allowed to continue, but their session is no longer recorded.

4. (Optional) Specify a non-default **Initial Failure Timeout** value (in seconds). The default value is 300.
5. (Optional) If you set the **Present an error and do not connect** option in Step 3, you can enter an **Error Message**. This error message is displayed if a user cannot connect or has been disconnected because of a mount error. If nothing is entered in this field, a generic message is presented.
6. Select the **UPDATE** button to save your changes.

#### **(Optional) Configure a Session Recording Purge Policy**

Optionally, configure a session recording purge policy to set up automatic deletion of session recordings after a specified number of days.

##### **NOTE**

The purge job runs nightly at midnight UTC.

##### **Follow these steps:**

1. Navigate to **Configuration, Logs, Session Recording**.
2. Select the **Purge Policy** tab.
3. Specify the number of days after which session recordings are automatically purged in the **Remove Records Older Than** field. For example, if you set **Remove records older than** to 5, session recordings made more than five days ago are purged

##### **NOTE**

To disable automatic purging of session recordings, set the **Remove records older than** value to zero (0).

4. Specify the number of days after which restored session recordings are automatically purged in the **Remove Restored Recordings Older Than** field. For example, if you set **Remove Restored Recordings Older Than** to 5, session recordings made more than five days ago are purged
5. To purge recordings that include violations, unset the **Exclude Recordings With Violations** option. When the "exclude" checkbox is selected, you retain recordings with violations rather than purge them.
6. To purge recordings that are identified as suspicious by Symantec Threat Analytics, unset the **Exclude Suspicious Recordings** option. When the "exclude" checkbox is selected, you retain suspicious recordings rather than purge them.
7. Select the **UPDATE** button to save your changes.

#### **(Optional) Archive and Restore Session Recordings**

To preserve sensitive session recording files that you might require later (for example, recordings that show suspicious activity), *archive* them to another location. You can then restore those files for viewing in the PAM UI later (for example, for a security audit).

##### **NOTE**

Archiving sensitive files is important if you have configured a purge policy that would otherwise delete them.

##### **To archive session recording files, do the following steps:**

1. Log in to the physical or virtual host where the session recordings are stored.

##### **NOTE**

Text-based recordings can be stored on a remote syslog server, a mounted network share, or both.  
Graphical recordings can be stored on a mounted NFS, CIFS, or S3 network share.

2. Navigate to the file system location in which the session recordings are stored.

##### **NOTE**

Recordings made by PAM versions earlier than 4.1.1 are stored directly in the mounted directory. Recordings that are made by PAM version 4.1.1 and later are stored in subdirectories that are created and named for the day on which they were recorded (*YYYYMMDDPAM*).

3. Locate the session recording files that you want to archive.
4. Copy or move the recording files *and their associated metadata files* to a designated archive location.

**To restore archived session recording files for viewing, do the following steps:**

1. Locate the session recording files and their associated metadata files in the archive location.
2. Move the files to the `mountpoint_sharepath/recoverPAM` directory. For example, if the mount point share path is `/var/cifsshare`, the `recoverPAM` directory is located at `/var/cifsshare/recoverPAM`.

Within an hour, a session recording reconciliation process restores the files to the session recording table in the database and the recordings appear in the **Session Recording Viewer**.

## Use Logs to Monitor Operations and User Sessions

As an administrator, set up the logs to audit server operation, monitor user sessions and log session recordings.

Two types of server log files are available:

- Session logs, which collect user activity
- Syslog, which captures system operations

You can also specify a Splunk server to collect and log appliance behavior. To specify a Splunk server, go to **Configuration, 3rd Party, Splunk**.

The following topics discuss these two logs:

### Session Logs for User Activity

The session logs contain records that capture user activities. These logs are stored in an internal MySQL database, or you can route them to an external MySQL server. For clustered systems, an external server is recommended to aggregate the messages.

For session log messages, you can:

- Purge the contents of a log file – manually or automatically, based on a schedule you determine. For automatic purges, you can email copies of purged messages to an administrator. We recommended that copies of the messages be sent to an outside syslog consolidation server.

To configure session logs, select **Configuration, Logs**. Expand **Logs** to see the configuration choices.

#### **NOTE**

Session log files contain the IP address of the device requesting access. If your server is behind a networking device, such as a proxy, load balancer, or router, verify that the device prevents against IP spoofing of the X-Forwarded-For HTTP header.

- Save the log files as reports. If necessary, you can download these reports. For information viewing session logs and create reports, see [Session Management](#).

### Syslog for System Operation

The syslog provides comprehensive information about system operation, down to the component level. The syslog data is written to a text file. To configure syslog, select **Configuration, Logs, Syslog**.

Syslog-based activities include:

- User logins and logouts
- User requests for resources
- Violations
- Alerts
- System information

For syslog messages, save logs to an external server. Logs are saved in a comma-separated value (CSV) file format, which can be imported to spreadsheets and other applications. Reporting can be performed at the syslog level. Alternatively, a security information management tool can collect the syslog messages. When clustering is used, events are not consolidated.

### WARNING

To save syslog data to a log, configure a remote syslog server. Otherwise, the syslog records are not saved.

## Purge Session Logs Automatically

Use the automatic log purge feature to schedule the ongoing emailing and purging of logs. You can automatically purge logs from the database at a specified interval, between one hour and 120 days. An email containing a copy of the deleted logs can be sent to the administrator for long-term storage.

To save and purge log entries on demand, use [Save or Purge Session Logs Manually](#).

### NOTE

**Prerequisite:** The email account that is configured in **Configuration, Monitor** is the recipient of the log email. To receive an email, you must configure the email settings in the Monitor fields **Admin Email**, **SMTP Server**, and **Appliance From Address**. For instructions, see [Set Up Email for Monitoring](#).

Follow these steps:

1. Go to **Configuration, Logs, Automatic Log Purge**.
2. Select the **Enable as scheduled below** checkbox to turn on automatic purging.
3. Select the **Purge Interval** from the list of defined intervals. This number determines the frequency that logs are deleted.
4. Select the **Require Email Be Sent Before Purge** checkbox to send an email containing a copy of the deleted logs to the administrator.  
Messages in the body of the email are separated by carriage returns.
5. Select the **Email Size** (1 MB to 10 MB) to correspond to limitations of your SMTP server.  
If the log is larger than the email, the email is divided into multiple emails.
6. Select **Purge All Members in This Site** to purge the session logs from all the cluster members in this cluster site.

### NOTE

In a primary site, session logs are replicated among the site members, but in secondary sites, session logs are not. When you select this option in a primary site, one member purges sessions logs. Then the purge action (not the selected option) is replicated to other primary site members. In a secondary site, selecting the option replicates the selection and directs each site member to purge its own session logs.

7. Select **Update** to save your settings.  
If you change your settings without updating them, you can return to the previous settings by selecting **Reset**. This action does not return the settings to a default.

## Save or Purge Session Logs Manually

Automatic log purges are the recommended method of deleting logs. However, begin with a manual log purge. For a manual log purge, the best practice is to save, purge, download, and then delete the logs.

**Follow these steps:**

1. Go to **Configuration, Logs, Manual Log Purge**.
2. Use the **Until** calendar to specify a date up to which logs are saved or purged. The date is inclusive, so the logs from that date are also saved or purged.
3. Select **Purge All Members in This Site** to purge the session logs from all the cluster members in this cluster site.
4. Save the logs to a temporary file on the server by selecting **Save to File**.  
The logs are saved in a CSV file that is named with the end date you specified. The file is listed on the **Download/Delete Log Files** tab.
5. Purge the logs by clicking **Purge**.  
The logs are purged up to and including the specified date.
6. Download the saved file to your local computer. Go to the **Download/Delete Log Files** tab, select the file, and select **Download**.
7. To delete the CSV file from the server now that it exists locally, select **Delete** on the **Download/Delete Log Files** tab.  
This action frees up space on the server.

To purge all logs without saving them, select **Purge All** at the bottom of the page. We do not recommend this action.

## Configure an External MySQL Database for Session Logs (Optional)

You can configure an external MySQL database to store session logs. A copy of the log files is automatically kept on the local server in an internal database.

### NOTE

These procedures apply only to session logs; not to syslog messages.

### Configuring User Privileges for your MySQL Database

The user for the MySQL database where PAM stores session logs must have the following privileges:

- SELECT
- INSERT
- UPDATE
- DELETE
- CREATE
- REFERENCES

The following example procedures describe how to create a database, and then create a user with the appropriate privileges. Your actual procedures may be different based on your environment.

### **Follow these steps to create a MySQL database and a user with the correct access rights:**

1. As the user `root` or as a database administrator, run the following command to create the database where PAM should store the session logs:

```
create database <db_name> DEFAULT CHARACTER SET utf8mb4 DEFAULT COLLATE utf8mb4_unicode_ci;
```

Where `<db_name>` is the name of the database you are creating.

2. Run the following command to create the DB user that PAM uses to access this database:

```
create user '<db_username>'@'%' IDENTIFIED WITH mysql_native_password BY '<db_password>';
```

Where:

- `<db_username>` is the name of the database user you are creating.
  - `<db_password>` is the password for the database user you are creating.
3. Run the following two commands to grant the database user the SELECT, INSERT, UPDATE, DELETE, CREATE, and REFERENCES privileges on the database that you created:

```
GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, REFERENCES ON <db_name>.* TO <db_username>@'%';
FLUSH PRIVILEGES;
```

Where:

- <db\_name> is the name of the database
  - <db\_username> is the name of the database user
4. if you are using MySQL version 8:
    - a. Edit the MySQL configuration file. Under [mysqld], change the default\_authentication\_plugin to mysql\_native\_password.
    - b. Restart MySQL

## Configuring PAM to Recognize your MySQL Database

Follow these steps to configure PAM to recognize your PAM Server:

1. Go to **Configuration, Logs, External Log Server**.
2. Select the **Enable logging to the external server** checkbox.
3. Select **local** or **external** for which logs are shown by default.
4. To allow regular users to change the view from **local** to **external**, select the **Allow user to change view** checkbox.
5. For the MySQL server settings, complete the following fields:
  - **Server:** Enter the IPv4 or IPv6 address of the MySQL server.
  - **Port:** By default the port is 3306, otherwise, enter the port number.
  - **DB Username:** Specify a user with SELECT, INSERT, UPDATE, DELETE, CREATE, and REFERENCES privileges to the database.
  - **DB Password:** Enter the password for the database user.
  - **Database Name:** Enter the name of the database.
6. Click **Update** to save your settings and activate external logging.

If you change your settings, but you do not update them, you can return to the previous settings by selecting **Reset**. This action does not return the settings to a default.

## Configure a Splunk Server for Logging

A Splunk server works with the PAM appliance to monitor logs. Splunk collects information from the application code, and then sends data as key/value pairs. This format makes the information easier to consume, such as in reports or on dashboards.

PAM forwards logs to Splunk servers using a logstash component that runs inside a docker container. This mechanism allows PAM to support more options to connect to Splunk servers, along with two additional formats, Space Delimited and JSON, for the audit and metric log messages. These new options are available immediately with a fresh installation.

### NOTE

Deployments with Splunk servers configured prior to **upgrading** to PAM 4.0.2 (or later) can preserve their legacy Splunk configuration to support backward compatibility. This is called legacy Splunk mode. Users that upgrade to 4.0.2 but do **not** have any Splunk servers currently configured use the new functionality. Such users will not see the **Use Legacy Splunk Mode** option.

In legacy Splunk mode, Splunk Forwarder 6.2 (instead of the new logstash) forwards the logs to the Splunk servers. The legacy Splunk mode has limited connectivity options, and only supports the TCP protocol.

Depending on your PAM version and current Splunk server configuration, have three options to configure your Splunk server. You can also configure your Splunk server as a Syslog server.

## Configure Splunk Servers

Use these steps to add or configure Splunk servers.

### Follow these steps:

1. Go to **Configuration, 3rd Party, Splunk**. The default display shows the **Splunk Servers** tab. This tab displays, if any, the currently-configured Splunk server name, access port, security protocol, and whether the Splunk server uses Transport Layer Security (TLS).
2. Select **Add**.  
The **Add Splunk Server Configuration** screen appears.
3. In the **Address** field, enter either the Splunk server IP address or Fully Qualified Domain Name (FQDN). For FQDN, the DNS must be set up properly on the **Configuration, Network, Network Settings** page. A specified FQDN can be no longer than 255 characters.
4. Enter the **Port** to use on the Splunk server.

#### NOTE

Configure the port on the Splunk server by selecting **Settings, Data Inputs**. Depending on the protocol to configure(TCP / UDP), select **Add New**.

5. Select the desired **Protocol** to use: **TCP** or **UDP**. If you select **TCP**, the **Enable TLS** option becomes available.
6. Select **Enable TLS** to ensure that data is sent over a secure communication channel.

#### NOTE

If you want to use the **Enable TLS** feature with PAM, make sure to configure TLS on the Splunk server as well.

7. Select the **Test** button before saving this information to assess if the Splunk configuration is correct. A message appears to remind you to check the Splunk server to verify that the test message appears on the Splunk server.

#### NOTE

The **Test** button does not verify the configuration by itself. Selecting the **Test** button means PAM sends a test log message to the address and port number of the Splunk server. You must check the Splunk server to verify if the message was received.

8. Select **OK** to save and exit this window.
9. Repeat for each server.
10. Use the **Update** button to edit a selected server in the Server list.
11. Select the **Splunk Settings** tab.
12. Select the format to send messages to Splunk servers from the **Message Format** drop-down list: **XML** (the default), **Space Delimited**, or **JSON**.

#### NOTE

The **Message Format** *ONLY* applies to the audit and metric logs.

Selecting **Update** on the **Splunk Settings** tab affects all currently-configured Splunk servers. You do not have to select the message format for each Splunk server.

13. Select **Update** to commit your selection.

#### NOTE

After saving the configuration, the system requires a few seconds for the logstash service to start, and for the server to receive the logs.

## Configure Splunk as a Syslog Server

A second option is to configure your Splunk server as a Syslog server. Syslog sends data on UDP port 514 by default. You can change this port to match your Splunk Receive Data port setting. Syslog is configured from the **Configuration, Logs, Syslog** page. See [Configure a Remote Syslog Server](#) for more information.

## **Configure Legacy Splunk Servers**

Follow these steps to configure or maintain your legacy Splunk configuration. On the **Splunk Settings** tab, the **Use legacy Splunk mode** option is enabled to indicate that you are in legacy mode. Note that the Legacy Splunk mode has limited Connectivity options, and only supports the TCP protocol.

### **Follow these steps:**

1. Go to **Configuration, 3rd Party, Splunk**.
2. Select **Add**.  
The **Add Splunk Server Configuration** window appears.
3. Enter the Splunk server IP address and port in the appropriate fields. For the **Address**, enter either the Splunk server IP address or Fully Qualified Domain Name (FQDN). For FQDN, the DNS must be set up properly on the **Configuration, Network, Network Settings** page. A specified FQDN can be no longer than 255 characters.  
**Note:** The port is configurable in Splunk, under **Settings, Forwarding and Receiving, Receive Data**.
4. Select **OK**.
5. Repeat for each server.
6. Use the **Update** button to edit a selected server in the Server list.

## **Migrate Legacy Splunk Servers**

Follow these steps to migrate your legacy Splunk servers to the new Splunk configuration. Upon successful migration, all existing server configurations will be used by Logstash inside PAM to forward logs to Splunk servers.

### **NOTE**

Be advised that you cannot reverse the migration. A warning message appears prompting you to confirm the migration. After this migration, you must reconfigure the Splunk server to ensure all logs get forwarded without any issues. Your Splunk server list in PAM does not require reconfiguration.

### **Follow these steps to migrate legacy Splunk servers:**

1. Go to **Configuration, 3rd Party, Splunk**.
2. Select the **Splunk Settings** tab.
3. Clear the **Use Legacy Splunk Mode** option.
4. Select **Update**.
5. In the message that appears, confirm that you want to disable legacy mode.

### **NOTE**

After you have disabled legacy mode, refer to the following section named [Configure New Splunk Servers](#) for more information.

## **Configure a Remote Syslog Server**

You can configure external Syslog servers to receive and save syslog events. You must configure a remote syslog server to save syslog records.

### **Follow these steps:**

1. Go to **Configuration, Logs, Syslog**.
2. Set the **Syslog Enabled** option.
3. From the **Message Format** drop-down list choose one of the following formatting options for messages that are sent to the Syslog servers:
  - **XML** (the default)
  - **Space Delimited**
  - **JSON**

**NOTE**

The specified **Message Format** *only* applies to the audit and metric logs. For more information, see [Syslog Message Formats](#).

4. Select the **Add Server** button (blue with a white plus sign) to add a new syslog server. A new row appears in the table.
5. In the **Server** column field, enter either the server IP address or Fully Qualified Domain Name (FQDN).
6. Optionally, specify a **Port** value for the remote syslog server. If you leave the port blank, it defaults to 514.
7. Select the desired **Protocol** to use: **TCP** or **UDP**. If you select **TCP**, the **TLS** option becomes available.
8. Optionally, select **TLS** to ensure that data is sent over a secure communication channel.

**NOTE**

If you want to use the **Enable TLS** feature with PAM, make sure to configure TLS on the Syslog server as well.

9. Select **Update** to save your settings and activate the servers.

**NOTE**

After saving the configuration, the system requires a few seconds for the logstash service to start, and for the server to receive the logs.

If you change your settings, but you do not update them, return to the previous settings by selecting **Reset**. This action does not return the settings to a default.

## Configure a Server Control User Activity Server

You can configure up to two external logging servers for Server Control Utility Appliances to receive and save user activity log events. You must configure a remote logging server to save Server Control user activity log records.

### Follow these steps:

1. Go to **Configuration, Logs, Server Control User Activity**.
2. Select the **Enable Event Forwarder** checkbox to send PAM Server Control user activity log events to the remote server.

**NOTE**

The **Event Forwarder** service uses the TCP protocol to forward the events to an external SIEM server (for example, splunk). Therefore, make sure to configure the SIEM server to listen over TCP.

3. In the **Primary Server** text box, enter either the server IP address or Fully Qualified Domain Name (FQDN) of the primary server.

**NOTE**

You can use a FQDN for the remote logging server if the Utility Appliance can resolve the domain name. If not, you must use the IP address instead.

4. In the **Failover Server** text box, enter either the server IP address or Fully Qualified Domain Name (FQDN) if the backup server takes over if the primary server fails.
5. Specify a **Remote Port** value for the remote server. If you configure two remote server destinations, both must use the same port.
6. Select **Update** to save your settings and activate the servers.

**WARNING**

If you change the **Port** value, you must do one of the following procedures after applying that change (as appropriate for your environment):

- **Standalone appliance:** Restart the appliance.
- **Clustered environment:**
  - a. Stop the cluster.

- b. Restart each node that is connected to a remote server.
- c. Start the cluster.

If you change your settings, but you do not update them, return to the previous settings by selecting **Reset**. This action does not return the settings to a default.

### WARNING

If one or more Server Control Utility Appliances are present in your deployment, any updates made on the Server Control User Activity config in PAM will get propagated to all Utility Groups. In a PAM cluster, any PAM node can overwrite the previously configured Event Forwarder that has been used by the Utility Groups.

## Troubleshoot User Interface Problems

As an administrator, you can capture logs from user interface interactions to help troubleshoot problems. You should only undertake these steps with the help of Broadcom Support.

### User Interface Activity

The user interface generates many messages, which the UI Logging captures as log entries. At the "Debug" level, each user can generate hundreds of entries logging in, hundreds of entries per minute, and thousands per day. UI logging is only done for one individual user at a time.

### NOTE

In clustered environments, UI logging is not supported on Secondary sites. A cluster user on a Secondary site must recreate the UI problem on a Primary site.

Example of UI Log entries:

```
Date,Username,ClientIP,LogLevel,Detail
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.view.common.main.MainGlobals.getConfigurationOptionValue() - configuration option
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.view.common.main.MainMenu.createMenuItems() - Menu item not visible for Devices
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.view.common.SystemGlobals.hideGlobalMask() called maskRequestCount = 1
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.view.common.NavigationManager.initializeNavigationManager() - Performing first setup
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.store.common.FilterView.afterLoadCallback() - successfully loaded 1 records
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.store.users.LoggedInUser.afterLoadCallback() - successfully loaded 1 records
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.view.common.SystemGlobals.hideGlobalMask() - hiding mask since no more requests!
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.view.common.SystemGlobals.showGlobalMask() called for first time!
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.view.common.main.MainGlobals.loadStores() - Starting load of global discovery stores
2018-02-01 16:51:30.0,standard,10.1.7.7,DEBUG,CA-
PAM.view.common.main.MainGlobals.loadConfigurationOptions() - Starting load of feature
```

## **Troubleshooting Example**

A user has an issue that is related to the user interface, and contacts an administrator. The administrator is unable to solve the problem, and contacts Broadcom Support. The support engineer assists the administrator in taking these steps:

1. If you are using a Multi-Site cluster, determine whether the user is logged on to a Primary or Secondary site member.
2. Request that the user log out from Privileged Access Manager.
3. The administrator logs in. If it is a cluster, log in to the Primary site.
4. Purge any UI logs.
5. Enable UI logging. The UI Log option only appears on the Primary site of a cluster.
6. The user must then log in again to the Primary site.
7. The user should repeat the actions that led to the issue.
8. Request that the user logout.
9. Disable UI Logging.
10. Inspect the UI Log entries. Look for errors, configuration problems, or other clues suggested by the specific user experience.

## **Enable UI Logging**

UI Logs can only be enabled for one user at a time. This user must already exist as a Session Manager User.

### **Follow these steps:**

1. Go to **Configuration, Diagnostics, UI Log**.  
The **UI Log Settings** tab appears.
2. Select the **Enable UI Logging** checkbox.
3. To select a **UI Logging User**, click the Select magnifying glass icon. The **Session Manager Users** dialog appears. Select a User and click **OK**.

### **NOTE**

The administrator can only enable UI logging on the Primary site of a cluster. The user must then log in again to the Primary site to recreate the issue.

4. Select the **Log Level**.
  - **Error** saves Error messages only.
  - **Info** saves Error and Info messages.
  - **Debug** saves Error, Info, and Debug messages.
5. The **Log Purge Interval** is how often the purge runs, in hours. **Log Purge Retention** is how much log data to retain, from one to seven days. For example, the default interval is hourly, and the default retention is daily. If enabled, this configuration keeps data for the most recent 24 hours, deleting anything older than that every hour. Therefore, you would always have from 24 through 25 hours of the most recent data.
6. Click **Save** to save your settings and activate UI logging.

## **Inspect Log Entries**

The second tab on the UI Log page is **UI Log Entries**. This tab is the only place to view the UI log entries, although you can download them. The entries are logged in the database, and can be downloaded as a CSV file.

### ***Filter***

You can filter the entries that are displayed using the **Column** and **Value** fields, and clicking **Filter**.

- You can combine filters by selecting **Add Filter** and selecting multiple **Column** and **Value** combinations.
- To search on a date and time range, use the **Start Timestamp** and **End Timestamp Columns**.
- The **Message** column Value accepts \* (asterisk) as wildcards. You can use \_ (underscore) as a single character wildcard.  
*For example, filtering on \*config\* can return changed configuration settings.*
- The **Reset** button removes all filters and displays all log entries.

### View

The **View** button displays the details for a selected (highlighted) log entry. Double-click the entry for the same result.

### Download

The **Download** button downloads the log entries to a CSV file on your local computer. If a **Filter** is active, only the results are downloaded.

### Purge All

The **Purge All** button deletes *all* log entries immediately.

## Diagnostics and Troubleshooting

The Privileged Access Manager Diagnostics page is available from the Configuration menu. The information that is collected there is used for Broadcom Support analysis of Privileged Access Manager operation.

### NOTE

When preparing a diagnostics package, use these functions only under the direction of Broadcom Support.

### Next Steps

- [Configure Diagnostic Logs](#)
- [Configure Performance Graphs](#)
- [Configure System Diagnostics, Maintenance, and Cluster Tuning Options](#)
- [Tools](#)

## Configure and Obtain Diagnostic Logs

Use the **Diagnostic Logs** pane (**Configuration, Diagnostic Logs**) to configure the detail level of and obtain diagnostic logs that are required to analyze issues with your environment.

### IMPORTANT

The **Diagnostic Logs** pane is intended for use when working with Broadcom Support to access diagnostic logs that they require to analyze issues with your environment. Only log levels if you are instructed to do so.

The **Diagnostic Logs** panel contains the following tabs:

- **Log Levels** tab: Change the detail level of diagnostic information that is collected by a particular log or logs, then select the **Submit** button to commit your changes. Otherwise, leave the default values.

### WARNING

Log files can grow rapidly if you set their log level to a more detailed value. Restore them to a lower level when the higher level is no longer required. To monitor disk usage, select **System Info** at the top of the PAM UI. If it is too high, reboot the PAM server to clear the logs.

- **Download** tab: Access recent log entries or download complete log files from the PAM server to your local system so that you can send them to Broadcom Support for diagnostic inspection.

The following sections describe how to set the detail level of and download log files, as applicable.

### Set the Detail Level of and Access the Tomcat Log

The Tomcat `catalina.out` log file is used to diagnose Credential Manager issues.

To change the detail level of the Tomcat log, open the **Log Levels** tab and select the required value from the **Tomcat Log Level** drop-down menu.

**Values:** "Severe" "Warning" (the default), "Info", "Config", "Fine", "Finer", "Finest", and "off"

To see recent unfiltered log entries from the Tomcat log in a dialog, open the **Download** tab and select the corresponding **Recent Log Entries** button. To download the `catalina.out` file, select the associated **Download** button.

### ***Access the Internal Connector Framework Log***

To view recent unfiltered Internal Connector Framework log entries, open the **Download** tab and select the associated **Recent Log Entries** button. To download the Internal Connector Framework log file, select the associated **Download** button.

### ***Set the Detail Level of and Access the Symantec PAM as SAML RP Log***

To change the detail level of the Symantec PAM as SAML RP log, open the **Log Levels** tab and select the required value from the corresponding drop-down menu.

**Values:** "Normal" (the default) or "Verbose"

To see recent unfiltered log entries from the Symantec PAM as SAML RP log, open the **Download** tab and select the corresponding **Recent Log Entries** button.

### ***Set the Detail Level of and Access the Symantec PAM as SAML IdP Log***

To change the detail level of the Symantec PAM as SAML IdP log, open the **Log Levels** tab and select the required value from the **Symantec PAM as SAML IdP Log Level** drop-down menu.

**Values:** "Normal" (the default) or "Verbose"

To see recent unfiltered log entries from the Symantec PAM as SAML IdP log, open the **Download** tab and select the corresponding **Recent Log Entries** button.

### ***Set the Detail Level of the Web Services Log***

To change the detail level of the Web Services log, open the **Log Levels** tab and select the required value from the **Web Services Log Level** drop-down menu.

**Values:** "Error" (the default), "Warning", or "Debug"

### ***Set the Detail Level of the Utility Orchestrator Log***

To change the detail level of the Utility Orchestrator log, open the **Log Levels** tab and select the required value from the **Utility Orchestrator Log Level** drop-down menu.

**Values:** "Off", "Error", "Warning", "Info", "Debug" (the default), or "Trace"

### ***Set the Detail Level of the LDAP Sync Log***

To change the detail level of the LDAP Sync log, open the **Log Levels** tab and select the required value from the **LDAP Sync Log Level** drop-down menu.

**Values:** "Normal" (the default) or "Verbose"

### ***Set the Detail Level of the Applet Log***

To change the detail level of the applet logs, open the **Log Levels** tab and select the required value from the **Applet Log Level** drop-down menu.

**Values:** "Error", "Warning", "Info", "Debug" The default is "Error".

**NOTE**

The specified value is replicated to all cluster members.

### ***Enter Applet Debugging Commands***

If Broadcom Support provides you with applet debugging commands, open the **Log Levels** tab and enter the commands in the **Applet Debugging** field. If there are multiple commands, enter them as a comma-delimited list.

**NOTE**

The specified commands are replicated to all cluster members.

### ***Download System Diagnostics Files***

To download system diagnostics files, open the **Download** tab and use the following **System Diagnostics Files** options (as applicable):

- If Broadcom Support asks you to change the number of days of system diagnostics files to download, use the **Past Days** field. (Range: 1 to 30; default: 14). Set the **All Logs** option to specify that the download should include all available days.
- Select the **Download** button to save the files to your local system.

**NOTE**

If core dumps are being collected, they are included in the system diagnostics download.

### ***Use a System Log Configuration File to Specify Multiple Log Files to Download***

To download multiple log files that are specified in a System Log Configuration File provided Broadcom Support, do the following steps using the **System Log Configuration File** controls on the **Log Levels** tab:

1. Select the **Choose File** button.
2. In the **File Upload** panel that opens, locate the System Log Configuration File on the local drive and select **Open** to upload it into PAM.
3. Select **Download** to download specified log files.

### ***Set the Detail Level of and Download SPFD (Secure Port Forwarding Daemon) Logs***

To change the detail level of the SPFD and WolfSSL logs, open the **Log Levels** tab and select the required value from the **SPFD Log Level** drop-down menu.

- **Info** (Default): Only info-level events are included in the SPFD and WolfSSL logs.
- **Debug**: Debug-level events are included in the SPFD log; Only info-level events are included in the WolfSSL log.
- **Info+WolfSSL**: Only info-level events are included in the SPFD log; Debug-level events are included in the WolfSSL log.
- **Debug+WolfSSL**: Debug-level events are included in the SPFD and WolfSSL logs.

To download the SPFD log for the service provider daemon to your local system, open the **Download** tab and select the corresponding **Download** button.

### ***Download Analytics Logs***

To download analytics logs to your local system, open the **Download** tab and select the corresponding **Download** button.

### ***Download Service Desk Logs***

To download service desk logs to help troubleshoot issues with an integrated [service desk solution](#), select the corresponding **Download** button.

## Configure Performance Graphs

Privileged Access Manager activity can be graphed by turning on Performance Graphs. Follow these steps:

1. Go to **Configuration, Diagnostics, Performance Graphs**.
2. Select **On**, then select **Submit**.  
Graphics can take 20 minutes to be displayed. The following dimensions are displayed:
  - a. **CPU Utilization**
  - b. **Outgoing Network Activity DD/MM/YYYY**
  - c. **Incoming Network Activity DD/MM/YYYY**

## Configure System Diagnostics, Maintenance, and Cluster Tuning Options

You can configure the following functions on the **Configuration, Diagnostics, System** page:

- system diagnostics
- maintenance options
- cluster tuning options

After enabling or disabling any modes, select the **Submit** button.

### System Diagnostics Options

Use the following system diagnostics options in coordination with Broadcom Support to allow them to analyze and troubleshoot the operation of your PAM environment.

#### **Enable AACTRL Debug Mode**

Set the **AACTRL Debug Mode** option (on the **Modes** tab) only if instructed to do so by Broadcom Support.

#### **Enable Remote Debugging Services**

The **Remote PAM Debugging Services** mode lets Broadcom Support access your appliance for debugging purposes. Enable this mode only at the instruction of Broadcom Support. Otherwise, keep this setting turned off.

If you enable Remote PAM Debugging Services, be aware of the following information:

- If you upgraded from PAM 3.2 with debugging enabled, the expiration date is automatically set to 30 days from the current date and time. You can update this expiration date.
- If you activate FIPS mode when Remote PAM Debugging Services mode is on, the service setting is turned off. If necessary, return to this screen and set this mode back on.
- If PAM is operating in FIPS mode and you set **Remote PAM Debugging Services** on, rebooting the appliance turns off the setting. If necessary, return to this screen and set this mode back on.

#### **Follow these steps:**

1. Select **Configuration, Diagnostics, System**.
2. For Remote Debugging Services, Select **On**. When you select On, an expiration date and time appears that is seven days from the current date and time.
3. To change the expiration date for access to these services, select **Until**. Select a date and time from the calendar and time selection drop-down list.
4. When your changes are complete, select **Submit**.

#### **Run System Diagnostics**

Use the System Diagnostic tool (on the **Download** tab) to gather information about specific file versions. The tool provides a listing of file names, showing the dates that they were modified and their file versions. To run the system diagnostic, follow these steps:

1. Obtain a configuration file from Broadcom Support.
2. Save the file in a location accessible to the appliance.
3. Go to the **Download** tab on the **Configuration, Diagnostics, System** page.
4. Select **Choose File** to access the configuration file.
5. Select **Run System Diagnostic**.  
The system downloads the result in the diagnostic.enc file.
6. Follow any further instructions from Broadcom Support.

### ***Activate the System Monitor Tool***

Select the **Activate System Monitor** button (on the **Download** tab) to obtain encrypted output of system diagnostics information.

## **Maintenance and Cluster Tuning Options**

Use the following options to enable maintenance mode and cluster tuning.

### ***Enable Maintenance Mode***

Enable the **Maintenance Mode** option (on the **Modes** tab) to prevent new user logins so that an administrator can perform configuration changes. These changes might otherwise disrupt or be disrupted by user activity. In Maintenance Mode, when a user who is not a Global Administrator tries to log in to the appliance, the user sees an error message: "This Privileged Access Manager is in maintenance mode. Only admin level users can log in."

The following conditions also apply in Maintenance Mode:

- Prevents new, scheduled jobs from running
- Prevents non-administrative users from logging in. To log in, a user role requires the privilege "configurationManage."
- The internal load balancer for the appliance does not send traffic to a node in maintenance mode. If all cluster members are in maintenance mode, traffic is still routed to one of the members. However, only a PAM administrator can log in.

### **NOTE**

Although new logins are prevented, current user logins are not disconnected at the time Maintenance Mode is set. The administrator might, for example, send an email requesting currently connected users log out, or when necessary, force disconnections through the **Sessions, Manage Sessions** interface.

Maintenance Mode does not disable the Credential Manager CLI.

### **To disable the Credential Manager CLI, follow these steps:**

1. Go to **Configuration, Security, Access**.
2. On the **Access** tab, select Disabled for **Credential Manager CLI**.
3. Save the change.
4. If necessary, restart the appliance.

### ***Enable Cluster Tuning Mode***

Enable the **Cluster Tuning Mode** option (on the Modes tab) to enable you to alter default settings for a cluster. If **Cluster Tuning Mode** is enabled, the tuning settings are found on the **Cluster Tuning** tab of the **Clustering Configuration** page. Certain of those settings should only be changed in consultation with Broadcom Support.

See [Set Up a Cluster](#) for more information about clustering, and [Cluster Tuning](#) for specifics about these settings.

## Networking Tools

The Networking Tools page (**Configuration, Tools**) provides network diagnostic tools. Use these tools to check device connectivity and troubleshoot communication from the Privileged Access Manager appliance. Test networking with the standard ping, traceroute, DNS resolution, and port scan. These settings define attributes to provisioned objects such as Users, Devices, and passwords, but are not derived from, or attached to any specific objects.

### *Ping*

Enter an IP address and select the **Ping** button to initiate an ICMP echo to the device associated with that address. The Ping Result window appears with ping statistics.

### *Traceroute*

Enter an IP address and select the **Traceroute** button to identify a network route from Privileged Access Manager to the device with that address. The Traceroute Result window appears with route trace results.

### *Resolve Name*

Enter a hostname and select the **Resolve Name** button to determine the IP address of that host. The Name Resolve Result window appears with the IP address result.

### *Port Scan*

No default range of ports is assumed for the Ports field. You must enter your desired port scan range. Use a comma between ports or a dash to specify a range of ports. You can combine these methods, for example: 22,23,45-1024. Do not insert spaces.

1. In the **IP Address** field, enter the target IP address for the port scan.
2. In the **Ports** field, enter the range of ports you want to scan.  
Commonly used ports:  
HTTP 80  
HTTPS 443  
RDP 3389  
SSH 22
3. In the **Timeout** field, enter a desired timeout in minutes.
4. Press the **Port Scan** button to initiate a scan of open ports on the device that is associated with that address.  
The Port Scan Result window appears with the port type, status, and service

### *Bulk Network Scan*

When enabled from [Global Settings](#), the Bulk Network Scan tool allows Administrators to run a bulk scan of their network (Host/Port) to determine the status of ports (open/filtered).

Bulk Network Scans are invoked by uploading a CVS file where each line is of the following format:

```
IP address, Port, Options
```

Both the IP Address and the Port fields can accept ranged values (example: 10.17.43.1/24,21-100). Options can be any valid nmap options except -oX, -oN, -oG, -oS, -oA, -iL (example: -n -T4 -sT -PN --max-scan-delay 0ms).

A Bulk Network Scan runs locally on the PAM node it is initiated from, so progress and results can only be checked on the same PAM node.

Only one Bulk Network Scan can be initiated on a PAM node at a time. Starting a new Bulk Network Scan after one has completed overwrites the results of the previous scan.

The maximum size of the CVS input file for a Bulk Network Scan must not exceed 1 MB. The file that results from the scan that you download is limited to 10 MB.

To run a Bulk Network Scan, follow these steps:

1. Select the **Download Sample File** link.
2. Prepare the CVS file.
3. Select **Start Scan**. The scan progress bar shows the status of the scan. You have the option to cancel the scan at any time. You can navigate away from this page and return at any time.
4. When the scan is complete, the **Download Results** button activates. The results are delivered as a CVS file compressed with gzip.
5. To start a new scan, select a new file and choose **Start Scan**.

## Set Up Email for Monitoring (Legacy)

Configure the general monitor parameters that Privileged Access Manager uses to send alert emails.

### NOTE

DNS must be configured in **Configuration, Network**, and working for the monitoring function to run.

To set these parameters, follow these steps:

1. Go to **Configuration, Monitor (Legacy)**.
2. Enter an email address for the Privileged Access Manager administrator in **Admin Email**. Consider a role account to allow multiple recipients.
3. Enter the **SMTP Server** as an IPv4 address, an IPv6 address, or an FQDN host. (For IPv6 addresses, enclose the IP with square brackets.)
4. Enter a valid email address as the **Appliance From Address**. This address appears as the "From" field of any Privileged Access Manager monitoring email.  
**Note:** A trailing or leading space also causes an error.
5. Select a value, in seconds for the **Re-check Time** to check for alerts.
6. Enter an FQDN in **DNS Test Query** to test that DNS is available and operating correctly.
7. To start the monitor, select the **Monitor** tab.
  - a. Select **Start at boot** to start the monitor when Privileged Access Manager boots up. Select **Save** to save that setting.
  - b. Select **Start** to start the monitor immediately.
  - c. Select **Stop** to stop the monitor immediately.

The read-only **Running** checkbox indicates whether the monitor is running.

## Microsoft Office 365 Configuration

Privileged Access Manager offers support for the protection of Microsoft online services to secure and audit privileged users accessing Microsoft Office 365. To connect to your Office 365 installation and configure Privileged Access Manager, follow these steps:

1. Go to **Configuration, 3rd Party, Microsoft Office 365**.
2. Enter your Office 365 configuration information:
  - a. Enter the **Security Token Service (STS) Endpoint URL**. In general, specify the appropriate URL that is exposed by your organization Active Directory Federation Service (ADFS). The endpoint must support the WS-Trust 2005 (username mixed mode) protocol.  
For example: `https://<ADFS Server FQDN>/adfs/services/trust/2005/usernamemixed`  
This value is user-supplied and might change.
  - b. Enter the **Security Token Service (STS) Endpoint Reference URI**. When ADFS is federated with Microsoft Online (MSOL), this value is typically:  
`urn:federation:MicrosoftOnline`

- c. Enter the **Microsoft Online Portal URL**. For example: <https://login.microsoftonline.com/login.srf>
- d. Enter the **Microsoft Online Portal Context Data**.
  - For Office 365 on Windows Server 2012 and later, ADFS 3.0 does not support "smart links." Make a connection to Office 365 from a browser and capture the entire URL string. You can use a product such as HTTP Analyzer or Fiddler to capture the string.
  - For earlier versions of Office 365, before ADFS 3.0, derive the value by "creating a smart link." Microsoft no longer supports or documents this procedure, but you can find smart link generators online.
3. Select **Save**.
4. Select **Ping** to test the information you entered.

## Power, Reboot, and FIPS Mode Controls

This content describes how to shut down or reboot a physical or virtual appliance instance. It also describes how to activate FIPS mode.

### Shut Down or Reboot a Physical Appliance

To shut down or reboot a physical appliance, navigate to the **Configuration, Power** pane in the PAM UI and select the corresponding option:

- **Power Off Appliance**: Shut down the appliance remotely. Note the following information
  - The power switch on the physical appliance remains in the ON position.
  - The **Configuration, Power** pane indicates that the appliance is shutting down but does not update.
- **Reboot Appliance**: Shut down then reboots the appliance remotely.

### Virtual Appliance Power Settings

To safely shut down or reboot a virtual appliance, navigate to the **Configuration, Power** pane in the PAM UI and select the corresponding option:

- **Stop Instance**
- **Reboot Instance**

If the PAM UI is not accessible, use the options for your platform:

- For Azure, use the **Start**, **Stop**, and **Restart** options from the Azure portal.
- For AWS and VMware instances, use the **Reboot** or **Power off** option on the PAM Utility Console.

### WARNING

If you are using the vSphere client, do not shut down the PAM instance using the Power Off option. Use the vSphere Power, Shutdown Guest OS, or Restart Guest OS option.

### Activate FIPS Mode

To implement FIPS encryption, complete the following procedures to enable FIPS mode on your PAM appliance.

### WARNING

After you activate FIPS mode, it cannot be undone.

### **Download the FIPS Software**

Download the software for this component from the Broadcom Support site. For information on how to download it, see [Download PAM Installation Media](#).

### **Activate FIPS**

### WARNING

- Before you activate FIPS mode for appliances in a cluster, turn off the cluster *first*. To turn off the cluster, navigate to **Configuration, Clustering**. Stopping or rebooting a cluster member requires cluster resynchronization.
- Ensure that you have access to the certificates that you have uploaded. You have to upload them again after activating FIPS.

After you install the PAM with FIPS, follow these steps:

1. If you are using PKI/Smart Card for user login, disable this feature:
  - a. Navigate to **Configuration, Security, Access**, and select the **PKI/Smart Card Options** tab.
  - b. Set the **PKI/SmartCard User Login** option to **Disabled**.
  - c. Select **Save**.

2. Navigate to **Configuration, Power** and select **Activate FIPS Mode**. The appliance reboots automatically after activation.

When PAM is rebooted from the UI, the message the following message displays:

"PAM appliance is rebooting... Please wait until the login screen appears ..."

After the appliance reboots, the UI login page is presented. When a reboot is initiated through a web browser, the login page might not display after the appliance reboots. If you are not returned to the login page automatically, refresh the browser or navigate to the login page by entering the URL for the UI.

3. To verify that FIPS is enabled, select **System Info** in the top-right corner of the UI. On the **Basic Info** tab, the FIPS Mode status should say Enabled.
4. After you enable FIPS mode, reload the certificates from the **Configuration, Security, Certificates** panel. See [Secure Connections Using SSL Certificates](#) for detailed instructions.
5. If you are using PKI/Smart Card for user login, re-enable the option on the **Configuration, Security, Access** panel.

### **Unavailable Configuration Options in FIPS Mode**

In FIPS mode, the following configuration options are not available:

- **Security, SAML, RP Configuration**, the Accept RSA-SHA1 Signed Responses option is hidden.
- **Security, SAML, RP Configuration, Configured Remote SAML IdP**, when you add an Identity Provider, RSA-SHA1 is disabled as a Signature Algorithm option.
- **Security, Access**, the TLS 1.0/1.1 Connection Allowed is disabled
- **Clustering** configuration, the **Generate Key** button is disabled.
- **SNMP** version 2c does not work. Use SNMP version 3 with FIPS Mode.

### **Upgrades and FIPS Mode Operation**

If PAM is already operating in FIPS mode, the appliance remains in FIPS mode after you upgrade to a newer release. If an upgrade impacts cryptographic operations relating to FIPS mode compliance, this information will be stated in the release notes.

Converting from commercial (Non-FIPS) to FIPS mode operation requires license changes. Contact your assigned Account Director for more details.

## **Configure Date/Time Settings**

This content describes how to configure Privileged Access Manager date and time settings which you access by selecting **Configuration, Date/Time**.

Change the date, time, and time zone configuration to set a new clock value.

### **WARNING**

Some processes that are running, such as SysInfo and Session Recordings, continue to use the previous clock value until the services are restarted. To ensure that all processes become synchronized after making a time change, reboot the system.

### **Set the Date and Time**

Modify the date and time settings for the Privileged Access Manager server using the controls on the **Date/Time** tab. The time settings implement the Network Time Protocol (NTP).

### **NOTE**

Each field in the **Date/Time** tab is static, reflecting the clock value at the time the page was opened. If you update the date and time manually, copy the time from a reliable source. Alternatively, use Time Servers.

To modify the date and time settings, enter accurate values in the **Date** and **Time** fields, and select **Update**.

## Specify Time Servers

To obtain the time from an NTP server, specify the time servers in the **Time Servers** tab. Some public servers are provided by default.

### NOTE

When you use a hostname rather than an IP address for an NTP server, ensure that a DNS server is configured. The DNS server ensures that the hostname resolves properly. Configure DNS Servers at **Configuration, Network, Network Settings**. See [Configure Network Settings](#) for details.

### Follow these steps:

1. To specify time servers, enter the fully qualified domain name of each time server you want to use to obtain the current time.
2. Optionally, select the **Synchronize at boot** check box to synchronize the time upon startup or a reboot the system.
3. Select **Save**.

If you are using NTP servers to set the time clock, you can configure NTP authentication so that the server can authenticate the time source.

## Configure the Use of Authenticated NTP

Configure the list of NTP servers in the **Authenticated NTP** tab.

### Follow these steps:

1. Paste the NTPv4 **Autokey** obtained from each NTP server into this section.
2. Select **Authentication Required** to use only authenticated NTP, and not communicate with unauthenticated peers.
3. Select **Save**.

## NTP Status

The **NTP Status** tab displays the status output from the NTP servers, in three parts:

### List of Time Servers

The first section is a list of time servers with a summary of the state of each server.

```

remote          refid          st t when poll reach  delay  offset  jitter
=====
+ntp.wdc1.us.lea 130.133.1.10    2 u  210 1024  377   43.580  -4.860  0.563
*ntp.your.org    .CDMA.          1 u  876 1024  337   25.847   1.148  0.148
-mtpbx.cytranet. 69.89.207.199   3 u   57 1024  377   44.839  -3.248  1.297
+linode.ibendit. 64.250.105.228  2 u  34m 1024  336   14.731  -3.632  0.444

```

The character in the left margin indicates time server status. This character is mapped to the value of the condition column in the Association Identifiers section.

Character	Condition	Description
space	reject	The peer is discarded as unreachable, synchronized to this server (sync loop), or outrageous synchronization distance.
x	falsesticker	The peer is discarded by the intersection algorithm as a <b>falsesticker</b> .

.	excess	The peer is discarded as not among the first ten peers, which are sorted by synchronization distance. This peer is probably a poor candidate for further consideration.
-	outlyer	The peer is discarded by the clustering algorithm as an <b>outlyer</b> .
+	candidate	The peer is a survivor and a candidate for the combining algorithm.
#	selected	The peer is a survivor, but not among the first six peers sorted by synchronization distance. If the association is ephemeral, it may be demobilized to conserve resources.
*	sys.peer	The peer has been declared the system peer and lends its variables to the system variables.
o	pps.peer	The peer has been declared the system peer and lends its variables to the system variables. However, the actual system synchronization is derived from a pulse-per-second (PPS) signal, either indirectly by the PPS reference clock driver or directly by kernel interface.

### Association Identifiers

The second section is a list of association identifiers for the server being queried, with **status** and **condition**. The **reach** column indicates the reachability of the server as **yes** or **no**. The **condition** column indicates its current state. The value `sys.peer` means that the time server is selected for use, while `candidate` means that the time server *can* be used.

```
ind assid status conf reach auth condition last_event cnt
=====
1 16746 943a yes yes none candidate sys_peer 3
2 16747 963a yes yes none sys.peer sys_peer 3
3 16748 9324 yes yes none outlyer reachable 2
4 16749 9424 yes yes none candidate reachable 2
```

### NTP Variables

The third section lists Privileged Access Manager NTP system variables in name-value pairs.

```
associd=0 status=0615 leap_none, sync_ntp, 1 event, clock_sync,
version="ntpd 4.2.6p5@1.2349-o Fri Jul 22 17:30:51 UTC 2016 (1)",
processor="x86_64", system="Linux/3.16.39+pam02", leap=00, stratum=2,
precision=-21, rootdelay=25.847, rootdisp=45.240, refid=204.9.54.119,
reftime=de7a5190.7b075a77 Thu, Apr 12 2018 21:43:44.480,
clock=de7a54fc.a51301ea Thu, Apr 12 2018 21:58:20.644, peer=16747,
tc=10, mintc=3, offset=0.071, frequency=38.384, sys_jitter=2.650,
clk_jitter=0.498, clk_wander=0.055, host="gatekeeper", group="server",
flags=0x410001, digest="sha1", signature="sha1WithRSAEncryption",
update=201804010400, cert="gatekeeper gatekeeper 0x0",
```

until=201904010400

## Troubleshooting

If no record in the second section has value `sys.peer` in its **condition** column, then you do not have a good time server. Because time server synchronization takes time, you may need to select the **Refresh** button several times to get the latest status.

### NOTE

- [Apply Global Settings](#)
- [Apply Your Account Settings](#)

## Set Your Locale

Privileged Access Manager can be set to another locale instead of English. Setting a new locale changes the language of new messages and log data, but not the user interface. Existing data does not change. This change requires an appliance restart to take effect.

### NOTE

All members of a cluster must use the same locale. This setting applies to the back-end server data, not to client user interfaces.

**To change your locale, follow these steps:**

1. Go to **Configuration, Locale**.  
Your current locale is displayed in the **Locale** drop-down list.
2. To change your locale, select it from the drop-down list.
3. Select **Save**.  
The change takes effect when your appliance restarts.

## Change Your UI Language

The Locale setting changes data at the back end. To change the UI language in the PAM Client, see [Deploy the CA PAM Client](#). To change the UI language in a browser, change your settings.

**For example, in Internet Explorer 11, follow these steps:**

1. Select the **Tools** gear icon at the upper right.
2. Select **Internet Options**.
3. On the **General** tab, select the **Languages** button at the bottom of the window.
4. Select the **Language and input settings** button.  
The Language Preference window appears.
5. If your desired language is not listed, select the **Add** button. Find your language and select **OK**.  
**Note:** Some languages have multiple versions.
6. Once your desired language appears in the Language list, drag it to the top of the list, or use the **Move Up** button. Select **OK**.
7. Refresh the browser (select the **F5** key).  
Privileged Access Manager displays in the new language.
8. To change languages, repeat this procedure, moving your desired language to the top of the list. Select the **Remove** button to remove an unwanted language from the list.

**For example, in Internet Google Chrome, follow these steps:**

**NOTE**

Chrome is not supported for Access due to Java limitations, but functions well for administration and configuration.

1. Select **Settings** from the Chrome menu.
2. Select Advanced Settings and find the Languages heading.
3. Select the **Language and input settings** button.  
The Languages window appears.
4. If your desired language is not listed, select the **Add** button.  
**Note:** Some languages have multiple versions. Some cannot be displayed in Chrome.
5. Once your desired language appears in the **Languages** list, select the **Move to the top** option to make it the active language
6. Select the **Display Google Chrome in this language** button.  
If this button does not appear, use the **Add** button to find a different version of your desired language.
7. Select **Done**.  
Privileged Access Manager displays in the new language.

**Localized User Interface**

The Privileged Access Manager UI is optimized for localization.

When you access a target device or other remote entity with the localized product, the access method applets use the same language as the browser. However, the target device or any other remote device remains using the language in which it was installed. For example, a browser is set to Japanese. You launch the SSH applet to connect to a target device operating in English. The SSH terminal menu options are in Japanese but the command-line interface on the target device is in English. The locale of the target device determines the locale of the CLI.

## Configure Custom Branding

This procedure describes how to configure PAM to use your own logo in place of the Symantec logo in the PAM UI.

**Follow these steps:**

1. Go to **Settings, Branding**.
2. Use **Choose File** to select the logo graphics file. Only PNG files are accepted, with dimensions of approximately 55 x 55 pixels.
3. Select **Upload Custom Logo**.  
To use the original Symantec logo instead, select **Revert Logo**.

The uploaded custom logo affects only the logo on:

- The pre-login page on Internet Explorer 11
- The header bar after login

The uploaded custom logo does **not affect** the logo for the following components:

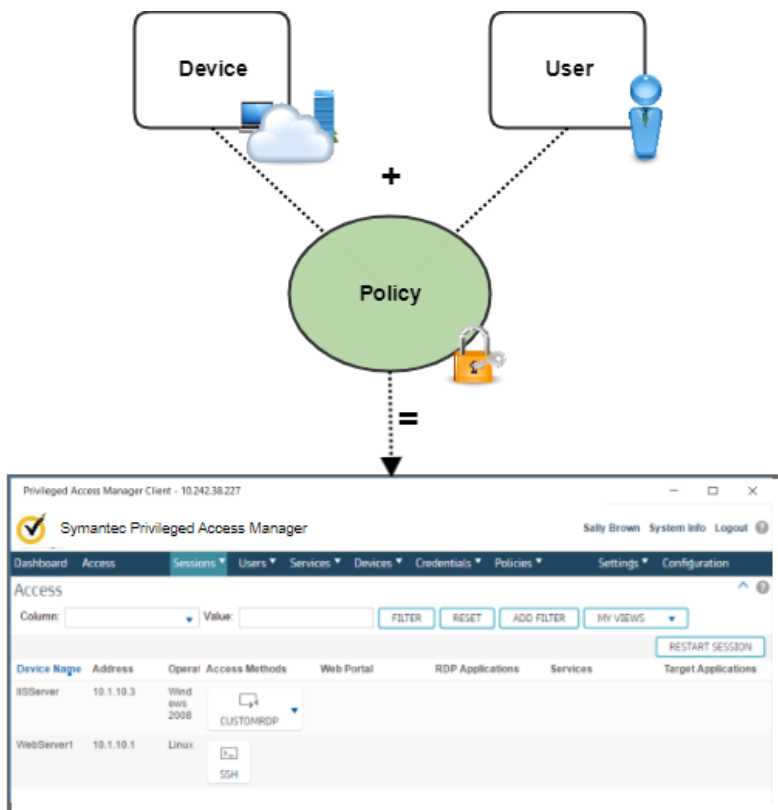

- The PAM Client
- The PAM Access Agent
- The text that appears after the logo

## Implementing Access Control

To configure PAM network-based access control, provision privileged access to devices and applications by configuring the following objects:

- **Devices** – Represent physical devices and IP-addressable applications.
- **Users** – Represent individuals who can log in to Privileged Access Manager.
- **Policies** – Define the relationships between users (or *user groups*) and *devices (or device groups)*, specifying what actions each user is permitted to do with each device.

In simplest terms, policies determine what device access options appear on the **Access** screen of each logged in user and whether their sessions are recorded.

This article describes these objects in more detail.

### Devices

A *device* object is a Privileged Access Manager-managed, IP-addressable network node that is the potential access *target* of a user. For example, a Windows or Linux system. You manage Devices from the **Devices, Manage Devices** screen in the UI.

When creating or importing devices, verify that the **Access** Device Type option is selected, or the device is not available in access policy selection lists.

**NOTE**

The **Password Management** and **A2A** device types are related to credential management. For more information, see [Protect Privileged Account Credentials](#).

**Access Types**

For each device, you specify one or more of the following *access types* to determine the ways in which it can be accessed:

- **Access Methods:** Prepackaged applets that provide standard connectivity
- **Services:** Configure services to extend the types of access beyond the predefined Access Methods to provide custom access to:
  - **TCP/UDP Services**
  - **RDP Applications**

**NOTE**

Access types that are configured at the device level determine all the possible access options available when configuring a policy involving that device. The access type or types that are presented to a *user* are specified in the corresponding access policy.

**Access Methods**

Access Methods are standard prepackaged Java communications applets that run in the PAM Client or a supported browser. Access Methods are available for VNC, TELNET, SSH, RDP, and serial connections. Access methods are predefined with standard ports and available to assign to devices out-of-the-box. To modify the default ports or disable Access Methods go to **Global Settings, Access Methods**.

**TCP/UDP Services**

Configure TCP/UDP Services to define custom access to known ports and to specific applications. These services may include fat client applications such as SQL query frontends, mainframe clients, or any proprietary application that uses a TCP or UDP connection. Web portals and web applications are also configured as Services.

Privileged Access Manager includes several preconfigured SFTP/FTP Services that support common SFTP/FTP servers including OpenSSH-derived Linux, AIX, Solaris SFTP, and Microsoft IIS implementations.

Configure other TCP/UDP Services (from **Services, TCP/UDP Services**) before configuring device definitions that require them.

**RDP Applications**

Define RDP Applications to provide access to RemoteApps – single target-hosted *applications that are published* through RDP protocol – instead of allowing access to the entire desktop.

Configure RDP Applications (from **Services, RDP Applications**) before configuring device definitions that require them.

**Device Groups**

For ease of administration, devices can be added and managed in groups. Devices in a *device group* are those which share common access methods and functionality, such as IIS Web Servers or UNIX and Linux variants. When using device groups, the concept of *deny* takes precedence: So, when selecting the access types available to a group, access types that are unavailable at the device level are not available at the group level. In other words, the most restrictive policy is used when a conflict arises.

When choosing Access Methods and Services for device groups, include *all* possible access methods and services for *all* devices in the group.

## Users

A *user* is a person who can log in to PAM. To simplify management, organize users in *user groups* for simplified management. Use *roles* to determine the permissions that a user has within Privileged Access Manager. User groups follow an inheritance model and roles can be assigned to groups and users.

### NOTE

[Credential Manager](#) has its own set of roles and user groups, separate from the roles and user groups defined for access.

### User Groups

User groups allow common sets of users to inherit the same role, authentication method, and other variables. User groups thus simplify management: a modification to the role for the group changes the role of all members. Groups can also be used when creating *access policies* instead of creating a policy for each individual user.

### Roles

A role is a predefined set of privileges in a functional area. PAM has many predefined roles that satisfy most requirements. You can also create custom roles using built-in granular privileges. *Standard user* is the common role that is assigned to general users accessing devices. For a complete list of user roles, see [User Roles](#).

### User Configuration Methods

You can create local user accounts manually or you can import them from CSV files. Users can also be imported from and synchronized with an LDAP user store such as Active Directory. When configured for RADIUS or PKI, users are added when they *first login* to PAM.

### NOTE

Most PAM production deployments use LDAP or RADIUS for authentication.

## Policies

A policy is a set of permissions that is granted to a PAM user or user group to access the interface of a PAM device or device group. For connections using the SSH and RDP access methods, you can even configure [transparent \(automated\) login](#). Simply put, a policy defines the relationship between a *user* and a *device* and results in an access link or links appearing on the Access page of that user.

For example, the following screenshot shows the Access page for a user for whom a policy assigns the SSH Access Method to a device named UNIX-AUX.

Access				
Column:	<input type="text"/>	Value:	<input type="text"/>	<input type="button" value="FILTER"/>
Device Name ▲	Address	Operatin	Access Methods	Web Por
UNIX-AUX	192.168.0.11	Other		

A policy also optionally specifies whether to record all or some of the actions a user performs while accessing a device. Recording can be enabled based on the specified Access Type. *Command line* and *bi-directional* apply to SSH/Telnet and Mainframe sessions. Graphical recording is available for RDP connection and web portal types.

You can create policies manually or can import them from a CSV file.

#### NOTE

Use [Credential Manager](#) to configure Policies with automated login.

#### NOTE

#### More Information

To configure policies to provision user access to devices and applications, do the following procedures in the order shown:

1. [Configure Devices](#)
2. [Configure Users](#)
3. [Provision Access Policies](#)

## Configure Devices

A *device* is a PAM-managed, IP-addressable network node that is the potential access or password target of a PAM user. Devices are displayed, defined, and otherwise managed through the **Devices** menu on the UI menu bar.

#### NOTE

A device that serves a PAM system is not necessarily an access target in that system. For example, a RADIUS authentication server or syslog storage that provides resources to PAM – but is managed by external administrators – is not listed or managed as a device. However, the attributes of that device are specified in the appliance configuration settings.

- [Set up Command Filters](#)
- [Setting Up Transparent Login](#)
- [Set Up the AWS API Proxy](#)
- [Configure Support for Citrix XenApp Resources](#)

## About Devices

A device represents a PAM-managed, IP-addressable network node. A device is a potential target for access or password management by a PAM user. For A2A deployments, a device can be considered a request server. Devices are displayed and managed through the Devices menu on the Administration menu in the UI.

You do configure other devices in PAM that are not Access or Password Management target systems. For example, RADIUS authentication servers and syslog servers provide resources to PAM, but they are not access targets. These systems are not listed or managed from the Devices page in the UI. These servers are typically configured as third-party systems.

### Access to Devices

Privileged Access Manager enables secure access to devices. PAM does not allow connection to any device until it has been approved at the device level. To complete this approval, access methods must be selected. This procedure can be done either when initially creating the device, finishing edits before access is enabled, or to change methods for existing devices.

### Access Types

#### **Software: Access Methods**

The first way that PAM provides controlled access is to specify fully the communication software that is used to implement a connection. The appliance downloads communication executables (implemented as Java applets) from the appliance to the user workstation or other local computer that wraps the user communication within Privileged Access Manager-controlled communication channels.

One applet is defined as the primary communication applet that is named the UP (Universal Ports). The UP is customized by the policy for each *user*, and is always downloaded at each User login session. Meanwhile, the user can download other applets to communicate with the UP to set up and maintain controlled communication to a *device* through Privileged Access Manager. These applets also have custom features, such as command filtering capability. When the session is finished, the applet disappears. These applets are known as **Access Methods**.

#### **Controlled Local Software: Services**

Another approach is to use ordinary (third party) communication software users have on their computers. This software might already be installed, or Privileged Access Manager can supply it (temporarily). Using parameters that are configured by the PAM administrator, the product directs that software to communicate with the UP so that, like an Access Method, a controlled session can be implemented. These definitions are known as Privileged Access Manager **Services**.

An administration user on known ports and to specific applications can create services. These services can include: fat client access such as SQL query front-ends, mainframe clients, and any proprietary applications, which use TCP or UDP connections. The appliance has several ways to do this:

- Download Privileged Access Manager packaged third-party software, such as a commercial SFTP/FTP package.
- Use a local software installation; for example, PuTTY can be available to implement SSH.
- Use Microsoft Windows RDP if the local computer is a Windows device.
- Establish a console.
- Access a web portal using the local default browser.

### ***Restrict Access to a Windows Application: RDP Applications***

Configure RDP applications With Microsoft Remote Desktop Services (RDS), single target hosted applications can be published through RDP instead of allowing access to the entire target device desktop.

### **Terminal Configuration for Device Access**

For line-mode communication, you have a range of options to package the interface. These options can be imposed generally, and then specifically for each Device Group or individual Device.

#### ***Device Types***

Terminal configuration supports the following device types, each with separate functionality and licensing:

- Access Devices
- Password Management Devices
- A2A Devices

#### ***Grouping Devices***

To provision and manage multiple devices, you can use the following two mechanisms:

- **Device Groups** – A set of devices that inherit the same attributes from the group.
- **Tags** – Tags are device attributes that allow you to assign labels to any particular device, and share the labels across many devices. You can filter on the labels to identify sets of devices.

## **Device Features**

### **Device Types**

Devices are categorized into three types. A Device object can represent any physical device logically using one or more of these types:

**Device Licenses** (Licensing page):

- **Access Device:** Network-addressable computing Device (identified by the label "Access" in Global Settings and in a Device template)
- **Password Device:** Device for which passwords are managed (pushed from Privileged Access Manager) are identified by the label "Password Management" in Global Settings and in a Device template.
- **A2A Device:** Device running application clients that connect to Privileged Access Manager to retrieve passwords (identified by the label "A2A" in Global Settings and in a Device template).

A Device Type license permits a maximum number of Devices for each Device Type. The maximum number and the current count of each Device Type appear on the on the Dashboard Overview Tab under License Usage. The same numbers also appear on the System Information dialog.

**License Usage** (Dashboard Overview Tab):

- **Session Management** license: for an Access Device (can co-exist with Credential Manager Device)
- **Credential Manager** license: for a Credential Manager Device (can co-exist with Access Device)
- **A2A Management** license: for an A2A Device

## **Access Types**

Privileged Access Manager enables secure access to devices, and does not allow connection to any device until it has been approved at the device level. To complete this approval, access methods must be selected. This choice can be made when creating or updating the device, or when changing methods for existing devices.

- **Prepackaged:** Standard access methods have been built as **Access Method applets** and do not require any additional software to be installed on a user desktop.
- **Custom:** In addition to the default applet access, virtually any connection application can be configured to allow access by configuring local Privileged Access Manager **Services**.

## **Access Methods**

Several prepackaged Access Method applets are available, with support for VNC, TELNET, SSH, RDP, and serial connections. Default ports can be modified if the application is running on a different port from the one indicated.

Configuration is required at the following levels:

- **Global-level:** For an access method to be available, it must first be permitted (or "switched on") through the Global Settings interface.
- **Device-level:** In addition to the default applet access, Privileged Access Manager can be configured to allow access to virtually any connection application.

## **Graphical and CLI Applets**

- **VNC:** VNC (Virtual Networking Computing) is a graphical desktop remote access application that transmits keyboard and mouse movements. VNC applet access requires a VNC server to be running on the destination device. To use recording, the VNC server must be set in basic unencrypted mode.
- **Telnet:** Administrators often use this tool to connect to UNIX hosts running the TELNET daemon.
- **SSH:** Secure Shell protocol. The SSH applet connects to servers running the SSH daemon. It does not require the client end user to have SSH client software such as Putty loaded.
- **RDP:** RDP is an access method for connecting to Microsoft Terminal Services and is commonly used for administration of Windows servers. The RDP applet is optimized to take advantage of RDP 6.x compression types, with noticeable reductions in file size in comparison with RDP 5.2.

RDP remote device usernames are not prepopulated from Privileged Access Manager login usernames. Instead, the User can populate this name through a field on the [User Information](#) page

### **WARNING**

Due to limitations in XRDP compression support, RDP-to-XRDP sessions use more bandwidth. Session recordings can be much larger than recordings for RDP-to-RDP sessions. Encryption support requires a setting in the xrdp.ini file on the XRDP host.

- **TLS levels:** As of release 2.6, the RDP client (the applet) supports TLS 1.2 connections and supports the TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA256 cipher suite.
- **Performance:** Sometimes, it is not possible to write an RDP recording to storage as fast as it is being created. In such cases, Privileged Access Manager throttles interaction. From the User point of view, it "slows down." The overall data transfer rate is reduced and writing to the share can be completed.
- **XRDP:** The Privileged Access Manager RDP client applet can also be used to connect with an XRDP server running on a managed Linux Device.

## **Mainframe Applets**

TN3270 and TN5250 are Telnet clients for the IBM mainframe or AS/400 server that emulate 3270 and 5250 terminals and printers. SSL versions are available to provide SSL/TLS support. Support for AS/400-class applet Display Names (TN5250 and TN5250SSL only) is provided on the [User Information](#) page with the Mainframe Display Name field.

- **TN3270**: IBM 3270 Telnet class
- **TN3270SSL**: IBM 3270 Telnet class with SSL
- **TN5250**: IBM 5250 Telnet class
- **TN5250SSL**: IBM 5250 Telnet class with SSL

Due to the variety of target mainframe applications, we do not have a standard automatic login option for the mainframe applets. For TN3270 and TN3270SSL, we offer built-in macros for the username (Ctrl-U) and password (Ctrl-P). During login, the user enters these key combinations to enter the configured user name and password. The password macro only works when the password entry field is hidden, so the password is not visible to the user.

## Services

Services are a way to customize access to the devices. An administrator can create services on known ports and to specific applications. These services can include: fat client access such as SQL query front ends, mainframe clients, or any proprietary applications, which use TCP or UDP connections.

### Prepackaged Services

Services that are prepackaged with the product are identified here.

#### WARNING

Privileged Access Manager ships with several preconfigured SFTP/FTP Services. These services currently support several SFTP/FTP servers including OpenSSH-derived Linux, AIX, and Solaris SFTP implementations. Microsoft IIS SFTP/FTP implementations are also supported with a known limitation when multiple hard drives are present.

While other FTP servers might be compatible, Privileged Access Manager does not test or verify them. The preconfigured services must be used to track target device SFTP/FTP activity to meet compliance requirements for many customers. The activity is tracked in session logs. The service names that are suffixed with "emb" provide the WinSCP client to users without any FTP client application installed. We encourage input on any FTP servers that appear incompatible with Privileged Access Manager, and consider adding support for more FTP servers as business needs permit. Our goal is to provide the most comprehensive access solution for our customers while balancing the need for Access Control and Audit.

## Types

- **sftpftp**: With use of an SFTP client, transports files to and from FTP servers.
- **sftpsftp**: With use of an SFTP client, transports files to and from SFTP servers.
- **sftpftpemb**: This service downloads an WinSCP client to the user desktop. WinSCP is a free and open source SFTP and FTP client for Microsoft Windows.
- **sftpsftpemb**: This service downloads the WinSCP client to the user desktop.

#### WARNING

When running SFTPFTPemb or SFTPSFTPemb, a default option for WinSCP file transfer causes the resulting file to be partially saved. Change the setting for **Preferences, Other general options: Preferences, Transfer: Endurance, Enable transfer resume/transfer to temporary filename for**. Change the default setting of "Files above: 100KB" to "Disable", then users can successfully "PUT" files onto the remote server.

## RDP Applications

With Microsoft Terminal Services, single target-hosted applications can be published through RDP instead of allowing access to the entire desktop. This functionality is only available to servers running Microsoft Terminal Server. On Windows Server 2008, more setup is required.

## Discover Devices on Your Network

To quickly discover and add multiple devices instead of adding each manually, use the device discovery feature, which identifies and registers devices in bulk.

To use device discovery to find network devices and bring them under management by PAM, navigate to **Devices, Discovery** and perform the following procedures:

1. [Create a device scan profile and optionally configure the scan to run on a schedule.](#)
2. [Run a device scan profile manually](#)
3. [View device scan results](#)
4. [Configure PAM to manage discovered devices](#)

Related procedures:

- [Export device information to a CSV file](#)
- [Update discovered devices](#)
- [Delete scan profiles](#)

### Create a Device Scan Profile

Create a device scan profile to specify the properties of the devices that the scan should include or exclude, such as operating systems and IP address ranges. You can also configure the scan to run automatically by configuring a schedule.

1. Select the **Device Scan Profiles** tab and select the **Add** button.
2. On the **Profile** tab, name the profile, and enter an optional description.
3. Optionally, set the **Auto-manage devices** option to automatically put all discovered devices under PAM management.

#### **TIP**

The **Auto-manage devices** option is not set by default because device discovery may identify many devices on your network that you will not want to manage with PAM. If you have a large amount of devices on your network that you will not want to manage with PAM, we recommend that you do not set this option and [manually configure PAM to manage appropriate devices](#) later.

4. In the **Default OS** field, select an OS to narrow the specific discovery criteria or select **Other**.

#### **NOTE**

Device discovery may not reliably identify certain Windows OS versions. If the scan results show an incorrect operating system version, you can change it once the device is under management by PAM. To update the OS, select **Devices, Manage Devices**, and update the **Operating System** field.

5. To specify the number of days after which discovered devices are deleted, set the **Purge Interval (in days)** field. Unless the device is discovered by a different scan profile, the device is deleted. (The default value for the purge interval default is set under **Global Settings, Basic Settings, Scan Purge Interval**.)
6. If device discovery does not determine a location automatically, specify it in the **Default Location** field.
7. Identify at least one target IP address or one device name to include in the discovery on the **Inclusions** tab. You can include multiple entries for each type of target. Select the plus sign to add entries.
  - Specify IPv4 addresses using slash notation (for example, 192.168.2.0/24). All subordinate addresses are included as part of the scan unless there is a corresponding Exclusion address. Wildcards and address range notation is allowed for IPv4 addresses. Use asterisks as wildcards in the format 192.169.0.\*. Specify ranges in the format x.x.x.x-x.
  - If IPv6 is enabled, IPv6 addresses can also be scanned. For IPv6, use CIDR notation (for example, fd6d:8d64:af0c:1:0:242:22:11/120).

**NOTE**

Take care when selecting the CIDR range, as the CIDR value determines the total number of addresses scanned by Device Discovery.

For example, entering `fd6d:8d64:af0c:1:0:242:22:11/120` specifies scanning 256 device addresses, while `fd6d:8d64:af0c:1:0:242:22:11/116` specifies scanning 4,096 device addresses.

- Device name discovery requires configuration of a DNS server in the appliance. Add DNS Servers in the Network Configuration section accessible from the **Config** menu.
8. Optionally, configure the following other settings to refine your scan results:
    - Specify IP addresses to exclude from the scan results on the **Exclusions** tab. Use the same notation as for inclusions.
    - Specify which of the default access methods (as defined on the **Settings, Access Methods** panel), to include in the scan results on the **Access Methods** tab.
    - Specify which services to include in the scan results from those listed on the **Services** tab. The available services are those defined on the **Services, Manage TCP/UDP Services** and **Services, Manage RDP Applications** panels.
    - Specify which device groups (as defined on the **Devices, Manage Groups** panel), to include in the scan results on the **Device Groups** tab.
    - Specify tags to add to discovered devices on the **Tags** tab. Tags are free-form labels that can be added to individual device definitions but which PAM compiles into a list which is available for addition to all devices. You can also create new tags in the **Tag Name** section below the selection columns.
    - Specify available target applications such as SSH, LDAP, and MSSQL to include in the scan results on the **Target Applications** tab.
  9. Optionally, configure a schedule on which to automatically run the device scan on the **Schedule** tab. After you select a frequency, other fields appear. Select the appropriate time intervals.
  10. Select **OK** to save the scan profile.

**Run a Device Scan Profile Manually**

To run a device scan manually, select the scan profile from the **Device Scan Profiles** list, and select the **Run** button.

**NOTE**

You can also create a schedule to run a scan when configuring the [device scan profile](#).

**Review the Status and Results of Your Device Discovery Jobs**

The topics in this section describe how to use the various ways you can view the status and results of your device discovery jobs.

***View the Status of Discovery Jobs in Progress***

Once a scan is running, review its progress on the **Discovery Jobs** tab. You can also cancel the job on this panel by selecting the **Cancel Job** button. Once it is complete, view a summary of its results on the **Device Scan History** tab.

**NOTE**

The **Discovery Jobs** and other tables are refreshed according to the **Table Refresh Interval** value set on the **Basic Settings** tab on the **Global Settings** panel. The default value is 60 seconds.

***View the Results of Completed Device Discovery Scans***

This content describes how to use a number of ways to view different information about the results of device discovery scans.

Navigate to **Devices, Discovery** and select the **Device Scan History** tab to open the **Most Recent Scans** panel from where you can access the results of all completed device discovery scans. The panel provides a sortable, filterable table

of the most recent scans, each row showing the name of the scan profile, when it was last run, and summary values for the following details:

- **Devices:** The total number of devices discovered.
- **New:** The number of new devices discovered since the scan profile was last run.
- **Not Found:** The number of devices that were discovered the last time the scan profile was run but *not* found by the latest scan.

#### NOTE

Select any of the summary values to open the **Scan Results** dialog at the corresponding tab. That is, selecting the **New** value displays the **New Devices** tab.

To see different views of a device scan on the **Most Recent Scans** panel, select the corresponding table entry and select one of the following buttons:

- **View Summary Details:** Opens the **Scan Results** dialog at the default **Scan Information** tab, which displays the scan profile name and the job time. The **Discovered Devices**, **New Devices**, and **Not Found Devices** tabs list the names of the corresponding devices. The **Logs** tab displays a table including each action that is taken regarding this scan.
- **View Scan Results:** Displays a table of the following information about discovered devices: device name, operating system, and status. The checkboxes in the "Is Managed" column specify whether devices are currently managed by PAM [and allow you to change that state](#).
- **View Scans:** Shows all the scans that are run for a given profile. The resulting table lists details for each job. Select a Scan Discovery Time and either View Summary Details for lists of discovered device names (use **View Scan Results** for detailed, updatable information).

To see all discovered devices rather than only devices for a given scan, select the **Discovered Devices** tab at the top of the Discovery panel.

#### NOTE

The number of items in the **Device Scan Results** is controlled by the **Global Settings** panel. **Default Screen Size**, under Basic Settings, defaults to 30. This option also controls the number of items that are shown in the Device discovery lists.

### View the Details of All Discovered Devices

To view the details of all discovered devices, navigate to **Devices**, **Discovery** and select the **Discovered Devices** tab, which displays a list of all discovered devices, their operating system, scan status, and latest discovery time. The checkboxes in the "Is Managed" column specify whether devices are currently managed by PAM [and allow you to change that state](#).

### Manually Configure PAM to Manage Discovered Devices

By default, the **Auto-manage devices** option in the device discovery profile is not set so the discovery job does *not* automatically place discovered devices under management by PAM. This is because device discovery may identify many devices on your network that you will not want to manage with PAM. This also allows you to "stage" devices and verify that they are valid before configuring PAM to manage them.

To enable access control and credential management for discovered devices, configure PAM to manage those devices.

**To configure PAM to manage specific discovered devices, follow these steps:**

1. Open the panel that displays the devices that you want to bring under PAM management:
  - Navigate to **Devices**, **Discovery**, select the appropriate scan profile entry, and select the **View Scan Results** button.
  - Navigate to **Devices**, **Discovery** and select the **Discovered Devices** tab
2. Select the rows of the devices that you want to manage.
3. Select the **Manage** button above the "Is Managed" column and select **Yes** in the dialog that appears.

To configure PAM to manage *all* discovered devices, follow these steps:

1. Navigate to **Devices, Discovery** and select the **Discovered Devices** tab
2. Select the **Manage All** button.

### **Export Devices**

Select the **Export** button to send detailed information about each discovered device to a CSV file.

### **Update Discovered Devices**

Select the **Update** button (which is only active for one device selection at a time) to display the **Update Discovered Device** dialog. The various tabs allow you to change the management, access methods, services, and applications associated with the selected device. The **Device Information** tab provides details, such as IP address, OS detail, status, and other information.

#### **NOTE**

The number of items in the **Discovered Devices** list is controlled by the **Default screen Size** setting on the **Basic Settings** tab of the **Global Settings** panel and defaults to 30. This setting also controls the number of items that are shown in the **Device Discovery** lists.

### **Delete a Device Scan Profile**

To delete a profile, select the scan and select **Delete**. The scan is deleted from the Device Scan History. The appliance also deletes any devices that are associated with that profile, unless the devices are associated with another scan profile.

## **Device Setup**

This topic describes how to use the **Manage Devices** screen to add devices.

### **Prerequisites for Adding a Device**

If necessary, set up access types before device setup. These types include:

- **Access Methods** invoke a proprietary Java applet that is downloaded from Privileged Access Manager to a local client computer. See [Access Methods](#) for more information.
- **TCP/UDP Services**: See [Create TCP/UDP Services](#) for more information.
- **Native Services** invoke a resident application on a local Client computer.
- **Web Portals** invoke an HTTP/HTTPS website. See [Configure Automatic Login to Web Portals](#) for more information.
- **RDP Applications** invoke resident application on target RDP Device. See [RDP Applications Configuration](#) for more information.

### **Basic Info Configuration**

The following procedure describes how to configure basic information for your device.

**Follow these steps:**

1. Log in to the UI.
2. Select **Devices, Manage Devices**.
3. To specify a new device, select **Add**.
4. Complete the fields on the **Basic Info** tab. Required fields are highlighted with a red asterisk.
  - **Address**: The device IP address or FQDN.

#### **NOTE**

Any literal IPv6 address entered in the **Address** field will be normalized according to the following standard: [RFC 5952: A Recommendation for IPv6 Address Text Representation](#).

For example, entering 1111:2222:000A:000B:0:0:0:D in the **Address** field, and then saving it, means this value converts to 1111:2222:a:b::d, enforcing the lowercased and compressed value according to the RFC 5952 standard.

- **Name:** This field specifies the name that is displayed on the Access page. You can enter double-byte characters.
- For FQDN, DNS must be set up properly on the **Configuration, Network, Network Settings** page.
- A specified FQDN can be no longer than 255 characters.
- If you are updating a Device that is imported from AWS, Azure, or VMware, an **Override Address** checkbox appears. To edit the Address, for example, to use a private IP address, select the Override Address checkbox.

**Scan:** Select this option to execute a port scan. The scan detects services that are configured. The detected services appear on the Access Methods and Services tabs. **Description:** Enter an optional description. **Location:** Enter an optional location. To help you organize your device list, you can sort entries in this column. **Operating System:** Select the device operating system from the drop-down menu. To help you organize your device list, you can sort entries in this column.

#### NOTE

If you are adding a device for a PAM SC Utility Appliance, select **Utility Appliance** from the drop-down menu. For more information, see [Configure PAM Devices for Utility Appliances](#).

**Version:** The **Version** field only appears for PAM SC devices.

#### NOTE

The **Version** field does not appear for non-PAM SC devices.

**Device Type:** Select the functions that you want to apply to the device:

- **Access** for access to remote systems
- **Password Management** for designating a device as a target device for credential management.
- **A2A** for Application-to-Application credential management. An A2A Client must be installed on the remote system: The following other A2A fields are required:
  - **Active:** Select **Active** to allow the A2A Client to receive credentials
  - **Preserve Hostname:** Select this box to prevent the host name of the request server from being overwritten each time the A2A Client registers. If you do not select this option, the existing host name can be overwritten.

5. Select **OK**.

## Tag Creation and Assignment

Device tags are text strings of any form and length that you can use to group and search for Devices. Tags have no dependence on any other characteristics of those devices. You create a device tag within a specific device record. After it is created, you can copy the tag to other devices. Multiple tags can be assigned to a device, so it is possible to create a wide variety of groupings.

A tag is applied to a device record. How you apply a tag depends on whether it exists or you are creating a tag:

- For an existing tag, select from drop-down list of tags. An existing tag must be used in at least one device record. Start typing and a list of available tags appears in the drop-down list.
- For a new tag, enter a tagname.

To view and edit tags, see [Manage Tags](#).

The following guidelines apply when you tag devices and device groups:

- A device in a device group does not inherit the tag that is assigned to the device group.
- If a device and a device group have the same tag, PAM treats the single device as part of the device group. If a single device has the same tag as a device group, any policy that applies to the device group also applies to the device.

**Example of Using Tags:** A number of devices use the Windows operating system, but some do not. For network maintenance purposes, you want to group all Windows devices. Tag all devices with the tag **Windows**. On the Manage Devices and Access pages, you can then search for "windows" to collect all instances.

## **Specify Access Methods**

From the **Access Method** tab, specify the method by which users gain access to a device. The default methods are RDP, SSH, Telnet, and VNC. Mainframe licenses also provide the following methods: TN3270, TN3270SSL, TN5250, TN5250SSL

### **Follow these steps:**

1. Select the **Access Methods** option.
2. Select the plus sign to add a method.
3. In the **Name** field, select an access method from the pull-down menu. The **SSH** access method can provide X11 forwarding using SSH. To enable X11 forwarding, select the **X11** checkbox. For forwarding to work, the client computer must have a configured X11 server, such as OpenText Exceed. Be aware of the following limitations with X11:
  - The product supports key stroke logging and command filtering for all activities that are conducted within the SSH applet. However, the X11 server runs on the local client, so it cannot provide graphical session recording or command filtering for the forwarded graphical application.
  - The X11 feature cannot currently be applied to device groups.**RDP** has a **Console** checkbox to specify that access is through the device console interface.
4. Optionally, specify a **Custom Name**. The default Name is the Access Method (such as SSH). A custom name is required if a device uses the same access method on two different ports. For example, if a device listens for SSH connections on port 22 and on port 2200, you define an SSH access method for each port. Both access methods cannot have the same name, so at least one of them has to have a custom name. You can also use a custom name to have a non-standard name appear on the access page for this method on this device.
5. In The **Port** field, accept the default port or specify a different port number.
6. Repeat the previous steps for each method you want added.
7. Select **OK** to save your selections, or continue to the next tab.

## **Select Services**

Select services to customize access to devices.

### **Follow these steps:**

1. Select the **Services** option.
2. For each service you want, select the associated checkbox.
3. Select the right arrow to move the services over to the **Selected Services** list.
4. Select **OK** to save your selections, or continue to the next tab.

### **NOTE**

If this target device will be used by a PAM Agent, verify that the **IP Version** setting of any selected service matches the type of IP address (IPv4 or IPv6) specified in the **Address** field on the **Basic Info** tab. For more information, see [Create TCP/UDP Services to Access a Device](#).

## **Customize Terminal Access to a Device**

Set up terminal access to a device so that any user receives an administrator-recommended screen presentation. Configuring the look of the terminal is helpful for users who do not know the ideal settings.

A user can override this customization by specifying user-based terminal settings.

### **Follow these steps:**

1. Select the **Terminal** option.
2. Configure each field using the pull-down lists. Most fields are self-explanatory.

**NOTE**

The "End to select" checkbox function is deprecated.

**Transparent Login**

Transparent login lets a user issue password-enforced commands whose passwords are unknown to the user. The user must be logged on to a target device to use transparent login.

The RDP and SSH services support transparent login. Support for the graphical RDP transparent login feature on Windows machines is on the [Services](#) page. Support for the SSH applet and the SSH proxy is also defined on the Services page. Specify one or both UNIX/Linux applications **pbrun** or **sudo**. When these applications are invoked, the applications are silently presented with valid managed credentials, effecting an automated transparent login.

To use sudo/pbrun at run time, specify a credential for auto-connection on the policy for this device, and select the Transparent Login checkbox.

**Follow these steps:**

1. Select the Transparent Login tab.
2. In the drop-down list, select sudo/pbrun. The **sudo/pbrun** fields appear.
3. In the **Full Path** field, enter the path on the target device where the application executable resides. For example, /usr/bin
4. In the **Password Prompt** field, specify a substring of the text that is presented to the user. The closer a string match that you provide, the greater the security. For example, the full prompt to the user might be **sudo password** for *user*, where *user* represents the dynamically applied user name. The maximum literal that can be applied is then "sudo password for".

**Command Strings for Transparent Login**

You can also specify a set of command strings and a prompt. This feature is disabled by default for security reasons. To enable it, go to **Configuration, Security, Access**, and select **Enabled** for **Command String**.

**To use the Command String feature, follow these steps:**

1. Enable **Command String** on the **Configuration, Security, Access** page.
2. Select the Transparent Login tab.
3. In the drop-down list, select **Command String**. The **Command String** fields appear.
4. In the **Authentication Prompt** field, specify a substring of the text that is presented to the user. The closer a string match that you provide, the greater the security. For example, the full prompt to the user might be password for *user*, where *user* represents the dynamically applied user name. The maximum literal that can be applied is then "password for".
5. Select the plus icon to add the actual command string. The user must match the command string exactly. To support shortened versions of the command string, add them as separate command strings. For example, "ENABLE" would be one command string, and "EN" would be another command string.
6. Select **OK** to save your settings.
7. [Set Up a Policy](#) for the device and an account to use the transparent login feature. Unlike sudo/pbrun, auto-connect configuration is unnecessary for Command String transparent login. The password from the specified target account is sent under the following conditions:
  - You type a string that matches the specified command string.
  - SSH returns the specified prompt, whether you are using an SSH applet or the SSH proxy.

## Check PAM SC Server Control Policies

The **Server Control** tab appears for all PAM SC devices except the following devices:

apikey.xceedium.com	tap.ca.com
ca.portal.azure.com	Utility-Server
nim.pam.ca.com	xceedium.aws.amazon.com
server.control.policies.pam	xceedium.nsx.vmware.com

The **Server Control** tab has two sections:

- **Policies Assigned:** Contains the list of policies assigned on the device.
- **Policies Deployed:** Contains the list of policies deployed on the device.

When assigning a server control policy on the server control device, it takes some time for the server control device to get this deployment information. All the assigned (queued) policies appear in the assigned table. Once the server control receives this deployment information, the policies appear the **Policies Deployed** list.

### Follow these steps:

1. To view the policy deployment status of the device agents, navigate to **Devices, Manage Devices**.
2. Select a device, and then select **Update**.
3. Select the **Server Control** tab.

## Check the Status of Agents

Use the following steps to check the status interval for Agents (endpoint devices) using PAM Integrated Server Control.

### Follow these steps:

1. To view the status of the device agents, navigate to **Devices, Manage Devices**. A list of Server Control, UNAB, and PUPM devices appears.
2. Select a device, and then select **Update**.
3. Select the **Agent Status** tab.
4. The **Agent** type, **Version**, **Activation Date**, **Last Update** for policy, and the **Utility Appliance** address appears.
5. Select **OK** or **Cancel** to exit this screen.

## Add a UNAB Configuration Token to a Device

Do this procedure to add a UNAB Configuration Token to a device. **Follow these steps:**

1. In the PAM UI, select **Devices, Manage Devices**.  
A list of all devices appears.
2. Select the UNAB device, and then select **Update**.  
The **Update Device** page appears.
3. Select the **UNAB** tab. The current **UNAB Configuration Token Update** page appears.
4. Select the **+** icon. A new blank row appears.
5. Select the appropriate section, token, and value from the drop-down menu.
6. Select **OK**.

## Edit a Device from a Policy

An administrator can edit a Device from the Manage Policies page.

1. Open the **Policy, Manage Policies** page.

2. Select a Policy to **Update** for a given Device.
3. Select the **Manage Device** button on the Policy window. The corresponding **Device** window appears.

### **Edit Targets from the Manage Devices panel**

An administrator can add a Target Application from the Manage Devices page:

1. Select a Device from the list, then select the **Manage Target Applications** button. If the Device record is already open, you can select **Save and Add Target Applications** at the bottom of the Device window.
2. The Add Target Application window opens in front of the **Target Applications** List. The GUI controls are presented as they are on Targets, Target Applications.
3. When finished, select **OK**.

#### **NOTE**

For information about importing Devices using a CSV file, and importing AWS and VMware Devices, see [Import and Export Devices](#).

## **Import and Export Devices**

As a Privileged Access Manager Administrator, you can import a device list in CSV format as an alternative to adding the devices individually. You can also export Devices and Device Groups. You can import AWS and VMware Devices, and Azure VMs.

### **Use a CSV to Import Devices and Device Groups**

You can import a CSV file with a list of Devices. A sample file can be downloaded by selecting **Devices, Manage Devices, Import/Export**, and **Download Sample File**. The sample file lists all of the required fields. You can use the format to manipulate an existing device list from another source, such as an inventory control database. For detailed information about the columns in the CSV file, see [Device Groups and Devices](#).

#### **NOTE**

Do not import a CSV of Devices and Device Groups that are provisioned by LDAP, AWS, VMware, or Azure. These types are ignored on import and should be managed according to their specific procedures, found on this page.

### ***Configure Internet Explorer***

To use the Import/Export functions with Internet Explorer (IE), changes might need to be made to the security settings. To establish IE security settings:

1. Open IE browser.
2. Select **Tools, Internet Options**.
3. In the Internet Options pop-up window, select the **Security** tab.
4. Select the slider zone
5. Select **Custom level**. Scroll to **Downloads**. For **File download**, select the **Enable** option.
6. Select **OK** to save changes.

### ***Import Devices from a CSV***

To import the Devices, follow these steps:

1. Go to **Devices, Manage Devices**.
2. Select the **Import/Export** button.  
The Import/Export Devices window appears .
3. Select Download Sample File, and save the file.

4. Create a CSV file from the downloaded template.

#### CSV Format

- Do not change the heading (first) row text.
  - New Device records:
    - Not all fields are required. Required fields include: **Type**, **DeviceName**, **Address**
    - For any fields not used: Preserve all headings on the first row, but leave other row cells blank.
  - Updates to existing Device records:
    - Each Device Group is represented by a line record with Type="device group".
    - Device Group records should be at the top of the file, ahead of all Device records.
    - Device membership in a Device Group is indicated in the Group Membership column.
5. In the **Import/Export Devices** window, select **Choose File** to select the file, and select **Import Devices**. The content of the file is added to the existing Device database. The new content does not replace the current database.
  6. Navigate to **Devices**, **Manage Devices**, and confirm that the import was successful by inspecting the Device list.

#### Use a CSV to Export Devices and Device Groups

A CSV list of all configured devices can be downloaded by selecting **Export Devices**. This exported file can be used to make a revised version, and then imported back into Privileged Access Manager.

#### WARNING

If you export a device file containing Special Type devices, the file does **not** contain the password. If you reimport that file into Privileged Access Manager, the passwords are not present in the import.

#### Import from AWS

After you configure access to an AWS account and activate **Enable Syncing**, the instances in that account with **State** green/"running" are imported as Devices. Instances that are tagged in AWS with the tag key **xsuiteignore** are not imported. The list is refreshed according to the **Configuration, 3rd Party** parameter **Enable Syncing**, or upon clicking the **Refresh AWS Devices** link at the top.

The Device records created cannot be deleted except upon disconnection from AWS.

The following Device attributes are populated from AWS instance attributes, and cannot be edited:

- The AWS **Name** and AWS **Instance** ID are combined to create a Device **Name** of "awsName ( awsInstance )".
- The Device **Operating System** is populated.

The following Device attributes are populated from AWS instance attributes, and *can be* edited in the Device record:

- Access Methods are populated with:
- **RDP** using port **3389** for Windows OS
- **SSH** using port **22** for UNIX and Linux OS

The Device **Address** is populated with the AWS **Public DNS**. To edit the Address, for example to use a private IP address, select the **Override Address** checkbox next to the Address field. The Override Address checkbox only appears for Devices that are imported from AWS, VMware, or Azure.

The device **xceedium.aws.amazon.com** is a Credentials Management placeholder Device. This device is created when AWS is configured to manage AWS access keys in Privileged Access Manager. It cannot be edited, but is created/removed in synch with an AWS configuration **Save**.

## Import from VMware

After Privileged Access Manager is configured in **Configuration, 3rd Party** to access a VMware account and **Enable Syncing** is activated, the instances in that account import as Devices. Instances that have been tagged in the VMware appliance **Summary, Annotations, Notes** field with the string: **Xsuitelgnore** (anywhere in the field) are not imported.

The list is cyclically refreshed according to the **Configuration, 3rd Party** parameter **Enable Syncing**, or upon clicking the **Refresh VMware Devices** link.

- During import, each virtual machine (instance) in VMware results in the creation of a Device
  - The Name of the Device that is created is the combination: "VMwareInstanceName – vm- nn" where "nn" is a VMware assigned number.
  - When available, the internal Address of each Device is provided; otherwise it is marked as "Not-Active- VMwareDeviceName - vm nn".
  - To edit the **Address**, for example to use a private IP address, select the **Override Address** checkbox next to the Address field. The Override Address checkbox only appears for Devices that are imported from VMware, AWS, or Azure.
- During import, each folder in VMware results in the creation of a Device Group
  - The Name of the Device Group that is created is the combination: "VMwareFolderName - group-v nn" where "nn" is VMware assigned number. You can edit it.
  - The Group Type is "VMware", and cannot be edited.
  - The Description is "VMware derived group", and can be edited.
- All VMware imported Devices are members of a VMware-determined Device Group. For VMware instances with no containing folder (in VMware), the Device Group named "VM" is used.

## Import from Azure

After you configure an [Azure connection](#) and activate syncing, the instances in that account are imported as Devices. The list is refreshed according to the **Refresh Interval** on the **Configuration, 3rd Party, Azure** page. You can immediately refresh them by selecting the **Refresh Azure Devices** link at the top of the **Manage Devices** page.

To prevent specific devices from importing, you can "tag" them in Azure. Follow these steps:

1. In Azure, select the Virtual Machine that you want to prevent importing.
2. Select **Tags** from its menu.
3. Select the **Name** drop-down list. If the **PAMIgnore** tag is not listed, enter `PAMIgnore`, and set the **Value** to `true`.
4. Select **Save**.  
The Tag is applied and available for every device in your Subscription.
5. Repeat for each VM that you want to ignore.
6. To see all tagged VMs, enter "Tags" into the **Search** field.  
The Tags list appears. Select a Tag to see all the objects to which the Tag is applied.

The imported Device records cannot be deleted except upon disconnection from Azure. The following Device attributes are populated from Azure instance attributes, and cannot be edited:

- The Azure Name is the Device Name
- The Location is the Azure location of the instance
- The Device Operating System is Linux

The following Device attributes are populated from Azure instance attributes, and *can be* edited in the Device record:

- Description
- Access Methods are populated with:  
**SSH** using port **22** for UNIX and Linux OS

The Device **Address** is populated with the Azure **Public IP**, or if DNS is set for the device in Azure, the **FQDN**. After you import a Device, you can edit its Address, for example, to use a private IP address. Follow these steps:

1. Select **Devices, Manage Devices**.
2. Select the Device and select **Update**.
3. On the **Basic Info** tab, select the **Override Address** checkbox.
4. Edit the **Address**.
5. Select **OK** to save.

The device **ca.portal.azure.com** is a Credentials Management placeholder Device, which is created when your instance is licensed. This Device manages Azure access keys in Privileged Access Manager. All Azure target accounts should be associated with this device.

### **Import from LDAP**

To import a Device Group from LDAP, see [Import LDAP Device Groups](#).

## **Device Group Setup**

Learn how to create PAM device groups to group devices that share common access methods and functionality.

Though any devices can be a member of a device group, group functionally similar devices. Before you can add a device to a group, you must first configure a device with Password Management as its device type.

When using device groups, the action **deny** takes precedence, unless otherwise specified. The service is available at the group level only if it is available at the device level. The most restrictive policy is used when a conflict arises.

The following topics apply to device groups:

### **Credential Sources for Device Groups**

A *credential source* is a particular target device or set of devices that stores user credentials. An Active Directory Server is an example of a credential source. If you specify a credential source for a device group, PAM can find the credentials that are applicable to devices in that device group. PAM uses these credentials to enable a user to log in to any device in the group.

#### ***Using Multiple Credential Sources***

You can assign more than one credential source for a particular device group. If you configure multiple credential sources, PAM gathers all available credentials from all sources. The appliance then creates a combined list of target accounts for a specific set of users or many users and applications.

A device group does not have to include the credential source device. If you exclude the credential source from the group, you can avoid creating a policy that provides direct access to the credential source. Instead, the group contains only the devices that rely on the credential source for authentication.

Credentials from any target account that is associated with any credential source can be used to access any device group member.

#### ***Using Credential Sources in a Policy***

When you configure a policy for a device group, all accounts from the multiple credential sources are available for selection. When a user initiates a connection, these administrator-selected options are presented so that the user can select one. You can use all access methods and services that are configured for the devices in a device group with one or more credential sources.

## Add or Modify a Device Group

1. On the **Devices, Manage Device Groups** page, select **Add**.  
The **Add Device Group** window opens.
2. Enter a **Name** and **Description** for the group. Double-byte characters are supported.
3. Select the type of group to provision from the **Provision Type** dropdown menu: **(Local)** for all device groups unless you are setting up the group for AWS.
  - **Local** (Default): Provision any type of device group except AWS
  - **AWS**: Provision an AWS device group.

### NOTE

AWS groups are determined by settings on the **Configuration, 3rd Party, AWS** page. AWS device groups act as a container for devices that are created as a result of importing AWS devices. Each device should have a tag Key of "PamGroups " and a Value of "[PAM Group Name]". Following import, the group cannot be deleted unless the AWS configuration is cleared from **Configuration, 3rd Party, AWS** or the group becomes empty. The group is updated according to the schedule in the AWS Configuration.

4. Optionally, select one or more **Credential Sources** from the available device list.
5. Optionally apply tags on the **Tags** tab, if available.
6. On the **Access Methods** and **Services** (to Access Type members) tabs, select Access Methods and Services to enable them for group members.
7. On the **Enable** tab, you can:
  - **Provide Credentials for 'Always Prompt For Password'**: If a Windows device has this setting, you can automatically provide obfuscated credentials. See [Enable a Password Push for RDP Password Enforcement](#) for details.
  - **Handle 'Legal Notice' on Logon Screen**: Select this option to handle the "Legal Notice" during login. This option only works when **Provide Credentials for 'Always Prompt for Password'** is enabled.
8. The **Server Control** tab only appears for PAM SC devices. This tab has two sections:
  - **Policies Assigned**: Contains the list of policies that are assigned on the device.
  - **Policies Deployed**: Contains the list of policies that are deployed on the device.

## Create an AWS Device Group for Linux/UNIX Devices

In AWS, Linux and UNIX instances use AWS Key Pairs. If all instances in a planned Device Group use the same key pair, a group policy can be provisioned to use that key pair for auto-connection.

1. Create an AWS Type Device Group.
2. Assign an AWS instance with imported Devices to it, all of which use the same key pair.
3. Create a policy with that Device Group.
4. From the SSH applet credential pop-up box, select the key pair that is held in common.

This key pair is used for auto-connection for any Device in the group.

## Edit a Device Group from the Manage Policies Page

An administrator can edit a Device Group record by invoking it directly from the Manage Policies page.

### Follow these steps:

1. Open the Policy, Manage Policies page.
2. Populate the Device (Group) field with a record name.
3. Double-click the name to display its editing template in a shadow box window.
4. When finished, select Save (or Cancel) to return to the Manage Policies page.

### NOTE

For information about importing an LDAP Group, see [Import LDAP Device Groups](#).

## Import LDAP Device Groups

An efficient method of creating an LDAP device group is to import an LDAP group from a remote LDAP server. To complete an import, you are required to use the built-in *PAM LDAP Browser*, which gets launched during the import procedure.

This topic explains the following tasks:

Only a Privileged Access Manager administrator has privileges to import an LDAP group.

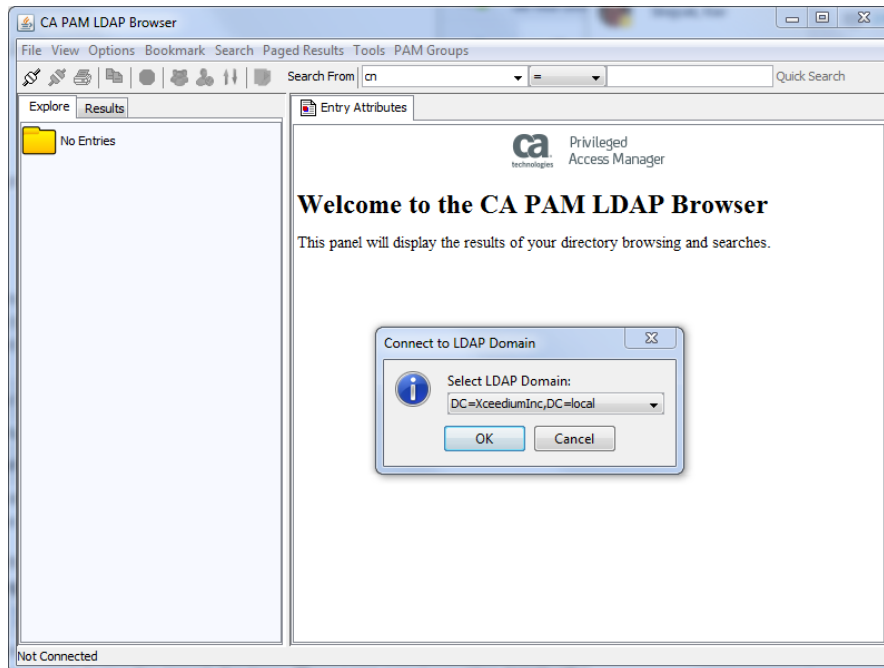

### Launch the LDAP Browser

Use the LDAP Browser to import an LDAP group.

#### Follow these steps:

1. Verify that your appliance is licensed. A license is required to launch the LDAP Browser.
2. Navigate to **Configuration, 3rd Party, LDAP** to configure access to an LDAP server. Provisioning the LDAP server is necessary to make LDAP groups available for import.
3. Select **Devices, Manage Device Groups**.
4. Select **Import LDAP Groups**.

The LDAP Browser launches. You are prompted to select an LDAP domain.

5. Go to the next procedure to import the LDAP group.

If the LDAP server does not support the cipher suite that is used by the Privileged Access Manager LDAP browser, a connection failure occurs. The following error message appears:

“Possible cipher mismatch with LDAP server.”

During provisioning, ensure that the ciphers that are supported on the target LDAP server include those ciphers that are supported by the LDAP browser.

### Cipher Suites Supported by the LDAP Browser

The LDAP browser supports newer cipher suites including Diffie-Hellman cipher suites that enable Perfect Forward Secrecy (PFS) and better performance through the elliptical curve.

- **(Default) When TLSv1.0 and 1.1 are allowed, the following ciphers are available for negotiation with the LDAP/Active Directory server:**

TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA256  
 TLS\_ECDHE\_RSA\_WITH\_AES\_256\_CBC\_SHA  
 TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA  
 TLS\_RSA\_WITH\_AES\_128\_GCM\_SHA256  
 TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA256  
 TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA256  
 TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA  
 TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA  
 TLS\_DHE\_RSA\_WITH\_AES\_128\_CBC\_SHA  
 TLS\_DHE\_DSS\_WITH\_AES\_128\_CBC\_SHA

- **When TLSv1.0 and 1.1 are disabled (only TLSv1.2 is enabled), the following ciphers are available:**

TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA256  
 TLS\_RSA\_WITH\_AES\_128\_GCM\_SHA256  
 TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA256  
 TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA256

#### **NOTE**

When you change the TLS configuration, the current LDAP browser connections are not affected. The configuration changes take effect after the LDAP browser is launched.

- **When FIPS mode is enabled, the following ciphers are available:**

TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA256  
 TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA256  
 TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA256

When TLS 1.0 and 1.1 are disallowed in the Privileged Access Manager configuration, SHA-1 HMAC is disallowed and only SHA256 is used.

The only Supported Elliptic curves are -secp256r1, secp384r1. These curves are NIST approved. Microsoft Windows can set curve support by group policy to ensure that the Active Directory Server allows Privileged Access Manager curves if ECDHE is required.

### **Import LDAP Groups**

In the LDAP Browser, the **Explore** tab in the left pane shows a graphical representation of an LDAP tree. Select any object to see the object attributes.

#### **Follow these steps:**

1. Select the LDAP domain and select OK to connect to it.  
The browser connects and displays all records below that domain.
2. Navigate the LDAP tree in the left pane and locate the device group that you want to import. Traverse the tree in any order or direction.
3. To import a device group to import, select the checkbox next to the group.

4. Repeat these steps for each group you want to import.
5. (Optional) Review the device groups that are selected for import:
  - a. Select **PAM Groups, Manage selected groups to register with the PAM appliance**.  
The list of the Distinguished Names for all selected groups displays.
  - b. Select and edit any group DN, or remove it from the staging list.
6. Select **PAM Groups, Register selected groups with the PAM appliance**.  
A window opens displaying a list of the staged groups. You can watch the progress, and can display any messages that are associated with the actions.
7. When ready to import the groups, select **Register Groups** in the lower-left corner.  
Privileged Access Manager imports the groups in the order that they are listed. The browser provides feedback and cancellation options throughout the process.

**TIP**

You can cancel registration of a group, or you can cancel the registration of all groups, even after they have started.

When the imports are finished, each line item in the registration window shows a green checkmark for success or a red **X** for import failure/cancellation.

8. (Optional) Review the status of the full list and each individual group by selecting its line item. If you made any changes, or any errors occurred for an individual group, the lower **Messages** panel provides details
9. Go to **Devices, Manage Device Groups**, and confirm that the imported groups appear on the page.

**NOTE**

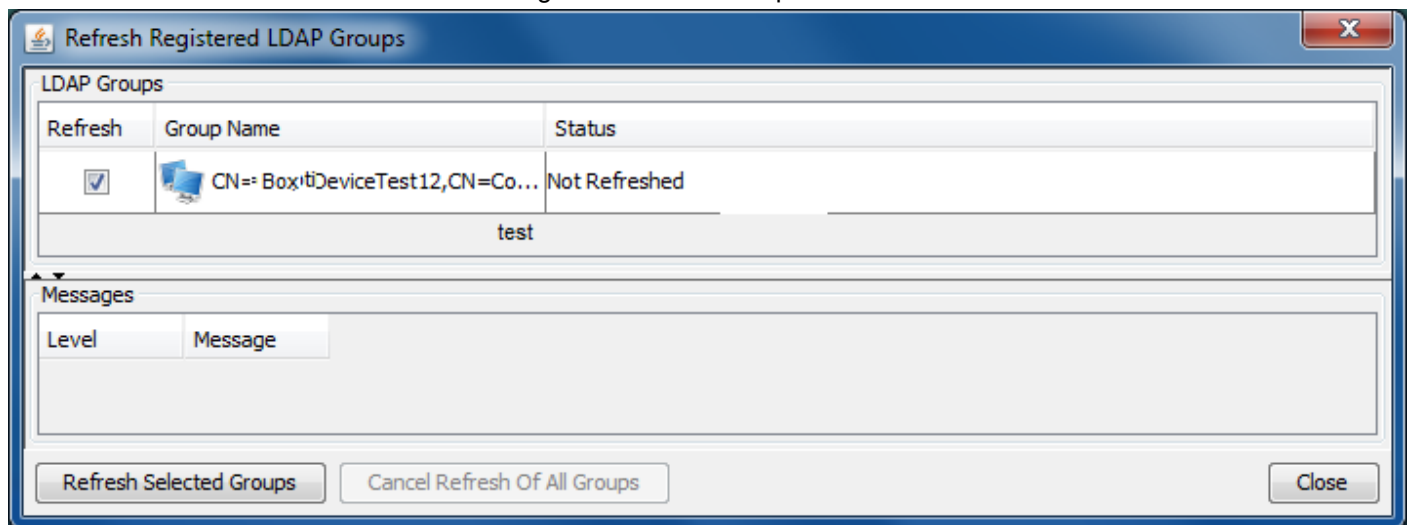

You cannot delete a record from an imported device group. Also, you cannot edit an LDAP-imported field.

**Refresh LDAP Groups**

You can refresh an LDAP Group to update the records in the group.

**Follow these steps:**

1. In the UI, select **Devices, Manage Device Groups**.
2. Toward the right side of the page, select **Refresh LDAP Groups**.  
The LDAP Browser launches the Refresh Registered LDAP Groups window.

3. Select one or more groups you want to refresh and select Refresh Selected Groups.

**Refresh Active Directory Device Groups After an OU Change**

A change to organization unit (OU) of a device results in a change to the device DN. The modified DN can impact an access policy. PAM handles an OU change when the Active Directory group is refreshed automatically. During a refresh, the appliance searches the remote Active Directory Server and updates its device record. Despite the OU change, the policy for that device is preserved.

### **WARNING**

To reflect an OU change immediately, you can manually refresh an Active Directory group in PAM. To keep the data in sync with Active Directory, refresh all the groups that now include the device *and* all the groups from where the device moved.

### **Nested LDAP Groups**

An LDAP group might be nested within another group as an element in a parent group member attribute. When the parent group is imported, all devices in the parent or the child are imported. For example, consider groups StateA and CityB, where group CityB is a member of (nested in) the group StateA. If you import the StateA group, you see every member of StateA and every member of CityB.

### **LDAP Browser Menus and Controls**

The following table shows LDAP Browser controls.

Menu Item	Function
Copy icon	Copy the Distinguished Name of selected entry to the Clipboard.
Group icon	Display all the groups in this container. After selecting an object in the tree under the Explore tab, click this button. You then switch to the Results tab, under which you see a fully expanded tree of all groups (objectClass: group) contained within the selected object.
<b>File</b>	
Connect	Log in to an LDAP database. Invokes a pop-up window from which you can select from currently accessible domains.
Disconnect	Log out from the current LDAP domain.
Print	Print currently selected node.
Exit	Close browser window. <b>Note:</b> The browser continues running while a connection is active. During that time, the browser can be invoked again from the Devices, Manage Device Groups, Import LDAP Group.
<b>View</b>	
Show Button Bar	Below the main menu bar, at the left side Default: On
Show Search Bar	Below the main menu bar, at the right side Default: On
<b>Options</b>	
Set LDAP Connection Timeout	Maximum time (seconds) before a connection attempt is canceled. This timeout is useful when multiple servers are specified for a particular LDAP domain. Default: 60 seconds

Set Result Set Page Size	Maximum number of records in an LDAP directory before pagination is triggered for representation in the browser tree. Number of records in each page of a paginated subtree. Default: 1000
<b>Bookmark</b>	A bookmark can be made on any leaf in a tree so you can select it later from the menu. Bookmarks are saved for each domain, and appear only when the browser is connected to that domain.
Add Bookmark	Opens an editing window for bookmarking currently selected leaf: DN – pre-populated with the current Distinguished Name (DN) Bookmark Name – pre-populated with the current Common Name (CN) Description
Edit Bookmark	Opens a bookmark selection window. Selection in turn opens a bookmark editing window (see Add Bookmark).
Delete Bookmark	Opens a bookmark selection window. Selection in turn deletes and confirms deletion of the bookmark.
<b>Search</b>	
Search Dialog	Opens a detailed search specification window. (Contrast to Quick Search.)
Delete Filter	Opens a window with a list of filters for selection and deletion.
Return Attribute Lists	
<b>Paged Results</b>	
Next Page of Results	Retrieve next page of results and display page wrapper in the Explore tree (when green; otherwise, gray when inapplicable).
<b>Tools</b>	
Stop Action	Suspends an LDAP request. Suspending a request is useful when the page size is large and the browser is searching a large database.
Privileged Access Manager <b>Groups</b>	Privileged Access Manager-specific menu items
Manage selected groups to register with the appliance.	Lists all items that are currently selected (or staged) for import to Privileged Access Manager.
Register selected groups with the appliance	Perform the input operation on the items that are selected, which are listed in Manage selected groups to register with the Privileged Access Manager appliance.

Icons appear in the Button Bar menu when that menu is active (or "on"). By default, the Button Bar is on.

## Device and Device Group Management

The following functions are available for **all devices** configured for use with Privileged Access Manager:

### Device Record Updates

#### *Editing a Device*

To edit the information of a device, select the Device from the **Manage Devices** page. In the device information screen, update the device information as needed, and select the **Save** button.

### ***Copying a Device***

The permissions and policies of an existing device can be copied to create a device with the same access.

To create a Device **ID** by copying an existing device, select the **Copy** button next to the Device ID intended to be used as a template. A copy of the device information is displayed. Add the required fields and make any appropriate changes. Select the **Save** button to create the Device. Associations and policies can be changed after the device is created.

### ***Deleting a Device***

To delete a particular device, select the Device from the **Manage Devices** page. In the device information screen, select the **Delete** button and select the appropriate response on the subsequent confirmation screen.

### **Manage Tags**

Tags, which are created within a Device create/edit template, are compiled by Privileged Access Manager into a list which spans all Devices.

#### ***View Tags***

Select the **Devices**, **Manage Devices**, **Manage Tags** link to display the **Manage Tags** shadow window. All tags are shown (paginated, if needed) with the number of occurrences in the right column.

- Search tags on the **Tag Name** (alphabetically).
- Sort tags on the **Tag Name** (results list alphabetically) or on **#Used** (occurrences) (results list from low to high).

#### ***Edit Tags***

Each tag can be edited or deleted in the Manage Tags window (not in the Create Device / Edit Device template). Select the Tag line item to open an editing box.

### **Manage Groups**

The **Manage Groups** page displays all the groups which have been configured.

### **Manage Services**

In the **Services** tab, the following management options are available.

#### ***Editing a Service***

To change a setting on a service:

1. Select the **Edit** button next to the service.

An Update service screen appears to allow parameters other than the name to be changed.

To change the *name* of a service:

1. Use **Copy** to clone the service attributes (while allowing the Service Name to be filled in).
2. **Delete** the original.

#### ***Copying a Service***

1. From the list in **Services**, **Manage TCP/UDP Services**, open the record of an existing Service.
2. At the bottom of the record, select the **Copy** button.  
A new record is created, populated with a copy of the original Services information except for the Service Name. This new record opens immediately below the record of the copied Service. The record of the copied Service is closed. To confirm this, look at the Service list above the new record editing pane. It should show the line item of the original Service.
3. Enter (the required) Service Name for the new Service. Edit other fields as desired, and select the **Save** button to create the Service.

## ***Deleting a Service***

Select the checkbox next to the service, and select the **Delete** button at the bottom of the screen. The Service is immediately removed, and the remaining Service list appears.

## **Device Viewing**

### **Initial Unfiltered View**

The first time that you access Manage Devices, you see an empty-list page view. The page is labeled "Unfiltered" because the list (initially empty) is shown without filters that are applied.

See [Filtered Views](#) for information about filtering.

### **Unfiltered Views**

From the **Devices**, **Manage Devices** menu, all current devices (initially) appear in alphabetical order by Device Name. You can also sort the list by clicking on any of the displayed field names: Name, Address, OS, Description, or Location; or by applying filters.

Global Settings, Default Page Size determines how many Devices are listed on each Manage Devices page. If there are more Device records than this value, the Manage Device list is paginated, with navigation controls at the bottom of the page.

### **Filtered Views**

The gray-field **Search** function in the upper-right corner of the page body performs the following actions:

- Accepts a non case-sensitive string
- Matches the string to the beginning of the Name field across all Device records
- Replaces what was an Unfiltered list with a new list. The new list is labeled "Filtered"

### ***Fields Available for Filtering***

When the Search box is clicked, a set of three pop-up windows appears at the right under the Search field. Each window contains a list of the unique values (in alphanumerical order) for each of the following Device record fields:

- Device Type
- OS (Operating System field)
- Location
- Tags

If no item is selected, no value is filtered against that field, so all records are shown. Selecting a value in the field, however, filters the set of Device records against that value. Only those records with the selected value are (immediately) shown in a revised list. If multiple values are selected, records that match any of the selected values is included. Any combination of the checkbox selections or strings from each Device field list can be selected for any particular search. For string selections in **OS**, **Location** and **Tags**:

- To select a **sequence** of values in one category: Select the first entry, then while holding the **Shift** key, select the last entry.
- To select any combination of **individual** values in one category: Select one entry after another while holding the **Ctrl** key.

## **Saved Views**

The filtering that you apply can be saved as a View, and used either by default or selected from a menu.

1. After applying desired list filtering, near the top left (to the right of "Unfiltered"), select **Save as View**. The **Save View** pop-up window appears.
2. Specify a label (**View Name**) to use.
3. Select **Set as Default** if you want the Manage Devices page to open to this view by default.
4. Select **Save New View**.

The view is relabeled to the saved view name, and the view can be selected at any time from the **My Views** menu to the left of the Search box.

## **Set Up Access to a Target Device**

You can access a target device from the appliance in one of these ways:

- **Access Method** – If you select an access method, the appliance invokes a proprietary Java applet to connect to a device. The connection uses one of several standard protocols (SSH, RDP, others)
- **Service** – If you select a service, the appliance invokes a local third-party application that resides on your client system. For example, your local Windows PC might be using PuTTY or WinSCP to handle a connection to a Linux target device.
- **RDP Application** – If you select an RDP application, the appliance uses the RDP protocol to invoke a specific application on a target Windows OS Device

The following topics describe the access types for connecting to a target device:

- [Access Methods](#)
- [Create TCP/UDP Services to Access a Device](#)
- [RDP Applications Configuration](#)
- [How to Set Up Auto-Login for Windows RDP](#)

## **Access Methods**

Access Methods are the out-of-the-box communications applets that provide connectivity and session recording. The applets support VNC, TELNET, SSH, RDP, and serial connections. You can change default ports and you can disable protocols for the whole system. Access method applets are downloaded from PAM to a local computer and rely on locally installed Java.

Configuring an Access method is a two-step process:

1. Select the Access Method from the Global Settings menu in the UI.
2. Assign an access method to one or more target devices.

This topic describes the following information and tasks:

### **Select Access Methods**

1. Select **Settings, Access Methods**.
2. Select the methods to be made generally available for a device configuration.  
If you do not want to use a particular access method, clear the checkbox it to disable it. If you disable a particular access method, it is unavailable for all devices.

### **RDP Client Applet Security Requirement**

If you select the RDP Client applet, the applet supports TLS 1.2 connections and the applet supports the TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA256 cipher suite. The RDP Client also supports forward secrecy using the following supported cipher suites:

- TLS\_DHE\_RSA\_WITH\_AES\_128\_GCM\_SHA256
- TLS\_ECDHE\_ECDSA\_WITH\_AES\_256\_GCM\_SHA384

For the highest level of security, ensure your RDP target device, that is the Windows server, is configured to use forward secrecy with TLS 1.2 communication.

#### NOTE

If PAM is operating in FIPS mode, but the RDP server does not offer a FIPS-compliant communication option, you receive an error. The error says "Cannot connect to *target\_server* because the server did not offer a FIPS-compliant option for communication." Ask your Administrator to verify the server configuration.

### Customize Access Methods

You can customize the access method. Changes apply globally.

#### Follow these steps:

1. Go to **Settings, Access Methods**.
2. Select an access method to customize, and select **Update**.
3. Modify the settings.  
If you update the default ports, only one port number can be specified per Access Method. No port ranges are allowed.
4. Select **OK**.

The set of Access Methods available depends on which license you have. You must have a mainframe license for the TN applets to be available. Otherwise, those applets do not appear as options.

### Assign an Access Method to a Device

The following procedure assumes you already configured a target device.

#### To assign an access method to a device:

1. From the UI, select Devices, Manage Devices.
2. Double-click the target device entry to open it.
3. Select the **Access Methods** tab.
4. Add an Access Method by selecting the plus sign. In the Name column, select an Access Method from the field drop-down list.
5. Select **Save and Configure Target Applications**. Repeat as necessary to allow more methods to be used.  
You can remove any entry by selecting the X at the end of the entry row.
6. When you finish adding methods, and making other changes to the Device record, select the **Save** button.

### Set Up File Transfer Capability (Optional)

Some access methods need further configuration for functionality, such as file transfers. PAM supports file transfer to and from remote target devices through the SSH access method using the Mindterm applet. File transfers can be recorded. SCP and SFTP protocols are supported. SSH file transfer is globally enabled or disabled on a per PAM appliance basis.

#### NOTE

The MindTerm applet command line window has a 512-column by 512-row limit. If you require a larger window, use PuTTY with [TCP/UDP Services](#).

### Enable SSH Terminal File Transfer (Administrator)

To set up file transfers using the SSH applet:

1. Log in to the UI as an administrator with privileges to access global settings.
2. Navigate to **Settings, Global Settings, Applet Customization**.
3. Select the **SSH Terminal File Transfer** checkbox.
4. Select **Save**.
5. Set up a policy for a PAM user to use the SSH as the access method for applicable target devices.

### Accessing a Target Device using the SSH Access Method (User)

After SSH terminal file transfers are enabled, the user has access to the SCP and SFTP file transfers.

The following procedure explains how a PAM user selects the SSH access method:

1. Log in to the UI as a User with permissions to execute the SSH access method.
2. If necessary, navigate to the Access page.
3. On the Access page, select an **SSH** icon to open a MindTerm applet to the configured target device.
4. In the MindTerm Java applet window (labeled with your device name), select **Plugins, SCP File Transfer** to open a file transfer window.
5. Use the **MindTerm – SCP *internal\_IP\_address*** applet file transfer window to perform the following functions:
  - Move files between your local client computer and the remote target Device. Use the arrows to move between directories in the list.
  - Use the following commands to execute tasks between the two system directories:
    - **Double-click: [..]** – to jump to the parent directory, or *directory\_name* to enter it.
    - **ChDir** – to specify a directory to jump to
    - **MkDir** – to create a directory
    - **Rename** – to change the name of the selected directory
    - **Delete** – to delete the currently selected file or directory
    - **Refresh** – to reload the current directory

### Logging for File Transfer Transactions (Optional)

This table describes the types of log entries that are effected by file transfer transactions.

UI Button	Log Entry Syntax	
	Transaction	Log Entry Details
-->	put	Upload <i>localpath/filename*</i> (size) to <i>remotepath/filename</i> as user <i>remote_user</i> .
<--	get	Download <i>localpath/filename*</i> (size) from <i>remotepath/filename</i> as user <i>remote_user</i> .
		*A directory (with or without files) can also be copied, but that action is not logged. Files within copied directories are each copied and logged.
<b>ChDir</b>	(no log entry)	
<b>Delete</b>	alert	[Remote   Local] [file   folder] <i>pathname</i> has been deleted by user <i>remote_user</i> .
<b>MkDir</b>	alert	[Remote   Local] folder <i>pathname</i> has been created by user <i>remote_user</i> .

<b>Refresh</b>	<i>(no log entry)</i>	
<b>Rename</b>	alert	[Remote   Local] [file   folder] <i>path/old name</i> has been renamed to <i>path/new name</i> by user <i>remote user</i> .

## Create TCP/UDP Services to Access a Device

Configure TCP/UDP services to define local (to the client system) third-party applications that can be used to access a target device instead of a predefined access method. Examples of such clients include:

- PuTTY: For PuTTY or another SSH client, see [Create an SSH Service to Access a Device](#).
- IBM TN3270 and TN5250 clients: See [Set Up a Native TN3270 or TN5250 Client](#).
- Web Portal: To provide access to websites automatically, see [Configure a Service to Access a Web Portal](#).
- SQL query front ends, mainframe clients, and other proprietary applications that use TCP or UDP connections: see [Configure a TCP/UDP Service](#)

You can also import Services in batch mode using a CSV file. See [Import or Export Services](#) for instructions.

### Configure a TCP/UDP Service

To add a TCP/UDP Service, follow these steps:

1. Select **Services, Manage TCP/UDP Services**.
2. Select **Add** to create a new TCP/UDP service.
3. On the **Add TCP/UDP Service** dialog that opens, complete the following fields as appropriate:

- **Service Name:** Enter a name for the customized service.
- **IP Version:** Allows the user to select the IP version: **IPv4** or **IPv6**.

#### NOTE

If this service is associated with a target device that will be used by a PAM Agent, the **IP Version** setting must match the type of IP address that is configured in the target device definition.

- **Local IP:** If you select IPv4, enter a local IPv4 address for this service. The **Local IP** column on the TCP/UDP Services page lists the existing IP addresses for other services.  
If you select IPv6, this step does not apply because ::1 is the only valid loopback address for the IPv6 protocol.
- **Ports:** Define all ports that the client application opens to gain access to the device, using one of these formats:
  - **Port combination/redirection** syntax: **RemotePort:LocalPort** or **RemotePort:\*** (separated by a colon)  
**RemotePort** is on the destination device. Specify an integer.  
**LocalPort** is the local port over which the listener waits for connections on the local user desktop. Enter an \* (asterisk) to let Privileged Access Manager set the value to any available port. Always specify an \* (asterisk) for the local port in Citrix XenApp environments. To enter a specific port number, enter an integer.  
Example: 22:\*  
Example: 22:8855
  - **Multiple ports** syntax: Each port is separated by a space, comma, or comma and space.  
Example: 67 3450 23  
Example: 5740, 3221, 31225
  - **Port range** syntax is: **FirstPort–LastPort** (minimum and maximum value that is separated, by dash). The port range limit is 500. A single range is allowed.  
Example: 14575–15004

Do not combine multiple ports with port ranges. Use only one entry type. The following example is incorrect:  
51000-51002, 55555

- **Protocol:** Select the transport protocol that the service uses from the drop-down list.
- **Enable:** Select this option to enable the service. Disabled services appear shaded in the Devices page, and do not work for any user, including *super*.
- **Show in Column:** Select this option to show the service as a button on the Access page. Otherwise, Services appear in a drop-down list, which is more compact.
- **Application Protocol:** Select one of the following protocols for communication to the remote target:
  - **Disabled** (Default) Accept this value to create a simple pass-through tunnel connection to the remote target.

#### NOTE

The service can be configured so that an application on the client is invoked when the tunnel is built.

- ICA
- RDP
- VNC
- Console
- SSH
- TELNET
- Web Portal

For some application protocols, contextual controls appear. For more information about specific controls for SSH, TELNET, and Web Portal application protocols, see the following topics:

- [Create an SSH Service to Access a Device](#)
- [Create an RDP Proxy Service to Access a Device](#)
- [Set Up a Native TN3270 and TN5250 Client](#)
- [Configure a Service to Access a Web Portal](#)

- **Hide Credential:** (Available when **Application Protocol** is set to **Disabled**.) Set this option to hide the **View Credential** link that is otherwise displayed when a user selects the corresponding service icon on the **Access** panel, as shown in the following screenshot:

- **Send keep-alive interval:** (Available when **Application Protocol** is set to SSH or TELNET.) Select this option to send keep-alive messages so that sessions do not time out. *The PAM Applet Timeout still applies.* Valid values are 60 seconds (minimum) to 172800 seconds (48 hours). Default is 0 (disabled mode). For more information about the Applet Timeout setting, see [Basic Settings](#). For additional information about how this option affects SSH services, see [Create an SSH Service to Access a Device](#).
- **Client Application:** To invoke the client automatically, specify the file path to its executable. The path that you specify here is launched when a user accesses the service. The user can also set or override this path at

launch time. To use a path that requires embedded spaces, enclose the directory path, including the application executable filename, in quotation marks. Do not enclose the entire string in quotes or the command does not execute.

Use these literal strings as variables that Privileged Access Manager substitutes:

- <Local IP> is replaced with the IP address in the **Local IP** field. Do not repeat the local IP here.

#### NOTE

If you are using IPv6, the <Local IP> in the command line must be surrounded with square brackets: [<Local IP>]

- <First Port> is replaced with the first local port (after the colon) that is defined in **Ports**. Do not repeat the first port here.
- <User> is replaced with the account name that is used in the access method. Do not repeat the account name here.
- <Second Port> is replaced with the second local port (if any) that is defined in **Ports**. Do not repeat the second port here.
- <Device Name> is replaced with the Name of the Device. Some application connection arguments can use this variable. For example, in WinSCP, /sessionname=<Device Name> displays the device name instead of the IP address in the application title bar.

For Example: If WinSCP is the application on the client, enter the following path:

"C:\Software\WinSCP\WinSCP.exe" scp://<User>:<Password>@<Local IP>

**Important!** In the WinSCP example, use the literal strings <User>, <Password>, and <Local IP>. Do not enter the actual values for these strings.

#### NOTE

The <Password> variable poses a security risk. It exposes the password to the client, which might log it or might expose it as an argument. When the user connects, a "View Credential" link is shown. You can mitigate this risk by configuring the [Password View Policy](#) with the **Change Password On View** option.

4. Select **OK**.
5. Create a Device that corresponds to the target device.
  - a. In **Devices, Manage Devices**, create a Device with the target IP address (do not use FQDN) in the **Address** field.
  - b. On the **Services** tab, use the controls to move the service that you created from the Available Services to the Selected Services.
  - c. Select **OK**.
6. Create a **Target Application** using the target device as **Host Name**. See [Add Target Applications](#) for more information.
7. Create a **Target Account** using the target application as **Application Name**. The **Account Name** is substituted for <User> and the **Password** for <Password>. See [Add Target Accounts](#) for more information.
8. Create a **Policy** linking the Target Device to a User or Group.
  - a. On the **Services** tab, select the Service that you created.
  - b. In the **Target Account** column, use the Edit magnifying glass icon to select the Account.

The Service appears on the **Access** page for the select User or Group.

#### **Additional information:**

- [Create an SSH Service to Access a Device](#)
- [Set Up a Native TN3270 and TN5250 Client](#)
- [Configure a Service to Access a Web Portal](#)
- [Import or Export Services for Access](#)

## Create an SSH Service to Access a Device

An SSH Service invokes a local third-party SSH application on a client to connect to a device. The target device does not have to host the SSH application, and it must reside on the user client computer. This feature extends the access control to any native SSH client. This feature allows control to include session recording, socket filtering, command filtering, and automatic connection with the target account.

### NOTE

When a native SSH client service policy is configured for session recording, select the **Bidirectional** checkbox for the recording to work.

Follow these steps:

1. Select **Services, Manage TCP/UDP Services**.
2. Select **Add** to create a new TCP/UDP service.
  - **Service Name:** Enter a name for the service.
  - **Local IP:** Enter a valid local loopback address.
  - **Ports:** Enter **22** (for SSH) and a local port mapping or an asterisk. For example: **22:12345** or **22:\***
  - Enable option the **Enable**.
  - Select the **Show in Column** option to display the service as a button on the **Access** page. Otherwise, Services appear in a drop-down list, which is more compact.
  - For **Application Protocol**, select the **SSH** option from the drop-down list. Configure the following SSH-specific controls that appear, as required:
    - **SFTP or SCP.** (Optional) For more information, see [Enable File Transfer](#) in the next section.
    - **Optionally, select X11.** (Optional) Select this option to enable the X11 protocol for the user interface. For more information, see [X11 Forwarding and Command Execution](#).
    - **Public Key Authentication.** (Optional) For more information, see [Enable Public Key Authentication](#).
    - **Send keep-alive interval:** (Optional) Send keep-alive messages so that sessions do not time out. (The PAM Applet Timeout still applies.) Valid values are 60 seconds (minimum) to 172800 seconds (48 hours). Default is 0 (disabled mode). For more information about the Applet Timeout setting, see [Basic Settings](#).  
This option also changes how SSH rekey operations, background jobs, and activity in SSH sessions (such as running commands like `top` that update the terminal at regular intervals), impact the applet timeout functionality of PAM. See the following table for examples of how this setting behaves in relation to the rekey operation.

Keep Alive Setting	If Rekey > Applet Timeout		If Rekey < Applet Timeout	
	Background Job	Activity in SSH	Background Job	Activity in SSH
0 (Disabled)	Timeout	No timeout	No timeout	No timeout
Keep-alive is less than applet timeout (overrides original the timeout behavior)	Timeout	Timeout	Timeout	Timeout
Keep-alive is greater than applet timeout	Same as 0 (Disabled)			

3. **Client Application**, enter the path if you want to invoke the client automatically.
4. The Client application path that you specify here is launched when the enabled SSH service is accessed.

Windows syntax:

```
C:\[path]\[clientApp].exe [options] <User> <Local IP> <First Port>
```

For PuTTY:

```
"C:\Program Files\PuTTY\putty.exe" -ssh -l <User> <Local IP> <First Port>
```

Linux syntax:

```
/usr/bin/putty -ssh -l <User> -P <First Port> <Local IP>
```

#### MacOS syntax:

- If you are using IPv4, enter the following command or the terminal app:

```
open -n -a "Terminal" ssh <User>@<Local IP> -p <First Port>
```

- If you are using IPv6, enter the following command or the terminal app:

```
open -n -a "Terminal" ssh <User>@[<Local IP>] -p <First Port>
```

Use these literal strings as variables that Privileged Access Manager substitutes:

#### NOTE

If you are using IPv6, the <Local IP> in the command line must be surrounded with square brackets: [<Local IP>]

- <Local IP> is replaced with the IP address in the **Local IP** field. Do not repeat the local IP here.
  - <First Port> is replaced with the first local port (after the colon) that is defined in **Ports**. Do not repeat the first port here.
  - <User> is replaced with the account name that is used in the access method. Do not repeat the account name here.
  - <Second Port> is replaced with the second local port (if any) that is defined in **Ports**. Do not repeat the second port here.
  - <Device Name> is replaced with the Name of the Device. Some application connection arguments can use this variable. For example, in WinSCP, "/sessionname=<Device Name>" displays the device name instead of the IP address in the application title bar.
  - Privileged Access Manager automatically inserts the password, so there is no need to provide it.
5. Select **OK**.
  6. Create a Device that corresponds to the SSH target you want to connect.
    - a. In **Devices, Manage Devices**, create a Device with the target IP address (do not use FQDN) in the **Address** field.
    - b. On the **Services** tab, use the controls to move the service that you created from the Available Services to the Selected Services.
    - c. Select **OK**.
  7. Create a **Target Application** using the target device as **Host Name**. See [Add Target Applications](#) for more information.
  8. Create a **Target Account** using the target application as **Application Name**. The **Account Name** is substituted for <User> and the **Password** for <Password>. See [Add Target Accounts](#) for more information.
  9. Create a **Policy** linking the Target Device to a User or Group.
    - a. On the **Services** tab, select the Service that you created.
    - b. In the Target Account column, use the Edit magnifying glass icon to select the Account.

The SSH Service appears on the Access page for the select User or Group.

### Enable File Transfer

You can configure a TCP/UDP SSH Service to do the file transfer operations for a native SFTP or SCP application. Session recording is not activated when either of these features are invoked.

### **Administrator Setup**

You can set up your native SSH Service to allow one of the following options: Automatic Invocation or Manual Invocation.

### **Prerequisites**

To use the file transfer over SSH service, verify that the SSH server on the target Device is configured to provide SFTP sub-system or SCP execution.

### **Automatic Invocation**

Automatically invoke the SSH application with options through the Privileged Access Manager Service command-line specification (in the **Client Application** field) when selecting the service link.

### Manual Invocation

Manual invocation of the SSH application by the user, who applies commands at execution. To invoke the application, select the service link on the Access page.

### User Experience

#### Automatic Invocation

A user on a properly configured client invokes an Access page Service link. The SFTP or SCP client executes automatically with the specified switches or commands. After logging in or auto-connecting to the target device, the user can execute the file transfer operations such as uploading or downloading functions that are provided by the native SFTP or SCP client application.

#### Manual Invocation

If the Privileged Access Manager Service **Client Application** setting is empty, the User starts a local SFTP or SCP client application manually to execute the SFTP or SCP connections.

### Log Entries

A session log entry is written each time a file transfer operation is executed. The following operations are written to a session log:

- Uploading a file to the target device
- Downloading a file from the target device
- Deleting a file on the target device (SFTP only)
- Creating a folder on the target device (SFTP only)
- Removing a folder on the target device (SFTP only)

### Supported SFTP and SCP Client Software

- Windows: WinSCP, FileZilla, Putty
- Mac: FileZilla, OpenSSH (SCP only)
- Linux: OpenSSH (SCP only)

For the FileZilla client, PAM supports the official release version and does not support the development version.

## X11 Forwarding and Command Execution

You can configure a TCP/UDP Service to do X Window System (X11) forwarding and command execution for a native SSH application.

### NOTE

Session recording is not activated when either of these features are invoked.

### Administrator Setup

You can set up your native SSH Service to allow one of the following options:

- Automatically invoke the SSH application with options through the Privileged Access Manager Service command-line specification (in the **Client Application** field)
- Manual invocation of the SSH application by the user, who applies commands at execution. To invoke the application, select the service link on the Access page.

### Prerequisites

To use X11 forwarding, verify that the target Device has X11 applications that are installed. Also confirm that the SSH server that is configured to provide X11 forwarding. The User workstation must run an X11 server to display the output.

**NOTE**

When used on UNIX, Linux, and other UNIX-like systems, the SSH Access Method requires the **socat** relay utility.

**Automatic Invocation**

To configure an SSH session so that it automatically invokes a client application with X11 forwarding, set the X11 option.

**Manual Invocation**

If a TCP/UDP Service is configured to use SSH without specifying the **Client Application**, the user can manually invoke any installed application, such as PuTTY. The service can then use the X11 forwarding or command execution options available to that application.

**User Experience****Automatic Invocation**

A user on a properly configured client invokes an Access page Service link. The SSH client (PuTTY) executes automatically with the specified switches or commands.

1. After logging in or auto-connecting to the target, the User can immediately run X11 applications on the target. The application output is forwarded to the workstation.
2. If a command is specified, the session immediately closes when the command is finished executing.

**Manual Invocation**

If the Privileged Access Manager Service **Client Application** setting is empty, the User must start a local SSH client application manually to execute the SSH connection. The User uses that application X11 forwarding or command execution features. For example, after invoking PuTTY on a Windows workstation, you would use PuTTY **Connection, SSH, X11, Enable X11 forwarding** or **Connection, SSH, Remote** options, respectively. If a command is specified (using the latter option), the session immediately closes when the command is finished executing.

**Log Entries**

A session log entry is written each time an X11 forward occurs or a command is executed for this feature.

**Enable Public Key Authentication**

You can configure a TCP/UDP Service to connect to a target device using the Public Key Authentication method for a native SSH Application.

**Administrator Setup****Prerequisites**

On the native SSH Application: To use Public Key Authentication, verify that the native SSH application enabled **Public Key Authentication** and enabled **Agent Forwarding**.

On the Target Device: Confirm that the SSH server is configured to authorize the public key of the user in their authorized key file (\$HOME/ssh/authorized\_key) or an equivalent file.

**NOTE**

When authenticating using the public key of the user, confirm that Privileged Access Manager has no auto-login configured under Policies.

You can set up the native SSH Service to allow one of the following options:

**Automatic Invocation**

Automatically invoke the SSH application with options through the Privileged Access Manager Service command-line specification (in the Client Application field).

To configure an SSH session so that it automatically invokes a client application with agent forwarding, set the agent forwarding option.

For PuTTY: -A option. For example: C:\apps\putty72\putty.exe -ssh -A <Local IP> <First Port>

### Manual Invocation

Manually invoke the SSH application by enabling agent forwarding. To invoke the application, select the service link on the Access page. Then, launch the native SSH application.

If a TCP/UDP Service is configured to use SSH without specifying the **Client Application**, the user can manually specify the public key authentication and agent forwarding in any installed application, such as PuTTY, and then open a connection. The service can use the public key authentication and agent forwarding options available to that application.

### User Experience

#### Automatic Invocation

A user on a properly configured client invokes an Access page Service link. The SSH client executes automatically with the specified switches. The user can immediately connect to the target using the public key authentication method.

#### Manual Invocation

If the Privileged Access Manager Service **Client Application** setting is empty, the user must start a local SSH client application manually to execute the SSH connection. The user uses that application public key authentication and agent forwarding. For example, after invoking PuTTY on a Windows workstation, use the **PuTTY Private key file for authentication** and **Allow agent forwarding** settings.

### Log Entries

A session log entry is written when trying to do a public key authentication without enabling this feature.

- Public Key Authentication is not permitted over the SSH TCP service. Contact your system administrator.
- Agent forwarding is required to connect using a public key over the SSH TCP service.

## Set Up a Native TN3270 and TN5250 Client

Create a TCP/UDP Service to invoke a local third-party application on a client to connect to a device. The target device does not have to host the client application, which must reside on the user client computer. Native TN3270 and TN5250 client support extends the access controls to any native IBM host client. These controls include session recording and automatic connection with the target account setup. Services and clients must be of the same type for session recording to work. For example, you must configure a TN5250 service to be used with a TN5250 client.

### NOTE

In a PCOMM client, negotiation for the function `CONTENTION-RESOLUTION` is enabled by default. When this function is enabled, session recording fails. You can disable the function by adding the following keyword to the .WS profile:

```
[Telnet3270] TN3270EContentionResolution=N
```

### Follow these steps:

1. On the **Basic Info** tab, enter values for the following fields:
  - Service Name:** enter a name for the portal.
  - Local IP:** enter a valid local loopback address.
  - Ports:** enter 23 (for TN3270 or TN5250) and a local port mapping or asterisk. For example: **23:12345** or **23:\***
  - Select the **Enable** checkbox.
  - For the **Application Protocol**, select **TELNET** from the drop-down list.
2. Select a **Mainframe Protocol** from the drop-down list.

For the **Client Application**, enter the path if you want to invoke the client automatically. The path that you specify here is launched when the enabled SSH service is accessed. Use the syntax in the sample line. Use or substitute the tags as identified here.

**Windows:** C:\path\clientApp.exe [options] username@<Local IP> <First Port>

<Local IP> is submitted and replaced with the IP address in the **Local IP** field.

<First Port> is replaced by the first Local port (after the colon).

Example for a Client Application specification: "C:\Downloads\QWS 3270\QWS3270.exe" <Local IP> <First Port>

When setting up a service for a mainframe proxy, use this execution path as an example:

C:\Program\putty.exe -ssh <Local IP> <First Port>

Some clients may require this syntax: C:\Program\TN5250.exe -ssl:<Local IP>:<First Port>

3. Select **OK**.
4. Create a Device that corresponds to the target device.
  - a. In **Devices, Manage Devices**, create a Device with the target IP address (do not use FQDN) in the **Address** field.
  - b. On the **Services** tab, use the controls to move the service that you created from the Available Services to the Selected Services.
  - c. Select **OK**.

#### NOTE

We recommend that all mainframe connections terminate by selecting the "Disconnect" option in the terminal emulator, not by directly shutting down the terminal emulator application.

#### WARNING

When a native TN3270 or TN5250 client service policy is configured for session recording, select the **Bidirectional** checkbox for the recording to work.

## Configure a Service to Access a Web Portal

Configure the Web Portal application protocol to access websites automatically. This application automatically launches a new browser window and navigates to a preset local IP and launch path.

#### NOTE

Establish a portal for every web server that the user accesses. Some servers provide content to the web pages that call them (through embedded links) but do not face users. See the **Hide From User** option.

#### WARNING

**Warning:** VMware NSX API is no longer supported as of PAM 3.3.

#### Follow these steps:

1. Select **Services, Manage TCP/UDP Services**.
2. Select **Add** for a new TCP/UDP service.
3. For **Service Name**, enter a name for the customized service.
4. For **Local IP**, enter a valid local loopback address.

#### WARNING

To set up a Web Portal for Microsoft SharePoint® and Mac client access, set the **Local IP** to 127.0.0.1 and provide a valid **Host Header**.

5. For **Ports**, enter **80** (for HTTP) or **443** (for HTTPS). Optionally, specify a local port mapping. For example, add **:8080** to map **Remote:Local** as **80:8080**
6. Select the **Enable** checkbox.
7. For **Application Protocol**, select the **Web Portal** option from the drop-down list.

8. **Auto Login Method** defaults to "Disabled." If you specify an automatic login method, such as SAML 2.0 SSO POST, two new tabs activate. For more information, see [How to Configure Automatic Login to Web Portals](#).
9. Enter a value for the **Launch URL** field. The URL specified here is launched when the web portal enabled service is accessed. Use the literal phrases "<Local IP>" and "<First Port>", which use the values in the **Local IP** and **Ports** fields. Use the following syntax: `http[s]://<Local IP>:<First Port>/path_to_target_page`
  - <Local IP> is a literal placeholder for the IP address in the **Local IP** field. Do not repeat the local IP address here.
  - <First Port> is a literal placeholder for the first local port (after the colon) that is defined in **Ports**. Do not repeat the first port here.
  - `path_to_target_page` is the path component of the URL. Create any legal subdirectory path, including:
    - `[directory/[subdirectory/[...]] ]` - optional directory path
    - `[terminal_component.ext]` - optional terminal page/program

Examples:

```
http://<Local IP>:<First Port>/index.html
https://<Local IP>:<First Port>/dashboard.jspa
```
10. Select the **Browser Type**:
  - **Native Browser**: Invoke a window to the Web Portal using the same browser that the User has used to access **Privileged Access Manager** instance.

**NOTE**  
The Symantec PAM Browser is required for web portal recording. The Symantec PAM Browser is also required for all Auto-Login methods except SAML 2.0 SSO POST.

  - **PAM Browser**: Invoke a custom restricted-function browser. PAM Browser is required for web portal recording and all Auto-Login methods except SAML 2.0 SSO POST.
11. Specify the applicable FQDN hostname in **Host Header** so that the portal is able to distinguish between multiple hosted websites, for example, `www.example.com`. If the IP address of the server hosts only one (FQDN) site, this field is not required. However, it is good practice to specify it explicitly.
  - Host Header is not applicable to HTTPS (SSL) sites.
  - Host Header is required for Microsoft SharePoint sites.
  - Host Header applies to a native browser only.
12. If any alias host names are used to reach the portal, enter these names in the **Aliases** field. Separate the names with commas. These aliases are mapped by Privileged Access Manager to the true host (see Host Header). This field applies to a native browser only.
13. If the portal is to be used in the background, select **Hide From User**. This option specifies that a server is available for Privileged Access Manager-internal access, but is not to be accessible to an end user. For example, a server that delivers graphic files that are requested from a browser after a baseline website delivers an HTML page. This field applies to a native browser only.
14. An **Access List** applies to the PAM Browser only. In the **Access List** field, include each host to which access is allowed. A good practice is to examine session logs to find blocked access attempts.
  - a. Enter one host per line.
  - b. An asterisk acts as a wildcard. For example: `*.ca.com`
  - c. Exclude any hosts that pose security risks.

**NOTE**  
In addition to hosts listed in the access list, the web portal can access any device configured in PAM which has an access policy that includes both the web portal itself and the user, whether directly or through groups.
15. Select the **Route Through Symantec PAM** checkbox so that all traffic is directed through Privileged Access Manager. Otherwise, traffic goes directly to the web service from the client workstation. Web Portal traffic can be recorded even if **Route Through Symantec PAM** is not selected.
 

**NOTE**  
The **Native Browser** option does not allow PAM session recording. The user must still select the **PAM Browser**.
16. Select **OK**.

17. Create a Device that corresponds to the web server you are aiming to reach. In Devices, Manage Devices, create a Device with the web server IP address (do not use FQDN) in the **Address** field.

### Next Step

- [How to Configure Automatic Login to Web Portals](#)

## How to Configure Automatic Login to Web Portals

You can create services that manage access to web portals. You can set up manual login or automatic login. This topic describes how to set up automatic login to web portals.

The following methods are available to log a user into a target web portal automatically:

- **PAM HTML Web SSO:** Use this option when the login method that the web portal employs is HTML-based. This method is the most common.  
As a web page is loaded into the PAM Browser, a JavaScript injection provides credentials to the web page HTML, then executes the login. This method requires that the administrator "teach" PAM which login page widgets to use. Some widgets capture the username and the password while another widget acts as the login trigger. Examples of web portals that use this method include Dropbox and Google.
- **PAM HTTP Web SSO:** Use this option when the login method that the web portal employs is the HTTP protocol. In this case, PAM encodes login credentials and inserts them into a header. The header is appended onto each HTTP or HTTPS request. Examples of web portals that use this method include Microsoft SharePoint installations.
- **Built-in Auto-Login Methods:** Built-in methods are also available. These built-in methods allow automatic login-in with the following specific web portals:
  - VMware vCloud Director
  - VMware vShield Manager
  - VMware vSphere Web Client v5; the VMware vSphere Web Client v5 auto login method is only suitable for vSphere v5. To configure auto login for vSphere Web Client 6.0, see [Automatic Login to vSphere Web Client 6.0 Configuration](#).

## Configure a TCP/UDP Auto-Login Service

Create a TCP/UDP auto-login service that is associated with the web portal.

### Follow these steps:

1. Navigate to **Services, Manage TCP/UDP Services**.
2. Select **Add** to create a TCP/UDP service.
3. On the **Add TCP/UDP Service** dialog that opens, complete the following fields as appropriate:
  - **Service Name:** Enter a name for the customized service.
  - **IP Version:** Allows the user to select between IPv4 or IPv6.
  - **Local IP:** If IPv4 is selected, enter a local IPv4 address for this service. The **Local IP** column on the TCP/UDP Services page lists the existing IP addresses for other services.  
If IPv6 is selected, this step does not apply since the value is automatically hard-coded to ' : : 1 ' .
4. For **Ports**, define the ports or port range that the client application opens to gain access to the device. Example: 8000
5. For **Application Protocol**, select Web Portal.  
More options appear on the right side of the page.
6. For **Auto-Login Method**, select the appropriate method, as described previously:

- **PAM HTML Web SSO** is best suited to websites that have user name and password entry fields. This method requires administrator configuration using the Learn Tool.
  - **PAM HTTP Web SSO** is best suited to websites that receive user names and passwords programmatically, such as through Windows Authentication. This method does not require using the Learn Tool.
  - **SAML2.0 SSO POST** requires information about the web portal SAML attributes. [See Set Up SAML 2.0 SSO POST for Auto-Login](#) for more information.
7. For **Launch URL**, follow the example URL. To access the URL `https://www.forwardinc.com/login.html`, replace the target login address (`www.forwardinc.com`) with the target template `<Local IP>:<First Port>`. The resulting entry is: `https://<Local IP>:<First Port>/login.html`
  8. For **Browser Type**, select CA PAM Browser to enable session recording.
  9. For **Access List**, enter \* (an asterisk) as a wildcard. The **Access List** indicates the URLs that can be accessed along with the launch URL. During the Auto-Login, to login to the web portal, the launch URL is followed by other URLs pertaining to the response of login. Therefore, to Auto-Login to the web portal, the **Access List** must be either "\*" or each host that is allowed access.
  10. Select **OK** to save the service.

### **Assign the Auto-Login Service to a Device**

Add the newly created service to the device hosting the web portal. The device is then available for a policy. See [Device Setup](#) for more information about configuring a device.

#### **Follow these steps:**

1. Select **Devices, Manage Devices**.
2. Add the target device hosting the web portal.
3. Select the **Services** tab then select the new TCP/UDP service that you defined.
4. Select **OK**.

### **Create a Target Application, Target Account, and Policy**

Configure a target application and account for the web portal. Completing these tasks enables the storage of credentials. The policy ties the users and the device together to access the web portal automatically.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**, then complete the following fields:
  - **Host Name:** Use the magnifying glass **Select** icon to find and select the host name of the device hosting the web portal.  
**Device Name** is automatically populated.
  - **Application Name:** Enter a descriptive application name.
  - **Application Type:** Accept the default, Generic.
3. Select **OK** to save the target application.
4. Select **Credentials, Manage Targets, Accounts**.
5. Select **Add**, then complete the following fields:
  - **Application Name:** Use the magnifying glass **Select** icon to find and select the application.  
**Host Name** is automatically filled.
  - **Account Name:** Enter the name of the account (user name) for logging in to the web portal. For example: **admin**.
  - **Password:** Enter the password for the account.
6. Select **OK** to save the target account.
7. Select **Policies, Manage Policies**.

8. Select **Add** and set up a policy that associates an existing user or group to the device that hosts the automated login service.
9. On the **Services** tab, select the Service that you created.
10. In the Target Account column, use the Edit magnifying glass icon to select the Account.
11. Select **OK**.

If your target website uses the PAM HTML Web SSO method, you must configure a "learn" procedure to activate the portal for end users.

### **Set up a Learn Procedure for PAM HTML Web SSO**

For target websites that use the PAM HTML Web SSO method, perform a "learn" procedure to activate the portal for end users. An HTML auto-connection portal requires that the HTML field and button widgets be identified. These settings capture a login username and password and activate the browser to submit the username and password for login processing.

#### **Follow these steps to set up the Learn procedure:**

1. Log in to the PAM UI.
2. Go to the **Access** page. A Web Portal drop-down is now available with two services for this device, for example, **MyApp (LEARN)** and **MyApp**.
  - The **Learn** option shows a red **X** to its left. The administrator uses the Learn option to contact the login address and teach the service to recognize the target widgets. After the setup is successful, the red **X** changes to a green checkmark. The checkmark indicates that access to the web portal is activated and is ready to use.
  - The **Login** option is for the actual login entry. The administrator must successfully apply the learn mode *first* for the login service to function.
3. Select the **Learn** option.  
The learn tool launches the target web portal page, but you cannot log in. The window name in the browser title bar is prefaced with "Learn mode for Web SSO."
4. For the service to use widgets for auto-login, teach the service where the widgets are located:
  - a. Right-click in the **User Name** (or other name identifier) field to open the learning menu.
  - b. Select **Mark Accountname Field**.  
The field is populated with the placeholder field "accountname ."
  - c. Right-click in the **Password** field and select **Mark Password Field**.  
The field is populated with an obfuscated password.
  - d. Hover over the button to log in then right-click to select **Mark Submit Button**.
  - e. For any other required widgets for your portal, perform the required action for each widget. (There is no right-click menu item to select, and there is no feedback, but all action is recorded.)

For example, to teach the service to learn the interface to another site, target the portal that requires LDAP authentication. In addition to teaching the service about the three widgets, select "LDAP" for the **Authentication Type** setting. Also, select the appropriate configured domain from the list. All these actions are preserved for auto-connection when you save them.
5. In the upper-right corner of the browser window, select the Save **auto-login template** disk icon.  
The configuration is saved and the browser window closes.
6. Repeat the learning process at any time to save new results.
7. Return to the **Access** page. The learning option now has the green checkmark, indicating that the Learn option is complete.

When an end-user logs in to the UI, the **Access** page now has a single access link without the learn-mode option. The user selects that link and gets auto-logged on to the target web portal.

## Set Up SAML 2.0 SSO POST for Auto-Login

You can set up automatic login to third-party web portals that support SAML SSO, such as Google.com. To configure many of the SAML SSO information fields and attributes for the Web Portal, you must refer to the third-party SAML provider instructions. Ideally, you want to import SAML 2.0 SP metadata from the provider as XML. See [How to Configure the Product as an Identity Provider \(IdP\)](#) for detailed information about setting up SAML authentication, including examples for AWS and Google applications.

See [Configure a TCP/UDP Auto-Login Service](#) for instruction on configuring the **Basic Info** tab of a TCP/UDP Service. When you select SAML 2.0 SSO POST as the **Auto-Login Method**, two tabs become active.

1. On the **Basic Info** tab, use the Web Portal **Entity ID** as the **Service Name**. This value is often a domain name.
2. For the **Auto Login Method**, select SAML 2.0 SSO POST.  
The SAML SSO Info and SAML SSO Attributes tabs become active.
3. In the **Launch URL** field, enter the Assertion Consumer Service (ACS) URL of the RP. The ACS URL is a combination of the PAM web portal URL root and the ACS URL. For example, the web portal URL root is: "https://local\_ipfirst\_port". The ACS URL is: `https://capamAsSp.example.com/samlsp/module.php/saml/sp/saml2-acps.php/capam-default-sp`  
Resulting Launch URL is:

```
https://111.12.123.21:239/samlsp/module.php/saml/sp/saml2-acps.php/capam-default-sp
```

4. Leave the **Route Through Symantec PAM** checkbox selected. This option directs all traffic through PAM. When this option is not selected, traffic goes directly to the web service from the client workstation.
5. On the **SAML SSO Info** tab, enter the following information from the third-party RP:
  - **SAML Entity ID:** This ID is typically a domain name.
  - **Initiating Party:** Select which partner initiates the call.
    - **SP Initiated** (default): If the user logs in to the SP/RP first, an authentication request is sent to the IdP to obtain the assertion. The returned assertion allows the SP to make a service access decision. (SAML 2.0 only)
    - **IdP Initiated** – The user logs in to the IdP to initiate connection and to obtain the assertion for a service at an SP.
  - **Require Signed Authn Requests:** This checkbox is selected by default. The SP must sign the authentication request that it sends to the IdP. To verify the signature, specify the supplied PEM signing certificate, gkcert.crt. in the PEM Signing Certificate field.
  - **Encryption:** By default, encryption is not enabled. Select whether PAM encrypts, the Name ID or the Assertion, then paste the base64 translation of X.509 certificate encryption certificate in the **PEM Encryption Certificate** field.  
Example: `<ds:X509Data> <ds:X509Certificate>encodedContent</ds:X509Certificate>`
6. On the **SAML SSO Attributes** tab, select the appropriate **SAML SSO Subject Name Identifier Formats** for your web portal. If your provider requires an attribute that is not listed, provide the attribute in the **Add a new SAML SSO Attribute** section. Complete the fields for each entry.
  - Name: Specify the attribute name.
  - Friendly Name: assign a name or tag for use by the appliance. If the imported SP metadata does not provide the friendly name, the entry for the Name field is used.
  - Required: Select if the SP requires this attribute.

### NOTE

You might have to add a SAML mapping on the **SAML** tab of the Policy configuration.

7. Select **OK**.
8. Follow the instructions in [Assign the Auto-Login Service to a Device](#).
9. Follow the instructions in [Create a Target Application, Target Account, and Policy](#).

## Automatic Login to vSphere Web Client 6.0 Configuration

To configure automatic login to vSphere Web Client 6.0, use the following settings when completing the previous procedures:

- **Port:** 443
- **Auto-Login Method:** PAM HTTP Web SSO
- **Launch URL:** `https://<Local IP>:<First Port>/vsphere-client`
- **Address:** Specify the vSphere server domain name. An IP address does not work. Example:  
`vcenter.north.afc.nfl.local`

## Import or Export Services for Access

As a Privileged Access Manager administrator, you can import or export Services using a CSV file. You can import three types of services in one file, from any of their respective pages:

- TCP/UDP Services
- RDP Applications

To create or edit services by importing a CSV file:

1. Select **Services**, and either Manage TCP/UDP Services, or Manage RDP Applications.
2. Select the **Import/Export** button.  
The Import/Export window appears.
3. Select **Download Sample File** to save a template file to a convenient editing location.
4. Copy the sample to a new file, and open it in a spreadsheet program or a plain-text editor.

### NOTE

**Microsoft Excel** incorrectly interprets the colon-embedded fields that are intended to be used as *RemotePort:LocalPort* representation. Cell E7 contains "4.815972..." This is an Excel conversion of the original plain-text CSV content that is provided in the file, namely, "23:5555". Even if adjustments are made to the Excel and file save-as settings, this behavior persists in reading or writing the file.

### Workarounds

- a. Always use plain-text editor (for example, Notepad) to prevent conversions from occurring.
  - b. Use Excel first for most editing. As a final editing stage, open the file in a plain-text editor, and delete any conversions. Repopulate those cells with colon-embedded values such as *RemotePort:LocalPort*.
5. Edit or add line items for each service desired and save the file. For descriptions of each field, see [CSV Files for Services](#).

### NOTE

Do not to alter the first (header) line.

6. Select **Choose File** to browse for your saved CSV file.
7. Select **Import Services**.

To export a CSV file of you existing services, follow these steps:

1. Select **Services**, and either Manage TCP/UDP Services, or Manage RDP Applications.
2. Select the **Import/Export** button.  
The Import/Export window appears.
3. Select the **Export Services** button to export a CSV file.

## Create an RDP Proxy Service to Access a Device

An RDP Service invokes a local third-party RDP application on a client to connect to a device. Native RDP Client support extends the Access controls to any native RDP client.

The RDP proxy configuration requires the RDP application configuration.

The RDP proxy service supports the following Privileged Access Manager policies:

- Socket-filtering
- Auto-login
- Session-recording
- Transparent-login

To Create an RDP Proxy Service, follow these steps:

1. Select **Services, Manage TCP/UDP Services**.
2. Select **Add** for a new TCP/UDP service.
  - **Service Name:** Enter a name for the service.
  - **Local IP:** Enter a valid local loopback address.
  - **Ports:** Enter **3389** (for RDP) and a local port mapping or an asterisk. For example: **3389:12345** or **3389:\***
  - Protocol should remain set to TCP.
  - Select the **Enable** checkbox.
  - Select **Show in Column** to show the service as a button on the Access page. Otherwise, Services appear in a drop-down list, which is more compact.
  - For **Application Protocol**, select the **RDP** option from the drop-down list.
3. **RDP Application:** Select a previously configured RDP Application Service that enables you to launch Transparent Login using the RDP Proxy service. To configure an application service, go to Services, Manage RDP Applications service. This option only appears when you select RDP as the application protocol.
4. **Learn Mode:** Check this box to provide an option on the Access page to launch Learn Mode using the RDP Proxy Service. During Learn Mode, Privileged Access Manager is taught the credential-processing interfaces of the provisioned RDP application. This process captures the required sequence in a transparent login configuration file that is stored in Privileged Access Manager. When you check this option, the Show In Column is also enabled, which shows a drop-down arrow on the RDP service displayed on the Access page. When you click on the arrow, you can launch the service with or without Learn Mode enabled. the drop-down arrow enables you to differentiate between services which have Learn Mode enabled and which do not on the Access Page. The Learn Mode drop-down arrow is only shown on the Access page for users with Global Administrator or Service Manager privileged and is hidden for all other users. This option only appears when you select RDP as the application protocol.
5. For **Client Application**, enter the path if you want to invoke the client automatically
6. The path that you specify here is launched when the enabled RDP service is accessed.

Windows remote desktop application:

If you are using IPv4, enter the following command:

```
C:\<path>\mstsc.exe <options>/v:<Local IP>:<First Port>
```

If you are using IPv6, enter the following command:

```
C:\<path>\mstsc.exe <options>/v:[<Local IP>]:<First Port>
```

For macOS:

If you are using IPv4, enter the following command:

Microsoft RDP:

```
open -a "Microsoft Remote Desktop" rdp://full%20address:<Local IP>:<First Port>
```

If you are using IPv6, enter the following command:

Microsoft RDP:

```
open -a "Microsoft Remote Desktop" rdp://full%20address:[<Local IP>]:<First Port>
```

These literal strings are substituted at run-time:

- <Local IP> is replaced with the IP address in the **Local IP** field. Do not repeat the local IP here.

#### NOTE

If you are using IPv6, the <Local IP> in the command line must be surrounded with square brackets.

- <First Port> is replaced with the first local port (after the colon) that is defined in **Ports**.

7. Select **OK**.
8. Create a Device that corresponds to the RDP target device that you want to connect to.
  - a. In **Devices, Manage Devices**, create a Device with the target IP address (do not use FQDN) in the **Address** field.
  - b. On the **Services** tab, use the controls to move the service that you created from the Available Services to the Selected Services.
  - c. Select **OK**.
9. Create a **Target Application** using the target device as **Host Name**. See [Identify Target Applications and Connectors](#) for more information.
10. Create a **Target Account** using the target application as **Application Name**. The **Account Name** is substituted for <User> and the **Password** for <Password>. See [Add Target Accounts to Target Applications](#) for more information.
11. Create a **Policy** linking the Target Device to a User or Group.
  - a. On the **Services** tab, select the Service that you created.
  - b. In the Target Account column, use the Edit magnifying glass icon to select the Account.

The RDP Service appears on the Access page for the select User or Group.

### Administrator Setup

You can set up your native RDP Service to allow one of the following options:

- Automatically invoke the RDP application with options through the Privileged Access Manager Service command line specification (in the **Client Application** field)
- Manual invocation of the RDP application by the user, who applies commands at execution. To invoke the application, select the service link on the Access page.

### Manual Invocation

If a TCP/UDP Service is configured to use RDP without specifying the **Client Application**, the user can manually invoke any installed application, such as mstsc.

### User Experience

#### Automatic Invocation

A user on a properly configured client invokes an Access page Service link. The RDP client (mstsc) launches automatically.

## Configure RDP Applications Templates

Configure an RDP application template to access Windows-hosted applications that have enabled RDP access. Assign that template to a device.

#### Follow these steps:

1. Select **Services, Manage RDP Applications**.
2. Select **Add** and complete the following information:
  - **RDP App Name:** Specify a unique name (up to 255 characters) for the RDP application service.
  - **Launch Path:** Enter the full path to the RDP application that runs after the user connects to it. The Launch Path field is case-sensitive, so pay attention to capitalization.  
For example: C:\Windows\System32\notepad.exe

You can enter an AWS URL to specify the AWS Management Console home page. This token is used as the target address of a browser on a recording-designated Windows “jump box.”

3. Select **Enable** to make this application available to Privileged Access Manager devices.
  4. Optionally, select the **Hide From User** check box so the RDP Application link is not displayed on the Access page.
  5. Optionally, select the **Transparent Login** tab and select the **Transparent Login** check box. Transparent login allows for the passing of vaulted credentials to applications hosted on a remote Windows server. A direct link to the RDP Application, which bypasses the Windows shell, is prevented. Transparent login credential handling (automatic login to the application target) for this application in an RDP session is still enforced.
- The **Application Fingerprint** field is optional. When using the Learn Tool, Specify the SHA-1 digest for the application obtained when using the Learn Tool. The product uses this digest value when the user accesses the application. For more information about Transparent Login, see [Set Up Transparent Login](#).

## Configure Auto-Login for Windows RDP

Learn how to configure Windows RDP access to a target device so that the end user logs in automatically without entering a password.

Complete the following procedures to configure Auto-Login for Windows RDP.

### Watch a Video

Watch this video to see a demonstration of this topic.

### Create a Device

Add the device to which you want to provide auto-login access. For more details about Device attributes that are not covered in this procedure, see [Device Group Setup](#).

#### Follow these steps:

1. Select **Devices, Manage Devices**.
2. To specify a new device, select **Add**.
3. Enter a **Name**. This name is displayed on the Access page. You can enter double-byte characters.
4. Enter the device IP address or FQDN in the **Address** field.
  - For FQDN, DNS must be set up properly on the **Configuration, Network, Network Settings** page.
5. For **Device Type**, select Access and Password Management.
6. Select **Scan** to detect services that are configured on the device. The detected services appear on the Access Methods and Services tabs. RDP should appear on the Access Methods tab after selecting **Scan**.
7. Select **OK** to save the Device.

### Create an Application

Add the Application and Target Connector for connecting users to your device. For Windows RDP, you can use one of the following connectors. Select an Application Type according to your Windows infrastructure and the type of login account you plan to use.

- [Windows Proxy Connector](#): To use the Windows Proxy connector, you must install the connector on a remote server in your target domain.
- [Windows Remote Target Connector](#): The Windows Remote target connector uses local Windows accounts to connect.
- [Active Directory Target Connector](#): The Active Directory connector uses Active Directory accounts to connect.

For ease of demonstration, we use the Windows Remote connector.

**Follow these steps in the UI:**

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Use the **Host Name** magnifying glass to find the target device. Select the device and select **OK**.
4. The **Host Name** and **Device Name** of the target server are populated.
5. Enter a unique **Application Name**. This name does not have to be an existing application on the target device.
6. In the **Application Type** field, select **Windows Remote**.
7. Select the **Windows Remote** tab.
8. For the **Account Type**, select **Local Account**. This type is only able to manage local accounts on target servers.
9. Select **OK** to save the Application.

**Create an Account**

Add the login account for Privileged Access Manager to use to log in to the target device. For more information about setting up accounts for different application types, see the following pages:

- [Windows Proxy Target Accounts](#): The Windows Proxy connector can use local accounts or domain accounts with the AD connector.
- [Windows Remote Target Accounts](#): The Windows Remote target connector uses local Windows accounts to connect.
- [Active Directory Target Account](#): The Active Directory connector uses Active Directory accounts to connect.

For ease of demonstration, we use the Windows Remote connector.

**Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**. The Target Account page appears with a list of existing accounts.
2. Select **Add**. The Add Target Account page appears.
3. Select the **Application Name** magnifying glass to find the target application. Select the application and select **OK**. The **Host Name**, **Device Name**, and **Application Name** fields are populated.
4. Enter the **Account Name**. The account name must be unique for a given target application and must be the account name that the target system uses.
5. Select the **Password View Policy** for the account.
6. Enter an initial account **Password** or select the Generate Credential key icon to generate a default password.
7. On the **Password** tab, Select **Discovery Allowed** to discover accounts on the Windows remote system.
8. Select the **Update both the Credential Manager Server and the target system**. Password updates are performed both in Credential Manager and on the target system to maintain consistency.
9. On the **Windows Remote** tab, select the Administrator **Account Type**.
10. Select **OK** to save the Account.

**Create a User**

Add a User that you want to use auto-login to access the target device. For information about authentication methods, roles, and other User attributes, see [Identify Users that Can Log in to the Server](#). For ease of demonstration, we create a "local" Privileged Access Manager user.

**Follow these steps:**

1. Select **Users, Manage Users**.
2. Select **Add** to create a user.
3. Complete the required fields in the **Basic Info** section (indicated by a red asterisk).
  - **User Name** accepts alphanumeric characters, a dash, an underscore, and spaces. For AWS users, a user name can be from 2 through 32 characters long because of restrictions on federated users within AWS.
4. Select **OK** to save the User.

## Create a Policy

Create a Policy linking the user, the device, and the account. For more detailed information about policies, see [Set Up a Policy](#).

### Follow these steps:

1. Select **Policies, Manage Policies**.
2. Create a policy by clicking **Add**.
3. Use the fields in the **Association** tab to locate the user and device that you want to associate in the policy. Select the search icon in each field to display the list of choices. Select an entry and **OK** to add it to the Association screen.
4. On the **Access** tab, select "RDP" and move it to the Selected Access list. Then select the target account that you created for auto-login. Use the magnifying glass button under the Target Account heading to find the account. Use the shuttle control to move the account from the Available column to the Selected column.
5. Select **OK**.
6. If [session recording capability is configured](#), you can specify the types of recording to make using the options on the **Recording** tab.
7. Select **OK** to save the Policy.

The User should now be able to log in to the Access page, and RDP into the Device without credentials.

## Manage Command and Socket Filters

In the PAM UI, select **Policies, Manage Policy Filters** to configure the following policy filters:

- [Command filters to prevent commands that you specify from executing and socket filters](#)
- [Socket Filter Lists \(SFLs\) that define the sockets to which a Socket Filter Agent allows or denies access.](#)

### Set up Command Filters

Command filters are access restrictions that prevent commands that you specify from executing. You configure command filter lists to enforce a policy in the command line applets TELNET, SSH, and serial consoles. Command filters do not work on Windows Devices.

#### Next Steps

- [Set up Command Filter Lists \(CFL\)](#)
- [Set up Command Filter Configuration \(CFC\)](#)

#### NOTE

For information about setting up Socket Filters, see [Socket Filter Agent Support](#).

### Set up Command Filter Lists (CFL)

Command filtering, like Socket Filters, uses whitelists and blacklists to set the appropriate policy.

- A **blacklist** is a list of commands that a user cannot type. If the user attempts to type the command, Privileged Access Manager can flag (log), alert, remediate, and stop the command from being processed. All other commands are allowed.
- A **whitelist** is a list of the commands that a user can type. All other commands are prohibited.

#### NOTE

Command filter whitelists cannot be configured for Mainframe TN3270 and TN5250 applets.

Create Command Filter Lists (CFLs) in the user interface using the CFL template or by importing a CSV. See [Import or Export Command Filter Lists](#) for information about importing a socket filter list with a CSV.

### Use the CFL Template

Use the following procedure to create and manage Socket Filter Lists using the SFL template. Follow these steps:

1. Select from the Menu Bar: **Policies, Manage Policy Filters.**
2. The **Command Filters** page appears.
3. Select the **ADD** button.  
The **Add Command Filter** window appears.
4. Enter a **Name** for this socket filter list.
5. Specify the **Type** of list:
  - A **Blacklist** denies only the listed command strings.  
If a user submits a CLI command to a device that is on the blacklist, the user request is denied. This denial applies **per character**: After sufficient characters (literal Keyword or Regexp) are entered match a violation criterion, the specified action (Alert/Block) is applied. You must configure a policy for this user that specifies the blacklist.
  - A **Whitelist** allows access only the listed command strings.  
If a user submits a CLI command to a device that is on the whitelist, then those commands are allowed. This allowance applies **per line string entered**. The permission test is made following a linefeed/Enter/carriage return. You must configure a policy for this user that specifies the whitelist.

#### NOTE

Command filter whitelists cannot be configured for Mainframe TN3270 and TN5250 applets.

6. Select the plus icon to Add a new Keyword.
7. In the **Keyword** field, enter a command string. Depending on which type of list you are creating:
  - a. If you are creating a **blacklist**, then for each Keyword to test, you must select one or more controls:
    - **Alert** – Select this box to alert Monitoring administrator immediately by email with each instance of Keyword violation.
    - **Block** – Select this box for the command line containing the Keyword to be canceled immediately, and prevented from executing.
    - **Regexp** – Select this box if the Keyword field specifies a regular expression to be applied to the actual command entered. Whenever a command that is entered by the User conforms to the regexp, the command is flagged as a violation.
    - When both **Regexp** and **Alert** are selected, the body of the alert message does not include the Keyword regular expression string for security reasons.

If the **Keyword** is a regular expression and not simply a literal character match, then you must select the **Regexp** checkbox. There is no action taken unless you select either **Alert** and/or **Block**.

#### NOTE

Alert and Block log the violation in the sessions log of the local node where the violation occurred. For example, if a standard user commits a violation after having logged into their access method from a secondary site node in a cluster, that violation is only logged in the sessions log of that particular secondary site cluster node. Furthermore, if you want to receive email on the Alerts, you must have the Admin Email configured and the Monitor started on the particular cluster node where the violation occurred. See [Set Up Email for Monitoring](#) for more details.

**Important:** When populating the Keyword field for a **blacklist** using **Regexp**, begin with a start-of-line metacharacter, typically **^**. However, because a blacklist keyword string is evaluated character by character, the end-of-line metacharacter (ordinarily: **\$**) is never interpreted and is therefore unnecessary.

**Example:** Match (prevent) a user key entry of exactly **who -a**

Fill the Keyword field with one of the following regular expressions:

- Correct: **^who -a**
- Correct: **^who -a\$**

However, each of the following regular expressions does *not* work correctly:

- Incorrect: **who -a**
- Incorrect: **who -a\$**

b. If you are creating a **whitelist**, then for each Keyword to test, you can select:

- **Regex** – Select this box if the Keyword field specifies a regular expression to be applied to the actual command entered. The regular expressions that are permitted follow the syntax that is supported by the Perl-based Oracle® `java.util.regex` API. The command succeeds only when it conforms to one or more of the regex or commands in this whitelist.

When populating the Keyword field for a **whitelist** when using **Regex**, it does not matter whether you include the start-of-line (ordinarily: `^`) or end-of-line (ordinarily: `$`) metacharacters. These metacharacters are implied. The string that the user enters is automatically anchored by both of these metacharacters.

**Example:** Match (allow) a user entry of exactly: **who**

Enter Keyword field content of any of the following regular expressions:

- Correct: **who**
- **^who**
- **^who\$**
- **who\$**

**Example:** `[LI][Ss] +`

This regular expression permits variations of uppercase or lowercase on the UNIX command **ls**, but requires that a space be added for the expression to be accepted.

**Example:** `[LI][Ss] +\-[LIAa][LIAa]?`

This regular expression is a variant of the previous example, which is based on **ls -al**, in which uppercase and lowercase are again permitted. But the order of the two characters **al** is arbitrary, and two or more spaces are required between the command and its argument. Because the command filter string is anchored by start-of-line and end-of-line metacharacters, trailing spaces are prohibited in this example.

8. Select the **OK** button to save the settings.

The list is now effective in Privileged Access Manager, and available for inspection or editing to the Command Filter list page.

## Search Command Filter Lists

You can search existing command filter lists for matches to a character substring by using the **Search** field. This search flags a list when there is a match in its **Name** field, and when there is a match in any of the **Keyword** fields for that list.

## Import or Export Command Filter Lists

Use the following procedure to create and manage command filter lists using a CSV file.

### Follow these steps:

1. Go to **Policies, Manage Policy Filters**.  
The **Command Filters** page appears.
2. Select the **Import/Export** button.  
The Import/Export command filters window appears.
3. A sample file is available by selecting the **Download Sample File** button. Copy the sample file to a new file, and edit it for your use.
4. All columns are required fields. See [Set up Command Filter Lists \(CFL\)](#) for detailed information about these fields.

- **Type:** Command Filter List
  - **List Name:** This text populates the **Name** field on the Command Filters list page.
  - **List Type:** white or black  
Use "white:" for a Whitelist, which is a list of commands that a user may use. All other commands are prohibited.  
Use "black:" for a Blacklist, which is a list of commands that a user may not use. All other commands are permitted.
  - **Keyword:** Enter the command or command subset to be restricted. Multiple commands for the same list are designated by multiple CSV line items using the same List Name.
  - **Alert:** t or f for true or false  
If true, immediately notify the monitoring administrator of any use of this command.
  - **Block :** t or f for true or false  
If true, this command is canceled and prevented from executing.
  - **Regexp :** t or f for true or false  
If true, the Keyword field is evaluated as a regular expression when matching a command. If there is a match, apply any Alert or Block specified.
5. Use the **Choose File** button to select the completed CSV file for import and select **Import Command Filters** to upload.  
The list is now effective, and available for inspection or editing on the **Command Filters** list page.

### WARNING

If you include a blacklist line in the CSV file with the same key fields (**Type**, **List Name**, **List Type**, and **Keyword**) found in an earlier line, the latter line replaces the earlier line. The values that are applied for **Alert**, **Block**, and **Regexp** are the last values read, or the values in the last key-matching line.

### Export Command Filters

Use the **Export Command Filters** button to export existing SFLs to a CSV file. These lists can be stored, modified, and imported or reimported later.

### Set up Command Filter Configuration (CFC)

This screen is used to create and manage command filtering.

1. Select from the Menu Bar: **Policies, Manage Policy Filters**.  
The Command Filters page appears.
2. In the upper corner of the white page body, select the **CONFIG** link.  
The Command Filter Config template appears.
3. Adjust the fields where necessary, and click **OK** to save the settings.

### Command Filter Configuration Pane

Field	Description
Messages	

Blacklist Violation Message	<p>The default is: Warning: [command] is an unauthorized command. You have [violations] violations. Your session will be terminated and account deactivated should violations continue. Contact the administrator if you have any questions ... where "[command]" is substituted during execution with the string (keyword) used, and "[violations]" is substituted during execution with the number of (including the current) occurrences of this violation by this user (and "[newline]" is substituted with a line feed).</p> <p><b>Note:</b> Double-byte characters such as those used for traditional Chinese are permitted.</p>
Whitelist Violation Message	<p>The default is: Warning: [command] is an unauthorized command. Contact the administrator if you have any questions ... where "[command]" is substituted during execution with the string (keyword) used (and "[newline]" is substituted with a line feed).</p> <p>NOTE Double-byte characters such as those used for traditional Chinese are permitted.</p>
Violation Additional e-mail Message	<p>This area is provided for information that is sent to the configured administrator if violations occur. (No default is provided.) NOTE Double-byte characters are NOT permitted in email messages. (They are permitted only in screen messages.)</p>
<b>Action</b>	
# Violations Before Action	<p>The numerical value of the number of violations that are permitted to occur. When the violation count matches the threshold, the action in the Action After Limit Exceeded is taken. Set this value to zero (0) if no count is enforced. The count of violations is on a per session basis regardless of how many times the user connects.</p>
Action After Limit Exceeded	<p>Select the appropriate action that complies with policy when the user exceeds the number of violations.</p>

## Socket Filter Agent Support

Socket Filter Agents (SFAs) are components that you can deploy to restrict access to and from server-based devices. SFAs are installed on a remote target device. For information about downloading and installing Socket Filter Agent software, see [Install and Configure a Socket Filter Agent](#).

Socket filters apply rules that are used in access policies. These rules are specified by configuring socket filter lists from the PAM UI.

### NOTE

If an SFA is installed on a Windows system, the SFA filters do not get applied to VNC connections.

To configure SFA lists and policies, follow these procedures:

### Create a Socket Filter List

A Socket Filter List (SFL) defines the sockets to which a Socket Filter Agent allows or denies access. An SFL can be a whitelist or a blacklist:

- **Blacklist:** A blacklist denies access only to the listed services and ports. A user can request access to a device with a policy that has this blacklist. Any user that requests a socket on this list is denied access. The user is allowed access for sockets that are *not* on the blacklist.
- **Whitelist:** A whitelist allows access only to the specified servers and ports. A user can request access to a device with a policy that has a whitelist. Any user that requests a socket that is on this list is allowed access. The user is denied access for sockets that are *not* on the whitelist.

Create an SFL using one of the following methods:

- Use the SFL template in the UI. Use the procedure in this topic.
- Import a CSV file. For instructions on how to import a CSV file and create an SFL, see [Import or Export Socket Filter Lists](#).

#### TIP

To ensure proper performance, define no more than 8000 sockets in each SFL.

#### Follow these steps to create a filter list:

1. From the PAM UI, select **Policies, Manage Policy Filters**.  
The **Policies** page appears.
2. Select the **Socket Filters** tab.
3. Select the **Add** button.  
The **Add Socket Filter** window appears.
4. Enter a **Name** for this socket filter list.
5. Specify the type (blacklist or whitelist) in the **Type** field.
  - When used against LDAP users, socket filter whitelists must also include IP addresses of the relevant domain controller or controllers. IP addresses can change in your environment, so whitelists can require active management. You might have to update the filters.
  - For PKI smartcard users, socket filters must be actively managed.
6. Select the plus sign (+) to add a new host.
7. Enter the IP Address and ports to filter. The **Ports** field is limited to 512 characters.

#### NOTE

If a host has both IPv4 and IPv6 addresses, you must add a host entry for each address.

8. Select **OK** to save the settings.

The list is now effective, and available for inspection or editing with the **Socket Filters** list page.

#### Configure a Socket Filter Policy

#### NOTE

Do not configure VNC access to log in to a Windows system installed with an SFA. This access method does not work with a Windows SFA.

#### Follow these steps:

1. From the PAM UI, select **Policy, Manage Policy Filters**.
2. Select the **Socket Filters** tab.
3. Select the **Config** button.  
The **Socket Filter Config** pane appears, populated with default values.
4. On the **Basic Info** tab, inspect these settings:
  - **Agent Port**  
The agent port must match the port where the agents are listening. The default is 8550.
  - **SFA Monitoring**

Select this box to enable monitoring socket filter agents. Agent status appears on the Devices, Socket Filter Agent page. Enable this option if policies disallow users to log in to a device if an agent is not running.

- **Appliance ID**  
Set a unique number (from 1 to 254) for each physical appliance, especially in a cluster. This ID is required for using SFAs with Windows.
  - **Log All Access**  
Select this box to log all access activity, whether a device is on a whitelist or it is missing from a blacklist. Second-generation Socket Filter Agent installation is required.
5. On the **Messages** tab, inspect these settings:
- **Violation Message**  
Customize the message ("Access is denied") that appears to the user when a policy is violated. The following strings (including brackets) are substituted as specified:  
[host] is Replaced by the IP address of the blocked host.  
[port] is Replaced by the port of the blocked connection.
  - **Violation Additional e-mail Message**  
Add text area for information that is sent to "super" if violations occur.**Prerequisite:** Administrator email must be configured.
- Double-byte characters are NOT permitted in email messages. They are permitted only in screen messages.
6. On the **Action** tab, inspect these settings:
- **Number of Violations Before Action**  
Set the number of violations that are permitted to occur. When the violation count matches this threshold, the action that is specified in Action After Limit Exceeded is taken. Set this value to zero (0) if no count should be enforced.  
The count of violations is persistent per user-device basis regardless of how many times the user connects. Thus a user is not permitted to reset the count by reconnecting and trying again.
  - **Action After Limit Exceeded**  
Select the appropriate action to comply with policy when the user exceeds the number of violations.
7. Select **OK** to save the settings.

### **Enable Socket Filter Agent Monitoring**

To enable monitoring of SFA Agents, follow these steps:

1. Navigate to **Policies, Manage Policy Filters, Socket Filters**
2. Select **Config**.
3. Select the **SFA Monitoring**.
4. Select **OK** to save your settings.

### **View Socket Filter Agent Status**

The appliance runs a scan at regular intervals to determine the status of all SFAs. After you enable SFA monitoring, you can view the status of the SFAs.

To see the list of SFAs:

1. Navigate to **Devices, Socket Filter Agent**. The Socket Filter List Status page displays.  
You only see entries on this page if you enabled monitoring.
2. Look at the **Status** column. The column shows one of the following values:
  - **Active:** The SFA is up and running. The appliance is able connect to the Agent on port 8550 of the remote host.
  - **Inactive:** The SFA was active but not for the past few minutes.
  - **Unknown:** The SFA was active but has not been active for an extended period of time. Reasons why the SFA might be unreachable are that the Agent is turned off, disabled, or uninstalled.

## Import or Export Socket Filter Lists

Use the following procedure to create and manage socket filter lists using a CSV file.

### NOTE

If your CSV file contains duplicate records, only one of the duplicate rows is imported; any others are ignored. For example, if a CSV file contains the following rows, one row is imported and the other row is ignored:

Type	List Name	List Type	IP Address	Port
Socket Filter List	whiteList	white	1.2.3.4	80
Socket Filter List	whiteList	white	1.2.3.4	80

### Follow these steps:

1. Go to **Policies, Manage Policy Filters**.  
The **Socket Filters** List page appears.
2. On the **Socket Filters** tab, select the **Import/Export** button.  
The Import/Export socket filters window appears.
3. A sample file is available by selecting the **Download Sample File** button.
4. All columns are required fields.
  - a. **Type:** Socket Filter List
  - b. **List Name:** This text populates the **Name** field on the Socket Filter List page.
  - c. **List Type:** white or black  
Use "white" for a Whitelist, which is a list of sockets (IP address and port combinations) that a user may use. All other sockets are prohibited.  
Use "black" for a Blacklist, which is a list of sockets that a user may not use. All other sockets are permitted.
  - d. **IP Address**  
The IP address can be a single address or a mask. All of these example addresses are valid:  
**IPv4:** 192.168.1.14, 192.168.1.14/24  
**IPv6:** fd6d:8d64:af0c:1:0:242:22:233, fd6d:8d64:af0c:1:0:242:22:233/64
  - e. **Port**  
You can include one or more port numbers, comma or space separated, or one port range. All these ports are valid (semicolons not included):  
5555; 0-65535; 5555 7777; \*; 21,22,23
5. Use the **Choose File** button to select the completed CSV file for import and select **Import Socket Filters** to upload.  
The list is now effective, and available for inspection or editing on the **Socket Filters** list page.

### NOTE

To add new socket filters to your existing socket filter list, create and import a *fresh* CSV file that contains only the new entries. The new socket filters are added to the existing list in PAM. Do *not* add the new entries to an existing socket filter CSV and reimport that file. To maintain an up-to-date socket filter list for your records, export the complete list to CSV after importing the new entries.

## Export Socket Filters

Use the **Export Socket Filters** button to export existing SFLs to a CSV file.

## Setting Up Transparent Login

Transparent login enables automated log-in to a remote target application that has been accessed through auto-connection login.

The two services that support transparent login are RDP and SSH.

### **Next Steps**

- [SSH Connections](#)
- [Set Up Transparent Login for RDP Servers](#)
- [Import or Export Transparent Login Configurations](#)

### **Associate Multiple Target Accounts for Use as Transparent Login Credentials**

Within a Policy, you can associate multiple Target Accounts for use as Transparent Login Credentials (TLC) for a Transparent Login enabled RDP Application Service (TL Service). TLC for a Policy containing a TL Service is decoupled from the TL Service Windows. There is no limit to the number of accounts you can select as TLC for a Policy containing a TL Service. This allows you to configure multiple accounts as TLCs for use within RDP sessions. End users can select from that list of TLC when they access the TL Service through the Access page.

This feature allows the use of Stacked Policies. A stacked Policy refers to multiple Policies that are assigned to same user who is a part of different user groups. Previously, the TL service applied a single Policy for the user, and the user could log in using only one TLC.

The functionality enables the user to select any credential that is aggregated across multiple Policies which the user may be a part of.

Multiple TLC can be on the same host device, or on multiple devices. This functionality enables you to select TLC from any applicable device that the user wants to go, and transfers them accordingly. To use this ability, the Transparent Login Configuration should have host="true" in the applicable location.

## **SSH Connections**

From the SSH access method applet, you configure a device to permit execution of **sudo** or **pbrun** commands using the login password for the device.

### **NOTE**

You cannot apply transparent login to Device Groups

### **NOTE**

Transparent login supports the following items at the target device:

- OS versions: UNIX and Linux
- Shell types: bash, csh, tcsh, and ksh
  - The following restrictions apply to the **ksh** shell type:
    - Vi command line history is not supported.
    - Emacs command line history does not support recalling commands. Example: If a command has one or more carriage returns in it, the command runs but cannot be recalled properly in emacs mode.
    - Using Ctrl-C to break a looping command is not supported.
- Applications: sudo and BeyondTrust PowerBroker pbrun

### **WARNING**

Configure sudo or pbrun on the target so that each execution requires a password from the client. Otherwise, security can be compromised

## Unix/Linux Configuration

Configure **sudo** or **pbrun** for target devices to request a password every time that it is invoked. Privileged Access Manager responds transparently to the request. For example, set `timestamp_timeout=0` so that a password is always required. The sudo execution must always require a password or security is compromised.

### Configure Transparent Login for a Device

To configure a Device to allow secondary transparent login, follow these steps:

1. Create or open an existing Device record on the **Devices, Manage Devices** page.  
If this device record is new, populate at least the required attributes (entitled in **red**).
2. In the **Access Methods** panel, select **SSH**.
3. Scroll to the **Transparent Login** panel. Complete the following fields to configure sudo or pbrun (or both):
  - **Full Path to** - Identify the directory location of the sudo or pbrun executable on the target Device.
  - **Password Prompt** - Specify a prompt (or a fully static substring) for user password input that is presented immediately upon executing sudo/pbrun.  
The full prompt that is experienced by the user might be "[sudo] password for *user*: ", where "*user*" represents the dynamically applied actual username. The maximum string that can be applied here is then: "[sudo] password for ", so use that string.
4. Complete configuring of other device fields as needed, and select Save.
5. Create or open an existing policy record on the **Policy, Manage Policies** page.
6. Scroll to the Transparent Login panel and select the checkbox to turn on transparent login. Clear it to turn it off for a particular User/User Group.
7. Complete the provisioning of other Policy fields as needed, and select Save.  
Transparent login is now ready for Access use to this Device.

#### NOTE

You can configure only a *single* account in the transparent login policy for a CISCO device. Multiple accounts are *not* supported in the transparent login policy.

## User Experience

The User logs in as usual to the target Device using the SSH Access Method applet. When sudo or pbrun is enabled, the normal response (prompting the user to enter a password) is not displayed. The product supplies the password for the auto-connection, and sudo/pbrun continues to execute the sudo commands.

#### WARNING

In some uncommon scenarios, transparent login does not behave as intended, and the user experiences unexpected behavior. For example, a token ("XGK####") is visible or a password prompt might appear. In these cases, exit the application by entering a return, or if necessary Control-C. Retry the command, taking care to apply the correct syntax.

### Complex Commands

You can use a configured privileged command (sudo or pbrun) anywhere, and multiple times, on a command line while Privileged Access Manager provides the login password for uninterrupted completion.

Examples:

```
$ for i in $(cat newusers.txt); do sudo useradd $i; done
$ sudo vi /etc/ssh/ssh_config && sudo /etc/init.d/ssh restart
```

You can also use a configured privileged command (sudo or pbrun) on multiple lines while Privileged Access Manager provides the login user password for uninterrupted completion.

Example:

```
$ *for i in $(cat a_remote_location/deep_in_some_subdirectory/*
> newusers.txt); do sudo useradd $i;\
> done
```

### **Unsupported Syntax**

Transparent login does not support the following command uses:

- Sending a sudo command argument to the background, such as:  
\$ sudo updatedb &
- Stringing a sudo command after a vi exit command, such as:  
:wq sudo updatedb

Exit the vi window with the Enter key first.

### **NOTE**

If a password prompt appears during execution of a sudo or pbrun command in a Windows device, exit using Ctrl-C. Any other response might trigger a password lockout, such as pressing Enter or another key entry

### **Audit Logs**

Following each invocation of or pbrun, an audit log entry like the following example is written:

```
2016-03-11 01:16:27      user      xssso      ubuntu      Executed "sudo pwd" using transparent login as username
```

## **Set Up Transparent Login for RDP Servers**

You can implement transparent login for a Windows RDP server. Transparent login provides secondary access through an application on that device. As with Privileged Access Manager HTML WebSSO, the administrator uses "Learn Mode" to teach the product to recognize the relevant access interface of a target application. In this case, it is a Privileged Access Manager-configured RDP Application.

The benefit of the feature is that credentials and software are not stored on the target RDP server. No installation of agents is needed on the access client or the RDP server. Optionally, these applications can be cached for improved load times.

### **NOTE**

#### **Transparent Login with RDP Proxy Fails with Protocol Error**

To use transparent login with an RDP proxy, you must enable drive mapping in the RDP client and disable other device mappings, such as printers, ports, and so on.

Otherwise, no special configuration is required on Privileged Access Manager or the target Device. This provisioning process embodies the required setup.

This topic explains the following information:

### **Target Devices Support**

- **OS versions:** Windows Server 2012, Windows Server 2016, Windows Server 2019; x86 and x64 versions for each
- **Applications:** VMware vSphere Client and vSphere Client console; Microsoft SQL Server Management Studio; WinSCP; Dell Toad; PuTTY; Oracle SQL\*Plus

## **Windows Configuration**

Windows (RDP server) devices that are the targets of Privileged Access Manager transparent login require the following configuration to work properly.

### **Certificates**

If you are using a signed certificate on Privileged Access Manager, you must install the CA certificate on each Windows target Device. Import this certificate as a Trusted Root.

### **Session Recording**

For transparent login activity to be successfully recorded when using Internet Explorer, configure all equivalent Privileged Access Manager addresses. For example, a cluster VIP name and VIP address in the browser security settings:

1. In Internet Explorer, select **Tools, Internet Options**.
2. Select the **Security** tab, then on **Trusted Sites**, and then the **Sites** button.
3. In the **Trusted sites** dialog window, key in and **Add** each equivalent Privileged Access Manager address in use. Select **Close** to exit Trusted sites.
4. Select **OK** to save and exit Internet Options.

This setting might not work fully. If that is the case, try this additional configuration in **Internet Options**:

1. Select the **Connections** tab, then on **LAN settings**. If the **Proxy server** checkbox is selected, select the **Advanced** button.
2. In the **Exceptions** section, remove any "127.\*" or equivalent construct
3. Select **OK** to save and exit **Proxy Settings**. Then, select **OK** again to save and exit **Local Area Network (LAN) Settings**, and then **OK** again to save and exit **Internet Options**.

## **Prerequisites**

### ***On Windows Server 2012***

1. Add your Windows Server 2012 to your Domain.  
For testing purposes, you can instead install a Domain Controller on the same server. See:  
<http://social.technet.microsoft.com/wiki/contents/articles/12370.step-by-step-guide-for-setting-up-a-windows-server-2012-domain-controller.aspx>
2. Install the Remote Desktop Session Host role using the following instructions:  
<https://support.microsoft.com/en-us/help/2833839/guidelines-for-installing-the-remote-desktop-session-host-role-service>
3. Configure cmd.exe as a RemoteApp using the instructions in the following article:  
<http://social.technet.microsoft.com/wiki/contents/articles/10817.publishing-remoteapps-in-windows-server-2012.aspx>  
For security reasons: In the **RemoteApp Properties** dialog, **Command-line arguments** option button, select the **Always use the following command-line arguments** option. Set its arguments to use the following string.  
Whether you copy-and-paste this string or you enter it in manually, ensure that you do not introduce any additional hidden characters or white space. Otherwise, the command might not work.

```
/C title Initializing RDP session&echo Please wait...&timeout 4 /nobreak>nul&"\
\tsc\client\virt\xcd_run.bat"
```

### ***On Windows Server 2016 and Windows Server 2019***

1. Add your Windows Server 2016 or Windows Server 2019 to your Domain.  
For testing purposes, you can install a Domain Controller on the same server. Refer to the following article for guidance:  
<http://pc-addicts.com/setup-dhcp-role-server-2016/>

2. Deploy your Remote Desktop environment, referring to the Microsoft documentation for guidance:  
<https://docs.microsoft.com/en-us/windows-server/remote/remote-desktop-services/rds-deploy-infrastructure>
3. Create a Remote Desktop Services collection for desktops and apps to run. See the following Microsoft documentation for guidance, stopping when you reach the "Publish RemoteApp Programs" section, then proceed to Step 4 in this procedure.  
<https://docs.microsoft.com/en-us/windows-server/remote/remote-desktop-services/rds-create-collection>
4. Follow these steps to publish cmd.exe as a RemoteApp:
  - a. In **Server Manager**, select the new collection
  - b. Under **RemoteApp Programs**, select **Tasks, Publish RemoteApp programs**
  - c. Select **Add**
  - d. In the file chooser, use the search box to locate and select the appropriate instance of cmd.exe
  - e. Select **Open**
  - f. Select **Next**
  - g. Select **Publish**
  - h. Under **RemoteApp Programs**, right-click **cmd** and select **Edit Properties**
  - i. Select **Parameters**
  - j. For security reasons, set the **Always use the following command-line parameters** option and set its arguments to use the following string:
 

```
/C title Initializing RDP session&echo Please wait...&timeout 4 /nobreak>nul&"\\tsclient\virt  

          \xcd_run.bat"
```

**NOTE**  
 Whether you copy-and-paste this string or you enter it manually, ensure that you do not introduce any additional hidden characters or white space. Otherwise, the command might not work.
  - k. Select **OK**

## Configure Windows Transparent Login

Learn how to configure PAM to enable automated log-in to remote Windows target applications.

Complete the following procedures to configure Windows transparent login on and through PAM:

1. [Preparing Target Device records, including an RDP server hosting an RDP Application](#)
2. [Running the Learn Tool at the RDP server in coordination \(through the RDP Access Method applet\)](#)
3. [Configure the RDP Application record](#)
4. [Provision Target Account records and activate PAM policy](#)

### NOTE

To run Learn Tool and edit transparent login configurations, a PAM administrator must have at minimum the role of Service Manager. This level of role permits the `servicesRead`, `servicesManage`, and `servicesDelete` privileges. Among the preconfigured roles, these privileges are also provided only to the Global Administrator and Operational Administrator roles.

This topic also describes the following other related topics:

- [Caching](#)
- [Auditing](#)
- [User Experience](#)

## Prepare Targets

Initially, as the PAM administrator, you provision a Device and the RDP Application that is the target (or intermediary) of the transparent login. You might also want to provision (in Credential Manager) the primary access credentials that

are consumed during login to the Device. At this stage, you do not need to provision the secondary credentials that are consumed by the RDP Application.

## Run Learn Mode

During Learn Mode, PAM is taught the credential-processing interfaces of the provisioned RDP Application. This process captures the required sequence in a transparent login configuration file that is stored at PAM.

## Example Procedure

This example procedure uses the execution of a connection to a Linux target device using the RDP Application PuTTY.

1. Confirm that you have provisioned the required target Device. Confirm that the target RDP Application, that is configured later, is installed on that Device.
2. If needed, log in to PAM as the administrator responsible for Learn Mode.
3. Navigate to the **Access** page.
4. Mouse over the **RDP** link to the target device until the **RDP options** dialog opens and then do the following actions:
  - a. Select the **Learn mode** option.
  - b. Optionally, expand the size of your RDP window in **Resolutions** to the largest practical value. Example: "Fullscreen" Learn Mode is easier to use when there is a large target desktop.
  - c. Select **Launch** to initiate the RDP connection.

Your RDP applet and connection launch.

Following login, a script window appears telling you that the Learn Mode Tool ("Transparent Login Learn Tool") is launching. The initial **Learn Tool** window opens. If transparent login configurations are already set up, they are shown in the drop box near the upper left corner of the Learn Tool.

Use the Learn Tool, to create a configuration script that allows PAM to recognize the username, password, submit, and other widgets of an RDP Application when your users connect to that application. This script also populates and executes these widgets for transparent login.

Initially, several configurations (Transparent Login Configurations, or TLCs) can be pre-populated in PAM. As the Learn Tool is launched, these configurations are loaded into Learn Tool memory and are available from the configuration name drop-down list.

In this example, we create a configuration. First, assign it a name, in this example PuTTY-to-LinuxTarget1. This name is found in the **Transparent Login Configurations** list on PAM. You can edit the name in the **Name** field when you prepare your RDP Application record.

- a. Select the "Add new configuration" button, and in the dialog window enter a **Name**, and select **OK**.  
The configuration name now appears in the field to the left of that button, and is immediately saved.
  - b. To save the (currently empty) configuration in PAM with this name, select the "Save configuration" button.
5. Open your target RDP application; a configuration interface is ordinarily presented (the **PuTTY Configuration** window).  
While both the Learn Tool and the application are open during this procedure, you populate the Learn Tool script window (the body of its GUI). You identify widgets on the target application using one of several Learn Tool widgets that are detailed in the following tables. Each use of a scripting widget inserts a script command.  
When executing PuTTY using its GUI, the simplest procedure might be to specify a target address, then execute a connection using PuTTY default parameters. Then automatically submit the username and password to affect a login: First, identify for the Learn Tool the location of the PuTTY Session screen, **Host Name (or IP address)** field. When the script is run, PAM knows where to insert that address.
6. To create the script command that provides this functionality, select the "Text input" tool. Like each of the other Learn Tool scripting controls, this tool invokes an **Add Edit Tag** dialog window. Specify parameters to identify and populate this command in this window.  
The first field is the **Element type**. In this case, select the default "Text Field", which is the type of control widget that PuTTY **Host Name (or IP address)** is. (The other choices are "Drop Down List", "Checkbox", "Radio Button", and "Keystrokes"). To identify where this field is, provide the **Element ID**. The first step is to invoke the application Autolt Control Viewer (v. 1.1) from the Learn Tool menu:

7. Select the "Run Control Viewer" button from the Learn Tool menu bar. You might briefly see a script window, and then in a minute or so the **Control Viewer** window appears. Now you have three windows. The Learn Tool window is resizable.
8. In the Control Viewer window, press and hold your mouse over the **Browse Tool** square area to the upper right. A magnifying glass icon appears, which is your control selection cursor.  
While you hold your mouse down, move this cursor over to the location of the widget (GUI field, or control) that you want to identify.  
As you move the cursor, the control of the target application that is under the cursor displays a red outline. Depending on how the application (PuTTY) was designed, the red outline might refer to a single control or a group of controls.
  - a. If the *specific* control (here, the host name field) is already outlined in red, you would now skip the remainder of this step 10.
  - b. However, a group of controls is selected, and you have not yet been able to identify the **Host Name (or IP address)** field itself.
    - a. Look at the additional characteristics for this specific control that is highlighted in the blue item in the **Controls** list at the bottom of the Control Viewer window. This list also identifies any subordinate controls that are contained by that control. In this case, we want to identify the specific host name control.
    - b. Scroll that list to select the other controls in the list, one by one, until you match the one you are searching for. When the selected control is outlined, note (under the **Control** tab in the central **Info** group) what its full **Instance** name (5) is: here, "[CLASS:Edit; INSTANCE:1]".
9. You have now identified the exact field that PAM must populate. Finish using the Learn Tool **Add Edit Tag** window that you opened in step 8:
  - a. Select the entire **Instance** name (from open bracket to close bracket, inclusive), and copy it in the **Element Id** field.
  - b. In the **Value type** field, select the "text" option. The other two options are "username" and "password." These options refer to data that is supplied by PAM during execution, and not embedded in the script.
  - c. In the **Value** field, enter the IP address that you use to populate that PuTTY field. Alternatively, you can specify a variable hostname by using **\*Value type="host"** (which has a fixed **Value="true"**). In that case, the Device that is associated with the secondary Target Account that is specified in policy is used. See also **Element type='Keystrokes'** in step 14, in which a Target Account is also used to populate the username and password.
  - d. Select **OK** to insert the populated script command. The command appears in the script body. Alternatively, you can specify a variable hostname by using **\*Value type="host"** (which has a fixed **Value="true"**). In that case, the Device that is associated with the secondary Target Account that is specified in policy is used. See also **Element type='Keystrokes'** in step 14, in which a Target Account is also used to populate the username and password.
10. The second element in the PuTTY Configuration window you identify is the **Open** button (on the same screen), which is used to execute the connection:
  - a. Use the Control Viewer procedure of step 10 to identify the **Element ID** for this button.
  - b. Once you have that ID, open the "Mouse click" tool because that is how this PuTTY control is used. The **Add Mouse Click Tag** popup window appears.
  - c. We are using the first option, **Click on the element**. The other option allows you to specify a specific pixel location for the mouse click. Enter the Element ID value that you identified in step 12a into the **ID** field.
  - d. Select **OK** to insert the populated script command. The command appears underneath the first command that you entered.

You have now specified the two elements that provide PuTTY a destination.  
However, the point of the transparent login feature is to insert PAM-supplied credentials transparently. Although the PuTTY application closes its configuration window and opens a console to execute the SSH connection, create a script to provide those credentials. Select the "Save configuration" button to save the current configuration. Then, select the "Add new configuration" button to create another configuration for PuTTY login credentials.  
PuTTY opens its console and communicates with the target Linux Device. Doing this might take some time, and we can account for it in the script.
11. Select the "Sleep" clock icon to open a new widget in which you enter a number of milliseconds. As a rough estimate, you might provide 1000, which allows PuTTY to open and close its windows and be ready with the prompt it receives from its target device.

Now you can assume that your console window is ready with the first of its login prompts from the target, for the username. The Learn Tool allows you to enter a script command that recognizes the Target Account Name:

12. Select the "Text input" again. Set up the **Add Edit Tag** as shown, with **Element type**="Keystrokes" (and then **Element ID**="window" by default) and **Value type**="username".  
Select **OK**. The script command that is created grabs the Account Name from the Target Account that is provided by PAM through your Policy specification. The command then passes it along to the PuTTY target.
13. However, to *submit* the username to the OS then, you have to send a return command. That is, the **Enter** key: Use the "Text input" tool as in the previous step. This time set **Value type**="text", and for **Value**, click your mouse inside its field and press the **Enter** key. The field then displays the text {ENTER} . Select **OK** to insert this tag.
14. Likewise, use the "Text input" tool to set a second command with **Value type**="password". Remember before entering that command to insert another "wait" command using the "Sleep" tool as already explained. You might need to experiment for the most efficient wait times.  
Save this TLC by selecting the (now-active) **Save configuration** floppy disk icon near the right side.  
Now you are ready with your script. However, you might want first to test it to see that it performs as expected. PAM provides this capability with the "Debug" tool.
15. (Optional) To test your configuration, run the Debug tool. This feature executes the currently staged TLC script while displaying debug-level messages in a console.
  - a. Select the "Debug" tool button to open the **Run dialog** window.
  - b. In the **App path** field, use the browse [...] button to the right to specify the location of the RDP Application executable.
  - c. Enter the **Title** of the first window, so that Debug can locate it.
  - d. When credentials and destination must be supplied to execute script processing fully, enter them in **Username**, **Password**, and **Host**.
  - e. When you are ready to run the debug program, select **Run**.  
The Debug console appears.
    - The Debug program first checks each tag for syntax errors, providing feedback in the console, under an initial "App #1" line label.
    - When you bring the RDP Application window (manually) into focus, the Debug program then executes the script. The sequence is labeled ("Try #1"), and then feedback is provided for each tag. If a tag fails to execute successfully, the script is restarted and executes again.
16. (Optional) To improve security in confirming your target application, generate, and copy the SHA-1 digest for the RDP Application. Use the Learn Tool's **Get Application Fingerprint** feature. When configuring the RDP Application in PAM, copy this value into the **Application Fingerprint** field.
17. Continue with [Configure RDP Application](#).

## Reference

The following tables describe the Learn Tool features.

### Learn Tool: Menu Bar

Menu		Description
View	Always on Top	When selected, this feature keeps the Learn Tool window in front of all other windows, even when it is not in focus. The selection state is persistent: After logging off this Device and then logging in again, the option value (whether selected or unselected) remains the same. Default: Selected

Action	Clear cache	Select to remove currently cached applications. When cache is set to "Enable" in <b>Global Settings, Applet Customization, Transparent Login Cache</b> , the Windows target caches the Transparent Login Agent (TLA), Learn Tool, and Control Viewer that are downloaded during connection from PAM when transparent login has been configured, provisioned, and activated. On subsequent connections to that Windows target, the load times for these applications are reduced.
Help	Learn Tool Help	Opens the Compiled HTML (CHM) Learn Tool Help file, which contains detailed descriptions of the Learn Tool controls.
	About	Identifies the Learn Tool application and build versions in a dialog window.

### Learn Tool: XML Scripting Controls

Icon and Tooltip		Description
		One set of <window></window> tags brackets a single-level sequence of XML commands for PAM to manipulate the windows of an RDP Application. Each script control inserts a line containing one XML tag with attributes at the end of the sequence, above the </window> tag. You can copy-and-paste the XML tag lines as in a text editing program, so you can move the lines when and where needed.

Camera icon	Screen verification	<p>Allows insertion of a tag that verifies that a portion of the screen image of the transparent login application matches a previously saved screen capture.</p> <p><b>Usage</b></p> <ol style="list-style-type: none"> <li>1. After selection, the mouse cursor becomes a crosshair, while the full screen area of the RDP window dims and becomes an active grid. Meanwhile, the Learn Tool window is hidden from the desktop so that it does not interfere with screen capture.</li> <li>2. Use the cross-hair cursor to define a rectangle indicating a portion of the RDP Application GUI to be compared to the same GUI during runtime.</li> <li>3. After mouse-up from the cursor, the dialog window Screen Capture Preview displays the comparison Screen capture and the Generated XML Tag to be inserted as PNG.</li> <li>4. Select OK to insert this tag and show the Learn Tool window again.</li> </ol> <p><b>Note:</b> Verify that the captured image portion does not vary from application invocation to invocation, and matches whether the window is active or inactive.</p>
		<p><b>Example:</b> (truncated): &lt;checking content="iVBORu... C6kYII=" /&gt;</p>
Clock icon	Sleep	<p>Allows insertion of a tag that pauses the script for a configurable number of milliseconds.</p> <p><b>Usage:</b> Upon selection, opens the Add Sleep Time Tag pop-up window to specify the milliseconds, then inserts the tag at the end of the script.</p>
		<p><b>Example:</b> &lt;sleep time="500" /&gt;</p>
Keyboard void icon	Freeze Input	<p>Allows insertion of a tag that disables user input (keyboard and mouse events) while a Transparent Login script is running. Freeze Input can prevent re-injection of the user password when using multiple browser tabs. This example freezes user input for 10 seconds. <b>Note:</b> Place this statement at the beginning of your script.</p>
		<p><b>Example:</b> &lt;inputfreeze action="enable"/&gt; &lt;sleep time="10000"/&gt; &lt;inputfreeze action="disable"/&gt;</p>
Duplicate windows icon	Activate window	<p>Allows insertion of a tag that places the named window into focus.</p> <p><b>Usage:</b> Upon selection, inserts this tag at the end of the script.</p>

		<b>Example:</b> <activate />
Mouse icon	Mouse click	Allows insertion of a <click> tag, which affects a mouse-click at a specified location: on a specified button as identified using the Control Viewer; or at the center of the target window; or at a location specified "x" pixels from the left and "y" pixels from the top of the target window.
		<b>Example:</b> button: <click id="[CLASS:Tedit; INSTANCE:2]" /> <b>Example:</b> window center: <click pos="center" /> <b>Example:</b> location: <click x="123" y="72" />

Icon and Tooltip		Description
Page with pencil	Text input	Allows insertion of a tag that submits one of these data types: <ul style="list-style-type: none"> <li>Edits a specified control (field, drop-down list, checkbox, radio button) so that it contains specified data (text, sequence value, Boolean value).</li> <li>Sends a text string, which is composed of literal values, key stroke shortcuts or labels, or parameters provided by PAM such as username or password.</li> </ul>

		Element type	Element ID	Value type	Value
		"Text Field"	as determined through the Control Viewer – see the example in the procedure.	"text"	String, to populate the field
				"username", or "password", or "host"	"true": For the specified Value Type, TLA sends the Value that is attached to the user policy through the target account record.
		"Combobox"		"text"	String, matching a (drop-down) list option
				"index"	Integer, as specified to select the ordinal location of a (drop-down) list option

		"Keystrokes"	"window" (or none)	"text"	As specified: (a) strings, and (b) key stroke tags: (i) entered into the dialog field by typing merely the named key: • includes: .ENTER,ESCAPE, TAB. • appear as: {ENTER}, {ESCAPE}, {TAB} • only one is permitted per XML tag. (ii) entered by typing the key sequence: for example: {F1} entered by typing the four keys: .{+ .F + 1 +} +
				"username", or "password", or "host"	"true": For the specified Value Type, TLA sends the Value in the Target Account that is chosen for the RDP Application that is specified in the PAM policy.
		<b>Element type</b>	<b>Element ID</b>		<b>Checked</b>
		"Checkbox"	As determined through the Control Viewer	"True" or "False"	
		"Radio Button"	"True"		

		<b>Example:</b> (using "Text Field", "text" options in dialog): The following tag inserts the text string "123" (without quotes) into the ID-specified text field: <edit id="[CLASS:TEdit; INSTANCE:1]" text="123" />
Checkmark icon	Element Verification	Allows insertion of a tag that confirms or denies the existence of an element. Optionally verifies that element in a specified state (for example, a text field containing a particular string).
		<b>Element types:</b> Text field   Combobox   Checkbox   Radio Button <b>Element ID:</b> Code identification of the GUI feature that is obtained through Control Viewer. <b>Value:</b> Literal. Ranges: Checkbox and Radio Button: (only) "checked" <b>Example:</b> The following tag verifies that the radio button that is identified has been selected: <verify component="radiobutton" id="[CLASS:TRadioButton; INSTANCE:3]" /> If the component is not confirmed, the TLC script halts.

**Learn Tool: Utilities**

Icon and Tooltip		Description
Page with magnifying glass	Run Control Viewer	<p>Runs the third-party, Learn Tool bundled application, Autolt Control Viewer version 1.1.</p> <p>This application can be used to determine the Element ID when needed in a script command. (No other Control Viewer functions are needed for PAM use.)</p> <p><b>Usage:</b> (to identify a control or widget): See example in steps 9-10 of the procedure.</p> <p><b>Usage:</b> (to identify a window name): To populate the &lt;window id= ""&gt; XML tag (top line of the TLC):</p> <ol style="list-style-type: none"> <li>1. From the Control Viewer window in the Browse Toolbox in the upper right, click your mouse button and hold it down to show the magnifying glass cursor.</li> <li>2. While holding your mouse button down, drag the cursor so that it is over your RDP Application window title bar, then release your mouse button.</li> <li>3. In the <b>Control Viewer Info</b> panel, <b>Window</b> tab, <b>Class</b> row, copy the text from its field. For example, for PuTTY, Control Viewer might display "PuTTYConfigBox".</li> <li>4. Paste the text from that field into the following string: [CLASS:WindowID; INSTANCE:1] substituting "WindowID" with your actual value.</li> <li>5. Paste the entire revised string between the quotation marks into the &lt;window id="" /&gt; tag on the first line of your TLC.</li> </ol> <p><b>Example:</b> &lt;window id="[CLASS:PuTTYConfigBox; INSTANCE:1]" /&gt;</p>

Fingerprint	Get Application Fingerprint	<p>Calculates and displays an application fingerprint for an RDP Application so that it can be used during transparent login attempts.</p> <p><b>Usage</b></p> <ol style="list-style-type: none"> <li>1. Select this button to open the Get Application Fingerprint dialog window. Select the path location of the application executable and a fingerprint string is generated and populated into the Application Fingerprint field. Copy the full text string into the Ctrl-C buffer or a text file.</li> <li>2. Paste the fingerprint to the corresponding Application Fingerprint field of a PAM RDP Application record.</li> <li>3. When PAM makes a transparent login attempt, it first checks this stored fingerprint against one generated for the RDP Application that is discovered on the target RDP server (Windows Device). If the fingerprints do not match, the attempt is canceled.</li> </ol>
Play icon	Debug	<p>Runs the TLC script currently staged in the Transparent Login Configuration panel (the main body of the window).</p> <p><b>Usage:</b> See the example in Step 17 of the previous procedure.</p>

### Learn Tool: File Controls

Icon and Tooltip		Description
Drop-down list	Filter by name / (configuration name)	Displays the name of the configuration staged in the Transparent Login Configuration field (the 'body' of the window).

	(configuration list)	<p>This drop-down list lists transparent login configurations, either:</p> <ul style="list-style-type: none"> <li>(a) all staged in the Learn Tool</li> <li>(b) filtered by name (string) entered</li> </ul> <p>When the Learn Tool is launched following an RDP connection, these configurations are copied from the full set that is managed in PAM Services, RDP Applications, Transparent Login Configurations. The initial set of configurations can include several configuration samples (for example, for PuTTY or WinSCP) corresponding to recent versions of those applications.</p>
Page with plus sign	Add new configuration	<ol style="list-style-type: none"> <li>1. Opens a dialog window into which you can enter the name for a new configuration.</li> <li>2. Upon selecting OK, the Learn Tool body is cleared (to &lt;window&gt; tags), a new config file is created on PAM with that name, and the name is loaded into the drop-down field.</li> <li>3. Upon creation of new XML tags, the name is marked with a preceding asterisk, indicating unsaved changes.</li> </ol>
Duplicate pages	Copy configuration	<ol style="list-style-type: none"> <li>1. While a configuration file is staged, this button opens a dialog window into which you can enter the name for a new configuration.</li> <li>2. The content of the first configuration is then copied into the new configuration so it appears in the Learn Tool GUI as if only the name has changed. You can then edit and save to that new file.</li> </ol>
Page with X	Remove configuration	<ol style="list-style-type: none"> <li>1. Opens a dialog window for confirmation.</li> <li>2. Upon selection, removes the currently staged configuration from the Learn Tool and from the file from PAM.</li> </ol>
Inactive - gray floppy disk Active - blue floppy disks	Save configuration	When active, saves the currently displayed configuration to PAM.
Inactive - gray floppy disks Active - blue floppy disks	Save all changes	When active, saves all configurations that are staged in the Learn Tool drop-down (that differ from currently saved versions) to PAM.
Cycle arrow	Refresh all	Loads all currently saved PAM TLCs into Learn Tool. If there are unsaved configurations in the Learn Tool, they are erased.

## Configure an RDP Application

After using Learn Mode, you have a transparent login configuration in PAM that you can apply to the RDP Application you are targeting.

### Follow these steps:

1. Navigate to **Services, Transparent Login Configurations**.  
Here you can confirm that the configuration you created with the Learn Tool is now available for use.
2. Select the line item for your configuration, and confirm that it is as created in the Learn Tool.  
Alternatively, you can create a configuration file from scratch by selecting the **Add** button to open a blank template and populate it. Configuration files are not dependent on creation with the Learn Tool.
3. Return to **Services, Manage RDP Applications**.
4. Select the **Add** button to open a blank template.
5. Enter an **RDP App Name** that is helpful to users when they access the link from their Access pages.
6. In **Launch Path**, provide the Windows pathname for the local target drive location of the application.
7. (Optional) - Select **Hide From User**. Select this option if you want a user to access the RDP applications in an RDP access method, but not allow the user individual access to the RDP application.
8. On the **Transparent Login** tab, select the **Transparent Login** box.
9. (Optional) In the **Application Fingerprint** field, paste the SHA-1 digest you generated while using the Learn Tool.
10. Select **OK**. A new line identifies the window of this RDP Application that is used to execute a transparent login. After PAM identifies the title of the designated window, it executes the associated configuration to perform transparent login, or other behavior requiring credentials supplied by PAM.
  - a. Enter the **Window Title** that is displayed in the RDP Application GUI.
  - b. From a drop-down list of currently managed transparent login configuration files (see Step 2), select an appropriate configuration in the **Transparent Login Configuration** field.
  - c. If you want this configuration to be available to the user during any RDP session (with access to the Windows Desktop) to this target Device, and not exclusively during a session to this RDP Application, set the **RDP Session** option. When the user connects to an RDP server, the Transparent Login agent is loaded and runs in the background. Once the configured RDP Application is launched, the Transparent Login Agent detects it and automatically fills out the necessary information to proceed. Enable this option if you are using **Hide From User** in step 7.
  - d. If you want to assign more transparent login configurations using this RDP Application, create more line items using **Add Window**. (For example, using PuTTY, you might specify alternate targets or a different login parameter.)
11. Select **Save**.
12. Edit the PAM Device record for the Windows RDP server so that it uses this RDP Application, now listed under **Services**.

## Activate the Policy

When you associate a Transparent Login RDP Application Service with a PAM policy, specify target accounts for use by the Transparent Login Agent on the target device. These target accounts are referred to as Transparent Login Credentials. They are the credentials that are used to fill in the "username" and "password" attributes in the Transparent Login scripts that are generated by the Learn Tool. They are associated with the Transparent RDP application.

### Follow these steps:

1. Ensure that the Transparent Login RDP Application is associated with the correct Target Device. Follow the steps to associate a Service with a Device.
2. Navigate to **Policies, Manage Policies**. Select the **Add** button to create a new policy or **Update** to add the Transparent Login RDP Application service to an existing policy.
3. Select the **Enabled** checkbox on the **Transparent login** tab to enable Transparent Login for this policy.

4. Select the **Services** tab.
5. Locate the Transparent Login RDP Application Service under **Available Services** and select the service. Use the right-arrow icon to move the service to the **Selected Services** area.
6. Select the login target account for auto login into the policy device. Select the gray magnifying glass icon under the **Target Account** column.
7. When you select a Transparent Login RDP Application service, the bottom half of the tab populates with the details about the service. If you do not require Transparent Login Credentials for the service, select **OK** to save the policy.
8. Select the magnifying glass icon next to **Transparent Login Credentials** on the bottom right of the tab.
9. Select the accounts that you want to make available for use with the selected Transparent Login RDP Application Service and select **OK**. These are the accounts that the Transparent Login Agent offers for use when the end user accesses a Transparent Login application from the **Access** panel.

#### **IMPORTANT**

To insert account credentials transparently, the Transparent Login Agent must be able to retrieve the password for the selected target account without further user interaction. The **Reason Required for Auto Connect** option must therefore be disabled in the [password view policy](#) associated with each target account.

### **Caching**

Depending on your security needs, and after using the Learn Tool and testing transparent login configurations, you might enable the Transparent Login Cache. This feature caches the Learn Tool (when used), the Transparent Login Agent, and the Control Viewer (when Learn Tool is used) on the RDP server. They do not need to be loaded onto a temporary local drive during each login at that Device, thus reducing application startup time.

### **Configuration**

To turn on caching, set **Global Settings, Applet Customization, Transparent Login Cache** = "Enable" .

### **Usage**

During login at a particular target, you see confirmation of the caching storage in the RDP initialization console of each application cached.

### **Auditing**

You can use logs and session recording for auditing access attempts.

- Logs  
PAM logs each access attempt, for example:

```
2016-03-11 01:16:27 super login Win 2008 R2 (32-bit) Xsuite user transparently logged
into RDP Application "putty.exe" to "PuTTY Configuration" window as "dev"
```

- Session Recording  
A session recording marks the location of the secondary transparent login attempt. For RDP connections to Windows, these attempts are marked in the **Events** list and by a red arrow on the timeline. You can see event detail as a tooltip from the line item in the **Events** list, and in the **Info** box at the lower left and in a pop-up window during cross-over on the timeline.  
For transparent login activity to be successfully recorded when the user has Internet Explorer, the administrator must configure all equivalent PAM addresses. Example: A cluster VIP name and VIP address in the browser security settings. See [Set Up Session Recording](#).

### **User Experience**

Script windows and the application interface are displayed briefly as the automation proceeds, and stops showing changes when the script completes.

Following selection of the RDP Application link PuTTY, the user sees this sequence following login at the RDP server host:

1. The console for the RDP session initialization appears.
2. The console for the transparent login Agent (TLA) that is running on the local virtual drive appears.
3. The RDP Application (PuTTY) is invoked, and (in this case) a configuration GUI is auto-populated and activated by the transparent login script, eventually invoking a second interface (the PuTTY console).
4. The RDP Application (PuTTY) invokes a new window (the console interface), and is auto-populated by the continuing transparent login script. After the script completes, the console interface is ready for user access.

## Import or Export Transparent Login Configurations

1. Select **Services, Transparent Login Configurations**.
2. Click the **Import/Export** button.  
The Import/Export window appears.
3. Click **Download Sample File** to save a template file to a convenient editing location.
4. Copy the sample to a new file, and open it in a spreadsheet program or a plain-text editor.
5. Edit or add line items for each configuration and save the file. For descriptions of each field, see [CSV File Format](#).

### NOTE

Do not alter the first (header) line.

6. Click **Choose File** to browse for your saved CSV file.
7. Click **Import Transparent Login Configurations**.

### CSV File Format

- To handle dependencies, when provisioning multiple objects using CSV files, Transparent Login Configurations should be the last group imported. Ensure that any related Services, Roles, User Groups, Users, Device Groups, Devices, Socket Filter Lists, Command Filter Lists, and Policies are configured first.
- Commas are the only allowed field separators, so a comma cannot be used in any field content.
- The first line in the file is for column names and is used for categorization during import.
- The Transparent Login Configurations CSV file has only three columns, all required:
  - **Type:** The only type that is allowed is "SSO Config".
  - **Name:** Enter a string, such as "Putty".
  - **Configuration:** Enter an XML single-level structure that is bounded by window tags. This XML script is applied to the application during transparent login use. For example:

```
<window> <activate/> <combobox id="[CLASS:Edit; INSTANCE:1]" index="1"/> </window>
```

### Export a CSV File

To export a CSV file of you existing Transparent Login Configurations, follow these steps:

1. Select **Services, Transparent Login Configurations**.
2. Click the **Import/Export** button.  
The Import/Export window appears.
3. Click the **Export Transparent Login Configurations** button to export a CSV file.

## Configure Support for Citrix Virtual Apps Resources

You can configure Privileged Access Manager to support the following specific resource types in a Citrix Virtual Apps environment:

- **Citrix StoreFront:** Access, transparent (automatic) login, and session recording.
- **Citrix XenDesktop:** Direct access, transparent (automatic) login, and session recording.

**Published Virtual Apps applications:** Direct access and session recording.

#### NOTE

Transparent login is not currently supported for published Citrix Virtual Apps applications.

This topic has the following contents:

### Requirements

Verify that the following requirements are configured in your Citrix Virtual Apps environment:

- HTML5 client is enabled on the Citrix Workspace.
- WebSocket connections are enabled on Citrix Virtual Apps and Citrix Virtual Apps and Desktops.
- If Privileged Access Manager and Citrix Virtual Apps are in different subnets, configure Citrix Workspace to allow remote users to access stores through NetScaler Gateway using the Enable Remote Connections task. For more information, see the Citrix Virtual Apps documentation for your version of Workspace.
- By default, concurrent connections by the same user from different IP addresses are not allowed. Because there are use cases where this concurrence might be necessary, there is an option to allow it. For example, your Citrix Virtual Apps environment might have several jump boxes and a load balancer. An end user might run several sessions simultaneously, and the user sessions originate at different jump boxes. If this concurrence is necessary, you can allow concurrent connections. Select **Enabled** for **Concurrent Remote Connections Allowed** on the **Configuration, Security, Access** Page. By default, this setting is set to **Disabled**.

### Configure a Service for Citrix Workspace

Use this procedure to configure a service for Citrix Workspace.

#### Follow these steps:

1. From the Menu bar, select **Services, Manage TCP/UDP Services**.
2. Select **Add**.
3. Complete the following fields:
  - **Service Name:** A unique name, for example, "Virtual\_Apps\_All".
  - **Ports:** *Workspace\_Ports*  
Where *Workspace\_Ports* are the port numbers for Workspace, separated by a colon. For example, "80:6513".
  - **Application Protocol:** Web Portal
  - **Launch URL:** https://<Local IP>:<First Port>/<Path\_to\_Workspace>  
Where *Path\_to\_Workspace* is the browser path to Workspace. For example, "Citrix/Store1Web"
  - **Browser Type:** PAM Browser
  - **Auto-Login Method:** PAM HTML Web SSO  
(Accept the default values for other fields.)
4. Select **Save**.

### Configure a Service for XenDesktop

Use this procedure to configure a service for Citrix XenDesktop.

#### Follow these steps:

1. From the Menu bar, select **Services, Manage TCP/UDP Services**.
2. Select **Add**.
3. Complete the following fields:

- **Service Name:** A unique name, for example, "Virtual Apps\_Desktop."
  - **Ports:** *XenDesktop\_Ports*  
Where *XenDesktop\_Ports* are the port numbers for XenDesktop, separated by a colon. For example, "80:6611"
  - **Application Protocol:** Web Portal
  - **Launch URL:** https://<Local IP>:<First Port>/<Path\_to\_XenDesktop>  
Where *Path\_to\_XenDesktop* is the browser path to XenDesktop. For example, "Citrix/Store2Web"
  - **Browser Type:** PAM Browser
  - **Auto-Login Method:** PAM HTML Web SSO  
(Accept the default values for other fields.)
4. Select **Save**.
  5. In the StoreFront console, navigate to **Stores, XenDesktop\_Store, Manage Receiver for Web Sites, Configure, Client Interface Settings**. Verify that the **Auto launch desktop** option is set.

### Configure a Service for Virtual Apps Applications

Use this procedure to configure a service for your Citrix Virtual Apps applications.

#### **Follow these steps:**

1. From the Menu bar, select **Services, Manage TCP/UDP Services**.
2. Select **ADD**.
3. Complete the following fields:
  - **Service Name:** A unique name, for example, "Virtual Apps\_Apps."
  - **Ports:** *Virtual Apps\_App\_Ports*  
Where *Virtual Apps\_App\_Ports* are the port numbers for your Virtual Apps applications, which are separated by a colon. For example, "80:6813"
  - **Application Protocol:** Web Portal
  - **Launch URL:** https://<Local IP>:<First Port>/<Path\_to\_Virtual Apps\_Apps>  
Where *Path\_to\_Virtual Apps\_Apps* is the browser path to your Virtual Apps applications. For example, "Citrix/Store3Web"
  - **Browser Type:** PAM Browser
  - **Auto-Login Method:** PAM HTML Web SSO  
(Accept the default values for other fields.)
4. Select **Save**.
5. In the StoreFront console, navigate to **Stores, Virtual Apps\_App\_Store, Manage Receiver for Web Sites, Configure, Client Interface Settings** and set the **Auto launch desktop** setting.

### Configure a Device for Virtual Apps

Use this procedure to configure a device for Virtual Apps.

#### **Follow these steps:**

1. From the Menu bar, select **Devices, Manage Devices**.
2. Select **ADD**.
3. Complete the following fields:
  - **Name:** A unique name, for example, "Virtual Apps"
  - **Address:** The IP address of the Virtual Apps server.
  - **Device Type:** Select the following option: **Access**. Optionally, select **Password Management**.
  - **Services:** Select **Add** and select the services that you configured for Virtual Apps resources. In this example, **Virtual Apps\_All, Virtual Apps\_Desktop, and Virtual Apps\_Apps**.  
(Accept the default values for other fields.)

4. Select **Save**.

### **Configure a Policy for Your Virtual Apps Resources.**

Configure a policy to associate your Virtual Apps device and its services with users who require access. If session recording is required, select **Web Portal** from the **Recording** options.

#### **NOTE**

Multiple users can launch CA PAM Client instances from *different* Virtual Apps sessions. That is, each user must start their own Virtual Apps session because multiple user logins from a *single* Virtual Apps session do not guarantee attribution and confidentiality.

## **Configure Users**

Each person accessing resources through PAM must have a user account.

A **user** represents a login account with a specific set of privileges to perform actions on the appliance. Every login account constitutes a user. Users are displayed, defined, and managed through the **Users** menu in the UI.

#### **NOTE**

When referring to users managed by the appliance, the user is a managed object or account. This user is distinct from the actual person ("user") who uses the managed account.

### **Privileges and Roles**

Each user must be represented by at least one **role** attribute. A role is a set of access privileges. Each privilege allows the user to perform certain functions on the appliance.

A set of predefined roles is provided with the basic installation. These user types include:

- **End Users**

An end user is a managed user who primarily accesses managed devices and views a password of a managed target account. This user has a predefined role of Standard User, which is assigned by default when the User template is used to create an account. All end-user activity is performed on the Access page (which is unlabeled). These Users have no access to the Admin menu.

#### **NOTE**

The privileges of a Standard User are *not* a subset of all other predefined roles. There are administrator roles that do not allow access or password viewing.

- **Administrators**

An **administrator** is a user who can exercise privileges beyond Standard User privileges. As a result, an administrator sees a full or partial Admin menu, or has access to the Config menu.

- **super and config administrators**

Two administrator accounts, **config** and **super**, are predefined on the appliance. These two administrators have certain special privileges and characteristics to perform initial configuration and other operations:

- **super** has a predefined role of Global Administrator. This role appears in the Users list on the Manage Users page.
- **config** has access only to the Configuration menu, including the Change Password menu. The config user does not appear on the Users list on the Manage Users page.

The privileges of the config account differ from the privileges that are assigned to the Configuration Administrator role. The config user gains access solely through the /config/ directory. The config user is also the only account with access to the Change Password menu.

Though you can change the names of the super and config users, we recommend that you leave the names as is. If you do change the names, these two accounts always constitute the two baseline user accounts.

## User Groups

**User Groups** let you apply user attributes to all members belonging to a group.

### NOTE

Privileged Access Manager user groups are distinct from Credential Manager user groups.

## Configuring User Accounts

User accounts can be created in two ways:

- Individually using the UI
- Imported from a CSV file, which contains a set of user records. When users are imported from a CSV file, these users are automatically established as a group.

## More Information

For more information, see the following articles:

- [User Roles](#)
- [Identify User Roles and Privileges](#)
- [Identify Users that Can Log in to the Server](#)
- [Configure User Groups](#)
- [User / User Group Management](#)
- [User Viewing](#)

## User Roles

To perform operations in Privileged Access Manager, each user must be assigned one or more *user roles*, which define sets of privileges that are related to different product functions. The many available [predefined roles](#) should satisfy most requirements. By default, new users are assigned the *Standard User* role, which allows them to access devices. Assign roles with more privileges to administrators. You can also create custom roles to assign privileges to match your own requirements. You manage roles from the **Users, Roles** screen.

## Manage Credentials Privilege

This content covers user roles for provisioning privileged access to devices and applications. For information about Credential Manager roles, see [Add or Modify Credential Manager Roles](#). However, users who require Credential Manager administrative privileges must be assigned a user role with the *Manage Credentials* privilege. The following preconfigured user roles provide the Manage Credentials privilege:

- Global Administrator
- Operational Administrator
- Password Manager

Also, by default, users are assigned to the "[Standard User](#)" role and are *silently* assigned to the "Standard Users" Credential Manager group. ("Standard Users" is not shown on the **Credential Manager Groups** tab). Membership of the "Standard Users" Credential Manager group provides privileges to view account passwords on the **Access** page. However, when a user is assigned any role with the "Manage Credentials" privilege (for example, "Password Manager"), that user is removed from the "Standard Users" Credential Manager group and cannot view passwords on the **Access** page. To find out how to provide password viewing privileges, see [Configure Users with the Manage Credentials Privilege to View Passwords on the Access Screen](#). To learn how to view the Target Account's password credential history, see [Configure a PAM User to View the Password History of Target Accounts](#).

**NOTE**

If you are creating a custom role that need to manage the Credential Manager's "System Admin Group", then add the Global Administrator role to the custom role.

**Identify User Roles and Privileges**

Privileged Access Manager provides a preconfigured set of user roles. You can also configure your own roles from a set of available user privileges.

**Predefined Roles**

A predefined set of roles is provided with the product. View these roles by selecting **Users, Manage Roles**. This set has the privileges that are required to perform various common activities. Roles are assigned to Users and User Groups during their creation and editing. See [Configure Users](#) for more information.

The following table lists the predefined roles:

Role	Description	Privileges
Administrative Auditor	Allow user read only access to administrative pages (services, users, devices, policies).	Read Services, Read Users, Read User Groups, Read Socket Filter Agent, Read Devices, Read Device Groups, Read Policies, Read Socket Filters, Read Command Filters, Read Roles
Auditor	Allow users to view PAM logging, session recording, and reporting data. Auditors have read-only access to Global Settings to inspect settings that have impact on log data.	Read Overview, All Logging, Read Session Recordings, Read Global Settings
Autodiscovery	Allow users to use the autodiscovery feature to find network devices.	autodiscovery
AWS API Proxy User	Allow the user to log in, select the access page, and remotely access the AWS API Proxy.	Access All, AWS API Proxy, Manage All
CA TAP API User	All the privileges that are needed for CA Threat Analytics to use the external API.	Access All, Manage BAP API, Read Devices, Read Users, Manage Sessions
Configuration Manager	Allow users to set "Global Settings" and access all "Configuration" tabs.	Read Global Settings, Manage Global Settings, Manage Configuration
Delegated Administrator	A combined user role that grants to users the ability to perform all User, Device, and Policy Manager tasks.	Read Users, Manage Users, Delete Users, Assign Users, Read User Groups, Upgrade User Groups, Approve CAC User, Read Socket Filter Agent, Delete Socket Filter Agent, Read Devices, Manage Devices, Delete Devices, Assign Devices, Read Device Groups, Update Device Group, Read Policies, Manage Policy, Read Socket Filters, Manage Socket Filters, Read Command Filters, Manage Command Filters, Manage User RDP User Name
Device and Device Group Manager	Allow users to read, create, update, and delete all types of devices.	Read Socket Filter Agent, Delete Socket Filter Agent, Read Devices, Manage Devices, Delete Devices, Assign Devices, Read Device Groups, Update Device Group

Global Administrator	Allow access to all and configuration of all Privileged Access Manager functionality.	Access All, Manage All, Monitor All, Read Sessions, Manage Sessions, Read Overview, All Tools, All Logging, Read Session Recordings, Read Global Settings, Manage Global Settings, Read Services, Manage Services, Delete Services, Read Users, Manage Users, Delete Users, Assign Users, Read User Groups, Upgrade User Groups, Approve CAC User, Read Socket Filter Agent, Delete Socket Filter Agent, Read Devices, Manage Devices, Delete Devices, Assign Devices, Read Device Groups, Update Device Group, Read Policies, Manage Policy, Read Socket Filters, Manage Socket Filters, Read Command Filters, Manage Command Filters, Import Policy, Export Policy, Manage Configuration, Read Roles, autodiscovery, Manage Credentials, Manage User RDP User Name Please see <a href="#">this important note</a> about roles with the Manage Credentials privilege.
Global Setter	Allow users to set "Global Settings".	Read Global Settings, Manage Global Settings
Management Console API User	Allow user access to CA Management Console API (Internal use only).	Manage Management Console API
Monitor	Allow users to monitor devices.	Monitor All
Operational Administrator	Allow access to all PAM administrative functionality, without configuration management.	Access All, Manage All, Monitor All, Read Sessions, Manage Sessions, Read Overview, All Tools, All Logging, Read Session Recordings, Read Global Settings, Manage Global Settings, Read Services, Manage Services, Delete Services, Read Users, Manage Users, Delete Users, Assign Users, Read User Groups, Upgrade User Groups, Approve CAC User, Read Socket Filter Agent, Delete Socket Filter Agent, Read Devices, Manage Devices, Delete Devices, Assign Devices, Read Device Groups, Update Device Group, Read Policies, Manage Policy, Read Socket Filters, Manage Socket Filters, Read Command Filters, Manage Command Filters, Import Policy, Export Policy, Read Roles, autodiscovery, Manage Credentials, Manage User RDP User Name Please see <a href="#">this important note</a> about roles with the Manage Credentials privilege.
Password Manager	Allow users to configure Credential Manager.	Manage Credentials Please see <a href="#">this important note</a> about roles with the Manage Credentials privilege.
Policy Manager	Allow users to read, create, update, and delete all policies, socket and command filters, and agents.	Read Socket Filter Agent, Delete Socket Filter Agent, Read Policies, Manage Policy, Read Socket Filters, Manage Socket Filters, Read Command Filters, Manage Command Filters
Secrets Management	Allow users and user groups to access the Secrets Management functionality.	<code>Enable Secrets Management</code> Users with this role are still unable to see or manage any vaults or secrets until they are assigned a Vault Owner, Secrets Owner, or a Secret Viewer role for a vault. See <a href="#">About Secrets Management and Roles</a> for procedures on assigning these more granular roles.

Server Control Administrator	Allow users to access the Server Control and UNAB policy management functionality.	Add Device Group, Delete Device Group, Read Device Group, Update Device Group, Assign Devices, Delete Devices, Manage Devices, Read Devices, All Logging, Read Server Control Deployment Audit Log, Deploy Server Control Policies, Read Device/Device Group Server Control Policy Assignments, Manage Server Control Policies, Read Server Control Policies, Manage UNAB Login and Config Policies, Add User Group, Delete User Group, Read User Groups, Update User Group, Assign Users, Delete Users, Manage Users, Read Users
Server Control Deploy Manager	Allow users to Assign, Unassign, Upgrade, and Downgrade Server Control Policies.	Read Device Group, Read Devices, Read Server Control Deployment Audit Log, Deploy Server Control Policies, Read Device/Device Group Server Control Policy Assignments, Read Server Control Policies
Server Control Policy Editor	Allow users to Create, Copy, Update, and Delete Server Control Policies.	Manage Server Control Policies, Manage User RDP User Name
Service Manager	Allow users to read, create, update, and delete service.	Read Services, Manage Services, Delete Services
Session Manager	Allow users to view and terminate PAM login and remote access.	Read Sessions, Manage Sessions
Standard User	Allow users to access and manage remote devices.	Access All, Manage All, Manage User RDP User Name
Target Connector Validator	Allow users to view and use the Target Connector Framework validator. The validator examines UI definitions from a JSON file, which renders pages for custom target connectors.	Validate Target Connector UI
Troubleshooter	Allow users to access the <b>Configuration, Tools</b> page	All Tools
UNAB Manager	Allows access to UNAB Host Login Policy management and UNAB Configuration Token management on devices and device groups.	Add Device Group, Delete Device Group, Read Device Group, Update Device Group, Assign Devices, Delete Devices, Manage Devices, Read Devices, All Logging, Manage UNAB Login and Config Policies, Add User Group, Delete User Group, Read User Groups, Update User Group, Assign Users, Delete Users, Manage Users, Read Users, Manage User RDP User Name
User and User Group Manager	Allow users to read, create, update, and delete all types of users	Read Users, Manage Users, Delete Users, Assign Users, Read User Groups, Upgrade User Groups, Approve CAC User, Manage User RDP User Name
VMware NSX API Proxy User	Allow the user to log in, select the access page, and remotely access the VMware NSX API Proxy.	Access All, Manage All, VMware NSX API Proxy

### Privilege Definitions

In addition to the set of predefined roles, administrators can also create custom roles. Create a custom role by selecting from a list of available privileges, as shown in the following table.

Role Privilege	Actions Allowed
Standard User	

Access All	Use the access page to connect to remote machines.
Manage All	Use the manage devices page to perform actions like power cycling remote machines.
<b>Monitoring</b>	
Monitor All	Use the monitor page to view the status of remote devices.
<b>Sessions</b>	
Read Sessions	Look at the manage sessions/logins page.
Manage Sessions	Use the manage sessions/logins page to kill sessions and logins.
Read Overview	Examine devices, out of band devices, and connections.
<b>Tools</b>	
All Tools	Use configuration tools such as ping and traceroute.
<b>Logging / Recordings</b>	
All Logging	Look at the log page and execute reports.
Read Session Recordings	Replay session recordings.
<b>Global Settings</b>	
Read Global Settings	See global settings.
Manage Global Settings	Alter global settings.
<b>Services</b>	
Read Services	See details of all services, of any type (TCP, RDP Application).
Manage Services	Add or change any existing services of any type (TCP, RDP Application).
Delete Services	Delete any existing services of any type.
<b>Users</b>	
Read Users	See details of all users. Allows export of users.
Manage Users	Create or change users including export. Allows import of users.
Delete Users	Delete any non-LDAP users.
Assign Users	Assign a user to a user group or a user group to a user.
Read User Groups	See details of user groups.
Upgrade User Groups	Change existing user groups, but not their memberships.
Approve CAC User	Approve candidate CAC users.
Read Roles	Read roles and privilege definitions.
Manage User RDP User Name	Edit the RDP User Name field in a user definition.
<b>Socket Filters</b>	
Read Socket Filter Agent	View socket filter agents.
Delete Socket Filter Agent	Delete socket filter agents.
Read Socket Filters	See socket filter lists and configuration.
Manage Socket Filters	Change or remove socket filter lists and configurations.
<b>Devices</b>	
Read Devices	See details of all devices, including power hosts and consoles. Allows export.
Manage Devices	Create and change devices and their memberships. Allows import.

Delete Devices	Delete any devices.
Assign Devices	Assign a device to a device group or assign a device group to a device.
Read Device Groups	See details of device groups.
Update Device Group	Change existing device groups, but not their memberships.
autodiscovery	Find devices on the network.
<b>Policy</b>	
Read Policies	See policies. Do not allow export.
Manage Policy	Change or remove policies. Do not allow import.
Import Policy	Import all kinds of associations.
Export Policy	Export all kinds of associations.
<b>Command Filters</b>	
Read Command Filters	See command recording lists and configuration.
Manage Command Filters	Change or remove command filter lists and configurations.
<b>Configuration</b>	
Manage Configuration	Use the Access configuration tab.
<b>Passwords</b>	
Manage Credentials	Create and update credential definitions for password chaining.
<b>APIs</b>	
AWS API Proxy	Allow access to the AWS (Amazon Web Services) API Proxy.
Manage BAP API	Manage the CA Threat Analytics API.
managementConsole	Manage the Management Console API.
nsxApiProxy	Allow access to the VMware NSX API Proxy.
<b>Server Control Policies</b>	
Deploy Server Control Policies	Assign, Unassign, Upgrade, and Downgrade Server Control Policies
Manage Server Control Policies	Create, Read, Update, and Delete Server Control Policies
Manage UNAB Login and Config Policies	Read, Write, and Delete UNAB Host Login Policies, as well as UNAB Configuration Token Definitions
Read Device/Device Group Server Control Policy Assignments	Look at Server Control Policy Assignments on Devices/Device Group
Read Server Control Deployment Audit Log	Look at Server Control Deployment Audit Log
Read Server Control Policies	See details for all the Server Control Policies
<b>Secrets Management</b>	
Enable Secrets Management	Allows access to the Secrets Management functionality. Users with this privilege are still unable to see or manage any vaults or secrets until they are assigned a Vault Owner, Secrets Owner, or a Secret Viewer role for a vault. See <a href="#">About Secrets Management and Roles</a> for procedures on assigning these more granular roles.

## User Role Cases

### Expanded User Privilege Assignment Under Restricted Administration

Privileged Access Manager administrators with less than a Global Administrator role were once restricted from creating or updating Users beyond Standard User or Monitor roles. Administrators could not then update their own profile, or that of any other User, with privileges higher than their own. This feature is named "restricted administration."

#### **NOTE**

Earlier implementations of restricted administration have also been known as "delegated administration." However, this feature name can easily be confused with the unrelated Delegated Administrator role. Privileged Access Manager documentation no longer uses the term "delegated administration."

Restricted administration is now fine-tuned to allow full assignment of any set of privileges less than one's own. An administrator below a Global Administrator can assign preset or custom roles other than Standard User or Monitor, up to and including its own privileges. Conversely, restricted administration prevents the assignment of roles, groups, and other objects that overstep the applicable privileges.

#### ***Provisioning Expanded User Privilege Assignment***

Assume that your organization has a population of Devices that are maintained in two geographical or network locations or regions. For each region, you want to assign an administrator with Delegated Administrator privileges to manage only its own Users and Devices. Meanwhile, a User Group is assigned the Device/Group Manager role to manage all Devices in both regions.

The options available to one of these two administrators when creating a User are then restricted. The Delegated Administrator role permits the required privileges within the User/Device scope. The Available Roles for this new User are therefore the "Delegated Administrator", its components ("Device/Group Manager", "Policy Manager", and "User/Group Manager"), and the typical "Standard User" (assuming this administrator also performs Device or credentials access activities).

Meanwhile, the Available Groups list identifies all User Groups that exist on this Privileged Access Manager appliance. The "DeviceManagers" group is dim, which allows management of all Devices rather than only those managed by this administrator. Because its choice would effectively result in elevated privileges, it cannot be selected.

## **Import and Export Roles**

### ***Configure Internet Explorer***

To use the Import/Export functions with Internet Explorer (IE), changes might need to be made to the security settings. To establish IE security settings:

1. Open IE browser.
2. Select **Tools, Internet Options**.
3. In the Internet Options pop-up window, select the **Security** tab.
4. Select the slider zone
5. Select **Custom level**. Scroll to **Downloads**. For **File download**, select the **Enable** option.
6. Select **OK** to save changes.

### ***Import Roles from a CSV***

To import the Roles, follow these steps:

1. Go to **Users, Manage Roles**.
2. Select the **Import/Export** button.  
The Import/Export Roles window appears .
3. Select Download Sample File, and save the file.
4. Create a CSV file from the downloaded template.

#### **CSV Format**

- Do not change the heading (first) row text.
  - Role Name is the only required field.
  - For any fields not used: Preserve all headings on the first row, but leave cells below blank.
5. In the **Import/Export Roles** window, select **Choose File** to select the file, and select **Import Roles**.  
The content of the file is added to the existing Role database. The new content does not replace the current database.
  6. Navigate to **Users, Manage Roles**, and confirm that the import was successful by inspecting the Roles list.

### **Export Roles and Role Groups**

A CSV list of all custom Roles can be downloaded by selecting **Export Custom Roles**. This exported file can be used to make a revised version, and then imported back into Privileged Access Manager.

## **Identify User Roles and Privileges**

Privileged Access Manager provides a preconfigured set of user roles. You can also configure your own roles from a set of available user privileges.

### **Predefined Roles**

A predefined set of 21 roles is provided with the product. View these roles by selecting **Users, Manage Roles**. This set has the privileges that are required to perform various common activities.

Roles are assigned to Users and User Groups during their creation and editing. See [Provisioning Users](#) for more information.

#### **Administrative Auditor**

Allow user read only access to administrative pages (services, users, devices, policies).

**Privileges:** servicesRead, usersRead, userGroupRead, socketFilterAgentRead, devicesRead, deviceGroupRead, policyRead, socketFiltersRead, commandFiltersRead, rolesRead

#### **Auditor**

Allow users to view PAM logging, session recording, and reporting data. Auditors have read-only access to Global Settings to inspect settings that have impact on log data.

**Privileges:** overviewRead, loggingAll, sessionRecordingRead, globalSettingsRead

#### **Autodiscovery**

Allow users to use the autodiscovery feature to find network devices.

**Privileges:** autodiscovery

#### **AWS API Proxy User**

Allow the user to log in, select the access page, and remotely access the AWS API Proxy.

**Privileges:** accessAll, awsApiProxy, manageAll

#### **CA TAP API User**

All the privileges that are needed for CA Threat Analytics to use the external API.

**Privileges:** accessAll, BAPApiManage, devicesRead, usersRead, sessionManage

#### **Configuration Manager**

Allow users to set "Global Settings" and access all "Configuration" tabs.

**Privileges:** globalSettingsRead, globalSettingsManage, configurationManage

**Delegated Administrator**

A combined user role that grants to users the ability to perform all User, Device, and Policy Manager tasks.

**Privileges:** usersRead, usersManage, usersDelete, usersAssign, userGroupRead, userGroupUpdate, cacUserApproval, socketFilterAgentRead, socketFilterAgentDelete, devicesRead, devicesManage, devicesDelete, devicesAssign, deviceGroupRead, deviceGroupUpdate, policyRead, policyManage, socketFiltersRead, socketFiltersManage, commandFiltersRead, commandFiltersManage

**Device and Device Group Manager**

Allow users to read, create, update, and delete all types of devices.

**Privileges:** socketFilterAgentRead, socketFilterAgentDelete, devicesRead, devicesManage, devicesDelete, devicesAssign, deviceGroupRead, deviceGroupUpdate

**Global Administrator**

Allow access to all and configuration of all Privileged Access Manager functionality.

**Privileges:** accessAll, manageAll, monitorAll, sessionRead, sessionManage, overviewRead, toolsAll, loggingAll, sessionRecordingRead, globalSettingsRead, globalSettingsManage, servicesRead, servicesManage, servicesDelete, usersRead, usersManage, usersDelete, usersAssign, userGroupRead, userGroupUpdate, cacUserApproval, socketFilterAgentRead, socketFilterAgentDelete, devicesRead, devicesManage, devicesDelete, devicesAssign, deviceGroupRead, deviceGroupUpdate, policyRead, policyManage, socketFiltersRead, socketFiltersManage, commandFiltersRead, commandFiltersManage, policyImport, policyExport, configurationManage, rolesRead, autodiscovery, credentialsManage

**Global Setter**

Allow users to set "Global Settings".

**Privileges:** globalSettingsRead, globalSettingsManage

**Management Console API User**

Allow user access to CA Management Console API (Internal use only).

**Privileges:** managementConsole

**Monitor**

Allow users to monitor devices.

**Privileges:** monitorAll

**Operational Administrator**

Allow access to all PAM administrative functionality, without configuration management.

**Privileges:** accessAll, manageAll, monitorAll, sessionRead, sessionManage, overviewRead, toolsAll, loggingAll, sessionRecordingRead, globalSettingsRead, globalSettingsManage, servicesRead, servicesManage, servicesDelete, usersRead, usersManage, usersDelete, usersAssign, userGroupRead, userGroupUpdate, cacUserApproval, socketFilterAgentRead, socketFilterAgentDelete, devicesRead, devicesManage, devicesDelete, devicesAssign, deviceGroupRead, deviceGroupUpdate, policyRead, policyManage, socketFiltersRead, socketFiltersManage, commandFiltersRead, commandFiltersManage, policyImport, policyExport, rolesRead, autodiscovery, credentialsManage

**Password Manager**

Allow users to configure Password Management.

**Privileges:** credentialsManage

### ***Policy Manager***

Allow users to read, create, update, and delete all policies, socket and command filters, and agents.

**Privileges:** socketFilterAgentRead, socketFilterAgentDelete, policyRead, policyManage, socketFiltersRead, socketFiltersManage, commandFiltersRead, commandFiltersManage

### ***Secrets Management***

Allow users and user groups to access the Secrets Management functionality. Users with this role are still unable to see or manage any vaults or secrets until they are assigned a Vault Owner, Secrets Owner, or a Secret Viewer role for a vault.

See [About Secrets Management and Roles](#) for procedures on assigning these more granular roles.

**Privileges:** enableSecretsManagement

### ***Server Control Administrator***

Allow users to access the Server Control and UNAB policy management functionality.

**Privileges:** devicesRead, devicesManage, devicesDelete, devicesAssign, deviceGroupRead, deviceGroupUpdate, deviceGroupDelete, deviceGroupAdd, loggingAll, usersRead, usersManage, usersDelete, usersAssign, userGroupRead, userGroupUpdate, userGroupDelete, userGroupAdd, devicesRead, deviceGroupRead, servercontrolPolicyManage, servercontrolPolicyRead, servercontrolPolicyDeploy, servercontrolPolicyDeployRead, UNABManage, servercontrolPolicyAuditRead

### ***Server Control Deploy Manager***

Allows full access to policy deployment features, including assign, unassign, upgrade and downgrade; Read only access to server control policies and devices/device groups.

**Privileges:** devicesRead, deviceGroupRead, servercontrolPolicyDeploy, servercontrolPolicyRead, servercontrolPolicyDeployRead, servercontrolPolicyAuditRead

### ***Server Control Policy Editor***

Allows user full access to server control policy create, updates, version, and finalization operations; Read only access to policy deployment and deployment audit features, and read only access to device/device groups. **NOTE:** This role is restricted from performing SC policy manage operations including Assign/Unassign, Upgrade and Downgrade. This role is also restricted from performing any UNAB operations.

**Privileges:** servercontrolPolicyManage

### ***Service Manager***

Allow users to read, create, update, and delete service.

**Privileges:** servicesRead, servicesManage, servicesDelete

### ***Session Manager***

Allow users to view and terminate PAM login and remote access.

**Privileges:** sessionRead, sessionManage

### ***Standard User***

Allow users to access and manage remote devices.

**Privileges:** accessAll, manageAll

### ***Target Connector Validator***

Enables users to view and use the Target Connector Framework validator. The validator examines UI definitions from a JSON file, which renders pages for custom target connectors.

Privilege: `validateTargetConnectorUI`

### **Troubleshooter**

Allow users to access the "Configuration, Tools" page.

**Privileges:** `toolsAll`

### **UNAB Manager**

Allows full access to UNAB Host Login Policy management and UNAB Configuration Token management on devices and device groups.

**Privileges:** `devicesRead, UNABManage, devicesManage, devicesDelete, devicesAssign, deviceGroupRead, deviceGroupUpdate, deviceGroupDelete, deviceGroupAdd, usersRead, usersManage, usersDelete, usersAssign, userGroupRead, userGroupUpdate, userGroupDelete, userGroupAdd, usersManage, usersDelete, usersAssign, userGroupRead, userGroupUpdate, userGroupDelete, userGroupAdd`

### **User and User Group Manager**

Allow users to read, create, update, and delete all types of users.

**Privileges:** `usersRead, usersManage, usersDelete, usersAssign, userGroupRead, userGroupUpdate, cacUserApproval`

### **VMware NSX API Proxy User**

Allow the user to log in, select the access page, and remotely access the VMware NSX API Proxy.

**Privileges:** `accessAll, manageAll, nsxApiProxy`

### **Privilege Definitions**

In addition to the set of predefined roles, administrators can also create custom roles. A role is constructed by selecting from a list of Privileges, described in the following table.

Role Privilege	Actions Allowed
<b>Standard User</b>	
<code>accessAll</code>	Use the access page to connect to remote machines.
<code>manageAll</code>	Use the manage devices page to perform actions like power cycling remote machines.
<b>Monitoring</b>	
<code>monitorAll</code>	Use the monitor page to view the status of remote devices.
<b>Sessions</b>	
<code>sessionRead</code>	Look at the manage sessions/logins page.
<code>sessionManage</code>	Use the manage sessions/logins page to kill sessions and logins.
<code>overviewRead</code>	Examine devices, out of band devices, and connections.
<b>Tools</b>	
<code>toolsAll</code>	Use configuration tools such as ping and traceroute.
<code>validateTargetConnectorUI</code>	Use the Target Connector Validator for TCF custom connectors.

<b>Logging / Recordings</b>	
loggingAll	Look at the log page and execute reports.
sessionRecordingRead	Replay session recordings.
<b>Global Settings</b>	
globalSettingsRead	See global settings.
globalSettingsManage	Alter global settings.
<b>Services</b>	
servicesRead	See details of all services, of any type (TCP, RDP Application).
servicesManage	Add or change any existing services of any type (TCP, RDP Application).
servicesDelete	Delete any existing services of any type.
<b>Users</b>	
usersRead	See details of all users. Allows export of users.
usersManage	Create or change users including export. Allows import of users.
usersDelete	Delete any non-LDAP users.
usersAssign	Assign a user to a user group or a user group to a user.
userGroupRead	See details of user groups.
userGroupUpdate	Change existing user groups, but not their memberships.
cacUserApproval	Approve candidate CAC users.
rolesRead	Read roles and privilege definitions.
<b>Socket Filters</b>	
socketFilterAgentRead	View socket filter agents.
socketFilterAgentDelete	Delete socket filter agents.
socketFiltersRead	See socket filter lists and configuration.
socketFiltersManage	Change or remove socket filter lists and configurations.
<b>Devices</b>	
devicesRead	See details of all devices, including power hosts and consoles. Allows export.
devicesManage	Create and change devices and their memberships. Allows import.
devicesDelete	Delete any devices.
devicesAssign	Assign a device to a device group or assign a device group to a device.
deviceGroupRead	See details of device groups.
deviceGroupUpdate	Change existing device groups, but not their memberships.
autodiscovery	Find devices on the network.
<b>Policy</b>	
policyRead	See policies. Do not allow export.
policyManage	Change or remove policies. Do not allow import.
policyImport	Import all kinds of associations.

policyExport	Export all kinds of associations.
<b>Command Filters</b>	
commandFiltersRead	See command recording lists and configuration.
commandFiltersManage	Change or remove command filter lists and configurations.
<b>Configuration</b>	
configurationManage	Use the Access configuration tab.
<b>Passwords</b>	
credentialsManage	Create and update credential definitions for password chaining.
<b>APIs</b>	
awsApiProxy	Allow access to the AWS (Amazon Web Services) API Proxy.
BAPApiManage	Manage the CA Threat Analytics API.
managementConsole	Manage the Management Console API.
nsxApiProxy	Allow access to the VMware NSX API Proxy.
<b>Server Control and UNAB Policies</b>	
servercontrolPolicyManage	Read, create, update, copy, finalize, and delete Server Control policies and their versions
servercontrolPolicyRead	Provides read-only access to Server Control policies and their versions
servercontrolPolicyDeploy	Provides access to deployment operations for Server Control Policies, including Assign, Unassign, Upgrade, and Downgrade
servercontrolPolicyDeployRead	Provides access to view the policy device and device group assignments, including Server Control Policies, devices, and device group assignments
UNABManage	Provides access to UNAB operations, including read, create, update, copy, and delete UNAB Host Login Policies, and UNAB Configuration Token management, including read, created, update and delete of UNAB configuration tokens on devices a device groups
servercontrolPolicyAuditRead	Provides read access to the Server Control Deployment Audit Log entries

**NOTE**

- [User Roles](#)

## Create and Manage Users

As an Administrator, follow these procedures to create or edit Users. Create and modify user records using a template or a CSV file. For LDAP or RADIUS groups, you can only modify existing user records.

Review the following ways to managing users:

### Add a User Account Using the Template

Create a user account using a template in the UI. The configurable characteristics for each user include:

- Basic profile information
- User authentication methods and the status of the user account
- Roles that define user privileges
- Time restrictions for user login
- User group membership
- API Keys

If you are updating an existing user account, a **Manage Policy** button is available. Select this button to navigate to the Policy page, but changes already made to the user record are lost. Populate the User(Group) field there with the current user name.

### ***Specify Basic Information***

Provide user name and contact information in the **Basic Info** section.

#### **Follow these steps:**

1. Log in to the UI.
2. Select **Users, Manage Users**.
3. Select **ADD** to create a user.  
A user account template appears in the list window.
4. Complete the fields on the **Basic Info** tab. Required settings are indicated by a red asterisk. Note the following information about some of the fields:
  - **User Name:** Accepts alphanumeric characters, dashes (-), underscores (\_), and spaces. For AWS users, a user name can be from 2 through 32 characters long because of restrictions on federated users within AWS.
  - **Password:** The user password

### ***Configure Administration Settings for the User Record***

The Administration tab contains information indicating how a user authenticates and the status of that user account.

#### **Follow these steps:**

1. Select the **Administration tab**.
2. Select an authentication method for the user from the menu in the Authentication field:
  - **Local:** Local user accounts are hosted in the PAM database.
  - **RADIUS:** User authenticates to a RADIUS server. The user enters credentials that are provisioned by the RADIUS server. This option is available only if a RADIUS server is configured (see **Configuration, 3rd party**). If a RADIUS User is provisioned through LDAP, that user authenticates against a RADIUS server.
  - **RSA:** Authentication with an RSA SecurID. Users log in with a name and passcode. The passcode is a combination of the personal identification number and the current readout from the SecurID device. For example, if your PIN is 3425 and the current readout from your SecurID device is 866329, the passcode is: 3425866329
  - **Smartcard/PKI** - User authenticates with a Smartcard. PAM checks the user certificate against an OCSP server, or a Certificate Revocation List (CRL). The first time that a Smartcard user accesses the server, the Designated Name, and User account is registered. The User name appears in the **Approve CAC User** tab. This user must be approved before device access can be assigned.  
To use Smartcard authentication, set the Smartcard parameters in the **Security, Access, PKI Options**.
3. Configure the deactivation and termination settings for the user account.
4. If you select the **Terminate Session on Account Expiration** check box, a user login and all current sessions are terminated at the expiration date/time or the account violation limit is exceeded. If a user account is deactivated while that user is logged in, the session is terminated.
5. Specify email accounts to receive notices when the configured user logs in. The **Email on Login** field triggers an email to a specific administrator. The **Email Self on Login** field triggers an email to the address in the Basic Info section of the user record.

6. If the user is accessing Privileged Access Manager from the PAMClient, enter a range of IP addresses permitted to log in. Delimiters that are permitted include the space, comma, semicolon, newline. Both IPv4 and IPv6 address formats are supported and can be combined.

IP address formats permitted include:

- Single IP: 192.0.2.1 (IPv4), fd6d:8d64:af0c:1:0:242:22:233 (IPv6)
- CIDR: 192.0.2.0/28 (IPv4), fd6d:8d64:af0c:1:0:242:22:233/64 (IPv6)
- Range: 192.0.2.1-32 (IPv4), fd6d:8d64:af0c:1:0:242:22:1-ffff (IPv6)

If this field is empty, no IP address restrictions are applied. The user definition overrides the User Group definition. If no user policy is defined but that User is a member of multiple groups with different rules, the group permissions are additive (less restrictive).

#### NOTE

If your PAM server sits behind a networking device, such as a proxy, load balancer, or router, ensure that the device prevents against IP spoofing of the X-Forwarded-For HTTP header.

### ***Assign Access Roles to the User***

An access role is a collection of access-defined privileges. To perform access operations, each user must be assigned one or more roles.

Before you can assign roles to a user, the roles must be defined in the **Users, Manage Roles** list. To define roles, see [User Roles](#).

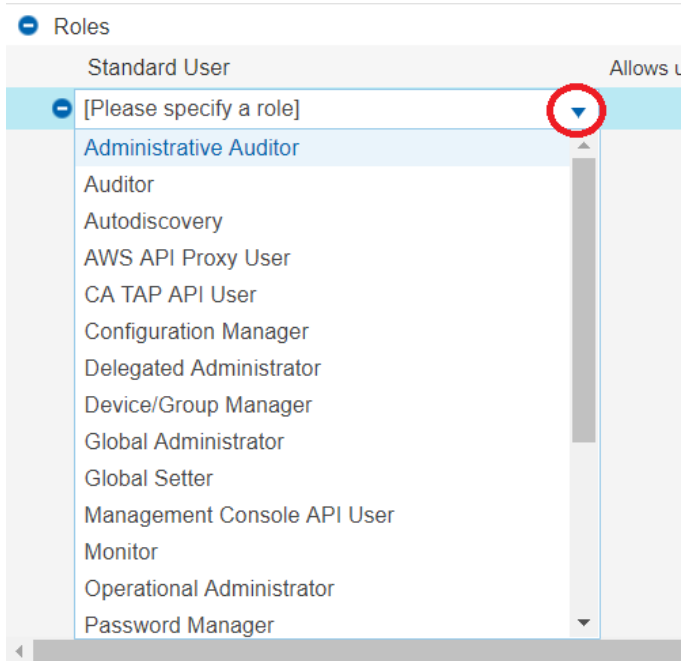

#### **Follow these steps:**

1. On the **Add** or **Update** user screen, select the **Roles** tab.
2. If necessary, expand the Roles list by selecting the plus sign to the left of the Roles table.  
"Standard User" is the default preassigned role. This role allows device access.

#### NOTE

The user can also inherit roles from Groups of which they are a member.

3. Do the following steps for each role that you want to assign:
  - a. Select the plus sign (+) to the right.
  - b. Select the **Please specify a role** field that appears, then select the caret symbol (highlighted in the following screenshot) to open a pull-down list of available roles.

- c. Select a role from the list to assign it.

If a role (for example Device/Group Manager or Policy Manager) requires you to specify the User Groups, Device Groups, or both, over which the role has control, corresponding entries appear below the role.

**To specify such groups, use one of the following options:**

- Select the plus (+) icon to the right of the entry to specify a required group.
- Select the **[Please specify a group]** entry that appears to open the **User Groups** or **Device Groups** selection dialog (as appropriate), as shown in the following screen capture:

## User Groups

☐ All Users

User Groups: \*

OK

Cancel

- Select **All Users** to include all user groups, start typing in the **User Groups** field, or select the magnifying glass icon to open a dialog with comprehensive search options.

### NOTE

You can only select one user or device group at a time. To specify additional groups, use the + option to the right of **User Groups** or **Device Groups** entry, as required.

After you have selected a group using any method, select **OK** to save it.

### NOTE

To provide a user with access to Credential Manager functions, add the **Password Manager** role.

Each user with Credential Manager access must also be assigned one or more predefined *Credential Manager groups* to determine the credential management functions they can access. For more information, see [Add Credential Manager Roles and Groups](#).

## Specify Login Time Periods

You can configure time-based access restrictions that determine when a user can log in to the server, select the **Access Times** option.

**Follow these steps:**

1. From the UI, select **Users, Manage Users**.
2. Add or modify an existing user entry.
3. Select the **Access Times** tab.
4. Select the plus sign then specify the days when to allow access.
5. In the **From** and **To** table columns, select the drop-down list to display a list of times. Access times are specified in UTC.
6. Select **OK** to save your entries.

**Add Users to Groups Including Credential Manager Groups**

Before a user can become a member of a user group, that group must be set up. Set up user groups by selecting **Manage Users, Manage User Groups**. After the group is configured, add users.

Follow these steps:

1. Open the User record.
2. Select one of the appropriate Group tabs:
  - **Groups**: Accessible by users with any roles unless they only have the Password Manager role, in which case the tab is grayed out.
  - **Credential Manager Groups**: Accessible by any user with the Password Manager role. Otherwise, the tab is grayed out.
3. To add the user to one or more groups, select the checkbox for each group.
4. Select the right arrow to move the groups to the Selected Groups list.
5. Select **Save**.

**NOTE**

User groups are not available for Active Directory or other directory users. Instead, users should be grouped in the directory and the attribute that is read by Privileged Access Manager. Setting policies for directory users is done at the group level.

**Grant Access to the External REST API**

The External REST API provides programmatic control over most PAM functions. The API uses HTTP basic authentication with API keys (secured using HTTPS) for user authentication. Authorization is provided by associating API keys with roles that determine privileges.

Assign API Keys and configure role assignments on the **API Keys** tab. For complete procedural information, see [Grant External REST API Access to Users](#).

**Configure Extended Identities**

Configure alternate accounts to access RDP applets, mainframe applets, Azure SQL Managed Instances and Azure AD instances on the **Extended Identities** tab.

**NOTE**

The Extended Identities are disabled during your initial login session or when logged in after being required to change your password.

To specify an alternate account, enter it in the corresponding **Value** field:

- **RPD User Name:** Enter the an account name for use by the RDP Applet or the MSSQL JIT target connector.
- **Mainframe Display Name:** Specify an account name to use to access the AS/400 applets (TN5250 and TN5250SSL).
- **User Principal Name:** (Imported LDAP users only) Provides an account name that can be used to access an Azure SQL Managed Instance.

**NOTE**

**User Principal Name** is read-only, populated with the value of the `User Principal Name` attribute (if present) from the LDAP record of the imported user.

- **Azure Username:** Specify a valid Azure AD account name (an email address) to use to access an Azure SQL Managed Instance. The specified value must be an account that already exists in Azure AD.

### **Edit User Records in LDAP or RADIUS Groups**

These user records are created through features in the **Users, Manage Groups** page. However, portions of their records can be edited on the **Manage Users** page. Note these characteristics:

- The user is already assigned (the copy of) the LDAP group it was imported from (see **Groups** panel).
- No fields that are imported from LDAP or RADIUS can be edited.
- You can edit certain assigned fields, including:
  - Keyboard Layout
  - RDP Username
  - Mainframe Display Name
  - Account Status
  - Terminate Session Upon Deactivation
  - Email on Login
  - Email Self on Login
  - Available Roles
  - The Access Time fields
  - Available Groups (the associated LDAP group cannot be removed).

### **Edit User Records from a Policy**

An administrator can edit a user record directly from the Manage Policies page.

1. Open the **Policies, Manage Policies** page.
2. Select **ADD** or **UPDATE**.
3. Populate the User (or Group) field with a record name.
4. Select **Manage User** to open the User record.
5. Open the User record.
6. When finished, select **Manage Policy** to return to the Manage Policies page.

## **Configure User Groups**

To combine users with similar attributes, define a user group. User groups allow for more manageable changes. Each user can be a member of one or more user groups. User group settings override the same individual user setting.

The following sections describe user group types and how to configure groups:

### **User Group Types**

- **Access User Groups**

Access User Groups are static collections of Users. Some User attributes, such as (Access) Roles and Access Time, can be assigned at the group level.

- **Credential Manager User Groups**

Credential Manager user groups are dynamically determined. User groups are based on a Credential Manager role and a Target or Request Group of the current set of users. Create these User Groups by navigating to **Policy, Manage Passwords, Users, User Groups**.

- **Local Groups**

Local groups are a collection of local users.

#### NOTE

Do not confuse Access user groups with Credential Manager user groups. User groups and roles are specified in two distinct locations, one for general use and one specifically for Credential Managers

### Use the UI Template to Create a Group

To create a user group consisting of local users, use the UI template. The instructions for each part of the template are explained.

#### **Basic Info Configuration**

##### **Follow these steps:**

1. Log in as an appropriate administrator.
2. Select **Users, Manage User Groups**.  
A User Group is necessarily restricted to a single Authentication scheme.
3. Select **Add** to create a local or SAML group.  
For RADIUS, TACACS+, and LDAP groups, see the relevant instructions.
4. Complete the fields in the **Basic Info** tab. Note the following information:
  - **Group Name:** Double-byte characters are allowed.
  - **Applet Recording Warning:** Set this option to **Yes** to display a notification that an applet (such as SSH or RDP) session is being recorded. (This option is ignored for TCP/UDP and RDP service sessions.) For example, when a user who is a member of the group opens an SSH applet console, the following warning appears in the title bar of the window and in the first line of console: **"Warning you are being monitored."**

#### NOTE

The related **Show Recording Warning** setting on the **Settings, Global Settings** page **Warnings** tab is ignored for applet sessions that are made by users who are a member of any group for which **Applet Recording Warning** is enabled. The global **Show Recording Warning** setting applies for all applet sessions that are made by users who are not members of any group and for *all* TCP/UDP and RDP service sessions.

If a user group is imported from an LDAP directory, the Group Name has the following format:

- From Active Directory: LDAPsourceGroupName + "@" + *LDAP\_domain*. The *LDAP\_Domain* is the base DN in the **Bind Credentials** field of the LDAP Domain configuration (**Configuration, 3rd Party, LDAP**).
- From other LDAP directory servers, such as OpenLDAP: LDAPsourceGroupName

Also, the **Description** field has the format: "LDAP Group" + LDAPsourceGroupName + "from" + LDAPsourceDistInUlshedName

#### **Administration Configuration**

The Administration section is where you specify the user authentication method

##### **Follow these steps:**

1. Select the **Administration** tab.

2. In the **Authentication** field, select an option from the drop-down list. The available options depend on which type of group is being created (Local, RADIUS, or imported LDAP).

If you select SAML as an authentication method, the user authenticates by a SAML assertion. The SAML attribute depends on the user provisioning source:

**For Active Directory:**

- Distinguished Name
- User Principal Name
- SAM Account Name

**LDAP directory like OpenLDAP or other:**

- Distinguished Name
- Unique Attribute

**If Authentication method is Local, RADIUS, or PKI:**

- User Name

3. If the user is accessing the server from the PAM Client, enter a range of IP addresses that are permitted to log in. Delimit each address with either a space, comma, semicolon, or newline. Both IPv4 and IPv6 address formats are supported and can be combined.

IP address formats permitted include:

- Single IP: 192.0.2.1 (IPv4), fd6d:8d64:af0c:1:0:242:22:233 (IPv6)
- CIDR: 192.0.2.0/28 (IPv4), fd6d:8d64:af0c:1:0:242:22:233/64 (IPv6)
- Range: 192.0.2.1-32 (IPv4), fd6d:8d64:af0c:1:0:242:22:1-ffff (IPv6)

If this field is empty, no IP address restrictions are applied. The user definition overrides the User Group definition. If no user policy is defined but that User is a member of multiple groups with different rules, the group permissions are additive (less restrictive).

**NOTE**

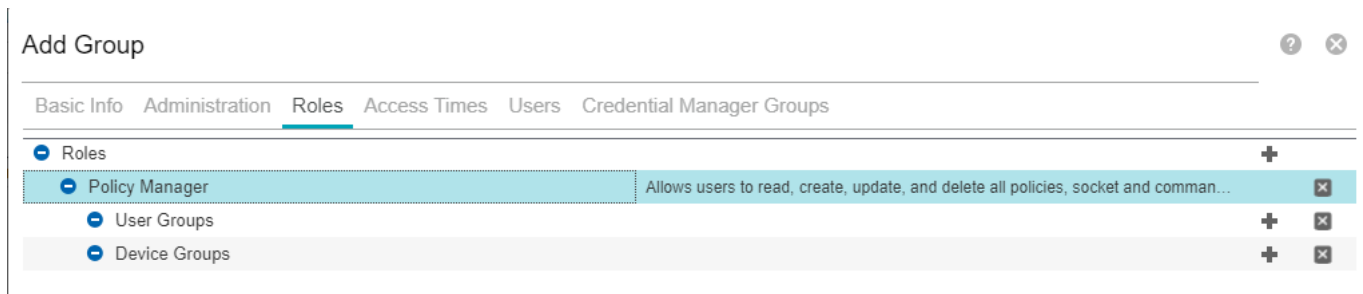

If your PAM server sits behind a networking device, such as a proxy, load balancer, or router, ensure that the device prevents against IP spoofing of the X-Forwarded-For HTTP header.

**Define Roles for a User Group**

Multiple roles can be assigned per group. The standard user is the default role.

**Follow these steps:**

1. From the **Add Group** screen, select **Roles**.
2. Expand the **Roles** list using the plus sign.  
The Standard User is the default preassigned role. This role allows device access.
3. Select the plus sign to the right and a new line displays prompting you to specify a role.
4. Select the **Please specify a role** field. Select the arrow for a pull-down list that becomes available.  
The list shows all currently defined roles and a set of predefined roles.
  - Specify a role using the **Available Roles** drop-down list.
  - If an access role has the Credential Manager permission, this role can provide access to the Credential Manager menu from the Policy, Manage Passwords selection. You must specify a Credential Manager user group to determine the scope of menu access. Use the expansion pane Credential Manager Groups.
  - If a role (for example Device/Group Manager or Policy Manager) requires you to specify the User Groups, Device Groups, or both, over which the role has control, corresponding entries appear below the role, as shown in the following screen capture:

Select the plus (+) icon to the right of the entry to specify a required group. Select the **[Please specify a group]** entry that appears to open the **User Groups** or **Device Groups** selection dialog (as appropriate), as shown in the following screen capture:

Select **All Users** to include all user groups, start typing in the **User Groups** field, or select the magnifying glass icon to open a dialog with comprehensive search options.

#### NOTE

You can only select one user or device group at a time. To specify additional groups, use the + option to the right of **User Groups** or **Device Groups** entry, as required.

After you have selected a group using any method, select **OK** to save it.

### Credential Manager Role Inheritance

The ability to map Credential Manager User Groups to Access Manager User groups enables role inheritance rather than assigning a Credential Manager Role for each user.

#### Follow these steps:

1. Go to **Users, Manage User Groups**.
2. Select **Update User Groups**.
3. Select the **Credential Manager Groups** tab.

Assign a Credential Manager group to an Access Manager group that has a role with the **Manage Credentials** privilege. You are not limited to the set of preconfigured roles in PAM for either Credential Manager or Device Manager. You can customize the permissions for a role to ensure the lease privilege is maintained (a user can view credentials but not make changes to the account in firecall users) Three roles included with PAM that contain the Manage Password Privilege are Global Administrator, Operational Administrator, and Password Manager.

If you attempt to do a Save and select OK without adding a Credential Manager group, an error occurs with the following message:

"Roles with the Manage Credential privilege must have at least one Password Authority group to manage."

When upgrading to PAM 3.4 from an earlier version, no changes are made to Access Manager users, usergroups, role, or Credential Manager groups or roles.

#### NOTE

PAM users not explicitly assigned to any **Credential Manager Group** always become default members of the **Credential Manager Group** (CMGroup) named **Standard Users**. The **Standard Users CMGroup** has the

**FirecallUser** role with the **View Account Password** privilege. So, any member of **Standard Users** can view all target account passwords. This remains true even when the user might have inherited a CMGroup other than **Standard Users**, such as by means of a **Session Manager User Group (SMGroup)**.

The only way to prevent the user from viewing the target account password in this case is to explicitly assign the user the **Session Manager Role** with the **Manage Passwords** privilege; for example, assign the **Password Manager** role, and then add the user to a CMGroup (such as **Base Users**) that does not have **View Account Password** privilege. This removes the user from the **Standard Users** CM group. The user, therefore, no longer has the **View Account Password** privilege.

### ***Specify Time Periods for Group Login***

To configure time-based access restrictions when users in a group can log in to the server, select the **Access Times** option.

#### **Follow these steps:**

1. Add an entry to the **access times table**.
2. Specify the days and times for the access entry. the **From** and **To** table cells to display a drop-down list of times.
3. Select **OK** to save your entries.

### ***Add Users to Groups***

After the group is configured, add users.

#### **Follow these steps:**

1. Select the check box next to any user you want to add to the group.
2. Select the right arrow to move the groups to the Selected Users list.  
For Imported LDAP groups, users cannot be added or removed. Modify user records in the source LDAP directory.
3. Select **OK**.

#### **NOTE**

User groups are not available for Active Directory or other directory users. Instead, users should be grouped in the directory and the attribute that is read by Privileged Access Manager. Setting policies for directory users is done at the group level.

### **Elevate User Privileges Temporarily**

To elevate the privileges of a user temporarily, add them to a user group that has the additional privileges for as long as necessary. When the user no longer needs the elevated, simply remove them from that user group.

### **Create a RADIUS or TACACS+ Group**

You can create a user group that is imported from a RADIUS or TACACS+ server. For the RADIUS or TACACS+ buttons to become active, first configure the RADIUS or TACACS+ server for access to Privileged Access Manager. See [RADIUS or TACACS+](#) for instructions on configuring RADIUS connectivity.

#### **Follow these steps:**

1. Open a template by clicking the relevant button:
  - **Create RADIUS Group**
  - **Create TACACS+ Group**
2. Complete each section of the template. The instructions are similar to creating a local user group.  
To locate users in a RADIUS or TACACS+ group, each group name you specify must match a corresponding group name or ID on the RADIUS or TACACS+ server. Privileged Access Manager uses the configured grouping to manage users.

The GroupID must match a corresponding group on the RADIUS or TACACS+ server. All the privileges that users maintain are derived from their group. Only users with a local account or whose group matches the group name in the UI is granted access. Contact the RADIUS or TACACS+ server administrator for the group name.

If a RADIUS group is provisioned but the user does not exist, a shadow RADIUS user is created. The shadow user is not visible in the user management screen or the user list.

### **Import an LDAP Group**

For information about importing an LDAP Group, see [Import LDAP User Groups](#).

### **Edit from the Manage Policies Page**

An administrator can edit a user group record by invoking it directly from the Manage Policies page.

1. Open the Policy, **Manage Policies** page.
2. Populate the **User (Group)** field with a record name.
3. Double-click the name to display its editing template in a shadow box window.
4. When finished, select **Save** (or Cancel) to return to the **Manage Policies** page.

### **SAML SSO with Juniper SA Using RADIUS Authentication**

See Network Configuration, SSO, Juniper Networks, Configure Privileged Access Manager for SAML SSO with Juniper SA using RADIUS Authentication.

For information about importing an LDAP Group, see [Import LDAP User Groups](#).

## **Import LDAP User Groups**

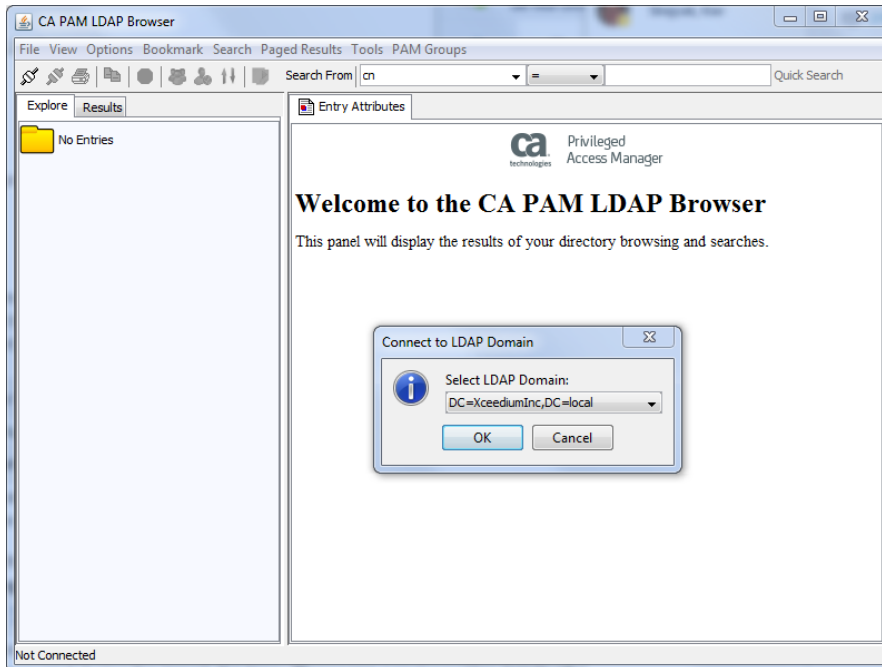

As an Administrator, an efficient method of creating an LDAP user group is to import an LDAP user group from a remote LDAP server. To import a user group, you must use the built-in *LDAP Browser*, which gets launched during the import procedure.

This topic explains the following tasks:

### **Launch the LDAP Browser**

To import LDAP Groups into Privileged Access Manager, follow these steps:

1. Verify that your appliance is licensed on the **Configuration, Licensing** page. A license is required to launch the LDAP Browser.
2. Navigate to **Configuration, 3rd Party, LDAP**, and configure access to an LDAP server. Provisioning the LDAP server is necessary to make LDAP groups available for import.
3. Select **Users, Manage User Groups**.
4. Select **Import LDAP Groups**.  
The LDAP Browser launches. You are prompted to select an LDAP domain.

## NOTE

Privileged Access Manager does not support SSH and LDAP connections from a native browser due to strong cryptography support. Update your local JCE with unlimited strength policy jars that are based on your JRE version.

5. Go to the next procedure to import the LDAP group.

If the LDAP server does not support the cipher suite that is used by the Privileged Access Manager LDAP browser, a connection failure occurs. The following error message appears: "Possible cipher mismatch with LDAP server." During provisioning, ensure that the ciphers that are supported on the target LDAP server include those ciphers that are supported by the LDAP browser.

## Import LDAP Groups

In the LDAP Browser, the **Explore** tab in the left pane shows a graphical representation of an LDAP tree. Select any object to see the object attributes.

### Follow these steps:

1. Select the LDAP domain and select OK to connect to it. The browser connects and displays all records below that domain.
2. Navigate the LDAP tree in the left pane and locate the user group that you want to import. Traverse the tree in any order or direction.
3. Select the user group to import.
4. Repeat these steps for each group you want to import.
5. (Optional) Review the user groups that are selected for import:
  - a. Select **PAM Groups, Manage selected groups to register with the PAM appliance**. The list of the Distinguished Names for all selected groups displays.
  - b. Select and edit any group DN, or remove it from the staging list.
6. Select **PAM Groups, Register selected groups with the PAM appliance**. A window opens displaying a list of the staged groups. You can watch the progress, and can display any messages that are associated with the actions.
7. When ready to import the groups, select **Register Groups** in the lower-left corner.

Privileged Access Manager imports the groups in the order that they are listed. The browser provides feedback and cancellation options throughout the process.

#### TIP

You can cancel registration of a group, or you can cancel the registration of all groups, even after they have started.

When the imports are finished, each line item in the registration window shows a green checkmark for success or a red **X** for import failure/cancellation.

8. (Optional) Review the status of the full list and each individual group by selecting its line item. If you made changes to an individual group or any errors occurred, the lower **Messages** panel provides details.
9. Go to **Users, Manage User Groups**, and confirm that the imported user groups appear on the page. Roles are inherited from the LDAP group. The default role is Standard User. Ignore the **Roles** panel, which indicates **"No roles selected."**

#### NOTE

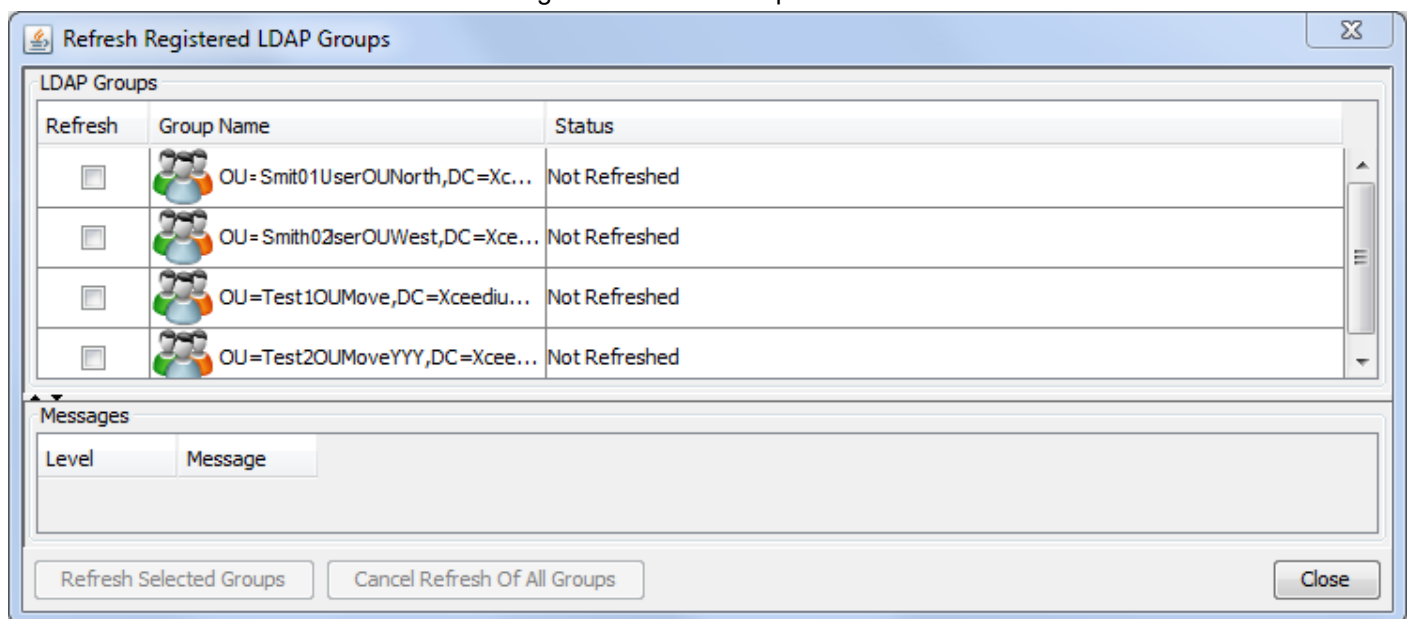

You cannot delete a record from an imported user group. Also, you cannot edit an LDAP-imported field.

### Refresh LDAP Groups

You can refresh an LDAP Group to update the records in the group.

#### Follow these steps:

1. In the UI, select **Users, Manage User Groups**.
2. Toward the right side of the page, select **Refresh LDAP Groups**.  
The LDAP Browser launches the Refresh Registered LDAP Groups window.

3. Select one or more groups you want to refresh and select Refresh Selected Groups.

### Refresh Active Directory User Groups After an OU Change

A change to organization unit (OU) of a user results in a change to the user DN. The modified DN can impact an access policy. PAM handles an OU change when the Active Directory group is refreshed automatically. During a refresh, the appliance searches the remote Active Directory Server and updates its user record. Despite the OU change, the policy for that user is preserved.

**WARNING**

To reflect an OU change immediately, you can manually refresh an Active Directory group in PAM. To keep the data in sync with Active Directory, refresh all the groups that now contain the user and all the groups from where the user moved.

**Nested Groups**

If an LDAP group is in a parent group **member** attribute, then users in the parent and child groups are imported with the parent. For example, consider groups CommunityA and CommunityB, and Person1. CommunityB is a member of CommunityA and it is nested in CommunityA. Person1 is the sole member of the group CommunityB. If you import the CommunityA group, you see every member of CommunityA and member Person 1 from CommunityB.

**LDAP Browser Menus and Controls**

The following table explains the LDAP Browser menus and controls options:

Text Menu	Function
Copy icon	Copy the Distinguished Name of selected entry to the Clipboard.
Group icon	Display all the groups in this container. After first selecting an object in the tree under the Explore tab, clicking this button will then switch you to the Results tab. Once there, you see a (fully expanded) tree of all groups (objectClass: group) contained within the selected object.
<b>File</b>	
Connect	Log in to an LDAP database. Invokes a pop-up window from which you can select from currently accessible domains.
Disconnect	Log out from the current LDAP domain.
Print	Print currently selected node.
Exit	Close browser window. The browser continues running while the connection is active. During that time, you can invoke the LDAP Browser by selecting Users, Manage Groups, Import LDAP Group.
<b>View</b>	
Show Button Bar	Icon-based menu Default: On
Show Search Bar	Icon-based menu Default: On
<b>Options</b>	
Set LDAP Connection Timeout	Maximum time (seconds) before a connection attempt is canceled. This timeout is useful when multiple servers are specified for a particular LDAP domain in <b>Configuration, 3rd Party</b> . Default: 60 seconds
Set Result Set Page Size	Maximum number of records in an LDAP directory before pagination is triggered for representation in the browser tree. Number of records in each page of a paginated subtree. Default: 1000
Enable/Disable Group Member SID Resolution	If enabled, resolve all members of security groups (including members of nested security groups) across domains.

<b>Bookmark</b>	A bookmark can be made on any leaf in a tree. You can select the bookmark later directly from the menu. Bookmarks are saved for each domain, and appear only when the browser is connected to that domain.
Add Bookmark	Opens an editing window for bookmarking currently selected leaf: <ul style="list-style-type: none"> <li>• DN – pre-populated with the current Distinguished Name (DN)</li> <li>• Bookmark Name – pre-populated with the current Common Name (CN)</li> </ul>
Edit Bookmark	Opens a bookmark selection window. Selection in turn opens a bookmark editing window (see Add Bookmark).
Delete Bookmark	Opens a bookmark selection window. Selection in turn deletes and confirms deletion of the bookmark.
<b>Search</b>	
Search Dialog	Opens a detailed search specification window. (Contrast to Quick Search.)
Delete Filter	Opens a window with a list of filters for selection and deletion.
Return Attribute Lists	
<b>Paged Results</b>	
Next Page of Results	Retrieve next page of results and display page wrapper (Page n Results) in the Explore tree (when green; otherwise, gray when inapplicable).
<b>Tools</b>	
Stop Action	Suspends current LDAP request. Stopping a request is useful when the page size is large and the browser is searching a large database.
Privileged Access Manager Groups	Privileged Access Manager-specific menu items
Manage selected groups to register with the appliance.	Lists all items that are currently selected (or staged) for importing to Privileged Access Manager.
Register selected groups with the appliance	Perform the input operation on the items that are selected, which are listed in Manage selected groups to register with the appliance.

## About Pagination

Pagination is available for Active Directory (AD) and OpenLDAP.

The LDAP Browser has a pagination feature to reduce overhead on LDAP access. The browser setting **Result Set Page Size** specifies the maximum number of members (directories, groups, or objects; or nodes) for any directory. (This value is initially set to a default of 1000.) If the overhead required to display all directory members is too heavy, the administrator can reduce this variable value.

For example, set this value to 5 to insert a pagination leaf for more than five members in any directory. The LDAP Browser inserts the initial pagination leaf is when that directory is opened, before displaying the actual directory contents.

## Search and Quick Search Options

If you know the name of the directory or object you are looking for, use one of two search options available in LDAP Browser. If the tree appears paginated in the browser, the search can still traverse the entire tree.

You can use the **Quick Search** button in the upper-right corner of the browser to locate the desired object.

**Follow these steps:**

1. In the **Explore** tab tree, select the node that you want to be at the top of the search.  
Your choice is reflected in the Quick Search label.
2. To the right of the Search From label, select an attribute from the drop-down list, and enter a search string in the text box.
3. Select **Quick Search**.  
A filtered tree appears in the **Results** tab.
4. Select an object in the tree to see **Entry Attributes** on the right.

**LDAP Browser Search Options**

To refine search results to a limited subset of objects or saved for future use, select menu item **Search, Search Dialog**.

The following table explains the search settings.

Field/Button	Definition
Filter Name	Assign a bookmark name for the filter: When you have filled in the remainder of this dialog, select Save in the lower right. The filter is then available from the Search menu.
Start Searching From	Identify the root node for your search.
<b>Alias Options</b>	
Resolve aliases while searching	When checked: LDAP Browser returns the real entry to which the alias points. When unchecked: LDAP Browser returns all alias entries as regular entries.
Resolve aliases when finding base object	
<b>Search Level</b>	
Select Search Level	Search Base Object Search Next Level Search Full Subtree
Information to retrieve	Allows you to select from a saved list in Return Attributes Lists.
<b>Filter Operators</b>	
Not	Negative of (entire) constructed entry
[Expression]	
[Attribute]	Menu of all LDAP attributes: accountExpires through x500uniqueIdentifier
[Operator]	Logic to apply to the attribute in this expression
[Character string]	Text being tested with this expression
More	Add another logic template to concatenate with other defined logic
Less	Remove most recently defined logic
Save	Save entire filled-in template to the label assigned in a filter name
Load	Load existing filter to this template for editing or copying.
View	Show the LDAP filter
<b>[Template Commands]</b>	
Search	Perform search as currently defined in this template.

Cancel	Close dialog without executing a search or saving it to a filter name
--------	---

### **Double-Byte Characters for User and User Group Names**

Privileged Access Manager provides double-byte character support. The appliance allows East Asian characters in data store and in the UI representation of user and user group names. LDAP user names are imported and displayed with the double-byte characters maintained.

User records with double-byte characters can be imported to LDAP groups but not to individual local user records.

## **Import and Export Groups**

### **NOTE**

You can create one CSV to import both Users and Groups rather than create one file for each page.

### **Add a Group from a CSV File**

#### ***Internet Explorer Requirements to Use a CSV File***

To use the Import/Export functions with Internet Explorer (IE), changes might need to be made to the security settings. To establish the necessary settings:

1. Open IE browser.
2. Select **Tools, Internet Options**.
3. In the Internet Options pop-up window, select the **Security** tab.
  - a. Select the slider zone.
  - b. Select **Custom level**. Scroll to **Downloads**. For **File download**, select the **Enable** option.
4. Select **OK** to save changes.

#### ***Import a CSV File***

To import the users, follow these steps:

1. Go to **Users, Manage User Groups**.
2. Select the **Import/Export** button.  
The Import/Export Users window appears .
3. Select Download Sample File, and save the file.
4. Create a CSV file from the downloaded template.

#### **CSV Format**

- Do not change the heading (first) row text.
  - New Group records:
    - For any fields not used: Preserve all headings on the first row, but leave the data cells blank.
  - Updates to existing Group records:
    - Each User Group is represented by a line record with Type="user group".
    - User Group records should be at the top of the file, ahead of all User records.
    - As it is for individual Users, an Authentication option can be applied to a User Group:
5. In the **Import/Export User Groups** window, select **Choose File** to select the file, and select **Import Users (User Groups)**.  
The content of the file is added to the existing User database. The new content does not replace the current database.
  6. Navigate to **Users, Manage User Groups**, and confirm that the import was successful by inspecting the User list.

### ***Export Users***

This button creates a CSV file of all Local, RADIUS, SecurID, and Smartcard/PKI users. For Local users, the **Password** field is masked.

#### NOTE

Whether you export a CSV from the Users or User Groups page, the same data is produced, including Users and User Groups.

## Manage User Accounts

Use the **Session Manager Users** panel, which lists all existing local, LDAP, RADIUS, and SecurID user accounts, to perform the following account management functions:

- [Add a User](#)
- [Edit a User](#)
- [Copy a User](#)
- [Disable a User](#)
- [Reactivate Accounts Disabled by Inactivity](#)
- [Delete a User](#)
- [Approve CAC Users](#)

#### NOTE

Imported LDAP values cannot be edited, but PAM-generated fields can. Smartcard/PKI user accounts can only be edited or deleted.

### Access the Session Manager Users Panel

To access the **Session Manager Users** panel, select **Users, Manage Users**.

#### Add a User

For information about adding users, see [Create and Manage Users](#).

#### Edit a User

Use this procedure to edit a user account.

#### To edit a user account, follow these steps:

1. On the **Session Manager Users** panel, select the line item record of the user account that you want to edit.
2. Select the **Update** button.
3. Edit the account details as required in the **Update User** dialog that opens.
4. Select the **OK** button to commit your changes.

#### Copy a User

Use this procedure to duplicate an existing user account to create a user account with the same access permissions and policies.

#### Follow these steps:

1. On the **Session Manager Users** panel, select the line item record of the existing user account that you want to duplicate.
2. Select the **Copy** button.  
A **Copy User** dialog that is populated with all the information of the original user account except for the username and password opens.

3. Do the following steps in the **Copy User** dialog:
  - a. Enter a username for the new account in the **User Name** field.
  - b. Enter an account password and confirm it in the **Password** and **Confirm Password** fields.
  - c. Optionally, change the other properties, as required.
  - d. Select the **OK** button.

The new user account is created and added to the list.

### **Disable a User**

Use this procedure to disable (preserve, but not allow activity by) a user account.

#### **Follow these steps:**

1. On the **Session Manager Users** panel, select the line item record of the user account that you want to disable.
2. Select the **Update** button.
3. On the **Update User** dialog that opens, select the **Administration** tab and deselect the **Account Enabled** option.
4. Select **OK**.

#### **To list disabled user accounts:**

Use the filters at the top left of the **Session Manager Users** panel:

1. Select **Account Enabled** from the **Column** drop-down list.
2. Select **False** from the **Value** drop-down list.
3. Select the **Filter** button to display only disabled user accounts.

#### **To reenable multiple user accounts:**

1. Use the filters at the top left of the **Session Manager Users** panel to display the disabled accounts:
  - a. Select **Account Enabled** from the **Column** drop-down list.
  - b. Select **False** from the **Value** drop-down list.
  - c. Select the **Filter** button to display only disabled user accounts.
2. Select individual users, or select them all by selecting the checkbox above the list to the left of the column headings.
3. When the list of choices is complete, select the **Enable** button.

### **Reactivate Accounts Disabled by Inactivity**

As an administrator, you can list user accounts disabled due to inactivity, and then reactivate some or all accounts. This bulk reactivation can help when multiple deactivated users request account reactivation.

#### **NOTE**

As an Administrator, you can also double-click individual users in the **Session Manager Users** page to display why the user is deactivated: Double-click a user to display the **Update User** window, and then find the reason in the **Administration** tab **Deactivation Reason** field.

The period after which users are disabled due to inactivity is specified in the Global Settings. For more information, see the [Accounts](#) section of the [Apply Global Settings](#) topic.

#### **Follow these steps:**

1. Use the filters at the top left of the **Session Manager Users** panel to display the deactivated accounts:
  - a. Select **Deactivation Reason** from the **Column** drop-down list.
  - b. Select **Inactivity** from the **Value** drop-down list.

#### **NOTE**

The **Other** value includes users who are actively disabled, or users disabled due to some sort of violation (for example: for violating command or socket filters).

- c. Select the **Filter** button. A list of user accounts disabled due to inactivity appears
2. Select the checkbox next to the **User Name** column heading to select all the users.
3. Select **Enable** to enable all selected users

#### NOTE

You can see the deactivation reason when you export users to a CSV file. The deactivation reason is also included in the response when adding or updating a user using the external REST api or the CLI. In all these cases, the deactivation reason is reported as an integer with the following values:

<u>Deactivation Reason</u>	<u>Numeric Value</u>
Other	0
Inactivity	1

#### Delete a User

To delete (completely remove) a user account, follow these steps:

1. On the **Session Manager Users** panel, select the line item record of the user account that you want to delete.
2. Select the **Delete** button.
3. Select **Yes** in the confirmation request. An acknowledgment is presented in a new dialog.
4. Close the acknowledgment box.

The user account is removed from the list.

#### Approve CAC Users

Smartcards, including Common Access Cards (CAC), use certificates to authenticate users. Privileged Access Manager validates the user certificate against a Certificate Revocation List. The smartcard parameters must be set in the **Global Configuration** under the **Security** tab.

The first time that a smartcard user accesses Privileged Access Manager their public key is registered and the user appears in the **Approve CAC User**. The user must be approved before device access can be assigned.

## User Viewing

#### Initial View

You log in to Privileged Access Manager initially as config, and then as super. When, as super, you switch over to the default Users menu, you see a list that is populated with the super account.

Later, you can view all and can edit any users here except for config. Config must be edited in the Toolbar: **Change Password** menu while logged in as config.

#### Filtering Populated User Views

After you have added users, they might not all be visible on the first Access page. If there is a large number, filter this set of users using the **Search** box to narrow the list to matches of the search string provided.

## Provision Access Policies

To enforce access rules for specific users and user groups. Policies for associating users and devices can be done at a granular level (device and port). Each user then has access only to devices and applications that they need to do their jobs.

A **policy** is a set of configuration values identifying permitted or required:

- **Access types** (access method applets, TCP/UDP, and application services)
- **Access restrictions** (command filters, socket filters)
- **Passwords** (which involve Devices and resident applications)
- **Recording** (graphical or command line)

A Policy specifies the interactivity between:

- one registered user or user group (including LDAP and RADIUS)

*and*

- one managed device or device Group

After a user logs in to a device using the policy assignments, the appliance can:

- Record user activity
- Perform command filtering
- Terminate user leapfrog attempts

### **Access Provisioning**

The access capabilities that you provide for a Device are available for specification in Policy. See [Set Up Access to a Target Device](#) for information about setting up access capabilities for Devices.

### **Access Restrictions**

Through a Policy, these restrictions to Device or Device Group access can be imposed on a particular User or User Group:

- Command Filtering
- Socket Filtering

### **Command Filtering**

You can use command filter lists to enforce policies in the command line applets TELNET, SSH, and serial consoles.

Both Command Filtering and Socket Filtering use whitelists and blacklists to set the appropriate policy.

- A command-filtering **blacklist** is a list of commands that a user *cannot* type. If the user attempts to type the command, the appliance can flag (log), alert, re-mediate, and stop the command from being processed. All other commands are allowed.
- A command filtering **whitelist** is a list of the commands that a user *can* type. All other commands are prohibited.

#### **NOTE**

Command filter whitelists cannot be configured for Mainframe TN3270 and TN5250 applets.

The Command Filter Configuration (CFC) sets the behavior of the blacklist and whitelist command filters.

### **Command Filter Alerts Example**

```
From: xsuitel@example.com
To: xs-admin1@example.com
Cc:
Subject: Alert Msg from xsuitel
```

```
-----
Date/Time: Fri, 1 Oct 2010 14:09:05
User ID: Traveler123
```

User Source IP: 168.0.2.123  
Violation on: LinuxBox12

Captured Keystrokes: rlogin

## **Socket Filtering**

Socket Filter Agents (SFAs) are Privileged Access Manager components that are used to restrict access either to server-based devices or from server-based devices. Socket filters provide a different kind of access control than devices with finite command sets, such as routers and switches, for which command filtering is applied.

Three components are required:

- Socket Filter Lists – to define either a socket blacklist (specifying where access is prohibited) or whitelist (specifying where access is allowed)
- Socket Filter Agents – to apply rules that are specified by Socket Filter Lists and used in Policies.
- Socket Filter Configuration – to apply agent behavior across all Privileged Access Manager-managed devices using socket filter agents.

### **Socket Filter Lists (SFLs)**

Socket Filter Lists define groups of servers or networks that can be applied to a policy for LeapFrog Prevention.

### **Socket Filter Agents (SFAs)**

Once a Socket Filter Agent is deployed and a user connects through Privileged Access Manager to the host Device, the SFA downloads the user policy. The SFA then enforces at the Device any blacklist or whitelist filters. A blacklist contains devices and ports that user is prevented from accessing. A whitelist identifies the only devices and ports that a user can connect to. The SFA does not inspect or disturb any other connections to that Device, such as production web traffic or Privileged Access Manager users who are not restricted.

SFAs can be installed on Windows and Linux devices. The Linux root account is exempt from SFA rules and restrictions. Windows administrator accounts are subject to SFA rules and restrictions.

### **Socket Filter Configuration (SFC)**

Global values that affect the behavior of the socket filter agents are found under Socket Filter Configuration, accessible through the Policies menu.

CA Technologies advises verifying your organization policies before setting up socket filtering. Network heartbeat checks might not be allowed.

## **Amazon Web Services (AWS)**

When connection is made to AWS after populating the Config, 3rd Party, AWS settings, the **Policy, Manage Policies, AWS Policies** link interface is established for specifying AWS IAM Policy.

### **Defining AWS Policies**

AWS policy is applied for AWS privileges when accessing the AWS management interface. Initially, the editing window **Manage AWS Policies** holds two default versions, but you can edit or create an IAM policy.

Although Privileged Access Manager is designed to pass an IAM Policy to AWS, AWS does not accept an **AWS Policy** that is "too lengthy." The length limit is not a predictable value, but can be evaluated by AWS before processing to avoid errors. Therefore, Privileged Access Manager sends all submitted policies to AWS for preprocessing. If the size limit is exceeded, an error message is relayed to the Privileged Access Manager user.

**Workaround:** Some guidance on permitted length is provided in this AWS Forum thread:

<https://forums.aws.amazon.com/thread.jspa?threadID=80882>

## Specifying AWS Policies

When a Service has been configured for access to the AWS management interface, the credential specification pop-up window in the Manage Policy interface also provides for the IAM policy specification through the **AWS Policy** field at the right-hand side of the pop-up window.

## Session Recording

In addition to the access controls that are applied in advance, session recording can be assigned to policy, providing a view of User actions after the fact. As recordings, they simulate the environment of the User to provide a view into what transpired during a connection session.

### NOTE

Privileged administrators also apply control during sessions with the ability to terminate a connection session or log a User off Privileged Access Manager, while Privileged Access Manager logging is another during, or post, session tracking resource.

In the command-line applets, TELNET, SSH, and Console user keystrokes can be recorded. Graphical session recording is available with the RDP and VNC applets.

Recordings are identified in the GUI as line items. They can be searched with variable text filtering. When a recording identifies a User violation, this fact is marked inside the recording as the User views it. The line item record is also highlighted in bold red.

The session recording logs are not stored on Privileged Access Manager. The session recording files can be stored on mount points or sent to a syslog consolidation server.

Use a directory mounted to a Windows or UNIX server for session recordings to be available through the administration interface. The session recordings can be viewed in **Sessions**, **Session Recordings**.

Session Recording policy is set for a user/user group – device / device group pair in **Policies**, **Manage Policies**.

In the **Recording** pane:

- Selecting **Command Line** records user entry, and if **Bidirectional** is selected, Privileged Access Manager records both the user and device responses.
- Selecting **Graphical** records the user GUI interaction with the Windows server as a movie that can be played, stopped at any point, and replayed from any point.

## Set Up a Policy

As an administrator, configure a policy to a user-device pair to define user access to the device.

Assign a policy using one of the following methods:

- [Policy template](#)
- [Imported CSV file](#)

A policy can also be applied based on inheritance from a parent group.

A user *effective policy* spans these categories, as the union of all policy assignments. It reflects the range of device and access options available to a user as represented on the **Access** page. As an administrator, you can view a user effective policy in **Users**, **Manage Users**, **Update**, **Manage Policy**.

### NOTE

PAM also dynamically adds devices and target accounts to the **Access** page of a user if those devices and target accounts are members of a Credential Manager target group that is referenced by a Credential Manager user group to which the user belongs. For more information, see [Dynamic Addition of Devices to the Access Page Based on Credential Manager Target Group Membership](#).

The configuration of a device provides a template for choosing which access methods are allowed for a particular user. The scope of this template has previously been defined by the attributes that are assigned in the device record.

A unique *policy* can exist between every match of each of the first (users and user groups) with each of the second (devices and device groups). For example, if there are three users and three devices, after matching each user with each device, there could be up to nine different policies. For information about overlapping policies, see [Overlapping Policies on Provision Access Policies](#).

#### NOTE

For information about Credential Manager password policies, see [Set Up Password Composition and View Policies](#).

### Prerequisites

- Session recording activation requires that storage be configured in advance on the **Configuration, Logs, Session Recording** page.
- The components of the policy are defined first so that they are available to include in a policy. Define users, devices, access types, services, and filters.

### Policy Template

Create an association with a user and device using the policy template. To import policies using a CSV file, see [Import or Export Policies](#).

These procedures begin from the Policy menu. However, for some user records, you can edit a policy template from the user record by selecting **Manage Policy**.

#### Follow these steps:

1. Select **Policies, Manage Policies**.
2. Complete *one* of the following actions:
  - Create a new policy by clicking **Add**.
  - Select an existing policy record and click **Update**. If the policy record is not listed, find it by selecting the User/User Group or Device/Device group search criteria at the top of the screen.
3. If you are adding a new policy, use the fields in the **Association** section to locate the user or device that you want to associate in a policy.
4. For the **User** or **User Group** field, use the search icon to display the list of choices, and select the matching full name from the drop-down list. Select **OK**.
5. For the **Device** or **Device Group** field, use the search icon to display the list of choices, and select the matching full name from the drop-down list. Select **OK**. If you select a device group, only those access methods that are specified for the group are displayed.
6. On the **Access** tab, select one or more entries from the list and move it to the Selected Access list.
7. On the **Services** tab, select one or more services available for a provisioned device.
8. On the **SAML** tab, set SAML options as appropriate. (SAML must already be configured for anything to show here.)
9. On the **Password** tab, select the passwords the user or user group can manage. Then, select from the available device or device group defined target applications. When you select a target application, you can also select one or more provisioned target accounts for that application that the user can manage. For AWS AMI instance on UNIX and Linux devices, only EC2 keys auto-populate as options.
10. If Socket Filter Agents are installed in the environment, select the available command and socket filters to assign to the black and white lists on the **Filters** tab. The filters that are listed are those that are configured in the **Filters** option of the UI. Select the **Restrict login if agent is not running** check box.

- If the product cannot detect a running SFA on the device and an SFA-monitored connection is attempted, the login is rejected. Unmonitored connection instances are never rejected by selecting this option.
  - SFAs monitor the following connections: Access Method GUI, CLI, and mainframe applets; and RDP, VNC, and ICA Services.
  - SFAs do not monitor: standard (customized) Services and Web Portal Services.
11. If [session recording capability is configured](#), specify the types of recording to make using the options on the **Recording** tab. Set one or more of the following available options (availability depends on the selected access methods on the **Access** tab):
- **Graphical** (available for RDP and VNC access methods): Record user activity graphically.
  - **Command Line** (available for TELNET, SSH, and Console access methods): Record user activity on the target device as plain text.
    - **Bidirectional** (applicable for command-line recordings only): Record command-line output from the operating system or application and input that the user types. Bidirectional recording is required for SSH Proxy applets. All mainframe-access applets apply bidirectional session recording when you enable recording.
  - **Web Portal** (available for VNC access method only): Record user activity on the web portal graphically.
  - **On Violation** (only valid if no other recording options are set): Start recording only when a user causes a violation against a Command Filter or Socket Filter during a session. The recording continues until the user ends the connection session.

#### NOTE

To view session recordings when accessed through a Juniper SA appliance, configure a policy for allowing custom headers. See [Junos configuration that is required for viewing session recordings](#).

12. If you are integrating with PAM Server Control, select **Login Integration** on the **PAM Server Control** tab. See [Privileged Access Manager Server Control Login Integration](#) for more information.
13. If you are using Transparent Login, select a **Login** on the **Transparent Login** tab. See [Device Setup, Transparent Login](#) for more information.
14. Optionally, set the **Extended Timeout** option on the **Timeout** tab to allow users who must run lengthy jobs (such as database backups) to specify a connection idle timeout longer than the default value. When extended timeout is enabled in an associated access policy, users are prompted to optionally specify a longer idle timeout (up to the new global **Maximum Connection Idle Timeout** setting) when starting an access session. This prevents such sessions from timing out (and the job in process abruptly terminated) if left unattended for longer than the global **Connection Idle Timeout** value (which is only 10 minutes by default). The maximum timeout that a user can request is defined by the global **Maximum Connection Idle Timeout** setting).

#### NOTE

For more information about global timeout settings associated with the extended timeout functionality, see the **Login Timeout**, **Connection Idle Timeout**, and **Maximum Connection Idle Timeout** entries in the [Global Settings](#).

15. Click **OK**. You return to the Policies list. The activated device or password access is now available for execution from the Access page of the user.

### **Junos Configuration Required for Viewing Session Recordings**

To view session recordings when Privileged Access Manager is accessed through a Juniper SA appliance, configure a policy for allowing custom headers.

#### **Follow these steps:**

1. Navigate to Resource Policies, Web, Custom Headers.
2. Create a policy.
3. Specify the IP address of the web portal resource that this policy applies to, with protocol specification, for example: `https://192.0.2.123 (IPv4)`, `https://[fd6d:8d64:af0c:1:0:242:22:233] (IPv6)`
4. Select the allow custom headers action.

**More information**

- [Import or Export Policies](#)
- [Set Up an AWS Policy](#)

**Import or Export Policies**

Instead of creating policies individually through the web interface, you can populate them into a comma-separated value (CSV) configuration file. The CSV file lets you load records for a batch of Users.

**Import a CSV Policy File**

A sample file is provided for spreadsheet editing and population.

**Download Sample CSV**

1. Go to **Policies, Manage Policies**.
2. Select the **Import/Export** button on the **Policies** page.  
The Import/Export Policies window appears.
3. Click **Download Sample File**.
4. Copy and rename the sample file, and open the new copy in any spreadsheet to inspect the column headers and cell values.  
Each line below the header is a full policy association.
5. Create and populate the new file. See [CSV Fields and Syntax](#) for details about each column.
6. In the Import/Export Policies window, click **Choose File** to locate your new file.
7. Click **Import Policy** to upload the CSV file.  
The imported policies are added to the Policies list.

**CSV Fields and Syntax**

Only the first three columns require a value. The order of the columns does not matter, but the spelling of their heading does, though they are not case-sensitive. Do not include empty columns (with no header).

- **Type:** Policy or SAML Service Policy  
SAML services are part of a policy, but they are imported in their own row:
  - A policy row deselects all SAML services for the specified policy. Therefore, if the policy row is not followed by SAML Service Policy (SSP) rows, all SAML services are deselected in the final policy.
  - SSP rows configure the specified SAML service only for the specified policy.
  - SSP rows that are not preceded by a policy row only update the SAML service configuration in the specified policy. It does not clear selected SAML services for the specified policy.
  - SSP rows depend on a preceding policy row or depend on the specified policy already existing. Attempting to import an SSP row without a policy results in an import error.
- **User:** User or User Group name of the User-Device pair.
- **Device:** Device Name or Device Group Name of the User-Device pair.
- **Services:** Specify built-in services (**sftpft**, **sftpftpemb**, **sftpstft**, **sftpstftpemb**, **TSWEB**) or custom Services. Separate multiple Services using a pipe character.  
For SAML Service Policy type rows, specify the name of the SAML service that is being configured.

Account information that is associated with these services can be specified by appending ',,, ' and using the following template to describe the account:

- **ts=DeviceName tap=TargetApplicationName tac=AccountName awsPolicyName=AWSPolicyName**
- *DeviceName* specifies the device name of the target account. This field is optional if the value is the same as the Device column. Specify this field only for the case where the account belongs to a credential source.
- *TargetApplicationName* specifies the name of the target application of the target account.
- *AccountName* specifies the account name of the target account.
- *AWSPolicyName* specifies the AWS policy that should be applied when this account is used. This field should only be specified for AWS accounts used with the special aws.amazon.com device.
- **Example:**  

```
TestService,,,ts=TestCredentialSourceDevice tap=TestApplication
tac=test_user,,,tap=TestAppBelongingToTestDevice tac=user1
```
- **Applets:** Use the following template for each Access Method applet: **name=Name custom\_name=CustomName**
  - *Name* options: **VNC, Telnet, SSH, SSH2, Telnet, RDP**
  - *Name* extra options if mainframe licensing is enabled: **TN3270, TN3270SSL, TN5250, TN5250SSL**
  - *CustomName* options: (empty); or any string
  - Separate any multiple applets (Access Methods) using a pipe character.

Account information that is associated with these applets can be specified by appending ',,, ' and using the following template to describe the account:

```
ts=DeviceName tap=TargetApplicationName tac=AccountName awsPolicyName=AWSPolicyName
```

  - *DeviceName* specifies the device name of the target account. This field is optional if the value is the same as the Device column. Specify this field only for the case where the specified account belongs to a credential source.
  - *TargetApplicationName* specifies the name of the target application of the target account.
  - *AccountName* specifies the account name of the target account.
  - *AWSPolicyName* specifies the AWS policy that should be applied when this account is used. This field should only be specified for AWS accounts used with the special aws.amazon.com device.
  - **Example:**  

```
name=SSH custom_name=OpenSSH,,,ts=TestCredentialSourceDevice tap=Active Directory
tac=Administrator,,,tap=TestAppBelongingToTestDevice tac=root
```

Multiple accounts can be associated with an applet by appending ',,, ' and more account descriptions as shown in the example.- **Command Filter:** If this policy uses one or more Command Filter Lists, enter them by name; otherwise, leave blank. If used, define CFLs (import CFL CSV file) first. Ensure that filters are imported before policy.
- **Socket Filter:** If this policy uses one or more Socket Filter Lists, enter them by name; otherwise, leave blank. If used, define SFLs (import SFL CSV file) first. Ensure that filters are imported before policy.
- **Restrict login if agent is not running:** Use "t" or "f" for true or false. Use this field only for applets that rely on this switch: RDP, VNC, and ICA.
- **Graphical Recording:** Use "t" or "f" for true or false. When true, CA PAM performs graphical recording of every RDP or VNC session between this User-Device (or Group) pair.
- **Command Line Recording:** Use "t" or "f" for true or false. When true, CA PAM performs command line recording of every CLI-based session between this User-Device (or Group) pair.
- **Bidirectional Recording:** Use "t" or "f" for true or false. When true (and Command Line Recording is true), CA PAM records the User and Device input for every CLI-based session between this User-Device (or Group) pair. Otherwise, only User input is recorded.
- **Web Portal Recording:** Use "t" or "f" for true or false. When true, CA PAM performs graphical recording of every web portal session between this User(Group)-Device(Group) pair.
- **Targets:** [**ts=deviceName**] **tap=targetApplicationName tac=accountName**
- **SAML Attributes:** | (pipe) delimited mapping of the attributes that are requested by the SAML service.  

```
name=(.*)\s+nameIdFormat=(.*)\s+provisionType=(.*)\s+xAttribute=(.*)\s+value=(.*)
```

SAML attributes should be on a row after a policy to which they apply, with SSP in the Type column. See **Type** for more information about the SAML Attribute column.

### **Export a CSV List of Policies**

To export existing policies to a CSV file:

1. Go to **Policies, Manage Policies**.
2. Select the **Import/Export** button on the **Policies** page.  
The Import/Export Policies window appears.
3. Select the **Export Policy** button.  
A CSV file is saved on your computer. The CSV file has the format of the sample file

### **Set Up an AWS Policy**

When a connection is made to AWS (Amazon Web Services), the **Manage AWS Policies** link interface is established for specifying an AWS IAM Policy. This policy is applied for AWS privileges when accessing the AWS management interface. To create an AWS policy, follow these steps:

1. Ensure that AWS is set up in **Configuration, 3rd Party, AWS**.
2. Select **Policies, Manage AWS Policies**.  
Two default policies are shown in the list. Edit these policies or create another IAM policy.
3. Enter values for each field, noting the following information:
  - **Access Key:** Lists the target accounts that are specified for use with the AWS Access Credential Accounts target application. Select the account whose credentials should be used to validate the AWS policy during save and update operations.
  - **Session Timeout** - Designates the amount of time that is permitted for the policy is applied before disconnection.
  - **Policy** - Shows the IAM policy content to be applied.

AWS does not accept a policy that is too lengthy. Privileged Access Manager sends all submitted policies to AWS for preprocessing so AWS can evaluate the length and avoid a disruptive error condition. If the policy exceeds the size limit, an error message is relayed to the user.

For guidance on permitted length, see this AWS Forum thread <https://forums.aws.amazon.com/thread.jspa?threadID=80882>

### **Use AWS Policies**

When a Service has been configured for access to the AWS management interface, the credential specification pop-up window in the Manage Policy interface also provides for the IAM policy specification through the **AWS Policy** field at the right-hand side of the pop-up window.

### **Dynamic Addition of Devices and Target Accounts to the Access Page Based on Target Group Membership**

Privileged Access Manager dynamically adds devices to the **Access** page if those devices are members a of a Credential Manager target group that is referenced by a Credential Manager user group to which the logged in user belongs.

If there is no policy for one of the devices in the group, PAM just allows the user to view the passwords for any credentials of the device from the **Access** page. If there is a policy for the device (either directly or via a device group) that has an applet or service that is attached then any relevant target accounts are added to the list of possible accounts for connection.

Devices are added to the **Access** page according to the following rules:

- If a user is not a Global (Super) Administrator or Operational Administrator,  
*and*
- The user belongs to a Credential Manager user group other than standard users that has the right to view passwords for some devices,  
*then:*
- The following logic is applied to each device and target account:
  - a. If there is an applet or service to which the target account can reasonably be assigned for autoconnect, that target account is assigned.
  - b. If not, the target account is available for viewing.

The mapping between target applications (each target account belongs to exactly one application) and applets/services is as follows:

- If a device has an SSH or Telnet applet, or an SSH or Telnet proxy service, any target account whose target application is either Generic or Unix will be assigned to it.
- If a device has an RDP applet, and RDP application, or an RDP Proxy service any target account whose target application is either Generic, Windows Proxy, or Active Directory will be assigned to it.
- If the device has a TN5250/TN5250 SSL applet a target application of either generic or AS400 will be assigned to it.
- Otherwise, if either the target account's target application is not one of the aforementioned types or if the device does not have the requisite applet or servlet assigned, the target account is available for viewing.

## Policy inspection

### View Policy

To view (and edit) explicitly assigned policy for a (User / User Group) and (Device / Device Group) pair, enter the policy editing mode.

### View Effective Policy

Without entering the policy editing mode, you can view a list of the current User or User Group effective policy across all individual Devices, directly from that User or User Group record. By "effective policy" is meant the combination of the policy that is:

- Explicitly set with each Device for that User or User Group
- Inherited from the policy of User Groups of which the current User is a member
- Inherited from the policy of Device Groups which are associated with the current User or User Group

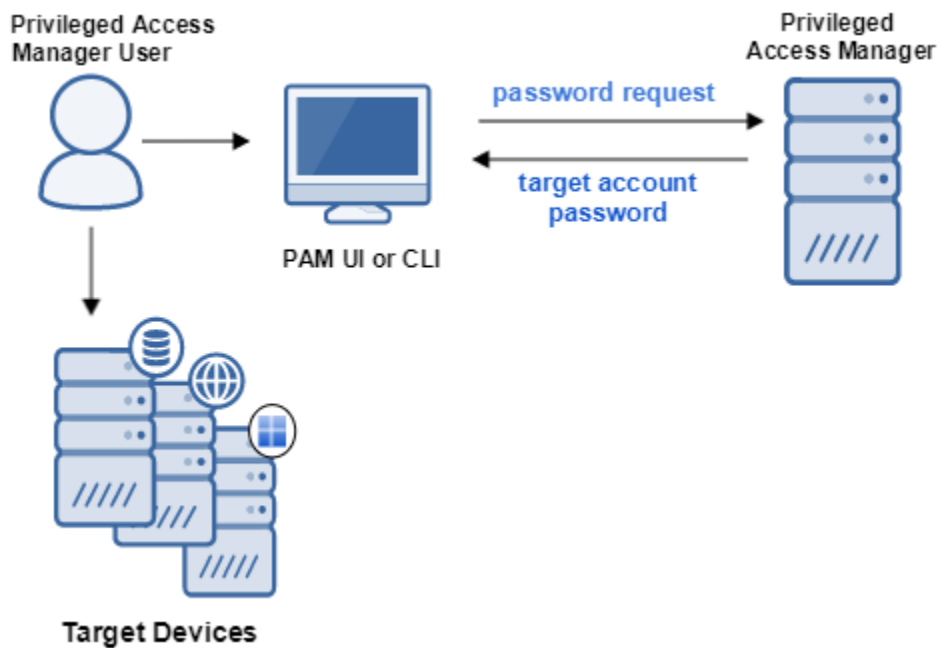

### **Procedure**

1. Open the **Users, Manage Users** page.
2. Move your mouse over a User record line item, and open it for editing by clicking it.
3. At the right-hand side of either the top or bottom of the User record, click the button **View Policy** .  
A shadow window appears with a list showing one Device record per line. Each Device displays its current access options (Access Methods, OOB, Services, SSLVPN, RDP Applications). Each Device record can be clicked to reveal, in a left pane, the actual policy pair generating the inheritance. By clicking **Expand All** or **Collapse All**, all records can be opened or closed, respectively.

## Implementing Credential Manager

Implement Credential Manager to protect privileged account credentials against a security breach. Privileged accounts have access to the most critical systems, services, and sensitive data so these types of accounts require secure management.

**Figure 22: Protecting Privileged Account Credentials**

Credential Manager allows you to:

- Vault existing credentials
- Automatically roll over parts of those credentials
- Specify rules for generating new credentials
- Specify rules for viewing credentials, granting permissions to view credentials, and what action occurs after the password is viewed.

To protect a privileged account, you must configure several Credential Manager objects. The following graphic shows you, in order, the basic configuration tasks:

**Figure 23: Credential Manager Configuration Task Flow**

To use Credential Manager, become familiar with the following terms:

- **Target Server/Device**  
A device or *target server* is an application server that hosts one or more target applications that require access credentials. Device names must be unique.
- **Target Application**

The target application is a container for all managed accounts of a single application, such as all privileged users of an Oracle database. A target application can contain one or more target accounts. The target application also defines the connector, the mechanism for accessing target accounts. The connector allows for multiple applications or entities within the same server to contain the same account user name. For example, if a given server hosts two databases, each database is a unique target application. Each database could have a uniquely identified user account `dbasys`. Target application names must be unique within a given device.

- **Application Type/Target Connector**

The application type identifies the target connector. The target connector is the mechanism that lets Credential Manager manage and change credentials at a target. When you configure a target application, you select an application type—not a target connector—to identify the single application at the target server.

**NOTE**

The UI uses the term **application type**, not target connector. When you select an application type during target application setup, you are configuring the related target connector.

A predefined set of target applications are included with the appliance. For example, to connect to an Oracle database, configure the Oracle application type/target connector to update and verify passwords for Oracle target accounts.

- **Target Accounts**

The target account identifies an account at the remote server. The account specifies the set of credentials (for example, user name and password or user certificate). When you configure a target account, you identify a target application for that account. Target account user names must be unique for a given target application.

- **Target Aliases (for A2A deployments only)**

Aliases uniquely identify a specific target account. When an application requests credentials for another application, the requesting applications use the target alias. Target aliases eliminate the need to hard-code the name of the privileged account that has access to the target application.

## Default Ports for Credential Manager

The following tables list the ports that enable Credential Manager and associated target connectors use to communicate with each other. Ensure that networks and firewalls permit data transfer between these ports.

### Default Port Assignments for Credential Manager Components

You can configure the port number in the following file: `installation_directory/cspmclient/config/cspm_client_config.xml`.

**NOTE**

In the **Source** column, the term **Appliance** represents the Privileged Access Manager virtual or hardware appliance.

Default Port	Source	Destination	Name of Config Variable	Description
5900, 3306, 7900, 7901, 443	Appliance	Appliance	N/A	Communication between PAM appliances on the network.
27077	Appliance	Windows Proxy	Windows Proxy configuration file: <code>daemonserver_port</code>	PAM appliance to Windows Proxy communications
28088	A2A requesting application	A2A client daemon	A2A Client configuration file: <code>daemonserver1_port</code>	Used for A2A client stub requests. Daemon validates request is local.
28888	Appliance	A2A Client	A2A Client configuration file: <code>daemonserver2_port</code>	PAM Appliance to A2A Client host
443	A2A Client	Appliance	A2A Client configuration file: <code>cspmserver_port</code>	A2A Client to PAM Appliance

8550	Appliance	Server with Socket Filter Agent (SFA)	Socket Filter configuration file: port#	Leapfrog prevention and containment.
443	Socket Filter Agent	Appliance	N/A	Reporting policy violations

The appliance uses TCP port 5900. Network security scans typically assume that TCP port 5900 is used by a VNC server. For that reason, security scans might erroneously indicate that the appliance has a security vulnerability.

### Default Ports for Target Connectors

The following tables list the default ports that the out-of-the-box target connectors use to communicate with Credential Manager. Target connectors represent supported application types.

#### NOTE

In the **Source** column, the term **Appliance** represents the Privileged Access Manager virtual or hardware appliance.

If a target connector is not listed here, then firewall ports do not have to be open.

#### NOTE

For AWS or Azure, ensure that these ports are also open in the AWS or Azure network settings, and the OS firewall of the instance.

### Active Directory

Default Port	Source	Destination	Configurable	Applicability
636	Appliance	AD Domain Controllers	In the target application	
27077	Appliance	Windows Proxy	Windows Proxy configuration file: daemonserver1_port	For a target account configured to discover services or to discover scheduled tasks

### AS/400

Default Port	Source	Destination	Configurable	Applicability
449	Appliance	Target server	No	
8475	Appliance	Target server	No	
8476	Appliance	Target server	No	
9475	Appliance	Target server	No	Port must be open to use SSL

The AS/400 target connector uses the IBM Toolbox for Java and JTOpen. For details, see [https://www.ibm.com/support/pages/node/1119561?mhsrc=ibmsearch\\_a&mhq=ibm%20toolbox%20for%20java](https://www.ibm.com/support/pages/node/1119561?mhsrc=ibmsearch_a&mhq=ibm%20toolbox%20for%20java).

- Port 8475 provides Remote Command functionality (`as-rmtcmd`).
- Ports 449 and 8476 are for non-SSL services, such as AS/400 server mapping (`as-svrmap`) and AS/400 user ID and password validation (`as-signon`).

**AWS Access Credentials Accounts**

Default Port	Source	Destination	Configurable	Applicability
443	Appliance	iam.amazonaws.com	No	
443	Appliance	sts.amazonaws.com	No	AWS Policy

**Azure Active Directory**

Default Port	Source	Destination	Configurable	Applicability
443	Appliance	portal.azure.com	No	

**Cisco**

Default Port	Source	Destination	Configurable	Applicability
22	Appliance	Target server	In target application	If ssh is used
23	Appliance	Target server	In target application	If Telnet is used

**Juniper JUNOS**

Default Port	Source	Destination	Configurable	Applicability
22	Appliance	Target server	In target application	

**LDAP**

Default Port	Source	Destination	Configurable	Applicability
389	Appliance	LDAP server	In target application	

**MSSQL**

Default Port	Source	Destination	Configurable	Applicability
1433	Appliance	Microsoft SQL Server database host	In target application	

**MySQL**

Default Port	Source	Destination	Configurable	Applicability
3306	Appliance	MySQL server database host	In target application	

**Oracle**

Default Port	Source	Destination	Configurable	Applicability
1521	Appliance	Oracle server database host	In target application	

**SPML**

Default Port	Source	Destination	Configurable	Applicability
8080	Appliance	Target server	In target application	

**UNIX**

Default Port	Source	Destination	Configurable	Applicability
22	Appliance	Target server	In target application	If ssh is used
23	Appliance	Target server	In target application	If Telnet is used

**VMware ESX/ESXi**

Default Port	Source	Destination	Configurable	Applicability
443	Appliance	Target server	In target application	

**VMware NSX Controller**

Default Port	Source	Destination	Configurable	Applicability
22	Appliance	Target server	In target application	

**VMware NSX Manager**

Default Port	Source	Destination	Configurable	Applicability
22	Appliance	Target server	In target application	

**WebLogic 10**

Default Port	Source	Destination	Configurable	Applicability
7001	Appliance	Target server	In target application	

**Windows Proxy**

Default Port	Source	Destination	Configurable	Applicability
389, 636, 445	Windows Proxy Server	AD Domain Controllers	No	Domain accounts
389 and 636	Appliance	AD Domain Controllers	No	Domain accounts
27077	Appliance	Windows Proxy	Windows Proxy configuration file: daemonserver1_port	Sybase database communications
443	Windows Proxy Server	PAM appliance	No	Proxy requests
445	Windows Proxy Server	Target Servers	No	SMB2 communication

**Windows Remote**

Default Port	Source	Destination	Configurable	Applicability
445	Appliance	Windows target device	No	SMB2 communication

135	Appliance	Windows target device	No	WMI communication
49152 through 65535 1024 through 4999	Appliance	Windows target device	No	WMI communication

## Credential Manager Operation Settings

Before you configure credential management features, configure Credential Manager operational preferences.

### Specify General Operation Settings

The General Settings are preferences for Credential Manager operations.

To access these settings:

1. In the UI, navigate to **Settings, Credential Manager, General Settings**.
2. Configure the following preferences:
  - **Disable CLI Host Name Check**  
If a server is executing Credential Manager commands from the CLI, the server must provide a certificate to execute CLI commands. Select this option to override the verification of the appliance host name in the certificate.
  - **Allow Self Approval of Password View Request**  
Allows users who are authorized approvers to approve their own password view requests.
  - **Maximum Number of Report Entries**  
Sets the number of Credential Manager entries in a report. The default is 5000. We recommend that you limit entries to less than 5000 records. The maximum size ultimately depends on the type of report, its output format, and the available memory in Credential Manager. If an HTML report runs out of memory, try generating a CSV or a PDF file instead. Alternatively, use the `setReportRowLimit` CLI command.
  - **Password View Request Delete Interval Days**  
This checkbox specifies the number of days after which a password view request expires.  
**Example:** If you set this field to 12, the password view requests are deleted automatically from the My Approvals list when they become 12 days old. For information about the My Approval list, see [Credentials, Workflow, My Approvals](#).
  - **Automatically Update Expired Passwords**  
This checkbox enables automatic updates to the passwords for synchronized accounts when the password age exceeds the specification in its Password Composition Policy.
  - **Enable External CLI**  
This option enables the Credential Manager CLI. The CLI provides administrative access to password management functions, such as adding and modifying target and request data. The CLI also provides access to a limited set of maintenance operations. The Remote CLI is supported on UNIX, Linux, and Windows platforms. For more information, see [Use the Credential Manager CLI](#).
  - **Password View Request Banner**  
Optional. Enter the text for a banner that is displayed on Password View Requests. This banner can contain information about what users must enter in the Reason Description and Reference Code fields when viewing a password for an account. You can also set this banner on the Create a Basic Password View Policy page. If set as part of a Password View Policy, it takes priority over this General Setting.

### Archive and Purge Metrics and Audit Logs

Credential Manager produces many log messages in the form of metrics and audit logs. These logs are saved on your appliance and they can fill up your hard drive, which can be disastrous. These logs are not purged by the Automatic Log Purge feature, which only removes session logs. Use Auto-Archive to archive and purge these logs automatically. You configure archive settings for Metrics and Audit Logs separately. For more information about Metrics and Audit Logs, see [Credential Management Log Formats](#).

### **Prerequisite**

Archived logs are saved to a session recording mount, which must be set up first. See [Set Up Session Recording](#) for instructions.

#### NOTE

If you are using a Syslog server to save these messages, you can opt to purge and not archive them.

Follow these steps:

1. Select **Settings, Credential Manager** and select the **Auto-Archive** tab.  
Metrics and Audit Log archive settings are configured separately. Each section has the same fields.
2. Select an archive **Option**:
  - PURGE only. Do not archive.
  - Archive to PRIMARY Mount, then purge.
  - Archive to FAILOVER Mount, then purge.

#### NOTE

The Primary and Failover Mounts behave independent of their session recording purposes. Either mount can be used for either or both log types. The "Failover Mount" does not act as a failover for the Primary when archiving.

3. Select the log **Age (Days)** after which the purge or archive is performed. For example, to keep the most recent week of logs locally, select 7. The archive happens at midnight GMT and is not configurable.
4. To store the logs in a specific folder or folder path, enter it in the **Folder** field. If the folder does not exist, it is created by the process. The process appends a `server-id` folder and a `metrics-id` or `auditlogs-id` folder beneath your specified folder. The `id` is the Hardware ID found on the **Configuration, System Info, Hardware Identifiers** page. The full path appears as the **Storage** field value once the archive settings are saved successfully.
5. Select **Save**.

Once saved, the **Storage, Mount Status, and Mount Availability** states appear on the page.

#### Archive Process

Once an archive process has begun, status and statistics appear in the **Archive Process** area. Each cluster member has a row in Metrics and Audit Log, with the most recent information for that process.

The **Site** column lists the configured cluster site name, if any. The **IP Address** column is for the individual appliance or cluster member.

The options for **Status** are: Purge OK, Archive OK, Error, No Storage. If the status is "No Storage," the storage mount is not available, and the process deletes only non-essential logs. The **Status Date** denotes when the status shown was recorded.

The **Action Date** column is when the purge or archive was taken. This column can be empty if there was nothing to purge or archive during the most recent process.

Select the **Reset Process Statistics** button to clear the data.

Error messages and warnings are posted on the top of the [Dashboard](#) on the **Overview Tab**. To get rid of warnings on the **Dashboard Overview Tab**, select the **Reset Dashboard Warnings** button. This button is only active when there are warnings on the Dashboard.

#### Configure Settings for Request Servers

A2A credential management permits customer applications and scripts to obtain credentials for target applications. To use this feature, first configure settings for A2A request servers (which host A2A Clients). For more information about A2A Request Servers and A2A Clients, see [Configure A2A Credential Management](#).

Follow these steps:

1. Select **Settings, Credential Manager** and select the **Request Server Settings** tab.

**NOTE**

Some of the settings on the **Request Server Settings** tab apply to Credential Manager proxies.

2. Disregard the **A2A Global Settings**, which are currently not in use:
  - Check Execution User
  - Check Execution Path
  - Check File Path
  - Perform Script Integrity Validation
3. Review the **Request Server Global Settings**:
  - **FIPS 140-2 Mode**: Enables FIPS 140-2 mode for Credential Manager proxies.
  - **Preserve Client/Proxy Host Names**: Set this option to preserve the host name that PAM obtains (by performing a reverse DNS lookup) for an A2A client or proxy when it initially registers with PAM. If not set (the default), PAM repeats the reverse lookup and updates the initial hostname whenever a client or proxy does one of the following:
    - Restarts, triggering reregistration.
    - Requests credentials that result in a call to the PAM server
  - **Enable Hardware Fingerprinting**: Set this option to add a **Get Fingerprint** button to the **View A2A Client** dialog. Selecting the **Get Fingerprint** button obtains the latest **hardware fingerprint** from the **request server**. PAM uses **hardware fingerprints** to [uniquely identify a A2A Clients](#).
4. Select **Save**.

**Request Server Subnets**

The **Request Server Subnets** tab displays a list of auto-registered request server settings by subnet.

**To add a Request Server Subnet, follow these steps:**

1. Select **Add**.
2. In the **Add Request Server Subnet** dialog that opens, complete the fields:
3. Select **OK** to save your subnet.

**Configure Email Templates**

When a user views a password, an administrator or other user can receive an email notification. Email notifications are available only for password view policies. They are sent only for successful initial password view requests. Configure the email templates by selecting **Settings, Credential Management**, and then **Email Templates**. Configure the email server by selecting **Configuration**, and then **Email Settings**. After you specify these settings, then enable the notification in the password view policy. Notifications are configured on a per-policy basis.

To set up the email preferences, see [Email Preferences for Password View Policies](#).

To enable notifications, see [Enable Email Notification](#).

**Monitor Default Credential Manager Activities**

To help monitor Credential Manager activity, such as passwords not verified, create an activities list from a set of predefined metrics. You can add, remove, and reposition list items. You can set a threshold for the number of occurrences for a given activity to display a warning indicator in the list.

**Follow these steps:**

1. Select **Settings, Credential Manager, Default Activities List**.
2. To add an item to the list:
  - a. Select the **+** (plus) symbol. The Item Name window appears.
  - b. Select one or more items from the activity list.

- c. Select **OK**.

To reposition a list item, select the item and use the Up or the Down arrow.

To remove an entry from the Activities list, select the **X** icon.

3. To set a threshold limit that displays a warning icon in the list, enter an integer in the Threshold column. For example, enter a five for the Passwords Not Verified setting. When the number of unverified passwords reaches five, a warning icon appears in the Activities List page.
4. Select **Save**.

To display the activity report, select **Credentials, Reports, Activities**.

## Configure Email Preferences for Password View Policies

Email notifications are available for password view policies. When a user views an account password, an email is sent to other users who are configured to receive notifications. Emails are sent only for successful initial password view requests. For example, if the password is viewed for an already checked out account, no email is sent. To receive email notifications, configure the email server and default templates. If you enable dual authorization, authorization requests, approvals, and password views all trigger email notifications. The email contains text and links.

### To configure email notifications:

After the setup of email notifications is complete, you enable notifications in the password view policy, on a per-policy basis.

### Set Up the Email Server

To enable email notifications, first configure the connection between Credential Manager and the email server.

#### NOTE

The email server, application, and account must already be provisioned as targets in the database before the email template can be configured through the UI.

### Configure the Email Server from the UI

#### Follow these steps:

1. Select **Configuration, Email Settings**.
2. Optionally, select **Enable SMTP Server Authentication**.
3. If you selected the **Enable SMTP Server Authentication** option, the **Account Name** field appears. Use the magnifying glass to select your email account or type the email target account name.
4. If you selected **Enable SMTP Server Authentication** option, the **Host Name** field is automatically populated with the name of the target server. If you did not select the **Enable SMTP Server Authentication** option, or if the email server is different from the target server, edit the field as required.
5. Enter the **Port** number for the email server.
6. Optionally, select **Enable SMTP Server Debug**. This option helps diagnose email problems if you can also reproduce the issue, and then review the Tomcat logs under **Configuration > Diagnostic** for related information and errors.
7. In the **From Email Address** field, enter the email address to use.
8. Select **Enable TLS** to establish a secure connection using TLS.
9. Select the **Test** button to test to see if a sample email is sent to the user whose Email Settings you are configuring. A message appears indicating success or failure.

#### TIP

If the test was successful, the test email appears in the user's email in-box. If a message indicates failure, check the logs: Select **Configuration, Diagnostics, Diagnostic Logs**, the **Download** tab, and then the **Recent Log Entries** button to display the most-recent logs.

**NOTE**

This configuration is not applicable to Monitor (Legacy). See [Set Up Email for Monitoring \(Legacy\)](#) for more information.

**Configure the Email Server from the CLI**

To configure the email server from the CLI, use the `setSystemProperty` command to specify values for email server properties.

Use the following CLI command syntax and specify each email service property. The following example shows how to configure the `emailServerHost` property.

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty
propertyName=emailServerHost propertyValues=mail.yourdomain.com encryptValue=false
```

You can specify one or more of the properties in the following table, as required. Each property is separated by a space.

Property Name	Value	Required	Notes	encryptValue
<code>emailServerHost</code>	mail.yourdomain.com	Yes	Host name of the mail server	False
<code>emailServerPort</code>	Port number	No	Port number the SMTP service is listening on. Default is 25.	False
<code>emailTransportType</code>	smtp or smtps	No	Email transport type. Default: <code>smtp</code> . Selecting the <code>smtps</code> type allows you to use the TLS email transport type.	False
<code>emailTargetAccount</code>	Target account ID	No	Target account ID of the email setting	False
<code>oneclickServerHost</code>	mail.yourdomain.com	Yes	Credential Manager Primary Host name	False
<code>emailFromAddress</code>	view_requests@yourdomain.com	Yes	The "From" address for emails	False

**Modify Email Templates**

Credential Manager supplies default templates for the following types of email:

- [Request email](#)
- [Request status email](#)
- [Retrospective approval request email](#)
- [Password view email](#)
- [Expired password view request email](#)
- [One-click approval email](#)
- [Report results email](#)

These tasks can be completed from the UI or from the CLI, using the command `setSystemProperty`.

To customize the content of email notifications, modify the default email templates. Each template is explained in this topic. You can modify the email settings in the UI or with the CLI command `setSystemProperty`.

All email templates contain tokens. When Credential Manager generates an email, it uses the tokens in the email templates to look up request-specific items. Credential Manager populates the tokens at runtime. The tokens are case-sensitive and use the following syntax: @ClassName.methodName@

Each template is described in the following subsections. The values of *ClassName* and *methodName* vary depending on the type of email.

### **Request Email Configuration**

A request email is sent from a requestor to list of approvers.

#### **Configure the Request Email Template from the UI**

**Follow these steps:**

1. Select **Settings, Credential Manager**, and then the **Email Templates** tab.
2. Modify the template text for the Request Subject and Request Body as desired.  
For the request email, @ClassName.methodName@ tokens can have the value pairs that are shown in the following table.

ClassName Values	methodName Values
TargetAccount	getUserName
TargetApplication	getName getType getExtensionType
TargetServer	getDeviceName getHostName
PasswordViewPolicy	getName
PasswordViewRequest	getReason getReasonDescription getSsoType getReferenceCode getConnectionTimeout
User (the user name generating the password view request)	getUserID getFirstName getLastName getEmail

#### **Configure the Request Email Template from the CLI**

**Follow these steps:**

1. Specify the first property for the request email template:  

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty
propertyName=emailRequestBody propertyValues="Do not reply to this email.
A password view request has been submitted by user @User.getUserID@ to view the
password for account @TargetAccount.getUserName@ of application
@TargetApplication.getName@ on server @TargetServer.getHostName@.
The password view request reason is @PasswordViewRequest.getReason@
(@PasswordViewRequest.getReasonDescription@). Please login to the CPA
system and manage this request."
```

2. Repeat the previous step for each property as required. Refer to the following table.

Property Name	Default Value	Required
emailRequestBody	Do not reply to this email. A password view request has been submitted by user @User.getUserID@ to view the password for account @TargetAccount.getUserName@ of application @TargetApplication.getName@ on server @TargetServer.getHostName@. The password view request reason is @PasswordViewRequest.getReason@ (@PasswordViewRequest.getReasonDescription@). Please log in to the CPA system and manage this request.	No
emailRequestSubject	Password View Request for target account @TargetAccount.getUserName@	No

### **Request Status Email Configuration**

The request status email is sent from an approver to a requestor. This notification informs the requestor whether the request was approved or denied.

### **Configure the Request Status Email Template from the UI**

Follow these steps:

1. Select **Settings, Credential Manager**, and then the **Email Templates** tab.
2. Modify the template text for the **Request Status Update Subject** and **Request Status Update Body** as desired. For the request status email, @ClassName.methodName@ tokens can have the value pairs that are shown in the following table.

ClassName Values	methodName Values
TargetAccount	getUserName
TargetApplication	getName getType getExtensionType
TargetServer	getDeviceName getHostName
PasswordViewPolicy	getName
PasswordViewRequest	getStatusString getSsoType getApprovalReason getApprovalReasonDescription getReferenceCode getConnectionTimeout
User (the approver of the password view request)	getUserID getFirstName getLastName getEmail

### **Configure the Request Status Email Template from the CLI**

Follow these steps:

1. Specify the first property for the request status email template:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty
```

```
propertyName=emailRequestStatusBody propertyValues="Do not reply to this email.
The status of your request to view password for the account @TargetAccount.getUserName@
of application @TargetApplication.getName@ in server @TargetServer.getHostName@, is:
@PasswordViewRequest.getStatusString@."
```

2. Repeat the previous step for each property as required. Refer to the following table.

Property Name	Default Value	Required
emailRequestStatusBody	Do not reply to this email. The status of your request to view password for the account @TargetAccount.getUserName@ of application @TargetApplication.getName@ in server @TargetServer.getHostName@, is: @PasswordViewRequest.getStatusString@.	No
emailRequestStatusSubject	Password View Request Status for account @TargetAccount.getUserName@	No

### ***Retrospective Approval Email Configuration***

Retrospective approval email is sent to an approver. This notification informs the approver that a user has requested immediate emergency "break glass" access to account credentials.

### **Configure the Retrospective Approval Request Email Template from the UI**

Follow these steps:

1. Select **Settings, Credential Manager**, and then the **Email Templates** tab.
2. Modify the template text for the **Retrospective Approval Request Subject** and **Retrospective Approval Request Body** as desired.  
For the retrospective approval email, @ClassName.methodName@ tokens can have the value pairs that are shown in the following table.

ClassName Values	methodName Values
TargetAccount	getUserName
TargetApplication	getName getType getExtensionType
TargetServer	getDeviceName getHostName
PasswordViewPolicy	getName
PasswordViewRequest	getStatusString getSsoType getApprovalReason getApprovalReasonDescription getReferenceCode getConnectionTimeout
User (the approver of the password view request)	getUserID getFirstName getLastName getEmail

### **Configure the Retrospective Approval Request Email Template from the CLI**

**Follow these steps:**

1. Specify the first property for the retrospective approval email template. For example:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty
propertyName=emailRetrospectiveApprovalRequestSubject propertyValues="Password View
Request for target account @TargetAccount.getUserName@"
```

2. Repeat the previous step for each property as required. Refer to the following table.

Property Name	Default Value	Required
emailRetrospectiveApprovalRequestBody	@TargetApplication.getName@ in server @TargetServer.getHostName@ with device name @TargetServer.getDeviceName@ has been submitted by user @User.getUserID@. This is a retrospective approval request. Please login to Privileged Access Manager system and manage this request.	No
emailRetrospectiveApprovalRequestSubject	Password View Request for target account @TargetAccount.getUserName@	No

Retrospective approval email is sent to an approver. This notification informs the approver that a user has requested immediate emergency "break glass" access to account credentials when the **Enable One Click Approval** option is enabled in the password view policy.

**Password View Email Configuration**

A password view email is sent from a user to a set of users when a password is viewed. This section describes how to configure the password view email through the template.

**Configure the Password View Email Template from the UI****Follow these steps:**

1. Select **Settings, Credential Manager**, and the **Email Templates** tab.
2. Modify the template text for the Password View Subject and Password View Body as desired.  
For the password view email, @ClassName.methodName@ tokens can have the value pairs that are shown in the following table.

ClassName Values	methodName Values
TargetAccount	getUserName
TargetApplication	getName getType getExtensionType
TargetServer	getHostName getDeviceName
PasswordViewPolicy	getName
PasswordViewRequest	getSsoType getReason getReasonDescription getReferenceCode getConnectionTimeout

User (the user name viewing the password)	getUserID getFirstName getLastName getEmail
--	--

### **Configure the Password View Email Template from the CLI**

#### **Follow these steps:**

1. Specify the first property for the password view email template:

```
capam_command adminUserID=admin capam=mycompany.com
cmdName=setSystemProperty propertyName=emailPasswordViewBody
propertyValues="Do not reply to this email. The Password for the account
@TargetAccount.getUserName@ of application @TargetApplication.getName@ on
server @TargetServer.getHostName@ has been accessed by user @User.getUserID@."
```

2. Repeat the previous step for each property as required. Refer to the following table.

Property Name	Default Value	Required
emailPasswordViewBody	Do not reply to this email. The Password for the account @TargetAccount.getUserName@ of application @TargetApplication.getName@ on server @TargetServer.getHostName@ has been accessed by user @User.getUserID@.	No
emailPasswordViewSubject	Password of account @TargetAccount.getUserName@ has been accessed by @User.getUserID@	No

### ***Expired Password View Request Email Configuration***

An approver who is expiring the request sends the expired password view request email to a requestor. The email is also sent to any other approvers in dual authorization list. The email is auto-generated when a request in Pending/Approved status expires.

### **Configure the Expired Password View Template from the UI**

#### **Follow these steps:**

1. Select **Settings, Credential Manager**, and then the **Email Templates** tab.
2. Modify the template text for the Expired Password View Request Subject and Expired Password View Request Body as desired.  
For the expired password view request email, @ClassName.methodName@ tokens can have the value pairs that are shown in the following table.

ClassName Values	methodName Values
TargetAccount	getUserName
TargetApplication	getName getType getExtensionType
TargetServer	getHostName getDeviceName
PasswordViewPolicy	getName

PasswordViewRequest	getSsoType getReferenceCode
User (the user name generating the password view request)	getUserID getFirstName getLastName getEmail

### **Configure the Expired Password View Template from the CLI**

#### **Follow these steps:**

1. Specify the first property for the expired password view request email template:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty
propertyName=emailExpiredPasswordViewRequestBody
propertyValues=" Do not reply to this email. The Password View Request
for the account @TargetAccount.getUserName@ of application
@TargetApplication.getName@ on server @TargetServer.getHostName@
requested by user @User.getUserID@ has expired."
```

2. Repeat the previous step for each property as required. Refer to the following table.

ClassName Values	methodName Values
TargetAccount	getUserName
TargetApplication	getName getType getExtensionType
TargetServer	getHostName
PasswordViewPolicy	getName
PasswordViewRequest	getReason getReasonDescription getStartDate getEndDate getReferenceCode getConnectionTimeout
User (user who is generating the password view request)	getUserID getFirstName getLastName getEmail

### **One Click Approval Email Setup**

A one-click approval email is sent from a requestor to a list of approvers.

#### ***Configure the One Click Approval Email Template from the UI***

#### **Follow these steps:**

1. Select **Settings, Credential Manager**, and then the **Email Templates** tab.
2. In the **One Click Approval Server Host Name** field, enter the Credential Manager server host name that you use in the approve or deny URL. The URLs are sent in the email whenever the request for viewing the account password with enabled one-click approval, is generated.

**NOTE**

By default, the primary site host name is used. Admin is authorized to edit this name.

3. Modify the template text for the One Click Approval Subject and One Click Approval Body as desired.  
For the one-click approval email, @ClassName.methodName@ tokens can have the value pairs that are shown in the following table.

ClassName Values	methodName Values
TargetAccount	getUserName
TargetApplication	getName getType getExtensionType
TargetServer	getHostName getDeviceName
PasswordViewPolicy	getName
PasswordViewRequest	getReason getReasonDescription getStartDate getEndDate getSsoType getReferenceCode getConnectionTimeout
User (user who is generating the password view request)	getUserID getFirstName getLastName getEmail

The one-click approval email template also contains following specialized tokens:

- @PasswordViewRequestIdentifier.getApprovalUrl@ - Use this token to show the URL to approve the password view request.
- @PasswordViewRequestIdentifier.getDenialUrl@ - Use this token to show the URL to deny the password view request.

### ***Configure the One Click Approval Email Template from the CLI***

#### **Follow these steps:**

1. Specify the first property for the one click approval email template:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty
propertyName=emailOne Click ApprovalBody propertyValues=" Do not reply to this email.
<br><br>A password view request has been submitted with the following details:
<br>Requestor: @User.getUserID@<br> Requested Account: @TargetAccount.getUserName@
<br> Requested Account Target Application Name: @TargetApplication.getName@
<br> Requested Account Target Server: @TargetServer.getHostName@
<br> Request Reason: @PasswordViewRequest.getReason@
(@PasswordViewRequest.getReasonDescription@)
<br>Start Date: @PasswordViewRequest.getStartDate@
<br>End Date: @PasswordViewRequest.getEndDate@<br>
<br><a href='@ApprovalURL@'>Click here to Approve this Request</a><br>
<br><a href='@DenialURL@'>Click here to Deny this Request</a>."
```

2. Repeat the previous step for each property as required. Refer to the following table.

Property Name	Default Value	Required
emailOneClickApprovalBody	Do not reply to this email.   A password view request has been submitted with the following details:  Requestor: @User.getUserID@   Requested Account: @TargetAccount.getUserName@   Requested Account Target Application Name: @TargetApplication.getName@   Requested Account Target Server: @TargetServer.getHost@   Request Reason: @PasswordViewRequest.getReason@ (@PasswordViewRequest.getReasonDescription@) Start Date: @PasswordViewRequest.getStartDate@  End Date: @PasswordViewRequest.getEndDate@   <a href='@ApprovalURL@ '>Click here to Approve this Request</a>  <a href='@DenialURL@ '>Click here to Deny this Request</a>	No
emailOneClickApprovalSubject	Password View Request for target account @TargetAccount.getUserName@	No

### **Report Results Email Configuration**

The report results email is sent from a requestor to a list of approvers.

### **Configure the External Retrospective Approval Request Email Template from the UI**

Follow these steps:

1. Select **Settings, Credential Manager**, and then the **Email Settings** tab.
2. Modify the template text for the Report Results Subject and Report Results Body as desired.

The report results email template contains following specialized tokens:

- @reportName@ - Use this token to show the report name.
- @reportStartDate@ - Use this token to show the "From" date of the report results.
- @reportEndDate@ - Use this token to show the "To" date of the report results.

### **Configure the Report Results Email Template from the CLI**

Follow these steps:

1. Specify the first property for the report results email template:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty
propertyName=emailReportResultsBody propertyValues=" Do not reply to this email.
The @reportName@ report has been run. The attached results encompass the period from
@reportStartDate@ to @reportEndDate@."
```

2. Repeat the previous step for each property as required. Refer to the following table.

Property Name	Default Value	Required
emailReportResultsBody	Do not reply to this email. The @reportName@ report has been run. The attached results encompass the period from @reportStartDate@ to @reportEndDate@ .	No
emailReportResultsSubject	Report results for @reportName@	No

## Secrets Expiration Notification Email Configuration

The secrets expiration notification email is sent to all users with the SecretOwners or VaultOwners permissions when a secret is about to expire. Users with a custom role receive the email if they have the updateSecret privilege. The email is sent daily starting at the number of days before expiration that you set in the **Secret Expiration Threshold (Days)** field.

### Configure the Secrets Expiration Notification Email Template from the UI

Follow these steps:

1. Select **Settings, Credential Manager**, and then the **Email Settings** tab.
2. Click the **Notify of Upcoming Secret Expirations** option to enable the notification email. No emails are sent unless this option is enabled.
3. Modify the template text for the secrets expiration notification email as desired.

The secrets expiration notification email template contains following specialized tokens:

- @reportName@ - Use this token to show the report name.
- @Secret.getVaultName@ - Use this token to show the name of the vault in which the expiring secret is stored.
- @Secret.getName@ - Use this token to show the name of the expiring secret.
- @Secret.getAutoExpireDate@ - Use this token to show the date that the secret expires.

### Configure the Secrets Expiration Notification Email Template from the CLI

Follow these steps:

1. Specify the emailSecretExpirationBody property for the Secrets Expiration Notification email template:

```
capam_command adminUserID=super capam=10.17.44.202 cmdName=setSystemProperty
propertyName=emailSecretExpirationBody "propertyValues=The following secrets are about to expire
or be deleted: <table width=\"800\" cellspacing=\"1\" bgcolor=\"#000000\"><tr bgcolor=\"#ffffff
\"><th>Vault Name</th><th>Secret Name</th><th>Expiration Date</th></tr>@<tr bgcolor=\"#ffffff\"><td
align=\"center\">@Secret.getVaultName@</td><td align=\"center\">@Secret.getName@</td><td align=\"center
\">@Secret.getAutoExpireDate@</td></tr>@</table> Please log in to PAM for more information about these
secrets."
```

Property Name	Default Value	Required
emailSecretExpirationBody	The following secrets are about to expire or be deleted: <table width="800" cellspacing="1" bgcolor="#000000"><tr bgcolor="#ffffff"><th>Vault Name</th><th>Secret Name</th><th>Expiration Date</th></tr>@<tr bgcolor="#ffffff"><td align="center">@Secret.getVaultName@ </td><td align="center">@Secret.getName@ </td><td align="center">@Secret.getAutoExpireDate@ </td></tr>@</table> Please log in to PAM for more information about these secrets.	Yes

## Specify a Target Server

After you configure the Credential Manager settings, identify the target servers, which host the target applications.

### Add a Target Server Using the UI

To identify a target server in the UI:

1. In the UI, select **Devices, Manages Devices**.
2. From the **Devices** page, select **Add**.
3. In the **Add Device** dialog, complete the required fields in the **Basic Info** tab.

4. For the **Device Type**, select the **Password Management** check box.
5. Go to the **Access Methods** tab and specify an access protocol. The appliance uses the access method to contact the remote target server.
6. Select **OK** to complete the configuration.

### **Add a Target Server using the CLI**

To add a target server using the CLI, use the command `addTargetServer`.

The following command examples show how to add a target server using the CLI.

#### **NOTE**

Any literal IPv6 address entered in the `Address` field will be normalized according to the following standard:  
[RFC 5952: A Recommendation for IPv6 Address Text Representation](#).

For example, entering `1111:2222:000A:000B:0:0:0:D` in the `Address` field, and then saving it, means this value converts to `1111:2222:a:b::d`, enforcing the lowercased and compressed value according to the RFC 5952 standard.

Windows example:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetServer ^
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetServer.ipAddress=11.1.0.3 ^
Attribute.descriptor1=Vienna Attribute.descriptor2=Lab
```

Linux example:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetServer \
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetServer.ipAddress=11.1.0.3 \
Attribute.descriptor1=Vienna Attribute.descriptor2=Lab
```

## **Identify Target Applications and Connectors**

Credential Manager protects remote applications by associating specific user accounts with the applications. You then apply password policies for these accounts.

The following graphic shows the relationship between the target application, the target connector, and the target account. The value of the `Application Type` field determines the target connector and its relevant settings. The target account is then associated with the application. Multiple target accounts can be associated with a single target application.

**Figure 24: PAM App, Connector, Account**

The diagram illustrates the configuration of a PAM application, connector, and account. It consists of three windows:

- Add Target Application (Left):**
  - Application: MySQL
  - Host Name: 123.22.23.4
  - Device Name: mylinux
  - Application Name: SQL1
  - Application Type: MySQL
  - Password Composition Policy: (empty)
  - Descriptor 1: (empty)
  - Descriptor 2: (empty)
- Add Target Application (Right):**
  - Application: MySQL
  - DB Port: (empty)
- Add Target Account (Bottom):**
  - Account: Password Compound Servers MySQL
  - Host Name: 123.22.23.4
  - Device Name: mylinux
  - Application Name: SQL1
  - Account Name: root
  - Account Type: Privileged Account
  - Access Type: (empty)
  - Descriptor 1: (empty)
  - Descriptor 2: (empty)

Arrows indicate the following relationships:

- A green arrow points from the **Application Name** field in the left **Add Target Application** window to the **Application Name** field in the **Add Target Account** window.
- A blue arrow points from the **Application Type** field in the left **Add Target Application** window to the **Application** field in the **Add Target Account** window.
- A blue arrow points from the **DB Port** field in the right **Add Target Application** window to the **Application** field in the left **Add Target Application** window.

### Application Types and Target Connectors

An application type corresponds to a third-party operating system, database, directory, or other application that is remote to Privileged Access Manager. These target applications contain privileged accounts that are protected by passwords, cryptographic keys, and other mechanisms. Credential Manager manages these applications using target connectors.

The target application type has a one-to-one relationship to the target connector, which enables Credential Manager to communicate with the remote target application. When you specify an application type, you are configuring the associated target connector.

Target applications can contain one or more target accounts. The applications are grouped by the server where they are hosted, known as the target server. A target server can contain one or more target applications.

### Out-of-the-Box Application Types

Each out-of-the-box application type has a related target connector that enables Credential Manager to communicate with remote target application. After you select an application type, the related tabs for the associated target connector display in the Add Target Application dialog. Configure the target connector by completing the configuration settings.

#### NOTE

The UI uses the term **application type** not target connector.

### List of Out-of-the-Box Application Types

Credential Manager currently provides out-of-the-box target connectors for the following applications:

- Generic
- Active Directory
- Active Directory SSH Key
- AWS Proxy Access Credentials
- AWS Access Credentials
- Azure AD
- Azure Access Credentials
- BMC Remedy
- CA NIM
- Cisco
- HP Service Manager
- IBM i
- Juniper Junos
- LDAP
- MSSQL
- MSSQL Azure Managed Instance
- MYSQL
- Oracle
- Palo Alto
- RADIUS/TACACS+
- ServiceNow
- SPML
- UNIX
- VMware ESX/ESXi
- VMware NSX Controller
- VMware NSX Manager
- VMware NSX Proxy
- WebLogic
- Windows SSH Key
- Windows SSH Password
- Windows Remote
- Windows Proxy
- API Key

***See Out-of-the-Box Application Types in the UI***

To see the list of out-of-the-box application types in the UI:

1. Log in to the UI.
2. Select **Credentials, Manage Targets, Applications**.
3. Select **Add**.
4. In the **Application Type** field, look at the drop-down list to see all the options.

**Custom Application Types and Target Connectors**

If the out-of-the-box application types and target connectors are not sufficient for your remote applications, you can build custom target connectors. A Custom Connector framework is available for Privileged Access Manager. This framework provides the necessary components to deploy a target connector framework and the required APIs to build custom target connectors.

The target connector framework and the custom target connectors enable password viewing and password changes to your remote target system.

For information about how to deploy the software and build a custom target connector, see [Add a Custom Target Connector](#).

### **Target Connector Configuration**

After you select an application type, a new tab for the target connector displays. This tab has the configuration settings for the connector. For fields descriptions of each connector, select the relevant connector from the Table of Contents in the left pane.

## **Add an Active Directory Target Connector**

The Active Directory connector, Windows Proxy connector, and Windows Remote connector all manage Windows accounts. Use the Active Directory connector to update the passwords of Active Directory accounts. This connector uses the LDAPS interface to Active Directory to update account passwords. If the connector communicates with a deployed Windows Proxy or a Windows Remote connector, you can use this connector to update Windows services and scheduled tasks.

The Active Directory target connector performs the following activities:

- Verifies and synchronizes the password against an Active Directory database
- Queries one or more DNS servers to find domain controllers (optional)
- Uses LDAPS to connect to the domain controller
- If you use a domain account for a service or for a scheduled task, one or more Windows Proxies update the credentials and restart services.
- Uses HTTPS and AES encryption for secure communications.

To add the target connector using the CLI, see [Active Directory CLI Configuration](#).

To add the target connector using the external API, see [Active Directory Target Connector External API Configuration](#).

### **Add the Target Application and Connector**

Follow these steps in the PAM UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - **Host Name**: Select the magnifying glass to pick the target server.
  - **Device Name**
  - **Application Name**: Application names must be unique for a given target server.
4. In the **Application Type** field, select **Active Directory**.
5. (Optional) Select a password composition policy.

#### **NOTE**

If you do not select a password composition policy, a default policy is used. This policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.

6. On the **Active Directory** tab, configure the following fields:
  - **Domain Controller Lookup**: Specify the DNS method to identify the domain controller:

- **Do not use DNS (target server is domain controller):** Use the target server as the domain controller.
- **Retrieve DNS list:** Use the first reachable DNS server that is configured in the [PAM server network settings](#) to look up the domain controller.
- **Use the following DNS server:** Specify the IP address or (comma-separated) addresses of one or more DNS servers to use to look up the domain controller. If there are multiple entries, PAM uses the first reachable DNS server in the list to look up the domain controller.
- **Domain Name:** Specifies the Windows domain to which accounts managed by this application are members.
- **Domain Controller Port (SSL):** Specify the port that is used to connect to the Domain Controller. The default is 636. If the LDAPS port is the default 636, this field can be left blank. Otherwise, the port must be populated. Port 389 is used for unencrypted LDAP. Credential Manager does not synchronize AD target accounts using unencrypted LDAP
- **Active Directory Site:** This field is used only if **Domain Controller Lookup** is set to **Retrieve DNS list** or **Use following DNS server**.
  - If a value is given, the connector uses the value to narrow the search for domain controllers.
  - If empty, the connector searches for all domain controllers in the DNS.
- **Use Kerberos:** (Optional) Set this option to enable authentication using the Kerberos protocol. The name of the Kerberos realm is displayed in the **Realm Name** field that appears.

**NOTE**

Kerberos verifies user identities using a Key Distribution Center (KDC), which is a service that runs on Windows domain controllers. PAM uses the KDC on the domain controller which is determined by the previously configured **Domain Controller Lookup** setting.

7. If you enabled [Account Discovery](#), also complete the following settings:
  - **Groups:** To limit the number of discovered accounts, specify one or more comma-separated Active Directory groups. Do not use the Active Directory Primary Group for Account Discovery. Account Discovery does not find users in the Primary Group.
  - **Active Directory Connect Timeout:** enter the timeout for connecting to the directory in milliseconds. The default is 3000.
  - **Active Directory Read Timeout:** enter the timeout for reading from the directory, in milliseconds. The default is 3000.
8. If you are using target groupings, provide descriptors for the target application.
9. Select **OK**.

**NOTE**

Next Step: [Add a target account to the target application](#).

## Active Directory Target CLI Configuration

This topic includes CLI commands and parameters for adding Active Directory target applications and target accounts.

### Active Directory Target Connector CLI Parameters

To add an Active Directory target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	windowsDomainService

**Attribute.disableAutoConnectTargetAccount**

Disable automatic connections to the remote target server for all target accounts using this application type.

Required	Default Value	Valid Values
no	false	<ul style="list-style-type: none"> <li>true - disables automatic connectivity. Automatic connections are not allowed.</li> <li>false - enables automatic connectivity. Automatic connections are allowed.</li> </ul>

**Attribute.domainName**

The Windows domain that is managed by the Active Directory Server.

Required	Default Value	Valid Values
yes	N/A	Domain name (text string)

**Attribute.enableKerberos**

Determines whether Kerberos authentication is enabled for a target application.

Required	Default Value	Valid Values
no	false	<ul style="list-style-type: none"> <li>true - Kerberos authentication is enabled.</li> <li>false - Kerberos authentication is not enabled.</li> </ul>

**Attribute.useDNS**

Determines the level to which DNS is used.

Required	Default Value	Valid Values
yes	none	<ul style="list-style-type: none"> <li>noDNS. DNS is not used</li> <li>retrieveDNS. Retrieve the DNS server that is used by the Credential Manager server</li> <li>specifiedDNS. Use the DNS server that is specified by the dnsServer attribute</li> </ul>

**Attribute.dnsServer**

The host names of the DNS servers to use.

Required	Default Value	Valid Values
Required if Attribute.useDNS is set to specifiedDNS	none	Comma separated list of DNS server host names.

**Attribute.dcPort**

The port that is used to connect to the Active Directory server.

Required	Default Value	Valid Values
no	636	Numeric

**Attribute.adSite**

The Active Directory site. This parameter is only used if `Attribute.useDNS` is set to `retrieveDNS` or `specifiedDNS`. If a value is given, Credential Manager uses the value to narrow the search for domain controllers based on the specified name.

Required	Default Value	Valid Values
no	N/A	String

**Active Directory Target Account CLI Parameters**

To add an Active Directory target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

**Attribute.extensionType**

Specifies the type of account to be used.

Required	Default Value	Valid Values
yes	N/A	windowsDomainService

**Attribute.userDN**

The users distinguished name on the Active Directory Server.

Required	Default Value	Valid Values
yes	N/A	String.

**Attribute.useOtherAccountToChangePassword**

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

**Attribute.otherAccount**

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
Required if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	String. A valid target account ID.

**Attribute.serviceInfo**

List of services.

Required	Default Value	Valid Values
No	N/A	<p>&lt;empty string&gt; no services</p> <p>Add <i>one</i> of the following entries for each service:</p> <ul style="list-style-type: none"> <li>• &lt;proxy_hostname&gt;:&lt;hostname&gt;:&lt;service_name&gt;</li> <li>• &lt;proxy_hostname&gt;:&lt;hostname&gt;:&lt;service_name&gt;</li> </ul> <p>Multiple services are delimited by the   character.</p> <p>&lt;proxy_hostname&gt; is the name of the server running the proxy.</p> <p>&lt;hostname&gt; is the name of the server where the service is hosted.</p>

### ***Attribute.tasks***

List of scheduled tasks.

Required	Default Value	Valid Values
No	none	<p>&lt;empty string&gt; no tasks</p> <p>Add the following for each task:</p> <p>&lt;proxy_hostname&gt;:&lt;hostname&gt;:&lt;task_name&gt;</p> <p>Multiple tasks are delimited by the   character.</p> <p>&lt;proxy_hostname&gt; is the name of the server running the proxy.</p> <p>&lt;hostname&gt; is the name of the server where the scheduled task is hosted.</p>

### **Active Directory CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myAD TargetApplication.type=windowsDomainService
Attribute.domainName=cspm2
```

```
Attribute.useDNS= specifiedDNS Attribute.dnsServer=dns1.cloakware.com,dns2.cloakware.com
```

```
Attribute.dcPort=636 Attribute.adSite=London
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=mywindows
```

```
TargetAccount.userName=admin TargetAccount.password=P@ssw0rd
TargetAccount.cacheAllow=true
```

```
TargetAccount.cacheDuration=19 Attribute.extensionType=windowsDomainService
Attribute.useOtherAccountToChangePassword=false
```

```
Attribute.forcePasswordChange=false Attribute.userDN=cn=admin,dc=cspm2
```

```
Attribute.serviceInfo=proxyhostA:HostA:serviceName:restart|
proxyhostB:HostB:serviceName:norestart
```

```
Attribute.tasks=proxyHostA:HostA:taskName|proxyHostB:HostB:taskName
```

## Active Directory Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating Active Directory target applications using the External API.

### Active Directory Target Application External API Attributes

To add or update an Active Directory target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call.

#### ***disableAutoConnectTargetAccount***

Disable automatic connections to the remote target server for all target accounts using this application type.

Required	Default Value	Valid Values
no	false	<ul style="list-style-type: none"> <li>true - disables automatic connectivity. Automatic connections are not allowed.</li> <li>false - enables automatic connectivity. Automatic connections are allowed.</li> </ul>

#### ***domainName***

The Windows domain that is managed by the Active Directory Server.

Required	Default Value	Valid Values
yes	N/A	Domain name (text string)

#### ***useDNS***

Determines the level to which DNS is used.

Required	Default Value	Valid Values
yes	none	<ul style="list-style-type: none"> <li>noDNS. DNS is not used</li> <li>retrieveDNS. Retrieve the DNS server that is used by the Credential Manager server</li> <li>specifiedDNS. Use the DNS server that is specified by the dnsServer attribute</li> </ul>

#### ***dnsServer***

The host names of the DNS servers to use.

Required	Default Value	Valid Values
Required if <code>useDNS</code> is set to <code>specifiedDNS</code>	none	Comma separated list of DNS server host names.

### ***dcPort***

The port that is used to connect to the Active Directory server.

Required	Default Value	Valid Values
no	636	Numeric

### ***adSite***

The Active Directory site. This parameter is only used if `useDNS` is set to `retrieveDNS` or `specifiedDNS`. If a value is given, Credential Manager uses the value to narrow the search for domain controllers based on the specified name.

Required	Default Value	Valid Values
no	N/A	String

### ***enableKerberos***

Determines whether Kerberos authentication is enabled for a target application.

Required	Default Value	Valid Values
no	false	<ul style="list-style-type: none"> <li>true - Kerberos authentication is enabled.</li> <li>false - Kerberos authentication is not enabled.</li> </ul>

### **Active Directory External API Example**

```
{
  "applicationName": "My Sample AD",
  "applicationType": "windowsDomainService",
  "attributes": {
    "domainName": "mydomain",
    "useDNS": "specifiedDNS",
    "dnsServer": "dns1.mydomain.com",
    "dcPort": "636",
    "adSite": "Boston"
  },
  "description1": "Sample AD Target App created from the External API"
}
```

## Add an Active Directory SSH Key Target Connector

Key authentication has long been recognized as providing a higher level of security than passwords when connecting to Linux/Unix devices over SSH. Key authentication suffers from two limitations:

- The user public key must be stored in the `Authorized_keys` file on the target device
- The user must protect the private key with a passphrase to prevent compromising all the target systems where that key-pair has access.

Rather than managing key pairs for many users on many devices, Symantec PAM can manage access to and the lifecycle of a key pair specific to each target system. This management ensures users only access the private key through PAM after authentication and authorization, making governance and audit simpler to administer. This approach still requires a public key to be held in the target system's `Authorized_keys` file, although the attack surface is greatly reduced and access control is centralized.

The Active Directory SSH Key Target connector supports managing a `sshKey` in Active Directory as an attribute of the Active Directory user. This functionality allows a PAM user to SSH into a Linux system, and then be authenticated using a public key stored in an Active Directory system.

This connector allows you to use PAM to manage the lifecycle of the Keypair, providing an automated solution using Active Directory-backed target accounts for Linux systems, without making any changes to the servers, and allowing credential rotation policies to work. This feature will provide a AD/LDAP connector where the secret is public key generated and managed by PAM and the target is a Unix or Linux device.

Configuring this connector requires the following sections:

### **1. Create a Device in PAM for the Active Directory System**

Create a device in PAM to represent the Active Directory system that will contain the credentials used to access the PAM Linux devices you want users to access. Follow the directions as described in the [Device Setup](#) topic.

### **2. Create an Active Directory SSH Key Target Application for the Active Directory Device**

This step requires that you create an Active Directory SSH Key target application for the Active Directory device. You must specify the attribute name where the public key will be stored.

The default attribute name is `sshPublicKeys`.

**Follow these steps:**

1. Log in to the UI.
2. Select **Credentials, Manage Targets**, and then **Applications**. The **Target Applications** screen appears.
3. Select **Add**.
4. Complete the fields as described in the [Add Target Accounts to Target Applications](#) topic, with the following modifications:
5. In the **Application Type** option, use the drop-down list to select **Active Directory SSH Key**. Selecting **Active Directory SSH Key** displays a new tab labeled **Active Directory SSH Key**.
6. In the **SSH Key Attribute Name** field, enter the name of the attribute in Active Directory where the actual public key is stored. The default is `sshPublicKeys`. However, the names must match.
7. In the **SSH Key Pair Policy** field, select the search icon (magnifying glass) to display the **SSH Key Pair Policies** window. The key pair policy controls the attributes of certain attributes of the key when generated by PAM.
8. Select the desired key pair policy, and then select **OK**. If left blank, the default policy is RSA with a key length of 2,048. For more information on SSH key pair policies, see [SSH Key Authentication for Accessing UNIX/LINUX Targets](#).
9. Select **OK** to create the application.

### **3. Create an Active Directory Target Application for the Active Directory Device.**

Create an Active Directory target application for the Active Directory device. Follow the steps in the [Add an Active Directory Target Connector](#) topic. You must create a target application for the Active Directory device to allow PAM to store public keys in Active Directory. This target application is a prerequisite to creating a target account with sufficient privileges to update the attribute (default name **sshPublicKeys**) of the user account.

### **4. Create a PAM Target Account for the Active Directory Target Application.**

This step creates a PAM target account that represents the Active Directory account that PAM uses to connect to Active Directory and update the attribute.

#### **NOTE**

This user account must have sufficient privileges to update the SSH Key attribute.

Follow the steps in the [Add Target Accounts to Target Applications](#) topic.

### **5. Create a PAM Target Account for the Active Directory SSH Key Target Application.**

The private key is stored as the PAM password, and the public key is updated in Active Directory. The PAM target account is an account of the Active Directory device.

Section 2 creates the application, and this step creates the PAM account. There will be a corresponding account with this name on the UNIX target system the user is trying to access.

You use the following account to change the public key stored in the attribute: The Active Directory account credentials used to connect to and write into Active Directory.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets**, and then **Accounts**. The **Target Accounts** screen appears.
2. Select **Add**.
3. Complete the fields as described in the [Add Target Accounts to Target Applications](#) topic, with the following modifications:
4. Select the **Search** icon next to the **Application Name** field to display the list of target applications.
5. Select the application you created in [Step 2: Create an Active Directory SSH Key Target Application for the Active Directory Device](#), and then select **OK**. Making this selection populates the **Host Name**, **Device Name**, **Password View Policy**, and **Account Type** fields. Key options also appear on the right-hand side of the screen.
6. In the **Account Name** field, enter the name of an account that exists in both the Active Directory (as a user account) and UNIX systems.
7. Do *one* of the following tasks:
  - For the appliance to generate the key pair, select the keys icon next to the **Private Key** box.
  - To upload keys that are generated by a utility, select **Choose File** next to the Private and Public key boxes. Browse to the relevant file on your local system.
8. Select the **Password** tab. In the **Synchronized** setting, select **Update both the Credential Manager Server and the target system**.
9. Select the **Active Directory SSH Key** tab. You will select the Active Directory Account built in step 4. This is the account that is used to connect to AD and update the attribute.
10. Select the magnifying glass **Search** icon next to the **Use the following account to change the password** field to display the **Target Accounts** screen. The accounts table is populated by any account for that host and for the Active Directory type.
11. Create target accounts for every UNIX account you want users to log into using the credentials in Active Directory
12. Select **OK**, and both the PAM database and Active Directory synchronize

## **6. Create PAM Devices for the Linux-PAM End Targets with SSH Access.**

In this step, create PAM devices for the Linux-PAM end targets that have SSH access.

Follow the directions as described in the [Device Setup](#) topic, paying special attention to the [Specify Access Methods](#) subtopic, to make sure the devices use SSH.

## **7. Create a Device Group Containing Linux-PAM Devices with a Credential Source that is the Active Directory System with SSH Access.**

In this section, you create a device group, pick the device to include in the device group, and then select the Active Directory device as the credential source to associate with the group.

### **Follow these steps:**

1. Complete the fields as described in the [Device Group Setup](#) topic, with the following modifications:
2. Select the **Basic Info** tab.
3. From the list of devices under **Available Credential Source**, use the shuttle controls to select the Active Directory device as the **Selected Credential Source**.
4. Select the **Devices** tab.
5. Select the device to associate with this credential source.
6. Select **OK** to confirm your choices.

## **8. Create a Policy for a PAM User for the Device Group Granting SSH Access to the Active Directory SSH Key Target Account.**

In this section, you create a policy that grants SSH access to the Active Directory SSH Key target account for a PAM user for the device group created in section 7.

### **Follow these steps:**

1. Select **Policies, Manage Policies**, and then **Add**.
2. Complete the fields as described in the [Set Up a Policy](#) topic, with the following modifications:
3. In the **Add Policy** screen, use the **Device Group** option to select the device group created in section 7.
4. Select the **Access** tab to grant SSH access and associate the required target accounts to which you want to allow access:
5. Select **SSH** from the list and move it to the **Selected Access** list.
6. Select the magnifying glass **Search** icon in the corresponding **Target Account** column to display the **SSH Access** screen. This screen lists the target accounts that can get SSH access, including the UNIX accounts the user wants to be able to access.
7. Use the shuttle to select the Selected Target Account.
8. Select **OK** to confirm your choices.

## **Active Directory SSH Key Target CLI Configuration**

Learn how to use CLI commands and parameters for adding and updating Active Directory SSH Key target applications and target accounts.

This topic includes CLI commands and parameters for adding and updating Active Directory SSH Key target applications and target accounts, as well as example command strings.

### **Active Directory SSH Key Target Connector CLI Parameters**

#### ***Add or Update Active Directory SSH Key Target Application***

To add an Active Directory SSH Key target application and connector using the CLI, use the `addTargetApplication` command and its parameters.

To update an Active Directory SSH Key target application using the CLI, use the `updateTargetApplication` command and its parameters.

Both add and update operations use the `keyattribute` parameter to specify the attribute name where to store the public key. The default attribute name is `sshPublicKeys`.

### ***Add or Update Active Directory SSH Key Target Account***

To add an Active Directory SSH Key Target Account using the CLI, use the `addTargetAccount` command and its parameters.

To update an Active Directory SSH Key Target Account using the CLI, use the `updateTargetAccount` command and its parameters.

You can also use the following parameters:

- **anotherAccount:** The account ID of the PAM Active Directory Administrator target account. This is an Administrator account on the Active Directory that is used to connect to Active Directory and update the `keyattribute` parameter.
- **passwordViewPolicyId:** The ID of the PAM password view policy that is assigned to the target account.

### **Active Directory SSH Key CLI Examples**

#### ***CLI to Add an Active Directory SSH Key Target Application***

```
capam_command capam=capamServer adminUserID=admin cmdName=addTargetApplication
TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=ActiveDirectorySSHKeyApp
TargetApplication.type=activeDirectorySshKey
Attribute.keyattribute="sshPublicKeys"
Attribute.descriptor1="sample"
```

#### ***CLI to Update an Active Directory SSH Key Target Application***

```
capam_command capam=capamServer adminUserID=admin
cmdName=updateTargetApplication
TargetServer.ID=7001 TargetApplication.name=adSSHkey
TargetApplication.type=activeDirectorySshKey
TargetApplication.ID=11001 Attribute.keyattribute="sshPublicKeys"
Attribute.descriptor1="updated"
```

#### ***CLI to Add an Active Directory SSH Key Target Account***

```
capam_command.bat capam=capamServer adminUserId=admin
cmdName=addTargetAccount
TargetServer.hostName=myhostname.mydomain.com
TargetApplication.ID=9001
TargetAccount.userName=johnSmith
TargetAccount.passwordViewPolicyId=1000
TargetAccount.privileged=true
TargetAccount.synchronize=true
Attribute.anotherAccount=34001
Attribute.protocol=SSH2_PUBLIC_KEY_AUTH
TargetAccount.password="_generate_pass_"
```

## CLI to Update an Active Directory SSH Key Target Account

```
capam_command capam=capamServer adminUserID=admin
cmdName=updateTargetAccount
TargetAccount.ID=49001
TargetServer.hostName=myhostname.mydomain.com
TargetApplication.ID=11001
TargetAccount.userName=johnSmith
TargetAccount.passwordViewPolicyId=1000
TargetAccount.privileged=true
TargetAccount.synchronize=true
Attribute.anotherAccount=34001
Attribute.protocol=SSH2_PUBLIC_KEY_AUTH
TargetAccount.password="_generate_pass_"
```

## Active Directory SSH Key Target Application External API Attributes

This topic describes the required and supported Attributes used when adding or updating Active Directory SSH key target applications using the External API.

### Active Directory Target Application External API Attributes for Applications

To add or update an Active Directory target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call.

#### keyattribute

In Active Directory, the attribute name where the public key will be stored. The default attribute name is sshPublicKeys.

Required	Default Value	Valid Values
yes	sshPublicKeys	alphanumeric string

### Active Directory Target Application External API Attributes for Accounts

To add or update an Active Directory target account using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call.

#### anotherAccount

The account ID of the PAM Active Directory Administrator target account. This is an Administrator account on the Active Directory used to connect to the Active Directory and update the keyattribute.

Required	Default Value	Valid Values
yes	no	numeric string

**protocol:SSH2\_PUBLIC\_KEY\_AUTH**

SSH2\_PUBLIC\_KEY\_AUTH indicates that the target account will use SSH Public Key authentication

Required	Default Value	Valid Values
yes	SSH2_PUBLIC_KEY_AUTH	SSH2_PUBLIC_KEY_AUTH

**REST Web Service External API Examples****Add an Active Directory SSH Key Target Application**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "ADSSHKeyApp",
  "applicationType": "activeDirectorySshKey",
  "attributes": {"keyattribute": "sshPublicKeys"},
  "description1": "sample description1",
  "description2": "sample description2"
}
```

**Update an Active Directory SSH Key Target Application**

```
PUT /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "id": "11001",
  "applicationName": "adSSHkey",
  "applicationType": "activeDirectorySshKey",
  "attributes": {"keyattribute": "sshPublicKeys"},
  "description1": "updated"
}
```

**Add an Active Directory SSH Key Target Account**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts
{
  "accountName": "johnSmith",
  "attributes": {
    "anotherAccount": "34001",
    "protocol": "SSH2_PUBLIC_KEY_AUTH"
  },
  "password": "_generate_pass_",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "t"
}
```

### **Update an Active Directory SSH Key Target Account**

```
PUT /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
  "accountId":"49001",
  "attributes":{
    "anotherAccount":"39001",
    "protocol":"SSH2_PUBLIC_KEY_AUTH"
  },
  "password":"_generate_pass_",
  "passwordViewPolicyId":1000,
  "privileged":"t",
  "synchronize":"t"
}
```

## **Add an AWS Access Credentials Target Connector**

The AWS Access Credentials target connector provides a placeholder application for Amazon Web Services (AWS) access credentials. The connector can be associated only with the built-in target server `xceedium.aws.amazon.com`

### **NOTE**

This connector is available only when Privileged Access Manager is licensed for AWS capability.

### **View the Target Application and Connector**

The AWS Access Credentials application type is pre-configured in the UI. To add the connector using the CLI, see [AWS Access Credential CLI Configuration](#).

#### **To view the settings:**

1. Select Credentials, Manage Targets, Applications.
2. Select Update. The default settings are shown:
  - Host Name: `xceedium.aws.amazon.com`
  - Device Name: `xceedium.aws.amazon.com`
  - Application Name: AWS Access Credential Accounts
  - Application Type: `AwsAccessCredentials`
3. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. This policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
4. Select **OK**.

### **Add an AWS Access Credentials Target Account**

Follow the standard steps for adding target accounts, but add accounts only for AWS access.

For the **AWS Access Credential Type** setting, you have two options. Complete the other fields for the option you select:

- Access key
- EC2 Private key

#### **Access Key Fields**

- **User Friendly Account Name:** Enter a string that functions like a username for AWS Account + Region access.
- **Access Key ID:** Specify an alphabetic string that functions in AWS like a username for AWS account access.
- **Secret Access Key:** Enter the longer string corresponding to the Access Key ID that functions like a password with the above ID.
- **View Private Key:** Select this checkbox to reveal the Secret Access Key characters (which are otherwise obfuscated).
- **Key Alias:** Assign a short name to this credential pair for easy identification. Other fields in the UI may require you select this alias.
- **Access Role Name:** If these credentials are applicable to an AWS API Proxy account, provide this parameter.
- **AWS Cloud Type:** Select one of the following options:
  - Commercial if these credentials are applicable to a regular AWS account.
  - Government if applicable to a United States government authorized AWS GovCloud (US) Region account.

### EC2 Private Key Fields

- **EC2 Instance User Name:** For most AWS Linux instances, this parameter is pre-assigned: “ec2-user”.
- **EC2 Private Key:** Displays the private key file after you upload it using the select File and Upload buttons.
- **Upload Key File:** Select the \*.pem file you downloaded while creating the key pair in the AWS interface. Upload this file into the **EC2 Private Key** field.
- **Enable Key Upload:** Select this checkbox to activate the select File and Upload buttons.
- **Passphrase:** If you assigned a passphrase when creating the EC2 private key, enter it here. Select **Show Passphrase** to see the passphrase characters.
- **Key Pair Name:** Assign a short name to this credential pair for easy identification. Other fields in the UI may require you select this alias.

### NOTE

Next Step: [Add a target account to the target application.](#)

## AWS Access Credentials CLI Configuration

You can add an AWS Access Credentials target application and connector using the CLI. This topic contains the parameters for target applications and target accounts:

### AWS Access Credentials Target Application CLI Parameters

To add a target application that uses the AWS Access credentials, use the [addTargetApplication](#) command and the following parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	AwsAccessCredentials

#### ***Attribute.extensionType***

Required	Default Value	Valid Values
yes	N/A	AwsAccessCredentials

**AWS Access Credentials Target Account CLI Parameters**

To add a target account that uses the AWS Access Credentials, use the [addTargetAccount](#) command and the following command parameters:

***Attribute.awsCredentialType***

The AWS access credential type.

Required	Default Value	Valid Values
yes	EC2_PRIVATE_KEY	<ul style="list-style-type: none"> <li>SECRET_ACCESS_KEY</li> <li>EC2_PRIVATE_KEY</li> </ul> X509_CERT_PRIVATE_KEY and CLOUDFRONT_PRIVATE_KEY are not supported.

***Attribute.passphrase***

The EC2 key passphrase.

Required	Default Value	Valid Values
no	N/A	A string consisting of alphanumeric characters (a-z, A-Z, 0-9)

***Attribute.awsKeyPairName***

The EC2 key pair name.

Required	Default Value	Valid Values
Yes when credential type is EC2_PRIVATE_KEY	N/A	A string consisting of any character except @

***Attribute.accountFriendlyName***

**NOTE:** This attribute is deprecated. See **Attribute.awsAccessKeyAlias**. The access key user-friendly name.

Required	Default Value	Valid Values
Yes when credential type is SECRET_ACCESS_KEY	N/A	A user-friendly account name string

***Attribute.awsAccessKeyAlias***

The access key user-friendly name.

Required	Default Value	Valid Values
Yes when credential type is SECRET_ACCESS_KEY	N/A	A user-friendly account name string

***Attribute.awsAccessRole***

The user defined AWS access role.

Optional	Default Value	Valid Values
When credential type is SECRET_ACCESS_KEY	N/A	A string of up to 64 alphanumeric characters. The string can also include '+=, @-'

### ***Attribute.awsCloudType***

The AWS cloud environment type.

Required	Default Value	Valid Values
yes when credential type is SECRET_ACCESS_KEY	commercial	<ul style="list-style-type: none"> <li>commercial</li> <li>government</li> </ul>

### **AWS Access Credentials CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com

TargetApplication.name=My_AWS_Access_Credentials
TargetApplication.type=AwsAccessCredentials
Attribute.extensionType=AwsAccessCredentials cmdName=addTargetAccount

TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=My_AWS_Access_Credentials
TargetAccount.userName=admin TargetAccount.password=ASJKNSKKA9FJJSFS
Attribute.extensionType=AwsAccessCredentials Attribute.awsMasterAccount=1001
Attribute.awsCredentialType=SECRET_ACCESS_KEY Attribute.accountFriendlyName=xceediumAWS
Attribute.awsAccessRole=Admin Attribute.awsCloudType=commercial
```

## **Add an Azure AD Target Connector**

Use the Azure Active Directory (AD) connector to update the passwords of Azure AD accounts. This connector can only manage Azure AD accounts, not any other accounts included in the Azure portal.

### **IMPORTANT**

The Azure AD target connector does not require that the PAM server is also running on Azure. However, if the PAM server is not running on Azure, the network firewall where the PAM server is running must permit data transfer over port 443 to access portal.azure.com over the internet.

### **TIP**

The Azure AD target connector does not support temporary passwords assigned to Azure AD user accounts when an Active Directory administrator creates a new account or changes the password of an existing user from within Azure. Users with such temporary passwords must log in to the Azure portal using the temporary password and change it to a permanent one before the Azure AD target connector can handle that user account.

### **Create the Application in Azure**

The Azure Application allows Privileged Access Manager to access Azure Resource Groups, VMs (for Azure device import), network interfaces, and public IPs (for clustering).

**NOTE**

For clustering, configure the Azure Application on the first Primary Site member. See [Set Up a Cluster](#) and [Cluster Deployment Requirements for Azure](#) for more information.

To create an Application in Azure, follow these steps:

1. In Azure, select **Azure Active Directory** from the left menu.
2. Select **App Registrations** from the resulting service list.
3. Select **+New Registration** on the resulting pane.
4. Enter a **Name** of your choice. Do not include spaces in the name.
5. Select **Supported Account Types**: Accounts in this organizational directory only
6. Select **Public client (mobile & desktop)** for **Redirect URI**.
7. Enter a **Redirect URI** for the application. Use your Privileged Access Manager URL. For example: `https://ip_address/cspm/home` For a cluster, select the IP address of the first node at the primary site.
8. Select **Register**. The application is created and its property page appears.
9. Under **Call APIs**, select **View API Permissions**.
10. On the API Permissions panel, select **Microsoft Graph**.
11. Select **Delegated permissions**.
12. Under **Select permissions**, type to search for "directory."
13. In the search results, select **Directory.AccessAsUser.All** (Access directory as the signed in user).
14. Select **Update Permissions**.
15. Under **Grant consent**, select **Grant admin consent for [your directory]**.
16. Close **Request API permissions**.

**NOTE**

When troubleshooting, ensure that the Azure application permissions are correct and intact.

17. On the application menu, select **Authentication**.
18. Locate the **Advanced Settings** section, and enable the **Allow public client flows** setting by selecting the **Yes** option.
19. Select **Save**.
20. Select **Overview** from the application menu.
21. Copy the **Application (client) ID** and the **Directory (tenant) ID** for use in creating a Privileged Access Manager Target Account.

Now, associate your Application to your Resource Group:

1. Select **Resource Groups** from the Azure left menu.
2. Select your Resource Group.
3. Select **Access Control (IAM)**.
4. Select **+Add, Role Assignment**.
5. Select **Contributor** from the **Role** drop-down list. Leave **Assign Access to** as "Azure AD user, group, or service principal."
6. In the **Select** field, enter the name of your application. Select the application from the resulting list.
7. Select **Save**.

**NOTE**

If you run several PAM server instances in different Azure Resource Groups (such as for clustering), repeat this association for each Resource Group.

## Create a Target Account

Managing Azure AD accounts, Clustering, Azure device import, and the Azure agent require a Target Account in Privileged Access Manager.

### Follow these steps:

1. Navigate to **Credentials, Manage Targets, Accounts**.
2. Select **Add**.
3. Use the **Application Name** magnifying glass icon to search and select **Azure Access Credential Accounts**. This action populates **Host Name** and **Device Name** with `ca.portal.azure.com`.
4. Select the **Key** tab.
5. Select the **Discovery Allowed** check box.
6. Select the **Update both the Credential Manager Server and the target system** radio button.
7. Select the **Access Credential** tab.
8. For **Azure Application Type**, select **Native Client**. A Native Client requires a user name and password.
9. For **User Name**, enter your Azure User Name.
10. For **Password**, enter your Azure Password. Do not use Generate Password for the account you use for discovery. Only Azure Global Administrators or Password Administrators can change their own passwords through Privileged Access Manager. Other users must use an administrator account as their master account.
11. Enter the **Application ID** from your Azure Application. If you did not copy it earlier, follow these steps:
  - a. In Azure, select **More Services** from the bottom of the left menu.
  - b. Enter "enterprise" in the filter field, and select **Enterprise Applications**.
  - c. Select **All Applications** from the menu.
  - d. Select your application from the application list.
  - e. Select **Properties**.
  - f. Copy the **Application ID** GUID from the property page.
12. Get the **Directory ID** from Azure. Follow these steps:
  - a. In Azure, select **Azure Active Directory** from the left menu.
  - b. Select **Properties** from its menu.
  - c. Select the **Directory ID** GUID from its property page.
13. Accept or change any other fields as appropriate.
14. Select **OK** to save the Target Account.

### IMPORTANT

If you are using the Azure SQL Managed Instance for JIT Provisioning, **stop here**. Do not do Step 15.

15. Follow the instructions in [Use Account Discovery to Add Target Accounts](#) to discover Azure Active Directory accounts using this target account. The account must be a Global Administrator for discovery.

### NOTE

Azure passwords expire independently of Privileged Access Manager. For this reason, you should configure Privileged Access Manager to rotate your Azure AD passwords more frequently than your Azure deployment does.

## Add a BMC Remedy Target Connector

The Remedy Target Connector helps you communicate with BMC Remedy Service Desk software.

For all the steps necessary to configure integration with BMC Remedy, see [BMC Remedy ITSM Integration](#).

## Add CA NIM Target Connectors

CA Normalized Integration Management (CA NIM) lets the Privileged Access Manager integrate with third-party service desk solutions. The appliance has two pre-existing target applications you can configure:

- CA NIM UM for User Management
- CA NIM SM for Service Management

For information about configuring CA NIM connectors, go to [Integrate with Your Service Desk Solution](#).

## Add a Cisco Target Connector

Use the Cisco connector to manage accounts on a Cisco router or switch. This connector uses either the SSHv2 or Telnet protocol for communication. The connector does not support SSHv1.

To add the target connector using the CLI, see [Cisco Target Connector CLI Configuration](#).

To add the target connector using the CLI, see [Cisco Target Connector External API Configuration](#).

### Add the Target Application and Connector

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - **Host Name:** Select the magnifying glass to pick the target server
  - **Device Name**
  - **Application Name:** Application names must be unique for a given target server.
4. In the **Application Type** field, select **Cisco**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. This policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
6. Select the tab for the access communication method you are using (SSH-2 or Telenet) and fill-in the required fields.

#### **SSH-2 Tab - Connection information**

- **Port:** Enter the port that connects to the Cisco host using SSH.
- **Communication Timeout:** Specify the amount of time the appliance waits for communication from the remote target server before ending the connection.
- **Enable strict host key checking:** Select this checkbox to control whether a system with an unknown or changed host key gets automatically added to the known host list. Provide the Known Host Key or the Known Host Key Fingerprint so the host can be verified

#### **SSH-2 Tabs - Cipher, Hash, Key Exchange, Compression, Server Host Key**

Selecting the checkbox on each tab results in the appliance using the supported settings for each feature. Clearing the checkbox displays more settings, letting you customize how the appliance handles the SSH-2 features.

- **Cipher:** Select the checkbox to use supported ciphers. Clear the checkbox to reveal fields for entering a list of inbound and outbound ciphers.
- **Hash:** Specifies whether the supported hashes should be used when making an SSH connection to the remote host. Clear the checkbox to reveal fields for entering a list of inbound and outbound hashes.
- **Key Exchange:** Select the checkbox to use supported key exchange methods. Clear the checkbox to reveal fields for entering a list of key exchange methods.
- **Compression:** Select the checkbox to use supported compression methods. Clear the checkbox to reveal fields for entering a list of inbound and outbound compression methods.
- **Server Host Key:** Select the checkbox to use supported server host key types. Clear the checkbox to reveal fields for entering a list of server host key types.

#### NOTE

Encryption standards continue to evolve with new vulnerabilities identified in what were previously accepted algorithms. Progress is also made with additional more-secure Cipher, Hash, Key Exchange, or Server Host Key options added to common utilities used for establishing secure communication channels. When upgrading PAM, be sure to consider any changes in the available more-secure cipher algorithms. Less secure Ciphers, Hashes, Key Exchanges, or Server Host Keys algorithms are not listed, but will continue working but may be subject to removal in a future release.

#### 7. Telnet Tab

- **Port:** Enter the port that the appliance uses to connect to the UNIX host with Telnet. Default: 23
- **Communication Timeout:** Specify the amount of time, in milliseconds, that the appliance waits for communication from the remote target server. When this interval ends, the appliance terminates the connection. Default: 60000

#### 8. Select **OK**.

#### Use a Script to Simplify Communication (Optional)

The Cisco target connector includes a large amount of low-level code to handle communications with the remote host. Credential Manager can use a script processor to simplify such communications.

The script processor (written in Java) executes a high-level version of the logic for manipulating credentials on remote hosts. Two scripts allow different levels of testing and production use. One script verifies passwords while the other script updates passwords.

A set of default scripts that is provided with the appliance. To use the default scripts, configure a set of default prompts and command values.

When adding target applications and target accounts, you can configure the script settings with the UI or the CLI.

#### ***Generate the Script***

#### **Follow these steps to generate the script in the UI:**

1. Select the **Script Processor** tab.
2. Complete the following fields
  - Cisco Variant: Select the version of Cisco IOS software you are using.
  - Script Timeout (optional): Enter the amount of time, from 5000 through 59999 milliseconds, that the appliance waits to receive expected input from the remote host. Default: 5000

When specified, the following prompts and commands are substituted into appropriate locations (variables) in the default scripts. You can enter a substitute string.

- **Password Change Prompt:** A regular expression that matches the remote host prompt when it requests that a password be changed because it has expired.  
Default: (?si).\*?change your password.\*?
- **Password Confirmation Prompt:** A regular expression that matches the remote host prompt when it requests a password confirmation.

Default: (?si).\*?password:.\*?

- **Password Entry Prompt:** A regular expression that matches the remote host prompt when it requests a password.

Default: (?si) (. .\*?password(\sfor|:). .\*?)

- **User Name Entry Prompt:** A regular expression that matches the remote host prompt when it requests a user name. Default: (?si). .\*?login:.\*?

### ***Apply the Script to Update and Verify Credentials***

#### **Follow these steps:**

1. Select the **Credentials Script** tab.
2. In the Update and Verify sections, select one of the available options:

#### **TIP**

We recommend that you use the default script. If a revised script is required, contact CA Services.

- **Use the default script**  
Select this option for the appliance to use the default script that is provided with the release. If changes to the script logic are required, contact CA Services.
- **Use a revised default script (requires patch)**  
Select this option to use a revised script that is provided by CA Services. Select the appropriate script from the drop-down list.
- **Use a replacement script**  
Select this option to use a replacement script. When selected, this option opens the **Replacement Script** text box. Paste the new script in the box, and try the operation.  
You might have to try more than one replacement script so the appliance conforms to your OS environment. Only edit the replacement scripts with assistance from CA Services.

#### **WARNING**

**Customer Responsibilities for Custom Scripts:** If you build custom scripts, you are responsible for the operation between the target application and the target endpoint. CA Technologies is responsible for operation up to the point where PAM passes information to the custom target application. After that point, you are responsible for how the custom script handles communication at an operational and security level.

#### **NOTE**

**Next Step:** [Add a target account to the target application](#)

## **Cisco Target CLI Configuration**

This topic includes CLI commands and parameters for adding Cisco target applications and target accounts.

### **Cisco Target Application CLI Parameters**

To add a Cisco target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	CiscoSSH

#### ***Attribute.sshPort***

The port that is used to connect to the UNIX host using SSH.

Required	Default Value	Valid Values
no	22	0-65535

#### ***Attribute.sshSessionTimeout***

When using the SSH communication channel, specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### ***Attribute.sshStrictHostKeyCheckingEnabled***

Enables or disables strict host key checking. When enabled, Credential Manager compares the public key that is received from the remote host when making a connection to the public key stored in the `sshKnownHostKey` attribute. If the keys do not match, then the connection attempt is canceled.

Required	Default Value	Valid Values
no	false	true, false

#### ***Attribute.sshKnownHostKey***

Contains the base-64 encoded public host key that is associated with the target server.

Required	Default Value	Valid Values
yes if <code>sshStrictHostKeyCheckingEnabled</code> is true	N/A	a base-64 encoded SSH public host key

#### ***Attribute.sshKnownHostKeyFingerprint***

Contains the fingerprint of the public host key that is contained in the `sshKnownHostKey` attribute. The fingerprint is used for display purposes only to allow the user to compare one key with another. The fingerprint that is specified must correspond to the specified public host key.

Required	Default Value	Valid Values
no	N/A	a public key fingerprint

#### ***Attribute.sshUseDefaultCiphers***

Specifies whether the default ciphers should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

#### ***Attribute.sshServerToClientCiphersList***

Specifies the list of ciphers to accept on the inbound data stream from the remote host. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

#### ***Attribute.sshClientToServerCiphersList***

Specifies the list of ciphers to use on the outbound data stream to the remote host. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

#### ***Attribute.sshDetectCiphersList***

Specifies the list of ciphers to detect when connecting to the remote host. Credential Manager does not attempt to use ciphers that are unavailable even if they are specified to use as inbound and outbound ciphers. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

#### ***Attribute.sshUseDefaultHashes***

Specifies whether the default hashes should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

#### ***Attribute.sshServerToClientHashesList***

Specifies the list of hashes to accept on the inbound data stream from the remote host. Hashes are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultHashes</code> is false	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

**Attribute.sshClientToServerHashesList**

Specifies the list of hashes to accept on the outbound data stream from the remote host. Hashes are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultHashes</code> is false	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

**Attribute.sshUseDefaultKeyExchangeAlgorithms**

Specifies whether to use the default key exchange methods when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

**Attribute.sshKeyExchangeAlgorithmsList**

Specifies the list of key exchange methods to use when connecting to the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultKeyExchangeAlgorithms</code> is false	diffie-hellman-group1-sha1,diffie-hellman-group14-sha1,diffie-hellman-group-exchange-sha1	A comma-separated list containing one or more of the following values: diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, diffie-hellman-group-exchange-sha1. Do not use spaces in the list.

**Attribute.sshUseDefaultCompressionAlgorithms**

Specifies whether the default compression methods should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

**Attribute.sshServerToClientCompressionAlgorithmsList**

Specifies the list of compression methods to accept on the inbound data stream from the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCompressionAlgorithms</code> is false	N/A (do not use compression)	comma-separated list containing one or more of the following values: zlib, zlib@openssh.com. Do not use spaces in the list.

**Attribute.sshClientToServerCompressionAlgorithmsList**

Specifies the list of compression methods to use on the outbound data stream from the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
Yes if <code>sshUseDefaultCompressionAlgorithms</code> is false	N/A (do not use compression)	A comma-separated list containing one or more of the following values: <code>zlib</code> , <code>zlib@openssh.com</code> . Do not use spaces in the list.

#### ***Attribute.sshUseDefaultServerHostKeyAlgorithms***

Specifies whether the default host key types should be accepted used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

#### ***Attribute.sshServerHostKeyAlgorithmsList***

Specifies the list of host key types to accept when Credential Manager connects to the remote host.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultServerHostKeyAlgorithms</code> is false	<code>ssh-rsa,ssh-dss</code>	A comma-separated list containing one or more of the following values: <code>ssh-rsa</code> , <code>ssh-dss</code> . Do not use spaces in the list.

#### ***Attribute.telnetSessionTimeout***

When using the Telnet communication channel, specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### ***Attribute.telnetPort***

The port that is used to connect to the UNIX host using Telnet.

Required	Default Value	Valid Values
no	23	0-65536

#### ***Attribute.ciscoVariant***

Specifies the type of Cisco system that is installed on the target server.

Required	Default Value	Valid Values
no	<code>IOS_12_4</code>	<code>IOS_10_0</code> , <code>IOS_12_4</code> or <code>ASA_IOS_7_0_1</code> .

#### ***Attribute.scriptTimeout***

Specifies the amount of time in milliseconds that Credential Manager waits to receive some expected input from the remote host.

Required	Default Value	Valid Values
no	5000	5000-59999

#### ***Attribute.useUpdateScriptType***

Specifies whether the default, revised or replacement update script should be used. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

#### ***Attribute.revisedUpdateScriptFilename***

Specifies the name of the file containing the revised update script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	N/A	a file name

#### ***Attribute.useVerifyScriptType***

Specifies whether the default, revised, or replacement verify script should be used. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

#### ***Attribute.revisedVerifyScriptFilename***

Specifies the name of the file containing the revised verify script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	N/A	a file name

#### ***Attribute.userNameEntryPrompt***

A regular expression that matches the prompt that is produced by the remote host when it requests a user name.

Required	Default Value	Valid Values
no	(?si).*(login username):.*?	valid regular expression syntax

#### ***Attribute.passwordEntryPrompt***

A regular expression that matches the prompt that is produced by the remote host when it requests a password.

Required	Default Value	Valid Values
no	(?si)(.*password(\\sfor :).*)	valid regular expression syntax

***Attribute.passwordConfirmationPrompt***

A regular expression that matches the remote host prompt that is produced when the host requests a password confirmation.

Required	Default Value	Valid Values
no	AIX: (?si).*?new password.*? All other platforms: (?si).*?password:.*?	valid regular expression syntax

***Attribute.passwordChangePrompt***

A regular expression that matches the prompt produced by the remote host when it requests that a password be changed because it has expired.

Required	Default Value	Valid Values
no	(?si).*?change your password.*?	valid regular expression syntax

***Cisco Target Account CLI Parameters***

To add an Active Directory target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

***Attribute.useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account when updating the target account.

Required	Default Value	Valid Values
yes	false	true, false

***Attribute.otherAccount***

Specifies which other account to use when updating the target account.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	a valid target account ID.

***Attribute.protocol***

Specifies the protocol to use for communicating with the remote host.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is false	SSH2_PASSWORD_AUTH	SSH2_PASSWORD_AUTH, TELNET

***Attribute.pwType***

The credential type; whether it pertains to a user or privileged (or "enable") account.

Required	Default Value	Valid Values
yes	user	user, privileged

**Attribute.useOtherPrivilegedAccount**

Required	Default Value	Valid Values
yes	false	true, false

**Attribute.otherPrivilegedAccount**

Required	Default Value	Valid Values
no	N/A	a valid target account ID

**Attribute.changeAuxLoginPassword**

Required	Default Value	Valid Values
no	N/A	true, false

**Attribute.changeConsoleLoginPassword**

Required	Default Value	Valid Values
yes	N/A	true, false

**Attribute.changeVtyLoginPassword**

Required	Default Value	Valid Values
no	N/A	true, false

**Attribute.numVTYPorts**

Required	Default Value	Valid Values
yes if changeVtyLoginPassword is true	N/A	1-15

**Cisco CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=www.ca.com
TargetApplication.type=CiscoSSH TargetApplication.name=Cisco
Attribute.extensionType=CiscoSSH Attribute.useDefaultUpdateScript=true
Attribute.useDefaultVerifyScript=true
```

```
cmdName=addTargetAccount TargetServer.hostName=www.ca.com TargetApplication.name=Cisco
TargetAccount.userName=account1
TargetAccount.password=password1 Attribute.protocol=SSH2_PASSWORD_AUTH
Attribute.useOtherAccountToChangePassword=false
pwType=user useOtherPrivilegedAccount=false changeAuxLoginPassword=false
changeConsoleLoginPassword=false
changeVtyLoginPassword=true numVTYPorts=1
```

## Cisco Target Connector External API Configuration

id="bodyContent">

This topic describes the required and supported Attributes used when adding or updating a Cisco Target application and target accounts using the External API.

### Cisco Target Application External API Attributes

To add or update a Cisco Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***sshPort***

The port that is used to connect to the UNIX host using SSH.

Required	Default Value	Valid Values
no	22	0-65535

#### ***sshSessionTimeout***

When using the SSH communication channel, specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### ***sshStrictHostKeyCheckingEnabled***

Enables or disables strict host key checking. When enabled, Credential Manager compares the public key that is received from the remote host when making a connection to the public key stored in the `sshKnownHostKey` attribute. If the keys do not match, then the connection attempt is canceled.

Required	Default Value	Valid Values
no	false	true, false

#### ***sshKnownHostKey***

Contains the base-64 encoded public host key that is associated with the target server.

Required	Default Value	Valid Values
yes if <code>sshStrictHostKeyCheckingEnabled</code> is true	N/A	a base-64 encoded SSH public host key

#### ***sshKnownHostKeyFingerprint***

Contains the fingerprint of the public host key that is contained in the `sshKnownHostKey` attribute. The fingerprint is used for display purposes only to allow the user to compare one key with another. The fingerprint that is specified must correspond to the specified public host key.

Required	Default Value	Valid Values
no	N/A	a public key fingerprint

**sshUseDefaultCiphers**

Specifies whether the default ciphers should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

**sshServerToClientCiphersList**

Specifies the list of ciphers to accept on the inbound data stream from the remote host. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

**sshClientToServerCiphersList**

Specifies the list of ciphers to use on the outbound data stream to the remote host. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

**sshDetectCiphersList**

Specifies the list of ciphers to detect when connecting to the remote host. Credential Manager does not attempt to use ciphers that are unavailable even if they are specified to use as inbound and outbound ciphers. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

**sshUseDefaultHashes**

Specifies whether the default hashes should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

**sshServerToClientHashesList**

Specifies the list of hashes to accept on the inbound data stream from the remote host. Hashes are listed in order of priority.

Required	Default Value	Valid Values
yes if sshUseDefaultHashes is false	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

**sshClientToServerHashesList**

Specifies the list of hashes to accept on the outbound data stream from the remote host. Hashes are listed in order of priority.

Required	Default Value	Valid Values
yes if sshUseDefaultHashes is false	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

**sshUseDefaultKeyExchangeAlgorithms**

Specifies whether to use the default key exchange methods when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

**hKeyExchangeAlgorithmsList**

Specifies the list of key exchange methods to use when connecting to the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
yes if sshUseDefaultKeyExchangeAlgorithms is false	diffie-hellman-group1-sha1,diffie-hellman-group14-sha1,diffie-hellman-group-exchange-sha1	A comma-separated list containing one or more of the following values: diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, diffie-hellman-group-exchange-sha1. Do not use spaces in the list.

**sshUseDefaultCompressionAlgorithms**

Specifies whether the default compression methods should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

**sshServerToClientCompressionAlgorithmsList**

Specifies the list of compression methods to accept on the inbound data stream from the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCompressionAlgorithms</code> is false	N/A (do not use compression)	comma-separated list containing one or more of the following values: <code>zlib</code> , <code>zlib@openssh.com</code> . Do not use spaces in the list.

### ***sshClientToServerCompressionAlgorithmsList***

Specifies the list of compression methods to use on the outbound data stream from the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
Yes if <code>sshUseDefaultCompressionAlgorithms</code> is false	N/A (do not use compression)	A comma-separated list containing one or more of the following values: <code>zlib</code> , <code>zlib@openssh.com</code> . Do not use spaces in the list.

### ***sshUseDefaultServerHostKeyAlgorithms***

Specifies whether the default host key types should be accepted used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

### ***sshServerHostKeyAlgorithmsList***

Specifies the list of host key types to accept when Credential Manager connects to the remote host.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultServerHostKeyAlgorithms</code> is false	<code>ssh-rsa,ssh-dss</code>	A comma-separated list containing one or more of the following values: <code>ssh-rsa</code> , <code>ssh-dss</code> . Do not use spaces in the list.

### ***telnetSessionTimeout***

When using the Telnet communication channel, specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

### ***telnetPort***

The port that is used to connect to the UNIX host using Telnet.

Required	Default Value	Valid Values
no	23	0-65536

### ***ciscoVariant***

Specifies the type of Cisco system that is installed on the target server.

Required	Default Value	Valid Values
no	IOS_12_4	IOS_10_0, IOS_12_4 or ASA_IOS_7_0_1.

### ***scriptTimeout***

Specifies the amount of time in milliseconds that Credential Manager waits to receive some expected input from the remote host.

Required	Default Value	Valid Values
no	5000	5000-59999

### ***useUpdateScriptType***

Specifies whether the default, revised or replacement update script should be used. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

### ***revisedUpdateScriptFilename***

Specifies the name of the file containing the revised update script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	N/A	a file name

### ***useVerifyScriptType***

Specifies whether the default, revised, or replacement verify script should be used. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

### ***revisedVerifyScriptFilename***

Specifies the name of the file containing the revised verify script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	N/A	a file name

### ***userNameEntryPrompt***

A regular expression that matches the prompt that is produced by the remote host when it requests a user name.

Required	Default Value	Valid Values
no	(?si).*(login username):.*?	valid regular expression syntax

***passwordEntryPrompt***

A regular expression that matches the prompt that is produced by the remote host when it requests a password.

Required	Default Value	Valid Values
no	(?si)(.*?password(\sfor :).*)	valid regular expression syntax

***passwordConfirmationPrompt***

A regular expression that matches the remote host prompt that is produced when the host requests a password confirmation.

Required	Default Value	Valid Values
no	AIX: (?si).*?new password.*? All other platforms: (?si).*?password:.*?	valid regular expression syntax

***passwordChangePrompt***

A regular expression that matches the prompt produced by the remote host when it requests that a password be changed because it has expired.

Required	Default Value	Valid Values
no	(?si).*?change your password.*?	valid regular expression syntax

**Cisco Target Account External API Attributes**

To add a Cisco target account that uses the target connector, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

***useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account when updating the target account.

Required	Default Value	Valid Values
yes	false	true, false

***otherAccount***

Specifies which other account to use when updating the target account.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is true.	N/A	a valid target account ID.

***protocol***

Specifies the protocol to use for communicating with the remote host.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is false	SSH2_PASSWORD_AUTH	SSH2_PASSWORD_AUTH, TELNET

***pwType***

The credential type; whether it pertains to a user or privileged (or "enable") account.

Required	Default Value	Valid Values
yes	user	user, privileged

***useOtherPrivilegedAccount***

Required	Default Value	Valid Values
yes	false	true, false

***otherPrivilegedAccount***

Required	Default Value	Valid Values
no	N/A	a valid target account ID

***changeAuxLoginPassword***

Required	Default Value	Valid Values
no	N/A	true, false

***changeConsoleLoginPassword***

Required	Default Value	Valid Values
yes	N/A	true, false

***changeVtyLoginPassword***

Required	Default Value	Valid Values
no	N/A	true, false

***numVTYPorts***

Required	Default Value	Valid Values
yes if changeVtyLoginPassword is true	N/A	1-15

**Cisco Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications

"changeConsoleLoginPassword": "false" false/true values only
"useOtherPrivilegedAccount": "false" false/true values only
"changeAuxLoginPassword": "false", false/true values only
"changeVtyLoginPassword": "false", false/true values only

```

## Add an HP Service Manager Target Connector

The HP Service Manager target connector lets you integrate with HP Service Manager service desk application. For all the steps necessary to configure integration with HP Service Manager, see [HP Service Manager Integration](#).

## Add an IBM i Target Connector

The IBM i (formerly AS/400) target connector manages user accounts and provides password synchronization functionality for iSeries IBM midrange systems.

**NOTE**

Port 8475 must be open on the IBM i device for this connector to function. For SSL/TLS connectivity, port 9475 must be open.

The IBM i connector supports SSL/TLS connections to endpoint systems running OS/400, i5/OS, or IBM i. On the IBM i platform, the targets must be at these PTFs (Program Temporary Fix) maintenance levels:

- V7R3: SI65622
- V7R2: SI65619
- V7R1: SI65613

To add the target connector using the CLI, see the [IBM i Target CLI Configuration](#).

To add the target connector using the external API, see [IBM i Target Connector External API Configuration](#).

### Add an IBM i Target Application and Connector

The IBM i application type defaults to using SSL/TLS. If you upgrade an existing IBM i (or AS/400) application, it does not use SSL/TLS until you enable it. If you are adding a new IBM i application that does not support SSL or TLS, you must disable SSL/TLS.

**Follow these steps:**

1. Select **Credentials, Manage Targets, Applications**.

2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.
4. In the **Application Type** field, select **IBM i**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, the appliance uses the default policy. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
6. On the **IBM i** tab, confirm that **SSL/TLS Enabled** checkbox is selected. Keeping the box selected to ensure the certificate is a trusted source. Clear the check box to disable SSL/TLS communication.
7. Select **OK**

Any password verification or changes to IBM i target accounts for this application now use an SSL/TLS connection. If your IBM i endpoint does not support SSL/TLS connections, an error occurs.

#### NOTE

Next Step: [Add a target account to the target application.](#)

## IBM i Target CLI Configuration

This topic contains the parameters to add IBM i target applications and target accounts:

### IBM i Target Connector CLI Parameters

To add an IBM i target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### *TargetApplication.type*

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	AS400

#### *Attribute.sslEnabled*

Specify whether to use a secure (SSL or TLS) connection.

Required	Default Value	Valid Values
yes	true	true, false

### IBM i Target Account CLI Parameters

To add an IBM i target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

#### *Attribute.useOtherAccountToChangePassword*

Specify whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

**Attribute.otherAccount**

Specify which other account to use to perform password change requests.

Required	Default Value	Valid Values
If <code>Attribute.useOtherAccountToChangePassword</code> is true, set this parameter to yes	N/A	A valid target account ID

**IBM i CLI Examples**

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
```

```
TargetApplication.name=my_AS400_app TargetApplication.type=AS400
```

```
Attribute.extensionType=AS400 Attribute.sslEnabled=true
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
```

```
TargetApplication.name=my_AS400_app TargetAccount.userName=admin
```

```
TargetAccount.password=p@ssw0rd Attribute.extensionType=AS400
```

**IBM i Target Connector External API Configuration**

This topic describes the required and supported Attributes used when adding or updating an IBM i (AS400) Target Application using the External API:

**IBM i Target Application External API Attributes**

To add or update an IBM i (aka AS 400) Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

***sslEnabled***

Specify whether to use a secure (SSL or TLS) connection.

Required	Default Value	Valid Values
yes	true	true, false

**IBM i Target Account External API Attributes**

To add an IBM i (aka As 400) target account that uses the target connector, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

***useOtherAccountToChangePassword***

Specify whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

### ***otherAccount***

Specify which other account to use to perform password change requests.

Required	Default Value	Valid Values
If useOtherAccountToChangePassword is true, set this parameter to yes	N/A	A valid target account ID

### **IBM i Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "AS400",
  "applicationType": "AS400",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "attributes": {
    "sslEnabled": "false"
  },
  "passwordCompositionPolicyId": null
}
```

### **IBM i Target Account External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
  "accountName": "AS400Acc",
  "attributes": {
    "otherAccount": "",
    "descriptor2": "",
    "discoveryGlobal": "f",
    "descriptor1": "",
    "discoveryAllowed": "f",
    "useOtherAccountToChangePassword": "false",
    "unlockLockedAccount": "f"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
```

```

    "privileged":"t",
    "synchronize":"f",
    "useAliasNameParameter":"f"
}

```

#### NOTE

"useOtherAccountToChangePassword": "false" false/true values only

## Add a Juniper Junos Target Connector

This target connector provides password synchronization functionality for Juniper Junos® accounts.

To add the target connector using the CLI, see [Juniper Junos Target CLI Configuration](#).

To add the target connector using the external API, see [Juniper Junos Target Connector External API Configuration](#).

### Add the Target Application and Connector

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.
4. In the **Application Type** field, select **Juniper Junos**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions
6. On the Juniper Junos tab, configure the following fields:
  - **Connect Timeout**: enter the timeout for connecting to the directory in milliseconds. Default: 60000
  - **Read Timeout**: enter the timeout for reading from the directory, in milliseconds. Default: 5000.
  - **SSH Port**: Specify the port for secure connections. Default: 22
7. Select **OK**.

#### NOTE

Next Step: [Add a target account to the target application](#).

## Juniper Junos Target CLI Configuration

This topic contains the parameters for adding Juno Junos target applications and target accounts:

### Junos Target Connector CLI Parameters

To add a Junos target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	juniper

#### **Attribute.extensionType**

The attribute extension type

Required	Default Value	Valid Values
yes	N/A	juniper

#### **Attribute.sshPort**

The port that is used to connect to the Juniper host using SSH.

Required	Default Value	Valid Values
yes	22	0-65535

#### **Attribute.connectTimeout**

Specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	60000	1000-99999

#### **Attribute.readTimeout**

Required	Default Value	Valid Values
no	5000	1000-99999

### **Junos Target Account CLI Parameters**

To add a Junos target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

#### **Attribute.extensionType**

Required	Default Value	Valid Values
yes	N/A	juniper

#### **Attribute.useOtherAccountToChangePassword**

Specifies whether to use the target account or a different account when updating the target account.

Required	Default Value	Valid Values
yes	false	true, false

#### **Attribute.otherAccount**

Specifies which other account to use when updating the target account.

Required	Default Value	Valid Values
If <code>Attribute.useOtherAccountToChangePassword</code> is true, set to yes	N/A	a valid target account ID.

### **Junos CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=JP1

TargetApplication.type=juniper Attribute.extensionType=juniper Attribute.sshPort=22
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=FW1

TargetAccount.UserName=admin TargetAccount.password=P@ssw0rd
Attribute.extensionType=juniper Attribute.useOtherAccountToChangePassword=false
```

## **Juniper Junos Target Connector External API Configuration**

This topic describes the required and supported Attributes used when adding or updating a Juniper Junos Target Application using the External API

This topic describes the required and supported Attributes used when adding or updating a Juniper Junos Target Application using the External API:

### **Junos Target Application External API Attributes**

To add or update a Junos Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***extensionType***

The attribute extension type

Required	Default Value	Valid Values
yes	N/A	juniper

#### **sshPort**

The port that is used to connect to the Juniper host using SSH.

Required	Default Value	Valid Values
yes	22	0-65535

#### **connectTimeout**

Specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	60000	1000-99999

#### **readTimeout**

Required	Default Value	Valid Values
no	5000	1000-99999

### **Junos Target Account External API Attributes**

To add a Junos target account that uses the target connector, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### **extensionType**

Required	Default Value	Valid Values
yes	N/A	juniper

#### **useOtherAccountToChangePassword**

Specifies whether to use the target account or a different account when updating the target account.

Required	Default Value	Valid Values
yes	false	true, false

#### **otherAccount**

Specifies which other account to use when updating the target account.

Required	Default Value	Valid Values
If useOtherAccountToChangePassword is true, set to yes	N/A	a valid target account ID.

### **Junos Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "JuniperApp",
  "applicationType": "juniper",
  "attributes": {
    "connectTimeout": "60000",
```

```

        "readTimeout":"5000",
        "sshPort":"22"
    }
}

```

### **Junos Target Account External API Example**

```

POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
    "accountName":"JuniperAct",
    "attributes":{
        "useOtherAccountToChangePassword":"false",
        "descriptor1":"sample descriptor1"
    },
    "cacheBehavior":"useCacheFirst",
    "cacheDuration":"30",
    "password":"sample",
    "passwordViewPolicyId":1000,
    "privileged":"t",
    "synchronize":"f",
    "useAliasNameParameter":"f"
}

```

## **Add an LDAP Target Connector**

Use the LDAP target connector to manage any accounts that support the OpenLDAP V3 protocol. Optionally, you can configure the LDAP connector for SSL communication.

To add the target connector using the CLI, see the [LDAP Target Connector CLI Configuration](#).

To add the target connector using the external API, see [LDAP Target Connector External API Configuration](#).

### **Add the Target Application and Connector**

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - **Host Name**: Select the magnifying glass to pick the target server
  - **Device Name**
  - **Application Name**: Application names must be unique for a given target server.
4. In the **Application Type** field, select **LDAP**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and A maximum length of 16 characters, with no character restrictions.
6. On the **LDAP Details** tab, configure the following fields:
  - **Protocol**: Select either LDAP or LDAPS (SSL).
  - **Server Type**: Specify the LDAP server type:

- **OpenLDAP:** A server running an OpenLDAP implementation
  - **Other:** A server running any other LDAP implementation
  - **CA LDAP for ACF2:** A CA LDAP Server configured with the ACF2 backend security option
  - **CA LDAP for Top Secret:** A CA LDAP Server configured with the Top Secret backend security option
  - **CA LDAP for RACF:** A CA LDAP Server configured with the RACF backend security option
  - **Port:** Enter the port that the LDAP application uses.
  - **Base-64 encoded x.509 Certificate:** If the protocol is SSL, a certificate is required. Search for a certificate.
  - **Connect Timeout:** Enter the time in milliseconds that Credential Manager waits before aborting the attempt to connect to the server. The value defaults to 3000.
  - **Read Timeout:** Enter the time in milliseconds that Credential Manager waits before aborting the request to the server for data. The read timeout applies to the LDAP response from the server, after the initial connection is established with the server.
7. On the **Additional LDAP Attributes for Password Modification** tab, specify the attribute name/value pairs to be updated with password modifications.
- If these attributes are not part of your LDAP schema, an error can occur during password modification. For the OpenLDAP **shadowLastChange** attribute, the appliance provides the dynamic value **%EPOCH\_DAYS%**, which calculates to the current number of days from the epoch (1/1/1970). **%EPOCH\_DAYS%** is the only available dynamic attribute.
- Select on the + (plus) sign on the page and provide the following values:
- **Attribute Name:** The name of the LDAP attribute to pass, such as `shadowLastChange`.
  - **Attribute Value:** The value to send for that LDAP attribute, such as `%EPOCH_DAYS%`.
8. To enable Account Discovery using this account, select the **Account Discovery** tab and enter values in at least the two required fields.
- Base DN (optional)
  - Account Object (required) is an objectClass name corresponding to accounts or users in the directory.
  - Name Attribute (required) denotes an account name.
  - Filter (optional) allows addition of an optional filter string to limit your results.
- For more information, see your LDAP provider documentation.

#### NOTE

Next Step: [Add a target account to the target application.](#)

### Add LDAP Target Account Details

When you select **Add from the Target, Accounts**, the Account Details panel opens. When you select an LDAP Application Name, extra fields appear specific to LDAP accounts.

**DN:** Enter a Distinguished Name for the LDAP Account to use.

**Change Process:** Set to one of these choices:

- Account can change its own password.
- Use the following account to change the password. Search to select an account.

### LDAP Target Connector CLI Configuration

This topic contains the parameters for adding the LDAP target application and target accounts:

#### LDAP Target Application CLI Parameters

To add an LDAP target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

**TargetApplication.type**

The target application connector type.

Required	Default Value	Valid Values
Yes	N/A	ldap

**Attribute.port**

The port that is used to connect to the LDAP Server.

Required	Default Value	Valid Values
Yes	N/A	0-65535. The GUI uses default value 389.

**Attribute.protocol**

The protocol that is used to connect to the LDAP server.

Required	Default Value	Valid Values
Yes	clear	clear, ssl

**Attribute.serverType**

The LDAP server type.

Required	Default Value	Valid Values
No	OpenLDAP	CA ACF2, CA Top Secret, CA RACF, Other, OpenLDAP

**NOTE**

If the specified LDAP server type contains a space (for example, CA Top Secret), the entire Attribute.serverType attribute must be enclosed in quotation marks (") as shown in the following example:

```
capam_command capam=10.10.10.10 userID=admin cmdName=addTargetApplication
TargetServer.hostName=myhostname TargetApplication.name=myLDAP
TargetApplication.type=ldap "Attribute.serverType=CA RACF" Attribute.port=389
Attribute.protocol=clear
```

**Attribute.sslCertificate**

The LDAP SSL certificate.

Required	Default Value	Valid Values
Required if the protocol is SSL.	N/A	X.509 digital certificate in BASE64 encoded format

**Attribute.ldapConnectTimeout**

Time in milliseconds that Credential Manager waits before aborting the attempt to connect to the server.

Required	Default Value	Valid Values
No	3000	1000-99999

**Attribute.IdapReadTimeout**

Time in milliseconds that Credential Manager waits before aborting the request to the server for data. The read timeout applies to the LDAP response from the server, after the initial connection is established with the server.

Required	Default Value	Valid Values
No	3000	1000-99999

**LDAP Target Account CLI Parameters**

To add an LDAP target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

**Attribute.useOtherAccountToChangePassword**

This attribute specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
Yes	N/A	true, false

**Attribute.otherAccount**

This attribute specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

**Attribute.userDN**

The distinguished name of the user on the LDAP server.

Required	Default Value	Valid Values
yes	N/A	String.

**LDAP CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myLDAP TargetApplication.type=ldap Attribute.port=389
Attribute.protocol=clear
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myLDAP TargetAccount.userName=admin
TargetAccount.password=p@ssw0rd TargetAccount.cacheBehavior=useCacheFirst
TargetAccount.cacheDuration=21 Attribute.userDN=admin
Attribute.useOtherAccountToChangePassword=false
```

## LDAP Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating an LDAP target application using the External API.

This topic describes the required and supported Attributes used when adding or updating an LDAP target application using the External API. External API Attributes

### LDAP Target Application External API Attributes

To add or update an LDAP Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### **port**

The port that is used to connect to the LDAP Server.

Required	Default Value	Valid Values
Yes	N/A	0-65535. The GUI uses default value 389.

#### **protocol**

The protocol that is used to connect to the LDAP server.

Required	Default Value	Valid Values
Yes	clear	clear, ssl

#### **serverType**

The LDAP server type.

Required	Default Value	Valid Values
No	OpenLDAP	CA ACF2, CA Top Secret, CA RACF, Other, OpenLDAP

#### **NOTE**

If the specified LDAP server type contains a space (for example, CA Top Secret), the entire serverType attribute must be enclosed in quotation marks (") as shown in the following example:

```
capam_command capam=10.10.10.10 userID=admin cmdName=addTargetApplication
TargetServer.hostName=myhostname TargetApplication.name=myLDAP
TargetApplication.type=ldap "serverType=CA RACF" Attribute.port=389
Attribute.protocol=clear
```

#### **sslCertificate**

The LDAP SSL certificate.

Required	Default Value	Valid Values
Required if the protocol is SSL.	N/A	X.509 digital certificate in BASE64 encoded format

#### **ldapConnectTimeout**

Time in milliseconds that Credential Manager waits before aborting the attempt to connect to the server.

Required	Default Value	Valid Values
No	3000	1000-99999

### ***ldapReadTimeout***

Time in milliseconds that Credential Manager waits before aborting the request to the server for data. The read timeout applies to the LDAP response from the server, after the initial connection is established with the server.

Required	Default Value	Valid Values
No	3000	1000-99999

### **LDAP Target Account External API Attributes**

To add an LDAP target account that uses the target connector use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***useOtherAccountToChangePassword***

This attribute specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
Yes	N/A	true, false

#### ***otherAccount***

This attribute specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes <i>useOtherAccountToChangePassword</i> is true.	N/A	A valid target account ID.

#### ***userDN***

The distinguished name of the user on the LDAP server.

Required	Default Value	Valid Values
yes	N/A	String.

### **LDAP Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "ldapApp",
  "applicationType": "ldap",
  "attributes": {
    "port": "389",
    "protocol": "clear",
    "serverType": "OpenLDAP",
    "ldapConnectTimeout": "3000",
```

```

        "ldapReadTimeout":"3000"
    }
}

```

### LDAP Target Account External API Example

```

POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
    "accountName":"ldapAct",
    "attributes":{
        "useOtherAccountToChangePassword":"false",
        "userDN":"CN=Administrator,CN=Users,DC=broadcom,DC=test"
    },
    "cacheBehavior":"useCacheFirst",
    "cacheDuration":"30",
    "password":"sample",
    "passwordViewPolicyId":1000,
    "privileged":"t",
    "synchronize":"f",
    "useAliasNameParameter":"f"
}

```

## Add an MSSQL Target Connector

Use the MSSQL connector to manage accounts on Microsoft SQL 2000 and later database servers. The Microsoft connector uses JDBC for communication.

To add the target connector using the CLI, see the [MSSQL Target Connector CLI Configuration](#).

To add the target connector using the external API, see [MSSQL Target Connector External API Configuration](#).

### Add the Target Application and the Connector

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.
4. In the **Application Type** field, select **MSSQL**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum of four characters and a maximum of 16 characters, with no character restrictions
6. On the MSSQL tab, configure the following fields:

- **SSL/TLS Enabled** Select this checkbox to enable a secure connection.
- **Port:** Specify the port for secure connections. Default: 1433. You can connect to a named MSSQL server instance that uses dynamic port binding instead of a specific port number. Enter the appropriate MSSQL instance name and leave the Port field empty.

7. Select **OK**.

#### NOTE

Next Step: [Add a target account to the target application.](#)

## MSSQL Target Connector CLI Configuration

This topic contains the parameters for adding MSSQL target applications and target accounts:

### MSSQL Target Application CLI Parameters

To add an MSSQL target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	mssql

#### ***Attribute.extensionType***

Required	Default Value	Valid Values
yes	N/A	mssql

#### ***Attribute.sslEnabled***

Required	Default Value	Valid Values
	false	true, false

#### ***Attribute.port***

The target application port.

Required	Default Value	Valid Values
no	N/A	0-65535. The GUI uses default value 1433

#### ***Attribute.instance***

The database instance name.

Required	Default Value	Valid Values
no	N/A. If an instance is not specified, the target connector connects with the default database instance.	String.

## MSSQL Target Account CLI Parameters

To add an MSSQL target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

### ***Attribute.useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

### ***Attribute.otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

## MSSQL CLI Example

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
```

```
TargetApplication.name=myMSsql TargetApplication.type=mssql
```

```
Attribute.extensionType=mssql Attribute.port=1433
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
```

```
TargetApplication.name=myMSsql TargetAccount.userName=admin
```

```
TargetAccount.password=p@ssw0rd
```

```
TargetAccount.cacheBehavior=useCacheFirst TargetAccount.cacheDuration=21
```

```
Attribute.useOtherAccountToChangePassword=false
```

## MSSQL Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or MSSQL target applications using the External API

This topic describes the required and supported Attributes used when adding or MSSQL target applications using the External API:

**MSSQL Target Application External API Attributes**

To add or update a MSSQL Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

***extensionType***

Required	Default Value	Valid Values
yes	N/A	mssql

***sslEnabled***

Required	Default Value	Valid Values
	false	true, false

***port***

The target application port.

Required	Default Value	Valid Values
no	N/A	0-65535. The GUI uses default value 1433

***instance***

The database instance name.

Required	Default Value	Valid Values
no	N/A. If an instance is not specified, the target connector connects with the default database instance.	String.

**MSSQL Target Account External API Attributes**

To add or update a MSSQL Target account using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

***useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

***otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

**MSSQL Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "mssqlApp",
  "applicationType": "mssql",
  "attributes": { "port": "1433", "sslEnabled": "true" }
}
```

**MSSQL Target Account External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts
{
  "accountName": "mssqlAct",
  "attributes": {
    "useOtherAccountToChangePassword": "false",
    "descriptor1": "sample descriptor1"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
}
```

**Add an MSSQL Azure Managed Instance Target Connector**

Configure an MSSQL Azure Managed Instance target connector to manage accounts on an Azure SQL Managed Instance.

To add the target connector using the CLI, see the [MSSQL Target Connector CLI Configuration](#).

To add the target connector using the external API, see [MSSQL Azure Managed Instance Target Connector External API Configuration](#).

**NOTE**

The MSSQL Azure Managed Instance target connector currently only supports IPv4 addressing. (The Microsoft Azure SQL Managed Instance does not currently support IPv6 addressing.)

**Add the Target Application and the Connector**

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - **Host Name**. Select the search icon and pick a target server that is configured for an Azure SQL Managed Instance target server from the dialog that opens.
  - **Device Name**: Accept the default populated value ("Azure SQL managed instance") or enter your own value.
  - **Application Name**: Enter a unique name for the application.
4. In the **Application Type** field, select **MSSQL Azure Managed Instance**.
5. (Optional) Select a password composition policy.

If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum of four characters and a maximum of 16 characters, with no character restrictions

6. On the **MSSQL Azure Managed Instance** tab, configure the following fields:
  - **SSL/TLS Enabled** Select this checkbox to enable a secure connection.
  - **Port:** Specify the port for secure connections. Default: 1433.
7. Select **OK**.

#### NOTE

Next Step: [Add a target account to the target application.](#)

## MSSQL Azure Managed Instance Target Connector CLI Configuration

This topic contains the parameters for adding MSSQL Azure Managed Instance target applications and target accounts:

### MSSQL Azure Managed Instance Target Application CLI Parameters

To add an MSSQL Azure Managed Instance target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	mssqlAzureMI

#### ***Attribute.extensionType***

Required	Default Value	Valid Values
yes	N/A	mssqlAzureMI

#### ***Attribute.sslEnabled***

Required	Default Value	Valid Values
	false	true, false

#### ***Attribute.port***

The target application port.

Required	Default Value	Valid Values
no	N/A	0-65535. The GUI uses default value 1433

#### ***Attribute.instance***

The database instance name.

Required	Default Value	Valid Values
no	N/A. If an instance is not specified, the target connector connects with the default database instance.	String.

## MSSQL Azure Managed Instance Target Account CLI Parameters

To add an MSSQL Azure Managed Instance target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

### ***Attribute.useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

### ***Attribute.otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

## MSSQL Azure Managed Instance CLI Example

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=mssqlAzureMIAppTargetApplication.type=mssql
Attribute.extensionType=mssqlAzureMI Attribute.port=1433
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=mssqlAzureMITargetAccount.userName=admin TargetAccount.password=p@ssw0rd
TargetAccount.cacheBehavior=useCacheFirst TargetAccount.cacheDuration=21
Attribute.useOtherAccountToChangePassword=false
```

## MSSQL Azure Managed Instance Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating MSSQL Azure Managed Instance target applications using the External API.

This topic describes the required and supported Attributes used when adding or updating MSSQL Azure Managed Instance target applications using the External API:

### **MSSQL Azure Managed Instance Target Application External API Attributes**

To add or update a MSSQL Azure Managed Instance target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***extensionType***

Required	Default Value	Valid Values
yes	N/A	mssqlAzureMI

***sslEnabled***

Required	Default Value	Valid Values
	false	true, false

***port***

The target application port.

Required	Default Value	Valid Values
no	N/A	0-65535. The GUI uses default value 1433

***instance***

The database instance name.

Required	Default Value	Valid Values
no	N/A. If an instance is not specified, the target connector connects with the default database instance.	String.

**MSSQL Azure Managed Instance Target Account External API Attributes**

To add or update a MSSQL Azure Managed Instance Target account using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

***useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

***otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

**MSSQL Azure Managed Instance Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "mssqlAzureMIApp",
  "applicationType": "mssqlAzureMI",
  "attributes": {"port": "1433", "sslEnabled": "true"}
}
```

## **MSSQL Azure Managed Instance Target Account External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts
{
  "accountName":"mssqlAzureMIAct",
  "attributes":{
    "useOtherAccountToChangePassword":"false",
    "descriptor1":"sample descriptor1"
  },
  "cacheBehavior":"useCacheFirst",
  "cacheDuration":"30",
  "password":"sample",
  "passwordViewPolicyId":1000,
  "privileged":"t",
  "synchronize":"f",
  "useAliasNameParameter":"f"
}
```

## **Add a MySQL Target Connector**

This target connector provides password synchronization<sup>1</sup> functionality for MySQL 5 databases.

### **NOTE**

When a target application is configured for MySQL on a Linux, UNIX, or Solaris server, associated target account credentials may fail to synchronize because of time zone nomenclature incompatibility. For more information, including a workaround, see [Known Issues](#).

To add the target connector using the CLI, see [MySQL Target Connector CLI Configuration](#).

To add the target connector using the external API, see [MySQL Target Connector External API Configuration](#).

## **Add the Target Application and the Connector**

**Follow these steps in the UI:**

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.
4. In the **Application Type** field, select **MYSQL**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. This policy specifies a minimum of four characters and a maximum of 16 characters with no character restrictions
6. On the MYSQL tab, enter a value for the DB Port field, which specifies the port on which the MySQL is listening. The default port is 3306.
7. Select **OK**.

### **NOTE**

Next Step: [Add a target account to the target application](#).

## MySQL Target Connector CLI Configuration

This topic contains the parameters for adding MSSQL target applications and target accounts:

### MySQL Target Application CLI Parameters

To add a MySQL target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	MySQL

#### ***Attribute.port***

The target application port.

Required	Default Value	Valid Values
yes	3306	0-65535

### MySQL Target Account CLI Parameters

To add a MSSQL target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

#### ***Attribute.schema***

The name of the database schema to which the account belongs.

Required	Default Value	Valid Values
yes	N/A	String

#### ***Attribute.useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

#### ***Attribute.otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

#### ***Attribute.hostNameQualifier***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	MySQL wildcard (%)	A valid target account ID.

### MySQL CLI Example

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=MySQL01
TargetApplication.type=MySQL Attribute.extensionType=MySQL Attribute.port=3306

cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=MySQL01
TargetAccount.userName=admin TargetAccount.password=p@ssw0rd
TargetAccount.cacheAllow=true TargetAccount.cacheDuration=21
Attribute.extensionType=MySQL Attribute.useOtherAccountToChangePassword=false
```

## MySQL Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating a MSSQL Target Application using the External API:

### MySQL Target Application External API Attributes

To add or update a MySQL application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### **port**

The target application port.

Required	Default Value	Valid Values
yes	3306	0-65535

### MySQL Target Account External API Attributes

To add a MySQL target account that uses the target connector, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### **schema**

The name of the database schema to which the account belongs.

Required	Default Value	Valid Values
yes	N/A	String

#### **useOtherAccountToChangePassword**

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

### ***otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if useOtherAccountToChangePassword is true.	N/A	A valid target account ID.

### ***hostNameQualifier***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if useOtherAccountToChangePassword is true.	MySQL wildcard (%)	A valid target account ID.

### **MySQL Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "mysqlApp",
  "applicationType": "mysql",
  "attributes": { "port": "3306" }
}
```

### **MySQL Target Account External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
  "accountName": "mysqlAct",
  "attributes": {
    "useOtherAccountToChangePassword": "false",
    "schema": "master"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
```

}

## Add an Oracle Target Connector

Use the Oracle target connector to manage accounts for an Oracle database and Oracle Internet Directory (OID). The configuration procedure for Oracle Internet Directory is the same as for an Oracle database. The Oracle connector uses JDBC to communicate.

To add the target connector using the CLI, see [Oracle Target Connector CLI Configuration](#).

To add the target connector using the external API, see [Oracle Target Connector External API Configuration](#).

### Add the Target Application and Connector

Follow these steps in the UI:

1. Select Credentials, Manage Targets, Applications.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.
4. In the **Application Type** field, select **Oracle**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
6. On the Oracle tab, specify values for the following settings:
  - **SSL/TLS Enabled:** Select this box to establish a secure connection using SSL or TLS. Selecting SSL\TLS and specifying a Distinguished Name (DN) value enforces DN Matching.
  - **DB Port (Required):** Specify the port that the database listens on. Default: 1521
  - **OID (LDAP) Port:** If you are connecting to an Oracle Internet Directory service, specify the port that the service is listening on. Default: 3060
  - **Base 64-encoded x.509 certificate:** This certificate includes a public key, digital signature, and information about both the identity associated with the certificate and its issuing certificate authority (CA). This certificate is used to verify the identity of the entity presenting it.
  - **SSL Certificate Server DN:** The Distinguished Name used to force the server's DN to match its service name. Providing a value means SSL ensures that the certificate is from the server. **Note:** This field is only applicable if the SSL/TLS option is enabled.
7. Select **OK**.

#### NOTE

Next Step: [Add a target account to the target application](#).

## Oracle Target Connector CLI Configuration

This topic includes CLI commands and parameters for adding Oracle target applications and target accounts.

### Oracle Target Application CLI Parameters

To add an Oracle target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

**Attribute.sslCertServerDN**

The Distinguished Name (DN) of the Oracle Server.

Required	Default Value	Valid Value
no	None	string

**TargetApplication.type**

The target application connector type.

Required	Default Value	Valid Value
yes	None	oracle

**Attribute.extensionType**

The target application extension type.

Required	Default Value	Valid Value
yes	None	oracle

**Attribute.port**

The port that is used to connect to an Oracle Database server.

Required	Default Value	Valid Value
yes	None	0-65535

**Attribute.oidport (Oracle Internet Directory)**

The port that is used to connect to an Oracle Internet Directory (LDAP) server. Do not specify for Oracle Database.

Required	Default Value	Valid Value
yes	None	0-65535

**Attribute.sslEnabled**

Specifies whether SSL is enabled.

Required	Default Value	Valid Values
yes	None	true, false

**Attribute.sslCertificate**

The SSL certificate.

Required	Default Value	Valid Value
Required if the protocol is SSL	None	X.509 digital certificate in BASE64 encoded format

**Oracle Target Account CLI Parameters**

To add an Oracle target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

***Attribute.schema (Oracle Database)***

The name of the database schema to which the account belongs. Do not specify this option for Oracle Internet Directory.

Required	Default Value	Valid Value
yes (for Oracle database)	None	string

***Attribute.useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	None	true, false

***Attribute.otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Value
yes, if Attribute.useOtherAccountToChangePassword is true	None	A valid target account ID

***Attribute.useOid (Oracle Database)***

Specifies the connection type in use. Do not specify this option for Oracle Internet Directory.

Required	Default Value	Valid Values
yes	false	true, false

***Attribute.sid (Oracle Internet Directory)***

Specifies the System Identifier (SID) of the Oracle Internet Directory database instance. Do not specify this option for Oracle Database.

Required	Default Value	Valid Value
yes (for Oracle Internet Directory)	None	A valid SID (as specified during Oracle database installation). Example: orcl

***Attribute.cn (Oracle Internet Directory)***

Specifies the Common Name (CN) for an Oracle Context. Do not specify this option for Oracle Database.

Required	Default Value	Valid Value
yes	cn=OracleContext	A valid CN

***Attribute.racService***

Specifies whether the schema is a RAC service name.

Required	Default Value	Valid Values
yes	None	true, false

#### ***Attribute.sysdbaAccount***

Specifies whether this user must authenticate as the `Sysdba` role.

Required	Default Value	Valid Values
yes	None	true, false

#### ***Attribute.replaceSyntax***

Specifies whether the `REPLACE` syntax must be used for changing the password that is associated with `otheraccounts`.

Required	Default Value	Valid Values
yes	None	true, false

### **Examples for Oracle Database**

To specify an Oracle target application:

```
cmdName=addTargetApplication TargetServer.hostName=rh72
  TargetApplication.name=myOracle
TargetApplication.type=oracle Attribute.port=1521
```

```
cmdName=addTargetAccount TargetServer.hostName=rh72
  TargetApplication.name=myOracle TargetAccount.userName=system
TargetAccount.password=myPasswd Attribute.schema=XE
  Attribute.useOtherAccountToChangePassword=false
TargetAccount.privileged=true
  TargetAccount.synchronize=true Attribute.useOid=false
```

To specify a synchronized Oracle target account:

```
cmdName=addTargetAccount TargetServer.hostName=rh72
  TargetApplication.name=myOracle
TargetAccount.userName=system TargetAccount.password=myPasswd
  Attribute.schema=XE
```

```
Attribute.useOtherAccountToChangePassword=false TargetAccount.privileged=true
```

```
TargetAccount.synchronize=true Attribute.useOid=false
```

### **Examples for Oracle Internet Directory**

To specify an Oracle Internet Directory target application:

```
cmdName=addTargetApplication TargetServer.hostName=rh72.forwardinc.com
  TargetApplication.name=myOracle
TargetApplication.type=oracle Attribute.port=1433 Attribute.oidPort=3060
```

To specify a synchronized Oracle Internet Directory target account:

```
cmdName=addTargetAccount TargetServer.hostName=rh72.forwardinc.com
TargetApplication.name=myOracle
TargetAccount.userName=admin TargetAccount.password=p@ssw0rd
TargetAccount.cacheBehavior=useCacheFirst
TargetAccount.cacheDuration=21 Attribute.sid=orclAttribute.cn=OracleContext Attribute.useOther
Attribute.racService=false Attribute.sysdbaAccount=false
Attribute.replaceSyntax=false
```

## Oracle Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating an Oracle Target Application using the External API.

### Oracle Target Application External API Attributes

To add or update an Oracle Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***sslCertServerDN***

The Distinguished Name (DN) of the Oracle Server.

Required	Default Value	Valid Value
no	None	string

#### ***extensionType***

The target application extension type.

Required	Default Value	Valid Value
yes	None	oracle

#### ***port***

The port that is used to connect to an Oracle Database server.

Required	Default Value	Valid Value
yes	None	0-65535

#### ***oidport (Oracle Internet Directory)***

The port that is used to connect to an Oracle Internet Directory (LDAP) server. Do not specify for Oracle Database.

Required	Default Value	Valid Value
yes	None	0-65535

#### ***sslEnabled***

Specifies whether SSL is enabled.

Required	Default Value	Valid Values
yes	None	true, false

### ***sslCertificate***

The SSL certificate.

Required	Default Value	Valid Value
Required if the protocol is SSL	None	X.509 digital certificate in BASE64 encoded format

### **Oracle Target Account External API Attributes**

To add a xxx target account that uses the target connector, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***schema (Oracle Database)***

The name of the database schema to which the account belongs. Do not specify this option for Oracle Internet Directory.

Required	Default Value	Valid Value
yes (for Oracle database)	None	string

#### ***useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	None	true, false

#### ***otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Value
yes, if useOtherAccountToChangePassword is true	None	A valid target account ID

#### ***useOid (Oracle Database)***

Specifies the connection type in use. Do not specify this option for Oracle Internet Directory.

Required	Default Value	Valid Values
yes	false	true, false

#### ***sid (Oracle Internet Directory)***

Specifies the System Identifier (SID) of the Oracle Internet Directory database instance. Do not specify this option for Oracle Database.

Required	Default Value	Valid Value
yes (for Oracle Internet Directory)	None	A valid SID (as specified during Oracle database installation). Example: orcl

### ***cn (Oracle Internet Directory)***

Specifies the Common Name (CN) for an Oracle Context. Do not specify this option for Oracle Database.

Required	Default Value	Valid Value
yes	cn=OracleContext	A valid CN

### ***racService***

Specifies whether the schema is a RAC service name.

Required	Default Value	Valid Values
yes	None	true, false

### ***sysdbaAccount***

Specifies whether this user must authenticate as the Sysdba role.

Required	Default Value	Valid Values
yes	None	true, false

### ***replaceSyntax***

Specifies whether the REPLACE syntax must be used for changing the password that is associated with otheraccounts .

Required	Default Value	Valid Values
yes	None	true, false

### **Oracle Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "OracleApp",
  "applicationType": "oracle",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "attributes": {
    "sslCertificate": "-----BEGIN CERTIFICATE-----atNlKIQ9DYYVvJMkmUgaq5HiALrRH/
qZut58K64vOgl7r5O0SS5jT1RwwKDq -----END CERTIFICATE-----",
    "port": "2484",
    "extensionType": "oracle",
    "sslEnabled": "true",
```

```

    "oidPort": "3060"
  },
  "passwordCompositionPolicyId": null
}

```

### **Oracle Target Account External API Example**

POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts

```

{
  "accountName": "oracleAcc",
  "attributes": {
    "schema": "schema1",
    "discoveryAllowed": "f",
    "sysdbaAccount": "false",
    "useOid": "false",
    "cn": "",
    "sid": "",
    "racService": "false",
    "otherAccount": "",
    "descriptor2": "",
    "discoveryGlobal": "false",
    "descriptor1": "",
    "replaceSyntax": "false",
    "useOtherAccountToChangePassword": "false"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
}

```

## **Add a Palo Alto Target Connector**

Use the Palo Alto connector to manage accounts on Palo Alto routers that use PAN-OS software. This connector uses the SSHv2 protocol for communication.

To add the target connector using the CLI, see [Palo Alto Target Connector CLI Configuration](#).

To add the target connector using the external API, see [Palo Alto Target Connector External API Configuration](#).

### **Add the Target Application and Connector**

**Follow these steps in the UI:**

1. Select **Credentials, Manage Targets, Applications**.

2. Select **Add**.
3. Select or enter values for the following fields:
  - **Host Name**. Select the magnifying glass to pick the target server
  - **Device Name**
  - **Application Name**. Application names must be unique for a given target server.
4. In the **Application Type** field, select **Palo Alto**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
6. Select the **SSH-2** tab and enter values for the following two fields to configure the connection.
  - Port: Enter the port that connects to the Palo Alto host using SSH. Default: 22
  - Communication Timeout: Specify the amount of time the appliance waits for communication from the remote target server before ending the connection. Default: 60000 milliseconds
7. Select **OK**.

### **Use a Script to Simplify Communication (Optional)**

The Palo Alto target connector includes a large amount of low-level code to handle communications with the remote host. Credential Manager can use a script processor to simplify such communications.

The script processor (written in Java) executes a high-level version of the logic for manipulating credentials on remote hosts. Two scripts allow different levels of testing and production use. One script verifies passwords while the other script updates passwords.

A set of default scripts is provided with the appliance. To use the default scripts, configure a set of default prompts and command values.

When adding target applications and target accounts, you can configure the script settings with the UI or the CLI.

### ***Generate the Script***

**Follow these steps to generate the script in the UI:**

1. Select the **Script Processor** tab.
2. In the Script Timeout field, enter the amount of time, from 5000 through 59999 milliseconds, that the appliance waits to receive expected input from the remote host. Default: 5000
3. When specified, the following prompts and commands are substituted into appropriate locations (variables) in the default scripts. You can enter a substitute string.
  - **Password Change Prompt**: A regular expression that matches the remote host prompt when it requests that a password be changed because it has expired.  
Default: (?si).\*?change your password.\*?
  - **Password Confirmation Prompt**: A regular expression that matches the remote host prompt when it requests a password confirmation.  
Default: (?si).\*?password:.\*?
  - **Password Entry Prompt**: A regular expression that matches the remote host prompt when it requests a password.  
Default: (?si) (. .\*?password(\sfor|:). .\*?)
  - **User Name Entry Prompt**: A regular expression that matches the remote host prompt when it requests a user name.  
Default: (?si).\*?login:.\*?

### ***Apply the Script to Update and Verify Credentials***

**Follow these steps:**

1. Select the **Credentials Script** tab.

2. In the Update and Verify sections, select one of the available options:

**TIP**

We recommend that you use the default script. If a revised script is required, contact CA Services.

- **Use the default script**  
Select this option for the appliance to use the default script that is provided with the release. If changes to the script logic are required, contact CA Services.
- **Use a revised default script (requires patch)**  
Select this option to use a revised script that is provided by CA Services. Select the appropriate script from the drop-down list.
- **Use a replacement script**  
Select this option to use a replacement script. When selected, this option opens the **Replacement Script** text box. Paste the new script in the box, and try the operation.  
You might have to try more than one replacement script so the appliance conforms to your OS environment. Only edit the replacement scripts with assistance from CA Services.

**WARNING**

**Customer Responsibilities for Custom Scripts:** If you build custom scripts, you are responsible for the operation between the target application and the target endpoint. CA Technologies is responsible for operation up to the point where PAM passes information to the custom target application. After that point, you are responsible for how the custom script handles communication at an operational and security level.

**NOTE**

Next Step: [Add a target account to the target application.](#)

## Palo Alto Target Connector CLI Configuration

This topic includes CLI commands and parameters for adding Active Directory target applications and target accounts.

### Palo Alto Add Target Application CLI Parameters

To add a Palo Alto target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### TargetApplication.type

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	Palo Alto

#### Attribute.sshPort

Indicates the port that is used to connect to the host using SSH.

Required	Default Value	Valid Values
no	22	0-65535

#### Attribute.sshSessionTimeout

When using an SSH connection, specifies the amount of time in milliseconds that Credential Manager waits for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### **Attribute.scriptTimeout**

Specifies the amount of time in milliseconds that Credential Manager waits to receive some expected input from the remote host.

Required	Default Value	Valid Values
no	5000	5000-59999

#### **Attribute.useUpdateScriptType**

Specifies whether the default, revised, or replacement update script should be used. If you require a revised or replacement script, use the default script and contact CA Services.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

#### **Attribute.revisedUpdateScriptFilename**

Specifies the name of the file containing the revised update script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if you require a revised or replacement script.

Required	Default Value	Valid Values
no	N/A	a file name

#### **Attribute.useVerifyScriptType**

Verifies whether the default, revised, or replacement script gets used. If you require a revised or replacement script, use the default script and contact CA Services.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

#### **Attribute.revisedVerifyScriptFilename**

Specifies the name of the file containing the revised verify script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if you require a revised or replacement script.

Required	Default Value	Valid Values
no	N/A	a file name

#### **Attribute.userNameEntryPrompt**

A regular expression that matches the prompt produced by the remote host when it requests a user name.

Required	Default Value	Valid Values
no	(?si).*(login username):.*?	valid regular expression syntax

**Attribute.passwordEntryPrompt**

A regular expression that matches the prompt produced by the remote host when it requests a password.

Required	Default Value	Valid Values
no	(?si)(.*?password(\sfor :).*)?	valid regular expression syntax

**Attribute.passwordConfirmationPrompt**

A regular expression that matches the prompt produced by the remote host when it requests a password be confirmed.

Required	Default Value	Valid Values
no	AIX: (?si).*?new password.*? All other platforms: (?si).*?password:.*?	valid regular expression syntax

**Attribute.passwordChangePrompt**

A regular expression that matches the prompt produced by the remote host when it requests that a password be changed because it has expired.

Required	Default Value	Valid Values
no	(?si).*?change your password.*?	valid regular expression syntax

**Palo Alto Add Target Account CLI Parameters**

To add an Active Directory target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

**Attribute.useOtherAccountToChangePassword**

Specifies whether to use the target account or a different account when updating the target account.

Required	Default Value	Valid Values
yes	false	true, false

**Attribute.otherAccount**

Specifies which other account to use when updating the target account.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	a valid target account ID.

**Attribute.protocol**

Specifies the protocol to use for communicating with the remote host.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is false	SSH2_PASSWORD_AUTH	SSH2_PASSWORD_AUTH

**Attribute.pwType**

The credential type; whether it pertains to a user or privileged (or "enable") account.

Required	Default Value	Valid Values
yes	user	user, privileged

**Attribute.useOtherPrivilegedAccount**

Required	Default Value	Valid Values
yes	false	true, false

**Attribute.otherPrivilegedAccount**

Required	Default Value	Valid Values
no	N/A	a valid target account ID

**Attribute.changeAuxLoginPassword**

Required	Default Value	Valid Values
no	N/A	true, false

**Attribute.changeConsoleLoginPassword**

Required	Default Value	Valid Values
yes	N/A	true, false

**Attribute.changeVtyLoginPassword**

Required	Default Value	Valid Values
no	N/A	true, false

**Attribute.numVTYPorts**

Required	Default Value	Valid Values
yes if changeVtyLoginPassword is true	N/A	1-15

**Palo Alto CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=www.ca.com
TargetApplication.type=????? TargetApplication.name=PaloAlto

Attribute.extensionType=????? Attribute.useDefaultUpdateScript=true
Attribute.useDefaultVerifyScript=true
```

```

cmdName=addTargetAccount TargetServer.hostName=www.ca.com
TargetApplication.name=PaloAlto TargetAccount.userName=account1

TargetAccount.password=password1 Attribute.protocol=SSH2_PASSWORD_AUTH
Attribute.useOtherAccountToChangePassword=false

pwType=user useOtherPrivilegedAccount=false changeAuxLoginPassword=false
changeConsoleLoginPassword=false

changeVtyLoginPassword=true numVTYPorts=1

```

## Palo Alto Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating a Palo Alto Target Application using the External API.

### **Palo Alto Add Target Application External API Attributes**

To add or update a Palo Alto Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### **sshPort**

Indicates the port that is used to connect to the host using SSH.

Required	Default Value	Valid Values
no	22	0-65535

#### **sshSessionTimeout**

When using an SSH connection, specifies the amount of time in milliseconds that Credential Manager waits for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### **scriptTimeout**

Specifies the amount of time in milliseconds that Credential Manager waits to receive some expected input from the remote host.

Required	Default Value	Valid Values
no	5000	5000-59999

#### **useUpdateScriptType**

Specifies whether the default, revised, or replacement update script should be used. If you require a revised or replacement script, use the default script and contact CA Services.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

#### **revisedUpdateScriptFilename**

Specifies the name of the file containing the revised update script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if you require a revised or replacement script.

Required	Default Value	Valid Values
no	N/A	a file name

#### **useVerifyScriptType**

Verifies whether the default, revised, or replacement script gets used. If you require a revised or replacement script, use the default script and contact CA Services.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

#### **revisedVerifyScriptFilename**

Specifies the name of the file containing the revised verify script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if you require a revised or replacement script.

Required	Default Value	Valid Values
no	N/A	a file name

#### **userNameEntryPrompt**

A regular expression that matches the prompt produced by the remote host when it requests a user name.

Required	Default Value	Valid Values
no	(?si).*(login username):.*?	valid regular expression syntax

#### **passwordEntryPrompt**

A regular expression that matches the prompt produced by the remote host when it requests a password.

Required	Default Value	Valid Values
no	(?si)(.*password(\sfor :).*)	valid regular expression syntax

#### **passwordConfirmationPrompt**

A regular expression that matches the prompt produced by the remote host when it requests a password be confirmed.

Required	Default Value	Valid Values
no	AIX: (?si).*?new password.*? All other platforms: (?si).*?password:.*?	valid regular expression syntax

**passwordChangePrompt**

A regular expression that matches the prompt produced by the remote host when it requests that a password be changed because it has expired.

Required	Default Value	Valid Values
no	(?si).*?change your password.*?	valid regular expression syntax

**Palo Alto Add Target Account External API Attributes**

To add a Palo Alto target account that uses the target connector, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

**useOtherAccountToChangePassword**

Specifies whether to use the target account or a different account when updating the target account.

Required	Default Value	Valid Values
yes	false	true, false

**otherAccount**

Specifies which other account to use when updating the target account.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is true.	N/A	a valid target account ID.

**protocol**

Specifies the protocol to use for communicating with the remote host.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is false	SSH2_PASSWORD_AUTH	SSH2_PASSWORD_AUTH

**pwType**

The credential type; whether it pertains to a user or privileged (or "enable") account.

Required	Default Value	Valid Values
yes	user	user, privileged

**useOtherPrivilegedAccount**

Required	Default Value	Valid Values
yes	false	true, false

**otherPrivilegedAccount**

Required	Default Value	Valid Values
no	N/A	a valid target account ID

**changeAuxLoginPassword**

Required	Default Value	Valid Values
no	N/A	true, false

**changeConsoleLoginPassword**

Required	Default Value	Valid Values
yes	N/A	true, false

**changeVtyLoginPassword**

Required	Default Value	Valid Values
no	N/A	true, false

**numVTYPorts**

Required	Default Value	Valid Values
yes if changeVtyLoginPassword is true	N/A	1-15

**Palo Alto Target Application External API Example**

POST /api.php/v1/devices.json/{deviceId}/targetApplications

```
{
  "applicationName": "PaloAltoApp",
  "applicationType": "PaloAlto",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "attributes": {
    "sshPort": "",
    "sshSessionTimeout": "",
    "instance": "",
    "passwordEntryPrompt": "",
    "useVerifyScriptType": "DEFAULT",
    "passwordChangePrompt": "",
    "useUpdateScriptType": "DEFAULT",
    "sslPort": "",
    "userNameEntryPrompt": "",
    "scriptTimeout": "",
    "mbean": "",
    "port": "",
    "extensionType": "PaloAlto",
  }
}
```

```

    "sslEnabled": "",
    "passwordConfirmationPrompt": ""
  },
  "passwordCompositionPolicyId": null
}

```

### **Palo Alto Target Account External API Example**

PaloAlto Target Account external API example

POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts

```

{
  "accountName": "PaloAltoAcc",
  "attributes": {
    "pwType": "privileged",
    "otherAccount": "",
    "descriptor2": "",
    "discoveryGlobal": "f",
    "descriptor1": "",
    "discoveryAllowed": "f",
    "useOtherAccountToChangePassword": "f"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
}

```

## **Add a RADIUS/TACACS+ Secret Target Connector**

Set up this connector to authenticate users against a RADIUS or TACACS+ server. For configuration instructions, see [Configure RADIUS or TACACS+ for Authentication](#).

## **Add a ServiceNow Target Connector**

The ServiceNow target connector helps you communicate with ServiceNow service management software. For all the configuration steps necessary to integrate with ServiceNow, see [ServiceNow Integration](#).

## **Office365 Integration Messages, SAML IdP and SP Messages**

PAM-CMN-0686 = Default default contact user {0} does not exist.

PAM-CMN-0687 = Invalid default contact method {0} specified.

PAM-CMN-0688 = Device monitor protocol required.

PAM-CMN-0689 = Device monitor port required for protocol {0}.

PAM-CMN-0690 = Device monitor contact required for protocol {0}.

PAM-CMN-0691 = Device monitor contact method required for protocol {0}.

PAM-CMN-0692 = Invalid device monitor protocol specified.

PAM-CMN-0693 = Invalid device monitor port {0} specified for protocol {1}.

PAM-CMN-0694 = Invalid device contact method specified for protocol {0}.

PAM-CMN-0695 = Device monitor contact {0} does not exist.

PAM-CMN-0696 = Maximum buffer size is 8192.

PAM-CMN-0697 = Invalid web session recording quality specified. Valid values are high and low.

PAM-CMN-0698 = Unauthorized attempt to delete policies associated with the Office365 service.

PAM-CMN-0699 = Calculating the certificate fingerprint for IdP {0} failed. The IdP configuration will not be saved.

PAM-CMN-0700 = The SAML SP's {0} is a required field. Please enter a valid value.

PAM-CMN-0701 = The SAML SP's Fully Qualified Hostname is not a valid hostname.

PAM-CMN-0702 = The {0} of Identity Provider {1} is a required field. Please enter a valid value.

PAM-CMN-0703 = Invalid Identity Provider SSO binding specified for Identity Provider {0}. Valid values are: {1}.

PAM-CMN-0704 = The Single Sign On Service URL for Identity Provider {0} is not a valid HTTP URL.

PAM-CMN-0705 = The specified {0} of Identity Provider {1} is invalid. Valid values are: true or false.

PAM-CMN-0706 = The specified certificate for Identity Provider {0} is not a valid PEM certificate.

PAM-CMN-0707 = Invalid Signature Algorithm specified for Identity Provider {0}. Valid values are: {1}.

PAM-CMN-0708 = Invalid Name ID Formats specified for Identity Provider {0}. Valid values are: {1}.

PAM-CMN-0709 = Invalid Authentication Contexts specified for Identity Provider {0}. Valid values are: {1}.

PAM-CMN-0710 = Identity Provider entity IDs must be unique. There are multiple identity providers with the following entity ID(s): {0}.

PAM-CMN-0711 = Invalid SAML version specified for Identity Provider {0}. Valid values are: 1.1, 2.0

PAM-CMN-0712 = CA PAM as SAML SP configuration updated.

PAM-CMN-0713 = Identity Provider friendly names must be unique. There are multiple identity providers with the following friendly name(s): {0}.

PAM-CMN-0714 = Invalid vulnerability reporting level specified. Valid values are 'Log' or 'Log And Warn'.

PAM-CMN-0715 = Invalid vulnerability enabled specified.

PAM-CMN-0716 = The following required fields in the SAML SP configuration must be specified before the configuration can be saved or an IdP can be configured: Entity ID, Fully Qualified Hostname, Certificate Key Pair.

PAM-CMN-0717 = The required field, 'Fully Qualified Hostname', in the SAML configuration on cluster member {0} has not been defined. Please specify a value for the field before downloading metadata.

PAM-CMN-0718 = SAML SP metadata for remote IdP {0} downloaded.

PAM-CMN-0719 = An attempt was made to access the SAML IdP Proxy service when CA PAM is not deployed in a cluster.

PAM-CMN-0720 = An error occurred while completing this request. Please contact your administrator for further assistance.

PAM-CMN-0721 = An attempt was made to access the SAML IdP Proxy service on this node but this node is not the cluster master.

PAM-CMN-0722 = The following remote IdP(s) have been deleted: {0}.

PAM-CMN-0723 = The following remote IdP(s) have been added: {0}.

PAM-CMN-0724 = The id of identity provider {0} is not a valid id: {1}.

PAM-CMN-0725 = Invalid value specified ({0}). Integer expected.

PAM-CMN-0726 = Invalid value specified for SAML Accept RSA-SHA1 Signed Responses. Valid values are: t,f.

PAM-CMN-0727 = Invalid value specified for Client Distribution Intranet URL. Only domain names and IP addresses are allowed.

PAM-CMN-0728 = Invalid port specified for Client Distribution Intranet URL.

PAM-CMN-1818 = No user name supplied for Office 365.

PAM-CMN-1921 = Updated Microsoft Office 365 configuration

PAM-CMN-1922 = Cleared Microsoft Office 365 configuration

PAM-CMN-1923 = Office 365 configuration test: Connected successfully to the supplied URLs

PAM-CMN-1924 = Office 365 configuration test: Error connecting to the supplied URLs

PAM-CMN-2346 = Updated Microsoft Office 365 configuration  
 PAM-CMN-2347 = Cleared Microsoft Office 365 configuration  
 PAM-CMN-2348 = Office 365 configuration test: Connected successfully to the supplied URLs  
 PAM-CMN-2349 = Office 365 configuration test: Error connecting to the supplied URLs

## Add an SPML Target Connector

Use the Service Provisioning Markup Language (SPML) connector to manage any SPML v2.0-compliant providers.

To add the target connector using the CLI, see [SPML Target Connector CLI Configuration](#).

To add the target connector using the external API, see [SPML Target Connector External API Configuration](#).

### Add the Target Application and Connector

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.
4. In the **Application Type** field, select SPML v2.0.
5. (Optional) Select a password composition policy.  
 If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
6. On the SPML v2.0 tab, complete the following fields:
  - Port (optional): The port that is used to connect to the SPML server. Default: 8080
  - Path: Specify the URL to the service. Credential Manager uses this path to communicate to the SPML application.
  - Protocol: Select whether the communication channel is SSL or not.
  - Base-64 encoded X.509 Certificate: Select the certificate for the SSL connection.

#### **NOTE**

Next Step: [Add a target account to the target application](#).

## SPML Target Connector CLI Configuration

This topic includes CLI commands and parameters for adding Active Directory target applications and target accounts.

### SPML Target Connector CLI Parameters

To add an SPML target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	SPML2

**Attribute.extensionType**

Required	Default Value	Valid Values
yes	N/A	SPML2

**Attribute.port**

The port that is used to connect to the SPML server.

Required	Default Value	Valid Values
yes	N/A	0-65535

**Attribute.path**

Path to the SPML service.

Required	Default Value	Valid Values
no	N/A	Text string

**Attribute.protocol**

The protocol that is used to connect to the SPML server.

Required	Default Value	Valid Values
no	clear	clear, ssl

**Attribute.sslCertificate**

The Active Directory SSL certificate.

Required	Default Value	Valid Values
Require if the protocol is SSL .	N/A	X.509 digital certificate in BASE64 encoded format

**SPML Target Account CLI Parameters**

To add an Active Directory target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

**Attribute.extensionType**

Required	Default Value	Valid Values
yes	N/A	SPML2

**Attribute.useOtherAccountToChangePassword**

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

**Attribute.otherAccount**

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

### **SPML CLI Example**

```
cmdName=addTargetApplication
TargetServer.hostName=myHostName.myDomain.com TargetApplication.name=spmlAppl
TargetApplication.type=SPML2 Attribute.path=myServletPath Attribute.port=389
cmdName=addTargetAccount
TargetServer.hostName=myhostname.mydomain.com TargetApplication.name=spmlAppl
TargetAccount.userName=admin TargetAccount.password='p@ssw0rd'
TargetAccount.cacheBehavior=useCacheFirst TargetAccount.cacheDuration=21
Attribute.useOtherAccountToChangePassword=false
```

## **SPML Target Connector External API Configuration**

This topic describes the required and supported Attributes used when adding or updating a SPML Target Application using the External API.

### **SPML Target Application External API Attributes**

To add or update a SPML Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***extensionType***

Required	Default Value	Valid Values
yes	N/A	SPML2

#### ***port***

The port that is used to connect to the SPML server.

Required	Default Value	Valid Values
yes	N/A	0-65535

#### ***path***

Path to the SPML service.

Required	Default Value	Valid Values
no	N/A	Text string

#### ***protocol***

The protocol that is used to connect to the SPML server.

Required	Default Value	Valid Values
no	clear	clear, ssl

### ***sslCertificate***

The Active Directory SSL certificate.

Required	Default Value	Valid Values
Require if the protocol is SSL .	N/A	X.509 digital certificate in BASE64 encoded format

### **SPML Target Account External API Attributes**

To add a SPML target account that uses the target connector, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***extensionType***

Required	Default Value	Valid Values
yes	N/A	SPML2

#### ***useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

#### ***otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if useOtherAccountToChangePassword is true.	N/A	A valid target account ID.

### **SPML Target Application External API Example**

SPML2 Target Application external API example

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "SPML2App",
  "applicationType": "SPML2",
  "attributes": {
    "port": "8080",
    "protocol": "clear"
  }
}
```

### **SPML Target Account External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
  "accountName": "SPML2Act",
  "attributes": {
    "useOtherAccountToChangePassword": "false",
    "databaseName": "master"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
}
```

## **Add a Sybase Target Connector**

The Sybase target connector provides password synchronization functionality for Sybase databases.

To add the target connector using the CLI, see [Sybase Target Connector CLI Configuration](#).

To add the target connector using the external API, see [Sybase Target Connector External API Configuration](#).

### **Add the Target Application and the Connector**

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - **Host Name**. Select the magnifying glass to pick the target server
  - **Device Name**
  - **Application Name**. Application names must be unique for a given target server.
4. In the **Application Type** field, select **Sybase**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. This policy specifies a minimum of four characters and a maximum of 16 characters with no character restrictions
6. On the **Sybase** tab that appears, specify the following properties:
  - **TLS Enabled**: Specifies whether to enable TLS connections.
  - **DB Port**: Specifies the port on which the database is listening.
  - **Base-64 encoded x.509 Certificate**: If TLS is enabled, the root certificate for the SAP ASE server
7. Select **OK**.

8. (Optional) To configure the Sybase target connector to connect to Sybase servers that are configured to accept only encrypted password authentication, see the next section, [Upload A Sybase Sdk JAR File for the Sybase Target Connector](#).

#### NOTE

Next step (now, or after optionally configuring the Sybase target connector to connect to Sybase servers that are configured to accept only encrypted password authentication): [Add Target Accounts to Target Applications](#).

## Upload a Sybase SDK JAR File for the Sybase Target Connector

The Sybase target connector provides password synchronization functionality for Sybase databases. This content describes how to upload the Sybase SDK JAR file that is required for the Sybase target connector to work.

#### Follow these steps:

1. Obtain a Sybase SDK JAR file from Sybase. We currently support the 16.0 SP02 and SP03 versions of the Sybase JAR:

- SHA256 HASH for 16.0 SP02  
F8EEB645E573F90AECBE63AD7E03642A6DE4A0CE79DE07CEDA9A7DE61EBCDF3B
- SHA256 HASH for 16.0 SP03  
A14856895D44DCFBF15756263EE672F7A4A36A1476F6E43401B995E2DEF86F33

To find the JAR version, run the following command:

```
java -JAR .\jconn4.jar
```

Example output:

```
jConnect (TM) for JDBC(TM)/16.0 SP02 PL08 (Build 27392)/P/EBF28559/JDK 1.6.0/jdbcmain/
OPT/Thu Nov 22 17:40:56 PST 2018
```

2. Copy the following SDK JAR file to a location accessible to the PAM Appliance:  
jconn4.jar
3. Log in to the PAM UI.
4. Select **Configuration, 3rd Party, Sybase**.
5. On the **Upload File** tab, select **Choose File** button and browse for the JAR files individually.
6. Select **Upload** to upload the file.

#### NOTE

If you are load balancing, you have to upload the JAR file to each server. The files are the same for Windows and Linux. There can be only one version of the JAR file at any given time. Uploading different versions of supported JAR files will replace the existing one on the PAM server.

7. On the **Sybase Files** tab, select **Restart PAM** to restart PAM. Wait until the process completes.

#### NOTE

Next Step: [Add the Sybase target application and connector](#).

## Add the Sybase Target Application and Connector

The Sybase target connector provides password synchronization functionality for Sybase databases.

To add the target connector using the CLI, see [Sybase Target Connector CLI Configuration](#).

To add the target connector using the external API, see [Sybase Target Connector External API Configuration](#).

#### Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:

- **Host Name.** Select the magnifying glass to pick the target server
  - **Device Name**
  - **Application Name.** Application names must be unique for a given target server.
4. In the **Application Type** field, select **Sybase**.
  5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. This policy specifies a minimum of four characters and a maximum of 16 characters with no character restrictions
  6. On the **Sybase** tab that appears, specify the following properties:
    - **TLS Enabled:** Specifies whether to enable TLS connections.
    - **DB Port:** Specifies the port on which the database is listening.
    - **Base-64 encoded x.509 Certificate:** If TLS is enabled, the root certificate for the SAP ASE server
  7. Select **OK**.

**NOTE**

Next Step: [Add a target account to the target application.](#)

## Sybase Target Connector CLI Configuration

This topic contains the parameters for adding Sybase target applications and target accounts:

### Sybase Target Application CLI Parameters

To add a Sybase target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	sybase

#### ***Attribute.sslEnabled***

Required	Default Value	Valid Values
	false	true, false

#### ***Attribute.sslCertificate***

The LDAP SSL certificate.

Required	Default Value	Valid Values
Required if the protocol is SSL.	N/A	X.509 digital certificate in BASE64 encoded format

#### ***Attribute.port***

The target application port.

Required	Default Value	Valid Values
no	N/A	0-65535.

## Sybase Target Account CLI Parameters

To add a Sybase target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

### ***Attribute.schema***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

### ***Attribute.useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	None	true, false

### ***Attribute.otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

### ***Attribute.extensionType***

Required	Default Value	Valid Values
yes	N/A	sybase

## Sybase CLI Example

```
cmdName=addTargetApplication TargetServer.hostName=rh72 TargetApplication.name=mySybase
TargetApplication.type=sybase Attribute.port=5000
```

```
cmdName=addTargetAccount TargetServer.hostName=rh72 TargetApplication.name=mySybase
TargetAccount.userName=sybaseUser TargetAccount.password=myPasswd
TargetAccount.privileged=true TargetAccount.synchronize=true
TargetAccount.cacheBehavior=useCacheFirst TargetAccount.cacheDuration=30
Attribute.extensionType=sybase Attribute.schema=master
Attribute.useOtherAccountToChangePassword=false
```

## Sybase Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating a Sybase Target Application using the External API:

### Sybase Target Application External API Attributes

To add or update a Sybase Target Connector using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***sslEnabled***

Required	Default Value	Valid Values
	false	true, false

#### ***sslCertificate***

The LDAP SSL certificate.

Required	Default Value	Valid Values
Required if the protocol is SSL.	N/A	X.509 digital certificate in BASE64 encoded format

#### ***port***

The target application port.

Required	Default Value	Valid Values
no	N/A	0-65535.

### Sybase Target Account External API Attributes

To add a Sybase target account that uses the target connector use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***schema***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

#### ***useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	None	true, false

#### ***otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes if useOtherAccountToChangePassword is true.	N/A	A valid target account ID.

### ***extensionType***

Required	Default Value	Valid Values
yes	N/A	sybase

### **Sybase Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "SybaseApp",
  "applicationType": "sybase",
  "attributes": { "port": "5000", "sslEnabled": "false" },
  "description1": "sample description1",
  "description2": "sample description2",
  "passwordCompositionPolicyId": null
}
```

### **Sybase Target Account External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
  "accountName": "SybaseAct",
  "attributes": {
    "useOtherAccountToChangePassword": "false",
    "schema": "master"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
}
```

## **Add a UNIX Target Connector**

Use the UNIX target connector to manage UNIX-based privileged accounts. This connector uses either the SSH-2 or Telnet protocol for communication.

To add the target connector using the CLI, see [UNIX Target Connector CLI Configuration](#).

To add the target connector using the external API, see [UNIX Target Connector External API Configuration](#).

## **Add the Target Application and Connector**

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - **Host Name:** Select the magnifying glass to pick the target server
  - **Device Name**
  - **Application Name:** Application names must be unique for a given target server.
4. In the **Application Type** field, select UNIX.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
6. Select the tab for the access communication method you are using (SSH-2 or Telenet) and fill-in the required fields.

### **SSH-2 Tab - Connection information**

- **Port:** Enter the port that connects to the Cisco host using SSH.
- **Communication Timeout:** Specify the amount of time the appliance waits for communication from the remote target server before ending the connection.
- **SSH Key Pair Policy:** Select the key pair that secures the connection. For more information, see [Create an SSH Key Pair Policy with the UI](#).
- **SSH Certificate Policy:** Select the certificate that secures the connection. For more information, see [Create an SSH Certificate Policy with the UI](#).
- **Enable strict host key checking:** Select this checkbox to control whether a system whose host key is unknown or whose key changed gets automatically added to the known host list. Provide the Known Host Key or the Known Host Key Fingerprint so the host can be verified

### **SSH-2 Tabs - Cipher, Hash, Key Exchange, Compression, Server Host Key**

Selecting the checkbox on each tab results in the appliance using the supported settings for each feature. Clearing the checkbox displays more settings, letting you customize how the appliance handles the SSH-2 features.

- **Cipher:** Select the checkbox to use supported ciphers. Clear the checkbox to reveal fields for entering a list of inbound and outbound ciphers.
- **Hash:** Specifies whether the supported hashes should be used when making an SSH connection to the remote host. Clear the checkbox to reveal fields for entering a list of inbound and outbound hashes.
- **Key Exchange:** Select the checkbox to use supported key exchange methods. Clear the checkbox to reveal fields for entering a list of key exchange methods.
- **Compression:** Select the checkbox to use supported compression methods. Clear the checkbox to reveal fields for entering a list of inbound and outbound compression methods.
- **Server Host Key:** Select the checkbox to use supported server host key types. Clear the checkbox to reveal fields for entering a list of server host key types.

### **NOTE**

Encryption standards continue to evolve with new vulnerabilities identified in what were previously accepted algorithms. Progress is also made with additional more-secure Cipher, Hash, Key Exchange, or Server Host Key options added to common utilities used for establishing secure communication channels. When upgrading PAM, be sure to consider any changes in the available more-secure cipher algorithms. Less secure Ciphers, Hashes, Key Exchanges, or Server Host Keys algorithms are not listed, but will continue working but may be subject to removal in a future release.

## 7. Telnet Tab

- **Port:** Enter the port that the appliance uses to connect to the UNIX host with Telnet. Default: 23
- **Communication Timeout:** Specify the amount of time, in milliseconds, that the appliance waits for communication from the remote target server. If the remote host does not respond when the time expires, the appliance ends the connection. Default: 60000

8. Select **OK**.

## Use a Script to Simplify Communication (Optional)

The UNIX target connector includes a large amount of low-level code to handle communications with the remote host. Credential Manager can use a script processor to simplify such communications.

The script processor (written in Java) executes a high-level version of the logic for manipulating credentials on remote hosts. Two scripts allow different levels of testing and production use. One script verifies passwords while the other script updates passwords.

A set of default scripts that is provided with the appliance. To use the default scripts, configure a set of default prompts and command values.

When adding target applications and target accounts, you can configure the script settings with the UI or the CLI.

### Generate the Script

Follow these steps to generate the script:

1. Select the **Script Processor** tab.
2. Complete the following fields:
  - **UNIX Variant:** Select the type of UNIX system that is installed on the target server. This option adapts the connection script that is used to that version. If the UNIX type is unknown, select Generic. If the type is known but not listed, select Other.
  - **Script Timeout:** (optional) Enter the amount of time (5000 through 59999 milliseconds), that the appliance waits to receive expected input from the remote host. Default: 5000
3. Optionally, specify regular expressions for the script variables. When specified, the following prompts and commands are substituted into appropriate variables in the default scripts. You can enter a substitute string.  
The following table lists the various prompts:

Prompt	Expression
Password Change Prompt	This regular expression matches the prompt that from the remote host when it requests a password change due to expiration. Default: (?si).*?change your password.*?
Password Confirmation Prompt	This regular expression matches the prompt from the remote host when it requests a password confirmation. Default: (?si).*?password:.*?
Password Entry Prompt	This regular expression matches the prompt from by the remote host when it requests a password. Default: (?si)(.*?password(\sfor :).*)?
User Name Entry Prompt	This regular expression matches the prompt from the remote host when it requests a user name.Default: (?si).*?login:.*?
Change File Permissions Command	The command on the remote host that changes file permissions. Default: chmod
Change Password Command	The command on the remote host that changes a password. Default: passwd

Echo Command	The command on the remote host that repeats a sequence of characters to the standard output, that is, the console. Default: <code>echo</code>
Pattern Matching Command	The command on the remote host that is used for pattern matching. Default: <code>grep</code>
Policy Management Command	The command on the remote host that manages policy. Default on AIX: <code>pwdadm</code> Default on any other platform: (none)
Privilege Elevation Command	The command on the remote host that elevates the level of privilege. Default: <code>sudo</code>
Substitute User Command	The command on the remote host that acts as another user. Default: <code>su</code>
System Information Command	Default: <code>uname</code>
Who Am I Command	The command on the remote host that is used to retrieve the effective ID of the currently logged-in user. Default: <code>whoami</code>
Exit Status of Last Command	Default: <code>\$?</code> To use <code>csch</code> on AIX, set this value to <code>"\$status"</code> .

### ***Apply the Script to Update and Verify Credentials***

#### **Follow these steps:**

1. Select the **Credentials Script** tab.
2. In the Update and Verify sections, select one of the available options:

#### **TIP**

We recommend that you use the default script. If a revised script is required, contact CA Services.

#### **NOTE**

For the script to work properly, the alias for the UNIX commands must be commented in the `.bashrc` file for that account. If you plan to use an alias, please contact Broadcom services to get a revised script.

3. – **Use the default script**  
Select this option for the appliance to use the default script that is provided with the release. If changes to the script logic are required, contact CA Services.
- **Use a revised default script (requires patch)**  
Select this option to use a revised script that is provided by CA Services. Select the appropriate script from the drop-down list.
- **Use a replacement script**  
Select this option to use a replacement script. When selected, this option opens the **Replacement Script** text box. Paste the new script in the box, and try the operation.  
You might have to try more than one replacement script so the appliance conforms to your OS environment. Only edit the replacement scripts with assistance from CA Services.

#### **WARNING**

**Customer Responsibilities for Custom Scripts:** If you build custom scripts, you are responsible for the operation between the target application and the target endpoint. CA Technologies is responsible for operation up to the point where PAM passes information to the custom target application. After that point, you are responsible for how the custom script handles communication at an operational and security level.

### Specify Account Discovery Criteria for the Server (Optional)

To simplify adding target accounts for a given server and application, you can use account discovery to find accounts. The settings on this tab let you specify the criteria that the appliance uses to determine a privileged account. To limit the accounts that Account Discovery returns, select the **UID** (User ID) or the **GID** (group ID). Enter a single ID or a range of values. For the account to be discovered, the account must satisfy *both* criteria.

#### NOTE

Next Step: [Add a target account to the target application.](#)

## UNIX Target Connector CLI Configuration

This topic includes CLI commands and parameters for adding a UNIX target applications and target accounts.

### UNIX Target Connector CLI Parameters

To add a UNIX target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	unixII

#### ***Attribute.extensionType***

Required	Default Value	Valid Values
no	N/A	unixII

#### ***Attribute.sshPort***

The port that is used to connect to the UNIX host using SSH.

Required	Default Value	Valid Values
no	22	0-65535

#### ***Attribute.sshSessionTimeout***

When using the SSH communication channel, specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### ***Attribute.sshKeyPairPolicyID***

Specifies the SSH Key Policy ID which controls how keys are generated; that is, the key type (ECDSA or RSA or DSA) and length.

Required	Default Value	Valid Values
no	N/A	0-9

**Attribute.sshStrictHostKeyCheckingEnabled**

Enables or disables strict host key checking. When enabled, a connection gets established after Credential Manager compares the public key from the remote host to the public key stored in the `sshKnownHostKey` attribute. If the keys do not match, then the connection attempt is canceled.

Required	Default Value	Valid Values
no	false	true, false

**Attribute.sshKnownHostKey**

Contains the base-64 encoded public host key that is associated with the target server.

Required	Default Value	Valid Values
yes if <code>sshStrictHostKeyCheckingEnabled</code> is true	N/A	a base-64 encoded SSH public host key

**Attribute.sshKnownHostKeyFingerprint**

Contains the fingerprint of the public host key that is contained in the `sshKnownHostKey` attribute. The fingerprint is for display purposes only. It allows the user to easily compare one key with another. The fingerprint that is specified must correspond to the specified public host key.

Required	Default Value	Valid Values
no	N/A	a public key fingerprint

**Attribute.sshUseDefaultCiphers**

Specifies whether the default ciphers should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

**Attribute.sshServerToClientCiphersList**

Specifies the list of ciphers to accept on the inbound data stream from the remote host. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

**Attribute.sshClientToServerCiphersList**

Specifies the list of ciphers to use on the outbound data stream to the remote host. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

#### ***Attribute.sshDetectCiphersList***

Specifies the list of ciphers to detect when connecting to the remote host. Credential Manager does not use ciphers that are unavailable even if they are specified to use as inbound and/or outbound ciphers. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

#### ***Attribute.sshUseDefaultHashes***

Specifies whether the default hashes should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

#### ***Attribute.sshServerToClientHashesList***

Specifies the list of hashes to accept on the inbound data stream from the remote host. Hashes are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultHashes</code> is false	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

#### ***Attribute.sshClientToServerHashesList***

Specifies the list of hashes to accept on the outbound data stream from the remote host. Hashes are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultHashes</code> is false	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

#### ***Attribute.sshUseDefaultKeyExchangeAlgorithms***

Specifies whether the default key exchange methods are used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

#### ***Attribute.sshKeyExchangeAlgorithmsList***

Specifies the list of key exchange methods to use when connecting to the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
yes if sshUseDefaultKeyExchangeAlgorithms is false	diffie-hellman-group1-sha1,diffie-hellman-group14-sha1,diffie-hellman-group-exchange-sha1	A comma-separated list containing one or more of the following values: diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, diffie-hellman-group-exchange-sha1. Do not use spaces in the list.

#### ***Attribute.sshUseDefaultCompressionAlgorithms***

Specifies whether the default compression methods are used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

#### ***Attribute.sshServerToClientCompressionAlgorithmsList***

Specifies the list of compression methods to accept on the inbound data stream from the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
yes if sshUseDefaultCompressionAlgorithms is false	N/A. Do not use compression	comma-separated list containing one or more of the following values: zlib, zlib@openssh.com. Do not use spaces in the list.

#### ***Attribute.sshClientToServerCompressionAlgorithmsList***

Specifies the list of compression methods to use on the outbound data stream from the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
Yes if sshUseDefaultCompressionAlgorithms is false	N/A (do not use compression)	A comma-separated list containing one or more of the following values: zlib, zlib@openssh.com. Do not use spaces in the list.

#### ***Attribute.sshUseDefaultServerHostKeyAlgorithms***

Specifies whether the default host key types should be accepted used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

#### ***Attribute.sshServerHostKeyAlgorithmsList***

Specifies the list of host key types to accept when Credential Manager connects to the remote host.

Required	Default Value	Valid Values
yes if sshUseDefaultServerHostKeyAlgorithms is false	ssh-rsa,ssh-dss	A comma-separated list containing one or more of the following values: ssh-rsa, ssh-dss. Do not use spaces in the list.

#### ***Attribute.telnetSessionTimeout***

When using the Telnet communication channel, specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### ***Attribute.telnetPort***

The port that is used to connect to the UNIX host using Telnet.

Required	Default Value	Valid Values
no	23	0-65536

#### ***Attribute.scriptTimeout***

Specifies the amount of time in milliseconds that Credential Manager waits to receive some expected input from the remote host.

Required	Default Value	Valid Values
no	5000	5000-59999

#### ***Attribute.unixVariant***

Specifies the type of UNIX system that is installed on the target server.

Required	Default Value	Valid Values
no	GENERIC	AIX, GENERIC, HPUX, LINUX, SOLARIS or OTHER.

#### ***Attribute.useUpdateScriptType***

Specifies whether the default, revised, or replacement update script should be used. If a revised script is required, use the default script and contact CA Services.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

#### ***Attribute.revisedUpdateScriptFilename***

Specifies the name of the file containing the revised update script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	N/A	a file name

#### ***Attribute.useVerifyScriptType***

Specifies whether the default, revised or replacement verify that script should be used. If a revised script is required, use the default script and contact CA Services.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

#### ***Attribute.revisedVerifyScriptFilename***

Specifies the name of the file containing the revised verify script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	N/A	a file name

#### ***Attribute.userNameEntryPrompt***

A regular expression that matches the prompt of the remote host when it requests a user name.

Required	Default Value	Valid Values
no	(?si).*(login username):.*?	valid regular expression syntax

#### ***Attribute.passwordEntryPrompt***

A regular expression that matches the prompt of the remote host when it requests a password.

Required	Default Value	Valid Values
no	(?si).*(password(\sfor :).*)	valid regular expression syntax

#### ***Attribute.passwordConfirmationPrompt***

A regular expression that matches the prompt from the remote host when it requests that a password be confirmed.

Required	Default Value	Valid Values
no	AIX: (?si).*(new password.*? All other platforms: (?si).*(password:.*?)	valid regular expression syntax

***Attribute.passwordChangePrompt***

A regular expression that matches the prompt of the remote host when it requests that a password be changed because it has expired.

Required	Default Value	Valid Values
no	(?si).*?change your password.*?	valid regular expression syntax

***Attribute.changePasswordCommand***

The command on the remote host that is used to change a password.

Required	Default Value	Valid Values
no	passwd	depends on remote host

***Attribute.elevatePrivilegeCommand***

The command on the remote host that is used to elevate the user's level of privilege.

Required	Default Value	Valid Values
no	sudo	depends on remote host

***Attribute.substituteUserCommand***

The command on the remote host that is used to act as another user.

Required	Default Value	Valid Values
no	su	depends on remote host

***Attribute.echoCommand***

The command on the remote host that is used to repeat a sequence of characters to the standard output; that is, the console.

Required	Default Value	Valid Values
no	echo	depends on remote host

***Attribute.patternMatchingCommand***

The command on the remote host that prints lines matching a pattern.

Required	Default Value	Valid Values
no	grep	depends on remote host

***Attribute.policyManagementCommand***

The command on the remote host that is used to manage policy.

Required	Default Value	Valid Values
no	AIX: pwdadm All other platforms: N/A	depends on remote host

**Attribute.whoAmICommand**

The command on the remote host that is used to retrieve the effective ID of the currently logged-in user.

Required	Default Value	Valid Values
no	whoami	depends on remote host

**Attribute.changeFilePermissionsCommand**

The command on the remote host that is used to alter the permissions on a file.

Required	Default Value	Valid Values
no	chmod	depends on remote host

**UNIX Target Account CLI Parameters**

To add a UNIX target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

**Attribute.useOtherAccountToChangePassword**

Specifies whether to use the target account or a different account when updating the target account.

Required	Default Value	Valid Values
yes	false	true, false

**Attribute.otherAccount**

Specifies which other account to use when updating the target account.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	a valid target account ID.

**Attribute.verifyThroughOtherAccount**

Specifies whether the credentials of a second target account are used to authenticate to the remote host when verifying the target account.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is true.	false	true, false

**Attribute.passwordChangeMethod**

Specifies which method to use when updating passwords. You might need to select a method that enables the authenticated user to obtain greater privileges without being impacted by policies at the remote host, such as the minimum length of time between password updates.

Required	Default Value	Valid Values
yes if <code>Attribute.useOtherAccountToChangePassword</code> is false.	DO_NOT_USE_SUDO	DO_NOT_USE_SUDO, USE_SUDO, IS_ROOT_ACCOUNT, USE_AUTHENTICATED_SUDO

### ***Attribute.protocol***

Specifies the protocol to use for communicating with the remote host.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is false	SSH2_PASSWORD_AUTH	SSH2_PASSWORD_AUTH, SSH2_PUBLIC_KEY_AUTH, TELNET

### ***Attribute.passphrase***

The passphrase that protects the private key.

Required	Default Value	Valid Values
no	N/A	a string

### ***Attribute.publicKey***

Specifies the public key that corresponds to the target account private key. The private key is stored as its password.

Required	Default Value	Valid Values
yes if the select protocol is <code>SSH2_PUBLIC_KEY_AUTH</code>	N/A	an OpenSSH-formatted public key

### ***Attribute.keyOptions***

Specifies a list of comma-separated option specifications from the `authorized_keys` file format that is described in the OpenSSH documentation.

Required	Default Value	Valid Values
no	N/A	comma-separated list of OpenSSH key options

### **UNIX CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=www.ca.com
TargetApplication.type=unixII TargetApplication.name=UNIX
Attribute.extensionType=unixII Attribute.useDefaultUpdateScript=true
Attribute.useDefaultVerifyScript=true Attribute.unixVariant=GENERIC
```

```
cmdName=addTargetAccount TargetServer.hostName=www.ca.com TargetApplication.name=UNIX
TargetAccount.userName=account1
```

```
TargetAccount.password=password1 Attribute.protocol=SSH2_PASSWORD_AUTH
Attribute.useOtherAccountToChangePassword=false
Attribute.passwordChangeMethod=DO_NOT_USE_SUDO
```

## UNIX Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating a UNIX (aka UNIXII) Target Application using the External API.

### UNIX Target Application External API Attributes

To add or update a UNIX Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***extensionType***

Required	Default Value	Valid Values
no	N/A	unixII

#### ***sshPort***

The port that is used to connect to the UNIX host using SSH.

Required	Default Value	Valid Values
no	22	0-65535

#### ***sshSessionTimeout***

When using the SSH communication channel, specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### ***sshKeyPairPolicyID***

Specifies the SSH Key Policy ID which controls how keys are generated; that is, the key type (ECDSA or RSA or DSA) and length.

Required	Default Value	Valid Values
no	N/A	0-9

#### ***sshStrictHostKeyCheckingEnabled***

Enables or disables strict host key checking. When enabled, a connection gets established after Credential Manager compares the public key from the remote host to the public key stored in the `sshKnownHostKey` attribute. If the keys do not match, then the connection attempt is canceled.

Required	Default Value	Valid Values
no	false	true, false

***sshKnownHostKey***

Contains the base-64 encoded public host key that is associated with the target server.

Required	Default Value	Valid Values
yes if <code>sshStrictHostKeyCheckingEnabled</code> is true	N/A	a base-64 encoded SSH public host key

***sshKnownHostKeyFingerprint***

Contains the fingerprint of the public host key that is contained in the `sshKnownHostKey` attribute. The fingerprint is for display purposes only. It allows the user to easily compare one key with another. The fingerprint that is specified must correspond to the specified public host key.

Required	Default Value	Valid Values
no	N/A	a public key fingerprint

***sshUseDefaultCiphers***

Specifies whether the default ciphers should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

***sshServerToClientCiphersList***

Specifies the list of ciphers to accept on the inbound data stream from the remote host. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

***sshClientToServerCiphersList***

Specifies the list of ciphers to use on the outbound data stream to the remote host. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

***sshDetectCiphersList***

Specifies the list of ciphers to detect when connecting to the remote host. Credential Manager does not use ciphers that are unavailable even if they are specified to use as inbound and/or outbound ciphers. Ciphers are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCiphers</code> is false	aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc	A comma-separated list containing one or more of the following values: aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-ctr, arcfour, arcfour128, arcfour256. Do not use spaces in the list.

### ***sshUseDefaultHashes***

Specifies whether the default hashes should be used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

### ***sshServerToClientHashesList***

Specifies the list of hashes to accept on the inbound data stream from the remote host. Hashes are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultHashes</code> is false	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

### ***sshClientToServerHashesList***

Specifies the list of hashes to accept on the outbound data stream from the remote host. Hashes are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultHashes</code> is false	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

### ***sshUseDefaultKeyExchangeAlgorithms***

Specifies whether the default key exchange methods are used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

### ***sshKeyExchangeAlgorithmsList***

Specifies the list of key exchange methods to use when connecting to the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultKeyExchangeAlgorithms</code> is false	<code>diffie-hellman-group1-sha1,diffie-hellman-group14-sha1,diffie-hellman-group-exchange-sha1</code>	A comma-separated list containing one or more of the following values: <code>diffie-hellman-group1-sha1</code> , <code>diffie-hellman-group14-sha1</code> , <code>diffie-hellman-group-exchange-sha1</code> . Do not use spaces in the list.

### ***sshUseDefaultCompressionAlgorithms***

Specifies whether the default compression methods are used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

### ***sshServerToClientCompressionAlgorithmsList***

Specifies the list of compression methods to accept on the inbound data stream from the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
yes if <code>sshUseDefaultCompressionAlgorithms</code> is false	N/A. Do not use compression	comma-separated list containing one or more of the following values: <code>zlib</code> , <code>zlib@openssh.com</code> . Do not use spaces in the list.

### ***sshClientToServerCompressionAlgorithmsList***

Specifies the list of compression methods to use on the outbound data stream from the remote host. Methods are listed in order of priority.

Required	Default Value	Valid Values
Yes if <code>sshUseDefaultCompressionAlgorithms</code> is false	N/A (do not use compression)	A comma-separated list containing one or more of the following values: <code>zlib</code> , <code>zlib@openssh.com</code> . Do not use spaces in the list.

### ***sshUseDefaultServerHostKeyAlgorithms***

Specifies whether the default host key types should be accepted used when Credential Manager makes an SSH connection to the remote host.

Required	Default Value	Valid Values
no	true	true, false

### ***sshServerHostKeyAlgorithmsList***

Specifies the list of host key types to accept when Credential Manager connects to the remote host.

Required	Default Value	Valid Values
yes if sshUseDefaultServerHostKeyAlgorithms is false	ssh-rsa,ssh-dss	A comma-separated list containing one or more of the following values: ssh-rsa, ssh-dss. Do not use spaces in the list.

### ***telnetSessionTimeout***

When using the Telnet communication channel, specifies the amount of time in milliseconds that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

### ***telnetPort***

The port that is used to connect to the UNIX host using Telnet.

Required	Default Value	Valid Values
no	23	0-65536

### ***scriptTimeout***

Specifies the amount of time in milliseconds that Credential Manager waits to receive some expected input from the remote host.

Required	Default Value	Valid Values
no	5000	5000-59999

### ***unixVariant***

Specifies the type of UNIX system that is installed on the target server.

Required	Default Value	Valid Values
no	GENERIC	AIX, GENERIC, HPUX, LINUX, SOLARIS or OTHER.

### ***useUpdateScriptType***

Specifies whether the default, revised, or replacement update script should be used. If a revised script is required, use the default script and contact CA Services.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

### ***revisedUpdateScriptFilename***

Specifies the name of the file containing the revised update script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	N/A	a file name

### ***useVerifyScriptType***

Specifies whether the default, revised or replacement verify that script should be used. If a revised script is required, use the default script and contact CA Services.

Required	Default Value	Valid Values
no	'DEFAULT'	'DEFAULT', 'REVISED' or 'REPLACEMENT'

### ***revisedVerifyScriptFilename***

Specifies the name of the file containing the revised verify script. The contents of the file is used as the revised script. We recommend that you use the default script and contact CA Services if a revised script is required.

Required	Default Value	Valid Values
no	N/A	a file name

### ***userNameEntryPrompt***

A regular expression that matches the prompt of the remote host when it requests a user name.

Required	Default Value	Valid Values
no	(?si).*(login username):.*?	valid regular expression syntax

### ***passwordEntryPrompt***

A regular expression that matches the prompt of the remote host when it requests a password.

Required	Default Value	Valid Values
no	(?si).*(password (?for :)).*?	valid regular expression syntax

### ***passwordConfirmationPrompt***

A regular expression that matches the prompt from the remote host when it requests that a password be confirmed.

Required	Default Value	Valid Values
no	AIX: (?si).*(new password).*? All other platforms: (?si).*(password:.*?)	valid regular expression syntax

### ***passwordChangePrompt***

A regular expression that matches the prompt of the remote host when it requests that a password be changed because it has expired.

Required	Default Value	Valid Values
no	(?si).*(change your password).*?	valid regular expression syntax

***changePasswordCommand***

The command on the remote host that is used to change a password.

Required	Default Value	Valid Values
no	passwd	depends on remote host

***elevatePrivilegeCommand***

The command on the remote host that is used to elevate the user's level of privilege.

Required	Default Value	Valid Values
no	sudo	depends on remote host

***substituteUserCommand***

The command on the remote host that is used to act as another user.

Required	Default Value	Valid Values
no	su	depends on remote host

***echoCommand***

The command on the remote host that is used to repeat a sequence of characters to the standard output; that is, the console.

Required	Default Value	Valid Values
no	echo	depends on remote host

***patternMatchingCommand***

The command on the remote host that prints lines matching a pattern.

Required	Default Value	Valid Values
no	grep	depends on remote host

***policyManagementCommand***

The command on the remote host that is used to manage policy.

Required	Default Value	Valid Values
no	AIX: pwdadm All other platforms: N/A	depends on remote host

***whoAmICommand***

The command on the remote host that is used to retrieve the effective ID of the currently logged-in user.

Required	Default Value	Valid Values
no	whoami	depends on remote host

***changeFilePermissionsCommand***

The command on the remote host that is used to alter the permissions on a file.

Required	Default Value	Valid Values
no	chmod	depends on remote host

### **UNIX Target Account External API Attributes**

To add a UNIX target account that uses the target connector, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account when updating the target account.

Required	Default Value	Valid Values
yes	false	true, false

#### ***otherAccount***

Specifies which other account to use when updating the target account.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is true.	N/A	a valid target account ID.

#### ***verifyThroughOtherAccount***

Specifies whether the credentials of a second target account are used to authenticate to the remote host when verifying the target account.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is true.	false	true, false

#### ***passwordChangeMethod***

Specifies which method to use when updating passwords. You might need to select a method that enables the authenticated user to obtain greater privileges without being impacted by policies at the remote host, such as the minimum length of time between password updates.

Required	Default Value	Valid Values
yes if <code>useOtherAccountToChangePassword</code> is false.	DO_NOT_USE_SUDO	DO_NOT_USE_SUDO, USE_SUDO, IS_ROOT_ACCOUNT, USE_AUTHENTICATED_SUDO

#### ***protocol***

Specifies the protocol to use for communicating with the remote host.

Required	Default Value	Valid Values
yes if useOtherAccountToChangePassword is false	SSH2_PASSWORD_AUTH	SSH2_PASSWORD_AUTH, SSH2_PUBLIC_KEY_AUTH, TELNET

### ***passphrase***

The passphrase that protects the private key.

Required	Default Value	Valid Values
no	N/A	a string

### ***publicKey***

Specifies the public key that corresponds to the target account private key. The private key is stored as its password.

Required	Default Value	Valid Values
yes if the select protocol is SSH2_PUBLIC_KEY_AUTH	N/A	an OpenSSH-formatted public key

### ***keyOptions***

Specifies a list of comma-separated option specifications from the authorized\_keys file format that is described in the OpenSSH documentation.

Required	Default Value	Valid Values
no	N/A	comma-separated list of OpenSSH key options

## **UNIX (UNIXII) Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "UnixApp",
  "applicationType": "unixII",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "attributes": {
    "passwordEntryPrompt": "",
    "sshSessionTimeout": "",
    "echoCommand": "",
    "telnetSessionTimeout": "",
    "useUpdateScriptType": "DEFAULT",
    "substituteUserCommand": "",
    "acctDiscGidValue": "",
    "acctDiscUidRangeLow": "",
    "acctDiscGidRangeLow": "",
    "sshUseDefaultKeyExchangeAlgorithms": "true",
    "sshKeyPairPolicyID": "",
  }
}
```

```

    "acctDiscUidValue": "",
    "passwordConfirmationPrompt": "",
    "changeFilePermissionsCommand": "",
    "sshPort": "",
    "changePasswordCommand": "",
    "useVerifyScriptType": "DEFAULT",
    "sshServerToClientCiphersList": "",
    "elevatePrivilegeCommand": "",
    "sshKnownHostKey": "",
    "sshKnownHostKeyFingerprint": "",
    "exitStatusOfLastCommand": "",
    "sshServerToClientCompressionAlgorithmsList": "",
    "extensionType": "unixII",
    "systemInfoCommand": "",
    "patternMatchingCommand": "",
    "acctDiscGidRangeHigh": "",
    "acctDiscGidType": "",
    "sshDetectCiphersList": "",
    "sshClientToServerCiphersList": "",
    "sshClientToServerCompressionAlgorithmsList": "",
    "passwordChangePrompt": "",
    "acctDiscUidType": "",
    "acctDiscUidRangeHigh": "",
    "sshUseDefaultCiphers": "true",
    "sshServerHostKeyAlgorithmsList": "",
    "userNameEntryPrompt": "",
    "sshUseDefaultHashes": "true",
    "unixVariant": "GENERIC",
    "whoAmICommand": "",
    "telnetPort": "",
    "sshKeyExchangeAlgorithmsList": "",
    "policyManagementCommand": "",

    "descriptor2": "",
    "discoveryGlobal": "f",
    "descriptor1": "",
    "useOtherAccountToChangePassword": "false",
    "passwordChangeMethod": "DO_NOT_USE_SUDO"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
}
```

**Add a VMware ESX/ESXi Target Connector**

Use this VMware ESX/ESXi connector to synchronize passwords of ESX/ESXi target accounts. This target connector uses WSDL over SSL.

To add the target connector using the CLI, see [VMware ESX/ESXi CLI Target Configuration](#).

To add the target connector using the external API, see [VMware ESX/ESXi Target Connector External API Configuration](#).

**Add the Target Application and Connector**

**Follow these steps in the UI:**

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.
4. In the **Application Type** field, select **VMware ESX/ESXi**.
5. (Optional) Select a password composition policy.

If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.

6. Select the VMware ESX/ESXi tab and specify the SSL port. The default is 443.
7. Select **OK**.

#### NOTE

Next Step: [Add a target account to the target application.](#)

## VMware ESX/ESXi Target Connector CLI Configuration

This topic includes CLI commands and parameters for adding a VMware ESX/ESXi target application and target account:

### VMware ESX/ESXi Target Application CLI Parameters

To add a ESX/ESXi target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	vmware

#### ***Attribute.extensionType***

Required	Default Value	Valid Values
yes	N/A	vmware

#### ***Attribute.sslPort***

The target application port.

Required	Default Value	Valid Values
yes	443	0-65535

### VMware ESX/ESXi Target Account CLI Parameters

To add a target account that uses the VMWARE ESX/ESXi target connector, use the [addTargetAccount](#) command and the following command parameters:

#### ***Attribute.extensionType***

Required	Default Value	Valid Values
yes	N/A	vmware

#### ***Attribute.useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

**Attribute.otherAccount**

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes Attribute.useOtherAccountToChangePassword is true.	N/A	A valid target account ID.

**VMware ESX/ESXi CLI Example**

```
cmdName=addTargetApplication
  TargetServer.hostName=myhostname.mydomain.com TargetApplication.name=myESXi

TargetApplication.type=vmware Attribute.extensionType=vmware Attribute.sslPort=443
```

```
cmdName=addTargetAccount
  TargetServer.hostName=myhostname.mydomain.com TargetApplication.name=myESXi

TargetAccount.userName=root TargetAccount.password=P@ssw0rd
  TargetAccount.cacheAllow=true

TargetAccount.cacheDuration=19 Attribute.extensionType=vmware
  Attribute.useOtherAccountToChangePassword=false
```

**VMware ESX/ESXi Target Connector External API Configuration**

This topic describes the required and supported Attributes used when adding or updating a VMware ESX/ESXi Target Application using the External API.

**VMware ESX/ESXi Target Application External API Attributes**

To add or update a VMware ESX/ESXi Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

**extensionType**

Required	Default Value	Valid Values
yes	N/A	vmwa

**sslPort**

The target application port.

Required	Default Value	Valid Values
yes	443	0-65535

### **VMware ESX/ESXi Target Account External API Attributes**

To add a VMware ESX/ESXi target account that uses the target connector, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### ***extensionType***

Required	Default Value	Valid Values
yes	N/A	vmware

#### ***useOtherAccountToChangePassword***

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

#### ***otherAccount***

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
yes useOtherAccountToChangePassword is true.	N/A	A valid target account ID.

### **VMware ESX/ESXi Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "vmwareApp",
  "applicationType": "vmware",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "attributes": {
    "mbean": "",
    "instance": "",
    "port": "",
    "extensionType": "vmware",
    "sslEnabled": "",
    "sslPort": "443"
  },
  "passwordCompositionPolicyId": null
}
```

### **VMware ESX/ESXi Target Account External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/targetAccounts
```

```
{
  "accountName": "vmwareAcc95",
  "attributes": {
    "otherAccount": "",
    "descriptor2": "",
    "discoveryGlobal": "f",
    "descriptor1": "",
    "discoveryAllowed": "f",
    "useOtherAccountToChangePassword": "false"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
}
```

**NOTE**

`useOtherAccountToChangePassword : "false"` false/true values only.

## Add a VMware NSX Controller Target Connector

**WARNING**

VMware NSX API support is deprecated and will be removed in a subsequent version of PAM.

Use the VMware NSX Controller target connector to provide synchronization support for NSX controller target accounts.

To add the target connector using the CLI, see [VMware NSX Controller CLI Target Connector](#).

To add the target connector using the external API, see [VMware NSX Controller Target Connector External API Configuration](#).

### Add the Target Application and Connector

#### Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.
4. In the **Application Type** field, select **VMware NXS Controller**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
6. Select the **VMware NXS Controller** tab and specify the following settings:

- **Script Timeout:** Specifies the amount of time in milliseconds that Credential Manager waits to receive some expected input from the remote host. Valid values are 5000-99999. Default: **5000**
- **Port:** If you are using an SSL connection, indicate the port that is used to connect to the UNIX host using SSH. Valid values are 0-65535. Default: 22
- **Communications Timeout:** If you are using an SSH connection, specify the amount of time in milliseconds that Credential Manager waits for the remote host to respond. Valid values are 1000-99999. Default: 5000

7. Select **OK** to save the changes.

#### NOTE

**Next Step:** [Add a target account to the target application.](#)

## VMware NSX Controller Target Connector CLI Configuration

This topic includes CLI commands and parameters for adding VMware NSX Controller target applications and target accounts:

### VMware NSX Controller Target Application CLI Parameters

To add a VMware NSX Controller target application and connector, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	nsxcontroller

#### ***Attribute.sshPort***

The port that is used to connect to the UNIX host using SSH.

Required	Default Value	Valid Values
no	22	0-65535

#### ***Attribute.sshSessionTimeout***

When using the SSH communication channel, specifies the amount of time in milliseconds that Credential Manager waits for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### ***Attribute.scriptTimeout***

Specifies the amount of time in milliseconds that Credential Manager waits to receive some expected input from the remote host.

Required	Default Value	Valid Values
no	5000	5000-59999

## VMware NSX Controller Target Account CLI Parameters

When using the CLI to add a VMware NSX Controller target account, this target connector does not require any parameters.

### VMware NSX Controller CLI Example

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myNXS
```

```
TargetApplication.type=nsxcontroller Attribute.extensionType=nsxcontroller
Attribute.sshPort=22
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myNSX
```

```
TargetAccount.userName=root TargetAccount.password=P@ssw0rd
TargetAccount.cacheAllow=true TargetAccount.cacheDuration=19
```

## VMware NSX Controller Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating a VMware NSX Controller Target Application using the External API:

### VMware NSX Controller Target Application External API Attributes

To add or update a xxx Target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call:

#### **sshPort**

The port that is used to connect to the UNIX host using SSH.

Required	Default Value	Valid Values
no	22	0-65535

#### **sshSessionTimeout**

When using the SSH communication channel, specifies the amount of time in milliseconds that Credential Manager waits for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### **scriptTimeout**

Specifies the amount of time in milliseconds that Credential Manager waits to receive some expected input from the remote host.

Required	Default Value	Valid Values
no	5000	5000-59999

### **VMware NSX Controller Target Account External API Attributes**

When using the API to add a VMware NSX Controller target account, this target connector does not have any additional attributes.

### **VMware NSX Controller Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "NSXControllerApp",
  "applicationType": "nsxcontroller",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "attributes": {
    "sshPort": "",
    "scriptTimeout": "",
    "sshSessionTimeout": ""
  },
  "passwordCompositionPolicyId": null
}
```

### **VMware NSX Controller Target Account External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
  "accountName": "nsxControllerAcc",
  "attributes": {
    "descriptor2": "",
    "discoveryGlobal": "f",
    "descriptor1": "",
    "discoveryAllowed": "f"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
}
```

## Add a VMware NSX Proxy Target Connector

This target connector provides synchronization support for NSX proxy target accounts. Use this VMware NSX Proxy connector to synchronize passwords of NSX target accounts.

To add the target connector using the CLI, see [NSX Proxy Target Connector CLI Configuration](#).

To add the target connector using the external API, see [VMware NSX Proxy Target Connector External API Configuration](#).

### Add the Target Application and Connector

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.
4. In the **Application Type** field, select **VMware NSX Proxy**.  
No VMware NSX Proxy tab displays; there are no settings to configure.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
6. Select **OK**.

#### NOTE

Next Step: [Add a target account to the target application](#).

## VMware NSX Proxy Target Connector CLI Configuration

For the NSX Proxy target connector, there are no additional parameters to add a target application or a target account.

### VMware NSX Proxy CLI Example

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myESXi
```

```
TargetApplication.type=nsxproxy Attribute.extensionType=nsxproxy
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myNSX_Proxy
```

```
TargetAccount.userName=root TargetAccount.password=P@ssw0rd
TargetAccount.cacheAllow=true TargetAccount.cacheDuration=19
```

## VMware NSX Proxy Target Connector External API Configuration

For the NSX Proxy target application and account, there are no additional attributes to add a target application or a target account.

### **VMware NSX Proxy Target Application External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "NSXProxyApp",
  "applicationType": "nsxproxy",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "passwordCompositionPolicyId": null
}
```

### **VMware NSX Proxy Target Account External API Example**

```
POST /api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
  "accountName": "nsxProxyAcc",
  "attributes": {
    "descriptor2": "",
    "discoveryGlobal": "f",
    "descriptor1": "",
    "discoveryAllowed": "f"
  },
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "sample",
  "passwordViewPolicyId": 1000,
  "privileged": "t",
  "synchronize": "f",
  "useAliasNameParameter": "f"
}
```

## **Add a WebLogic Target Connector**

This target connector provides password synchronization functionality for Oracle WebLogic v10 application servers.

To add the target connector using the CLI, see [WebLogic Target Connector CLI Configuration](#).

### **Add the Target Application and Connector**

**Follow these steps in the UI:**

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name. Select the magnifying glass to pick the target server
  - Device Name
  - Application Name. Application names must be unique for a given target server.

4. In the **Application Type** field, select **WebLogic**.
5. (Optional) Select a password composition policy.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions
6. On the WebLogic tab, configure the following fields:
  - **Server Port:** The port that connects to the WebLogic server. Valid values: 0-65535. Default value: 7001
  - **MBean:** Enter the object name of the *managed bean (MBean)*. An MBean is a *JavaBean* that provides a *Java Management Extensions (JMX)* interface. The format is *domain:key=property*.
7. Select **OK**.

**NOTE**

Next Step: [Add a target account to the target application.](#)

## WebLogic Target Connector CLI Configuration

This topic contains the parameters for adding WebLogic target applications and target accounts:

### WebLogic Target Application CLI Parameters

To add a WebLogic target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### **TargetApplication.type**

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	weblogic10

#### **Attribute.extensionType**

Required	Default Value	Valid Values
yes	N/A	weblogic10

#### **Attribute.port**

The port that is used to connect to the WebLogic server.

Required	Default Value	Valid Values
yes	N/A	0-65535

### WebLogic Target Account CLI Parameters

To add a WebLogic target account that uses the target connector, use the [addTargetAccount](#) command and the following command parameters:

#### **Attribute.extensionType**

Required	Default Value	Valid Values
yes	N/A	weblogic10

**Attribute.realm**

Required	Default Value	Valid Values
yes	N/A	valid realm name

**Attribute.useOtherAccountToChangePassword**

Specifies whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

**Attribute.otherAccount**

Specifies which other account to use to perform password change requests.

Required	Default Value	Valid Values
Yes, if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

**WebLogic CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=weblogic10
```

```
TargetApplication.type=weblogic10 Attribute.extensionType=weblogic10 Attribute.port=7001
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=weblogic10
```

```
TargetAccount.userName=admin TargetAccount.password=p@ssw0rd
TargetAccount.cacheAllow=true
```

```
TargetAccount.cacheDuration=21 Attribute.extensionType=weblogic10
Attribute.realm=myrealm
```

```
Attribute.useOtherAccountToChangePassword=false
```

## Add a Windows SSH Key Target Connector

Use the PAM Windows SSH Key target connector to manage local account credentials on Windows systems using key-based SSH authentication.

The PAM Windows SSH Key target connector provides a highly secure solution for managing local privileged credentials on supported SSH-enabled Windows systems.

### NOTE

For a list of Windows versions that support the Windows SSH Password target connectors, see [Supported Platforms](#).

### TIP

The following alternative Windows connectors are available:

- **Windows SSH Password Connector:** Manages local Windows account credentials using password-based SSH authentication (less secure, also requires supported, SSH-enabled target system).
- **Windows Remote Target Connector:** Manages local Windows account credentials using the Windows Remote Desktop Service API (less secure than either SSH connector).
- **Windows Proxy Connector:** Functions similar to the Windows Remote Connector but requires the connector to be installed on a remote server in your target domain.

To add the target connector using the CLI, see [Windows SSH Key Target Connector CLI Configuration](#).

To add the target connector using the external API, see [Windows SSH Key Target Connector External API Configuration](#).

### IMPORTANT

Do not configure scheduled jobs that change more than one Windows SSH Key target account using the **Use Same Password For All** option. This is not a supported use case and will result in errors.

## Add the Target Application and Connector

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - **Host Name:** Select the magnifying glass to pick the target server.
  - **Device Name:** The name of the target server. Populated dynamically when you pick the target server.
  - **Application Name:** A unique application name for the specified target server.
4. In the **Application Type** field, select **Windows SSH Key**.
5. Select the **SSH Connection** tab and complete the following fields:
  - **Port:** Enter the port that connects to the Windows host using SSH. The default value is 22.
  - **Communication Timeout:** Specify the amount of time that PAM waits for communication from the Windows host before ending the connection (in ms). The default value is 60000.
  - **SSH Key Pair Policy:** Specify the SSH key policy PAM uses to generate SSH key pairs. The key policy specifies the characteristics for the key pair, specifically the cryptographic algorithm, and the key size. When you update the target account that uses the key pair, the appliance pushes the public key to the target device.  
To configure or edit an SSH key policy, see [Configure SSH Key Pair Policies](#).  
Select the key pair that secures the connection. For more information, see [Configure SSH Key Pair Policies](#).
  - **Enable strict host key checking** (Optional) Select this option to protect against man-in-the-middle attacks by validating an SSH host key from the target server (specified in the required **Known Host Key** field) when establishing a connection.

**NOTE**

If a man-in-the-middle attack occurs, the malicious server to which your connection is redirected does not have the same SSH host key as the intended server and the connection is rejected.

- **Known Host Key** (Required if strict host key checking is enabled): Specify the base64 host key value of one of the SSH host keys configured on the target server. For example:

```
AAAAC3NzaC11ZD11NTE5AAAAIGq3L+ECE5S8CUJyZ0jiXbZReY7G/boxDUMrYlhrlK9w
```

**NOTE**

To obtain an SSH host key, you can use the [ssh-keyscan](#) utility on the target device. For example, `ssh-keyscan 127.0.0.1 2>$null` returns the IP address, host Key type and base64 host key value for all configured SSH host keys.

- **SHA256 Fingerprint** (Optional, only applicable if **Enable strict host key checking** is enabled): Specify a SHA256 fingerprint generated from the SSH host key on the target server to confirm that the value that you entered in the **Known Host Key** field matches. If the values do not match, PAM displays a dialog with an error message like the following:

```
PAM-CF-0005: Failed to validate target connector attributes. PAM-WS- 0103:Host key fingerprint does not match computed fingerprint: VpszjfaB00J5N43NQsawv1DsdeXyTzAd1bWLCak6GZl=..
```

**NOTE**

To obtain a SHA256 fingerprint, you can use the [ssh-keyscan](#) utility on the target device. For example, `ssh-keyscan 127.0.0.1 2>$null | ssh-keygen -E md5 -lf -` returns all the configured SSH host Keys and their SHA256 fingerprints.

6. Optionally, use the **Ciphers**, **Hashes**, **Key Exchange Methods**, and **Server Host Key Types** tabs to configure specific encryption algorithms to use when making an SSH connection to the remote host.

**NOTE**

By default, a **Use supported...** option is set on each tab, configuring support for all available encryption algorithms, as shown in the following screenshot:

Application	SSH Connection	Cipher	Hash	Key Exchange	Server Host Key Type
Use supported ciphers: <input checked="" type="checkbox"/>					
Use aes128-gcm: <input type="checkbox"/>					
Use aes128-ctr: <input type="checkbox"/>					
Use aes128-cbc (non FIPS): <input type="checkbox"/>					
Use aes192-ctr (non FIPS): <input type="checkbox"/>					
Use aes192-cbc (non FIPS): <input type="checkbox"/>					
Use aes256-gcm: <input type="checkbox"/>					
Use aes256-ctr: <input type="checkbox"/>					
Use aes256-cbc: <input type="checkbox"/>					

**Important:** if you unset the **Use supported...** option, you *must* select at least one of the listed encryption algorithms.

- **Cipher Tab:** Unset the **Use supported ciphers** option to select specific ciphers.
- **Hash Tab:** Unset the **Use supported hashes** option to select specific hashes.
- **Key Exchange Tab:** Unset the **Use supported key exchange methods** option to select specific key exchange methods.
- **Server Host Key Type Tab:** Unset the **Use supported server host key types** option to select specific server host key types.

**NOTE**

Encryption standards continue to evolve with new vulnerabilities that are identified in what were previously accepted algorithms. Progress is also made with other more-secure cipher, hash, key exchange, or server host key options added to common utilities used for establishing secure communication channels. When upgrading PAM, be sure to consider any changes in the available more-secure cipher algorithms. Less secure ciphers, hashes, key exchanges, or server host keys algorithms are no longer listed, but continue working. However, they may be subject to removal in a future release.

7. Select **OK**.

**NOTE**

**Next Step:** [Add a Windows SSH Key target account.](#)

## Windows SSH Key Target Connector CLI Configuration

This topic contains the CLI parameters for adding a Windows SSH Key target application and target account:

### Windows SSH Key Target Connector CLI Parameters

To add a Windows SSH Key target application using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	windowsSshKey

#### ***Attribute.extensionType***

Required	Default Value	Valid Values
no	N/A	windowsSshKey

#### ***Attribute.sshPort***

The TCP port used to connect to the Windows host using SSH.

Required	Default Value	Valid Values
yes	22	0-65535

#### ***Attribute.sshSessionTimeout***

When using the SSH communication channel, specifies the amount of time in milliseconds, that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	60000	1000-99999

#### ***Attribute.sshKeyPairPolicyID***

Specifies the SSH Key Policy ID which controls how keys are generated; that is, the key type (ECDSA or RSA or DSA) and length.

Required	Default Value	Valid Values
no	N/A	Integer that matches the ID of the required SSH Key Pair Policy.

#### ***Attribute.sshStrictHostKeyCheckingEnabled***

Enables or disables strict host key checking. When enabled, a connection gets established after Credential Manager compares the public key from the remote host to the public key stored in the `sshKnownHostKey` attribute. If the keys do not match, then the connection attempt is canceled.

Strict host key checking helps to provide protection from man-in-the-middle attacks. If such an attack happens, the malicious server you are redirected to would not have the same SSH host keys as the intended server. Thus attempts to connect to such a server would fail with strict host key checking.

Required	Default Value	Valid Values
no	false	true, false

#### ***Attribute.sshKnownHostKey***

Contains the base-64 encoded public host key that is associated with the target server.

Required	Default Value	Valid Values
yes if <code>sshStrictHostKeyCheckingEnabled</code> is true	N/A	a base-64 encoded SSH public host key

#### ***Attribute.sshKnownHostKeyFingerprint***

Contains the SHA-256 fingerprint of the public host key that is contained in the `sshKnownHostKey` attribute. The fingerprint that is specified must correspond to the specified public host key. This attribute is optional when you specify a Known Host Key. Specifying this attributes value can help you ensure that you did not make a typographical error entering the Known Host Key.

Required	Default Value	Valid Values
no	N/A	a valid public key fingerprint

#### ***Attribute.sshUseDefaultCiphers***

Specifies the default ciphers to used when Credential Manager makes an SSH connection to the remote host.

When set to true, Credential Manager uses all supported ciphers, ignoring the setting to use specific ciphers. When set to false, Credential Manager only uses the selected ciphers.

Required	Default Value	Valid Values
no	true	true, false

### ***Ciphers That Support FIPS***

The following list displays the cipher algorithms that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useCipher_aes128-gcm</li> <li>Attribute.useCipher_aes128-ctr</li> <li>Attribute.useCipher_aes256-gcm</li> <li>Attribute.useCipher_aes256-ctr</li> <li>Attribute.useCipher_aes256-cbc</li> </ul>	no	false	true, false

### ***Ciphers That Do NOT Support FIPS***

The following list includes the algorithms that use a non-FIPS method, and are ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useCipher_aes128-cbc</li> <li>Attribute.useCipher_aes192-ctr</li> <li>Attribute.useCipher_aes192-cbc</li> </ul>	no	false	true, false

### ***Attribute.sshUseDefaultHashes***

Specifies whether the default hashes should be used when Credential Manager makes an SSH connection to the remote host.

When set to true, Credential Manager uses all supported hashes and ignores the setting to use specific hashes. When set to false, Credential Manager only uses the selected hashes.

Required	Default Value	Valid Values
no	true	true, false

### ***Hashes That Support FIPS***

The following list displays the hashes that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useHash_hmac-sha2-256</li> <li>Attribute.useHash_hmac-sha2-512</li> </ul>	no	false	true, false

### ***Hashes That Do NOT Use FIPS***

The following hash uses a non-FIPS method, and is ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
Attribute.useHash_hmac-sha1	no	false	true, false

**Attribute.sshUseDefaultKeyExchangeAlgorithms**

Specifies whether the default key exchange methods are used when Credential Manager makes an SSH connection to the remote host. When set to true, the Credential Manager uses all supported key exchange methods, and ignore the setting to use specific key exchange methods. When set to false, the Credential Manager only uses the selected key exchange methods.

Required	Default Value	Valid Values
no	true	true, false

**These Key Exchange Methods Support FIPS**

The following list of displays the Key Exchange Methods that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useKeyExchange_curve25519-sha256</li> <li>Attribute.useKeyExchange_ecdh-sha2-nistp384</li> <li>Attribute.useKeyExchange_ecdh-sha2-nistp256</li> <li>Attribute.useKeyExchange_ecdh-sha2-nistp521</li> <li>Attribute.useKeyExchange_diffie-hellman-group14-sha1</li> <li>Attribute.useKeyExchange_diffie-hellman-group16-sha512</li> <li>Attribute.useKeyExchange_diffie-hellman-group18-sha512</li> <li>Attribute.useKeyExchange_diffie-hellman-group-exchange-sha256</li> </ul>	no	false	true, false

**These Key Exchange Methods Do NOT Support FIPS**

The following Key Exchange Methods use a non-FIPS method, and are ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useKeyExchange_curve25519-sha256</li> <li>Attribute.useKeyExchange_diffie-hellman-group14-sha256</li> </ul>	no	true	true, false

**Attribute.sshUseDefaultServerHostKeyAlgorithms**

Specifies whether the default host key types should be accepted used when Credential Manager makes an SSH connection to the remote host. When set to true, the Credential Manager uses all supported server host key types, and ignore the setting to use specific ones. When set to false, the Credential Manager uses only the selected server host key types.

Required	Default Value	Valid Values
no	true	true, false

**These Host Key Types Support FIPS**

The following list displays the Host Key Types that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useHostKeyType_ecdsa-sha2-nistp384</li> <li>Attribute.useHostKeyType_ecdsa-sha2-nistp256</li> <li>Attribute.useHostKeyType_ecdsa-sha2-nistp521</li> <li>Attribute.useHostKeyType_rsa-sha2-512</li> <li>Attribute.useHostKeyType_rsa-sha2-256</li> <li>Attribute.useHostKeyType_ssh-rsa</li> </ul>	no	false	true, false

### ***These Host Key Types Do NOT Support FIPS***

The following Host Key Type uses a non-FIPS method, and is ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
Attribute.useHostKeyType_ssh-ed25519	no	false	true, false

### **Windows SSH Key Target Application CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName={host name} TargetApplication.type=windowsSshKey
"TargetApplication.name=Windows SSH Key App" Attribute.sshPort=22
```

### **Windows SSH Key Target Account CLI Example**

```
cmdName=addTargetAccount TargetServer.hostName={hostname} "TargetApplication.name=Windows SSH Key App"
TargetAccount.privileged=true TargetAccount.synchronize=false TargetAccount.userName=WinSshKeyAct
TargetAccount.password=_generate_pass_ Attribute.changePasswordAccount={other account id}
Attribute.changeProcess=CHANGE_PROCESS_USE_DIFFERENT_ACCOUNT_TO_CHANGE_PASSWORD
```

## **Windows SSH Key Target Connector External API Configuration**

This topic describes the required and supported Attributes used when adding or updating a Windows SSH Key target application using the External API.

### **Windows SSH Key Target Application External API Attributes**

To add or update a Windows SSH Key target application, use the following properties as members of the `attributes` associative array included in the `body` parameter of the `/api.php/v1/devices.json/{id}/targetApplications` External API method:

:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	windowsSshKey

**extensionType**

Required	Default Value	Valid Values
no	N/A	windowsSshKey

**sshPort**

The TCP port used to connect to the Windows host using SSH.

Required	Default Value	Valid Values
yes	22	0-65535

**sshSessionTimeout**

When using the SSH communication channel, specifies the amount of time in milliseconds, that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	60000	1000-99999

**sshKeyPairPolicyID**

Specifies the SSH Key Policy ID which controls how keys are generated; that is, the key type (ECDSA or RSA) and length.

Required	Default Value	Valid Values
no	N/A	Integer that matches the ID of the required SSH Key Pair Policy.

**sshStrictHostKeyCheckingEnabled**

Enables or disables strict host key checking. When enabled, a connection gets established after Credential Manager compares the public key from the remote host to the public key stored in the `sshKnownHostKey` attribute. If the keys do not match, then the connection attempt is canceled.

Strict host key checking helps to provide protection from man-in-the-middle attacks. If such an attack happens, the malicious server you are redirected to would not have the same SSH host keys as the intended server. Thus attempts to connect to such a server would fail with strict host key checking.

Required	Default Value	Valid Values
no	false	true, false

**sshKnownHostKey**

Contains the base-64 encoded public host key that is associated with the target server.

Required	Default Value	Valid Values
yes if <code>sshStrictHostKeyCheckingEnabled</code> is true	N/A	a base-64 encoded SSH public host key

**sshKnownHostKeyFingerprint**

Contains the SHA-256 fingerprint of the public host key that is contained in the `sshKnownHostKey` attribute. The fingerprint that is specified must correspond to the specified public host key. This attribute is optional when you specify a Known Host Key. Specifying this attributes value can help you ensure that you did not make a typographical error entering the Known Host Key.

Required	Default Value	Valid Values
no	N/A	a valid public key fingerprint

### ***sshUseDefaultCiphers***

Specifies the default ciphers to used when Credential Manager makes an SSH connection to the remote host.

When set to true, Credential Manager uses all supported ciphers, ignoring the setting to use specific ciphers. When set to false, Credential Manager only uses the selected ciphers.

Required	Default Value	Valid Values
no	true	true, false

### ***Ciphers That Support FIPS***

The following list displays the cipher algorithms that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useCipher_aes128-gcm</li> <li>useCipher_aes128-ctr</li> <li>useCipher_aes256-gcm</li> <li>useCipher_aes256-ctr</li> <li>useCipher_aes256-cbc</li> </ul>	no	false	true, false

### ***Ciphers That Do NOT Support FIPS***

The following list includes the algorithms that use a non-FIPS method, and are ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useCipher_aes128-cbc</li> <li>useCipher_aes192-ctr</li> <li>useCipher_aes192-cbc</li> </ul>	no	false	true, false

### ***sshUseDefaultHashes***

Specifies whether the default hashes should be used when Credential Manager makes an SSH connection to the remote host.

When set to true, Credential Manager uses all supported hashes and ignores the setting to use specific hashes. When set to false, Credential Manager only uses the selected hashes.

Required	Default Value	Valid Values
no	true	true, false

### ***Hashes That Support FIPS***

The following list displays the hashes that support FIPS:

Hash Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useHash_hmac-sha2-256</li> <li>useHash_hmac-sha2-512</li> </ul>	no	false	true, false

### ***Hashes That Do NOT Use FIPS***

The following hash uses a non-FIPS method, and is ignored if you are running in FIPS mode:

Hash Name	Required	Default Value	Valid Values
useHash_hmac-sha1	no	false	true, false

### ***sshUseDefaultKeyExchangeAlgorithms***

Specifies whether the default key exchange methods are used when Credential Manager makes an SSH connection to the remote host. When set to true, the Credential Manager uses all supported key exchange methods, and ignore the setting to use specific key exchange methods. When set to false, the Credential Manager only uses the selected key exchange methods.

Required	Default Value	Valid Values
no	true	true, false

### ***Key Exchange Methods That Support FIPS***

The following list of displays the Key Exchange Methods that support FIPS:

Key Exchange Method	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useKeyExchange_curve25519-sha256</li> <li>useKeyExchange_ecdh-sha2-nistp384</li> <li>useKeyExchange_ecdh-sha2-nistp256</li> <li>useKeyExchange_ecdh-sha2-nistp521</li> <li>useKeyExchange_diffie-hellman-group14-sha1</li> <li>useKeyExchange_diffie-hellman-group16-sha512</li> <li>useKeyExchange_diffie-hellman-group18-sha512</li> <li>useKeyExchange_diffie-hellman-group-exchange-sha256</li> </ul>	no	false	true, false

### ***Key Exchange Methods That Do NOT Support FIPS***

The following Key Exchange Methods use a non-FIPS method, and are ignored if you are running in FIPS mode:

Key Exchange Method	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useKeyExchange_curve25519-sha256</li> <li>useKeyExchange_diffie-hellman-group14-sha256</li> </ul>	no	true	true, false

### ***sshUseDefaultServerHostKeyAlgorithms***

Specifies whether the default host key types should be accepted used when Credential Manager makes an SSH connection to the remote host. When set to true, the Credential Manager uses all supported server host key types, and ignore the setting to use specific ones. When set to false, the Credential Manager uses only the selected server host key types.

Required	Default Value	Valid Values
no	true	true, false

### **Host Key Types That Support FIPS**

The following list displays the Host Key Types that support FIPS:

Host Key Type	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>• useHostKeyType_ecdsa-sha2-nistp384</li> <li>• useHostKeyType_ecdsa-sha2-nistp256</li> <li>• useHostKeyType_ecdsa-sha2-nistp521</li> <li>• useHostKeyType_rsa-sha2-512</li> <li>• useHostKeyType_rsa-sha2-256</li> <li>• useHostKeyType_ssh-rsa</li> </ul>	no	false	true, false

### **Host Key Types Do NOT Support FIPS**

The following Host Key Type use a non-FIPS method, and is ignored if you are running in FIPS mode:

Host Key Type	Required	Default Value	Valid Values
useHostKeyType_ssh-ed25519	no	false	true, fals

### **Windows SSH Key Target Application External API Example**

```
POST api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "Windows SSH Key App",
  "applicationType": "windowsSshKey",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "sshKeyPairPolicyId": null,
  "attributes": {
    "extensionType": "windowsSshKey",
    "sshPort": "22",
    "sshSessionTimeout": "60000",
    "sshStrictHostKeyCheckingEnabled": "false",
    "sshKnownHostKey": "",
    "sshKnownHostKeyFingerprint": "",
    "sshUseDefaultCiphers": "true",
    "useCipher_aes128-gcm": "false",
    "useCipher_aes128-ctr": "false",
    "useCipher_aes128-cbc": "false",
    "useCipher_aes192-ctr": "false",
    "useCipher_aes192-cbc": "false",
```

```

    "useCipher_aes256-gcm": "false",
    "useCipher_aes256-ctr": "false",
    "useCipher_aes256-cbc": "false",
    "sshUseDefaultHashes": "true",
    "useHash_hmac-sha2-256": "false",
    "useHash_hmac-sha2-512": "false",
    "useHash_hmac-sha1": "false",
    "sshUseDefaultKeyExchangeAlgorithms": "true",
    "useKeyExchange_curve25519-sha256": "false",
    "useKeyExchange_ecdh-sha2-nistp384": "false",
    "useKeyExchange_ecdh-sha2-nistp256": "false",
    "useKeyExchange_ecdh-sha2-nistp521": "false",
    "useKeyExchange_diffie-hellman-group14-sha256": "false",
    "useKeyExchange_diffie-hellman-group16-sha512": "false",
    "useKeyExchange_diffie-hellman-group18-sha512": "false",
    "useKeyExchange_diffie-hellman-group-exchange-sha256": "false",
    "useKeyExchange_diffie-hellman-group14-sha1": "false",
    "sshUseDefaultServerHostKeyAlgorithms": "true",
    "useHostKeyType_ed25519": "false",
    "useHostKeyType_ecdsa-sha2-nistp384": "false",
    "useHostKeyType_ecdsa-sha2-nistp256": "false",
    "useHostKeyType_ecdsa-sha2-nistp521": "false",
    "useHostKeyType_rsa-sha2-512": "false",
    "useHostKeyType_rsa-sha2-256": "false",
    "useHostKeyType_ssh-rsa": "false"
  }
}

```

### **Windows SSH Key Target Account External API Example**

```

POST api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{
  "accountName": "keysample",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "cacheBehavior": "useCacheFirst",
  "cacheDuration": "30",
  "password": "_generate_pass_",
  "passwordViewPolicyId": "1000",
  "privileged": "t",
  "synchronize": "t",
  "useAliasNameParameter": "f",
  "attributes": {
    "extensionType": "windowsSshKey",
    "changePasswordAccount": "{other_acct_id}",
    "changeProcess": "CHANGE_PROCESS_USE_DIFFERENT_ACCOUNT_TO_CHANGE_PASSWORD"
  }
}

```

```

}
}

```

## Add a Windows SSH Password Target Connector

Use the PAM Windows SSH Password target connector to manage local account credentials on Windows systems using password-based SSH authentication.

The PAM Windows SSH Password target connector provides a secure solution for managing local privileged credentials on supported SSH-enabled Windows systems.

### NOTE

For a list of Windows versions that support the Windows SSH Password target connectors, see [Supported Platforms](#).

### TIP

The following alternative Windows connectors are available:

- **Windows SSH Key Connector:** Manages local Windows account credentials using key-based SSH authentication (most secure, also requires supported, SSH-enabled target system).
- **Windows Remote Target Connector:** Manages local Windows account credentials using the Windows Remote Desktop Service API (less secure than either SSH connector).
- **Windows Proxy Connector:** Functions similar to the Windows Remote Connector but requires the connector to be installed on a remote server in your target domain.

To add the target connector using the CLI, see [Windows SSH Password Target Connector CLI Configuration](#).

To add the target connector using the external API, see [Windows SSH Password Target Connector External API Configuration](#).

## Add the Target Application and Connector

Follow these steps in the UI:

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - **Host Name:** Select the magnifying glass to pick the target server.
  - **Device Name:** The name of the target server. Populated dynamically when you pick the target server.
  - **Application Name:** A unique application name for the specified target server.
4. In the **Application Type** field, select **Windows SSH Password**.
5. (Optional) Select a **Password Composition Policy**.  
If you do not select a password composition policy, a default policy is used. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.
6. Select the **SSH Connection** tab and complete the following fields:
  - **Port:** Enter the port that connects to the Windows host using SSH. The default value is 22.
  - **Communication Timeout:** Specify the amount of time that PAM waits for communication from the Windows host before ending the connection (in ms). The default value is 600ee00.
  - **Enable strict host key checking** (Optional) Select this option to protect against man-in-the-middle attacks by validating an SSH host key from the target server (specified in the required **Known Host Key** field) when establishing a connection.

**NOTE**

If a man-in-the-middle attack occurs, the malicious server to which your connection is redirected does not have the same SSH host key as the intended server and the connection is rejected.

- **Known Host Key** (Required if strict host key checking is enabled): Specify the base64 host key value of one of the SSH host keys configured on the target server. For example:

```
AAAAC3NzaC11ZD11NTE5AAAAIGq3L+ECE5S8CUJyZ0jiXbZReY7G/boxDUMrYlhrlK9w
```

**NOTE**

To obtain an SSH host key, you can use the [ssh-keyscan](#) utility on the target device. For example, `ssh-keyscan 127.0.0.1 2>$null` returns the IP address, host Key type and base64 host key value for all configured SSH host keys.

- **SHA256 Fingerprint** (Optional, only applicable if **Enable strict host key checking** is enabled): Specify a SHA256 fingerprint generated from the SSH host key on the target server to confirm that the value that you entered in the **Known Host Key** field matches. If the values do not match, PAM displays a dialog with an error message like the following:

```
PAM-CF-0005: Failed to validate target connector attributes. PAM-WS- 0103:Host key fingerprint does not match computed fingerprint: VpszjfaB00J5N43NQsawv1DsdeXyTzAd1bWLCak6GZl=..
```

**NOTE**

To obtain a SHA256 fingerprint, you can use the [ssh-keyscan](#) utility on the target device. For example, `ssh-keyscan 127.0.0.1 2>$null | ssh-keygen -E md5 -lf -` returns all the configured SSH host Keys and their SHA256 fingerprints.

7. Optionally, use the **Cipher**, **Hash**, **Key Exchange**, and **Server Host Key Type** tabs to configure specific encryption algorithms to use when making an SSH connection to the remote host.

**NOTE**

By default, a **Use supported...** option is set on each tab, configuring support for all available encryption algorithms, as shown in the following screenshot:

Application	SSH Connection	Cipher	Hash	Key Exchange	Server Host Key Type
Use supported ciphers: <input checked="" type="checkbox"/>					
Use aes128-gcm: <input type="checkbox"/>					
Use aes128-ctr: <input type="checkbox"/>					
Use aes128-cbc (non FIPS): <input type="checkbox"/>					
Use aes192-ctr (non FIPS): <input type="checkbox"/>					
Use aes192-cbc (non FIPS): <input type="checkbox"/>					
Use aes256-gcm: <input type="checkbox"/>					
Use aes256-ctr: <input type="checkbox"/>					
Use aes256-cbc: <input type="checkbox"/>					

**Important:** if you unset the **Use supported...** option, you *must* select at least one of the listed encryption algorithms.

- **Cipher Tab:** Unset the **Use supported ciphers** option to select specific ciphers.
- **Hash Tab:** Unset the **Use supported hashes** option to select specific hashes.
- **Key Exchange Tab:** Unset the **Use supported key exchange methods** option to select specific key exchange methods.
- **Server Host Key Type Tab:** Unset the **Use supported server host key types** option to select specific server host key types.

**NOTE**

Encryption standards continue to evolve with new vulnerabilities that are identified in what were previously accepted algorithms. Progress is also made with other more-secure cipher, hash, key exchange, or server host key options added to common utilities used for establishing secure communication channels. When upgrading PAM, be sure to consider any changes in the available more-secure cipher algorithms. Less secure ciphers, hashes, key exchanges, or server host keys algorithms are no longer listed, but continue working. However, they may be subject to removal in a future release.

8. Select **OK**.

**NOTE**

**Next Step:** [Add a Windows SSH Password target account](#).

## Windows SSH Password Target Connector CLI Configuration

This topic contains the CLI parameters for adding a Windows SSH Password target application and target account:

### Windows SSH Password Target Connector CLI Parameters

To add a Windows SSH Password target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***TargetApplication.type***

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	windowsSshPassword

#### ***Attribute.extensionType***

Required	Default Value	Valid Values
no	N/A	windowsSshPassword

#### ***Attribute.sshPort***

The TCP port used to connect to the Windows host using SSH.

Required	Default Value	Valid Values
yes	22	0-65535

#### ***Attribute.sshSessionTimeout***

When using the SSH communication channel, specifies the amount of time in milliseconds, that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

#### ***Attribute.sshStrictHostKeyCheckingEnabled***

Enables or disables strict host key checking. When enabled, a connection gets established after Credential Manager compares the public key from the remote host to the public key stored in the `sshKnownHostKey` attribute. If the keys do not match, then the connection attempt is canceled.

Strict host key checking helps to provide protection from man-in-the-middle attacks. If such an attack happens, the malicious server you are redirected to would not have the same SSH host keys as the intended server. Thus attempts to connect to such a server would fail with strict host key checking.

Required	Default Value	Valid Values
no	false	true, false

#### ***Attribute.sshKnownHostKey***

Contains the base-64 encoded public host key that is associated with the target server.

Required	Default Value	Valid Values
yes if <code>sshStrictHostKeyCheckingEnabled</code> is true	N/A	a base-64 encoded SSH public host key

#### ***Attribute.sshKnownHostKeyFingerprint***

Contains the SHA-256 fingerprint of the public host key that is contained in the `sshKnownHostKey` attribute. The fingerprint is for display purposes only. It allows the user to easily compare one key with another. The fingerprint that is specified must correspond to the specified public host key. This attribute is optional when you specify a Known Host Key. Specifying this attributes value can help you ensure that you did not make a typographical error entering the Known Host Key.

Required	Default Value	Valid Values
no	N/A	a valid public key fingerprint

#### ***Attribute.sshUseDefaultCiphers***

Specifies the default ciphers to used when Credential Manager makes an SSH connection to the remote host.

When set to true, Credential Manager uses all supported ciphers, ignoring the setting to use specific ciphers. When set to false, Credential Manager only uses the selected ciphers.

Required	Default Value	Valid Values
no	true	true, false

#### ***Ciphers That Support FIPS***

The following list displays the cipher algorithms that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useCipher_aes128-gcm</li> <li>Attribute.useCipher_aes128-ctr</li> <li>Attribute.useCipher_aes256-gcm</li> <li>Attribute.useCipher_aes256-ctr</li> <li>Attribute.useCipher_aes256-cbc</li> </ul>	no	false	true, false

### ***Ciphers That Do NOT Support FIPS***

The following list includes the algorithms that use a non-FIPS method, and are ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useCipher_aes128-cbc</li> <li>Attribute.useCipher_aes192-ctr</li> <li>Attribute.useCipher_aes192-cbc</li> </ul>	no	false	true, false

### ***Attribute.sshUseDefaultHashes***

Specifies whether the default hashes should be used when Credential Manager makes an SSH connection to the remote host.

When set to true, Credential Manager uses all supported hashes and ignores the setting to use specific hashes. When set to false, Credential Manager only uses the selected hashes.

Required	Default Value	Valid Values
no	true	true, false

### ***Hashes That Support FIPS***

The following list displays the hashes that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useHash_hmac-sha2-256</li> <li>Attribute.useHash_hmac-sha2-512</li> </ul>	no	false	true, false

### ***Hashes That Do NOT Use FIPS***

The following hash uses a non-FIPS method, and is ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
Attribute.useHash_hmac-sha1	no	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

### ***Attribute.sshUseDefaultKeyExchangeAlgorithms***

Specifies whether the default key exchange methods are used when Credential Manager makes an SSH connection to the remote host. When set to true, the Credential Manager uses all supported key exchange methods, and ignore the

setting to use specific key exchange methods. When set to false, the Credential Manager only uses the selected key exchange methods.

Required	Default Value	Valid Values
no	true	true, false

### **Key Exchange Methods That Support FIPS**

The following list of displays the Key Exchange Methods that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useKeyExchange_curve25519-sha256</li> <li>Attribute.useKeyExchange_ecdh-sha2-nistp384</li> <li>Attribute.useKeyExchange_ecdh-sha2-nistp256</li> <li>Attribute.useKeyExchange_ecdh-sha2-nistp521</li> <li>Attribute.useKeyExchange_diffie-hellman-group14-sha1</li> <li>Attribute.useKeyExchange_diffie-hellman-group16-sha512</li> <li>Attribute.useKeyExchange_diffie-hellman-group18-sha512</li> <li>Attribute.useKeyExchange_diffie-hellman-group-exchange-sha256</li> <li>—</li> </ul>	no	false	true, false

### **Key Exchange Methods That Do NOT Support FIPS**

The following Key Exchange Methods use a non-FIPS method, and are ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useKeyExchange_curve25519-sha256</li> <li>Attribute.useKeyExchange_diffie-hellman-group14-sha256</li> </ul>	no	true	true, false

### **Attribute.sshUseDefaultServerHostKeyAlgorithms**

Specifies whether the default host key types should be accepted used when Credential Manager makes an SSH connection to the remote host. When set to true, the Credential Manager uses all supported server host key types, and ignore the setting to use specific ones. When set to false, the Credential Manager uses only the selected server host key types.

Required	Default Value	Valid Values
no	true	true, false

### **Host Key Types That Support FIPS**

The following list displays the Host Key Types that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>Attribute.useHostKeyType_ecdsa-sha2-nistp384</li> <li>Attribute.useHostKeyType_ecdsa-sha2-nistp256</li> <li>Attribute.useHostKeyType_ecdsa-sha2-nistp521</li> <li>Attribute.useHostKeyType_rsa-sha2-512</li> <li>Attribute.useHostKeyType_rsa-sha2-256</li> <li>Attribute.useHostKeyType_ssh-rsa</li> <li>—</li> </ul>	nofalse	false	true, false

### Host Key Types Do NOT Support FIPS

The following Host Key Type uses a non-FIPS method, and is ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
Attribute.useHostKeyType_ssh-ed25519	no	false	true, false

### Windows SSH Password CLI Examples

Here is an example for adding a Windows SSH Password target application via the CLI:

```
cmdName=addTargetApplication TargetServer.hostName={host name} TargetApplication.type=windowsSshPassword
"TargetApplication.name=Windows SSH Password App" Attribute.sshPort=22
```

Here is another example for adding a Windows SSH Password target application via the CLI:

```
cmdName=addTargetAccount TargetServer.hostName= {host name} "TargetApplication.name=Windows SSH Password
App" TargetAccount.privileged=true TargetAccount.synchronize=false TargetAccount.userName=WinSshPwdAct
TargetAccount.password=sample Attribute.changeProcess=CHANGE_PROCESS_CAN_CHANGE_OWN_PASSWORD
```

## Windows SSH Password Target Connector External API Configuration

This topic describes the required and supported Attributes used when adding or updating a Windows SSH Password target application using the External API.

### Windows SSH Password Target Application External API Attributes

To add or update a Windows SSH Password target application, use the following properties as members of the `attributes` associative array included in the `body` parameter of the `/api.php/v1/devices.json/{id}/targetApplications` External API method:

#### TargetApplication.type

The target application connector type.

Required	Default Value	Valid Values
yes	N/A	windowsSshPassword

**extensionType**

Required	Default Value	Valid Values
no	N/A	windowsSshPassword

**sshPort**

The TCP port used to connect to the Windows host using SSH.

Required	Default Value	Valid Values
yes	22	0-65535

**sshSessionTimeout**

When using the SSH communication channel, specifies the amount of time in milliseconds, that Credential Manager should wait for the remote host to respond.

Required	Default Value	Valid Values
no	5000	1000-99999

**sshStrictHostKeyCheckingEnabled**

Enables or disables strict host key checking. When enabled, a connection gets established after Credential Manager compares the public key from the remote host to the public key stored in the `sshKnownHostKey` attribute. If the keys do not match, then the connection attempt is canceled.

Strict host key checking helps to provide protection from man-in-the-middle attacks. If such an attack happens, the malicious server you are redirected to would not have the same SSH host keys as the intended server. Thus attempts to connect to such a server would fail with strict host key checking.

Required	Default Value	Valid Values
no	false	true, false

**sshKnownHostKey**

Contains the base-64 encoded public host key that is associated with the target server.

Required	Default Value	Valid Values
yes if <code>sshStrictHostKeyCheckingEnabled</code> is true	N/A	a base-64 encoded SSH public host key

**sshKnownHostKeyFingerprint**

Contains the SHA-256 fingerprint of the public host key that is contained in the `sshKnownHostKey` attribute. The fingerprint is for display purposes only. It allows the user to easily compare one key with another. The fingerprint that is specified must correspond to the specified public host key. This attribute is optional when you specify a Known Host Key.

Specifying this attributes value can help you ensure that you did not make a typographical error entering the Known Host Key.

Required	Default Value	Valid Values
no	N/A	a valid public key fingerprint

### ***sshUseDefaultCiphers***

Specifies the default ciphers to used when Credential Manager makes an SSH connection to the remote host.

When set to true, Credential Manager uses all supported ciphers, ignoring the setting to use specific ciphers. When set to false, Credential Manager only uses the selected ciphers.

Required	Default Value	Valid Values
no	true	true, false

### ***Ciphers That Support FIPS***

The following list displays the cipher algorithms that support FIPS:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useCipher_aes128-gcm</li> <li>useCipher_aes128-ctr</li> <li>useCipher_aes256-gcm</li> <li>useCipher_aes256-ctr</li> <li>useCipher_aes256-cbc</li> </ul>	no	false	true, false

### ***Ciphers That Do NOT Support FIPS***

The following list includes the algorithms that use a non-FIPS method, and are ignored if you are running in FIPS mode:

Cipher Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useCipher_aes128-cbc</li> <li>useCipher_aes192-ctr</li> <li>useCipher_aes192-cbc</li> </ul>	no	false	true, false

### ***sshUseDefaultHashes***

Specifies whether the default hashes should be used when Credential Manager makes an SSH connection to the remote host.

When set to true, Credential Manager uses all supported hashes and ignores the setting to use specific hashes. When set to false, Credential Manager only uses the selected hashes.

Required	Default Value	Valid Values
no	true	true, false

### ***Hashes That Support FIPS***

The following list displays the hashes that support FIPS:

Hash Name	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useHash_hmac-sha2-256</li> <li>useHash_hmac-sha2-512</li> </ul>	no	false	true, false

### ***Hashes That Do NOT Use FIPS***

The following hash uses a non-FIPS method, and is ignored if you are running in FIPS mode:

Hash Name	Required	Default Value	Valid Values
useHash_hmac-sha1	no	hmac-md5,hmac-sha1,hmac-sha1-96,hmac-md5-96	A comma-separated list containing one or more of the following values: hmac-md5,hmac-sha1, hmac-sha1-96, hmac-md5-96. Do not use spaces in the list.

### ***sshUseDefaultKeyExchangeAlgorithms***

Specifies whether the default key exchange methods are used when Credential Manager makes an SSH connection to the remote host. When set to true, the Credential Manager uses all supported key exchange methods, and ignore the setting to use specific key exchange methods. When set to false, the Credential Manager only uses the selected key exchange methods.

Required	Default Value	Valid Values
no	true	true, false

### ***Key Exchange Methods That Support FIPS***

The following list of displays the Key Exchange Methods that support FIPS:

Key Exchange Method	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useKeyExchange_curve25519-sha256</li> <li>useKeyExchange_ecdh-sha2-nistp384</li> <li>useKeyExchange_ecdh-sha2-nistp256</li> <li>useKeyExchange_ecdh-sha2-nistp521</li> <li>useKeyExchange_diffie-hellman-group14-sha1</li> <li>useKeyExchange_diffie-hellman-group16-sha512</li> <li>useKeyExchange_diffie-hellman-group18-sha512</li> <li>useKeyExchange_diffie-hellman-group-exchange-sha256</li> </ul>	no	false	true, false

### ***Key Exchange Methods That Do NOT Support FIPS***

The following Key Exchange Methods use a non-FIPS method, and are ignored if you are running in FIPS mode:

Key Exchange Method	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useKeyExchange_curve25519-sha256</li> <li>useKeyExchange_diffie-hellman-group14-sha256</li> </ul>	no	true	true, false

### ***sshUseDefaultServerHostKeyAlgorithms***

Specifies whether the default host key types should be accepted used when Credential Manager makes an SSH connection to the remote host. When set to true, the Credential Manager uses all supported server host key types, and ignore the setting to use specific ones. When set to false, the Credential Manager uses only the selected server host key types.

Required	Default Value	Valid Values
no	true	true, false

### ***Host Key Types That Support FIPS***

The following list displays the Host Key Types that support FIPS:

Host Key Type	Required	Default Value	Valid Values
<ul style="list-style-type: none"> <li>useHostKeyType_ecdsa-sha2-nistp384</li> <li>useHostKeyType_ecdsa-sha2-nistp256</li> <li>useHostKeyType_ecdsa-sha2-nistp521</li> <li>useHostKeyType_rsa-sha2-512</li> <li>useHostKeyType_rsa-sha2-256</li> <li>useHostKeyType_ssh-rsa</li> <li>—</li> </ul>	nofalse	false	true, false

### ***Host Key Types Do NOT Support FIPS***

The following Host Key Type use a non-FIPS method, and is ignored if you are running in FIPS mode:

Host Key Type	Required	Default Value	Valid Values
useHostKeyType_ssh-ed25519	no	false	true, fals

### **Windows Target Application External API Example**

Here is an example for adding a Windows SSH Password target application via the External API:

```
POST api.php/v1/devices.json/{deviceId}/targetApplications
{
  "applicationName": "Windows SSH Password App",
  "applicationType": "windowsSshPassword",
  "description1": "sample descriptor1",
  "description2": "sample descriptor2",
  "passwordCompositionPolicyId": null,
  "attributes": {
    "extensionType": "windowsSshPassword",
```

```

    "sshPort": "22",
    "sshSessionTimeout": "60000",
    "sshStrictHostKeyCheckingEnabled": "false",
    "sshKnownHostKey": "",
    "sshKnownHostKeyFingerprint": "",
    "sshUseDefaultCiphers": "true",
    "useCipher_aes128-gcm": "false",
    "useCipher_aes128-ctr": "false",
    "useCipher_aes128-cbc": "false",
    "useCipher_aes192-ctr": "false",
    "useCipher_aes192-cbc": "false",
    "useCipher_aes256-gcm": "false",
    "useCipher_aes256-ctr": "false",
    "useCipher_aes256-cbc": "false",
    "sshUseDefaultHashes": "true",
    "useHash_hmac-sha2-256": "false",
    "useHash_hmac-sha2-512": "false",
    "useHash_hmac-sha1": "false",
    "sshUseDefaultKeyExchangeAlgorithms": "true",
    "useKeyExchange_curve25519-sha256": "false",
    "useKeyExchange_ecdh-sha2-nistp384": "false",
    "useKeyExchange_ecdh-sha2-nistp256": "false",
    "useKeyExchange_ecdh-sha2-nistp521": "false",
    "useKeyExchange_diffie-hellman-group14-sha256": "false",
    "useKeyExchange_diffie-hellman-group16-sha512": "false",
    "useKeyExchange_diffie-hellman-group18-sha512": "false",
    "useKeyExchange_diffie-hellman-group-exchange-sha256": "false",
    "useKeyExchange_diffie-hellman-group14-sha1": "false",
    "sshUseDefaultServerHostKeyAlgorithms": "true",
    "useHostKeyType_ed25519": "false",
    "useHostKeyType_ecdsa-sha2-nistp384": "false",
    "useHostKeyType_ecdsa-sha2-nistp256": "false",
    "useHostKeyType_ecdsa-sha2-nistp521": "false",
    "useHostKeyType_rsa-sha2-512": "false",
    "useHostKeyType_rsa-sha2-256": "false",
    "useHostKeyType_ssh-rsa": "false"
  }
}

```

### **Windows Target Account External API Example**

Here is another example for adding a Windows SSH Password target application via the External API:

```

POST api.php/v1/devices.json/{deviceId}/targetApplications/{applicationId}/
targetAccounts
{

```

```

"accountName": "WinSshPwdApp",
"description1": "sample descriptor1",
"description2": "sample descriptor2",
"cacheBehavior": "useCacheFirst",
"cacheDuration": "30",
"password": "sample",
"passwordViewPolicyId": "1000",
"privileged": "t",
"synchronize": "f",
"useAliasNameParameter": "f",
"attributes": {
  "extensionType": "windowsSshPassword",
  "changeProcess": "CHANGE_PROCESS_CAN_CHANGE_OWN_PASSWORD"
}
}

```

## Add a Windows Remote Target Connector

The Windows Remote target connector lets PAM manage Windows accounts and the passwords for services and scheduled tasks that are local to the Windows server. The Windows Remote Target Connector is an alternative to the Windows Proxy Connector, but does not require that you install software in the Windows domain.

### NOTE

Starting in PAM 4.1.5, the Windows Remote connector does not support target accounts that are members of the [Windows Protected Users Security Group](#) and [Add a Windows Remote Target Connector](#).

### TIP

The following alternative Windows connectors are available:

- **Windows SSH Key Connector:** Manages local Windows account credentials using key-based SSH authentication (most secure, but requires supported, SSH-enabled target system).
- **Windows SSH Password Connector:** Manages local Windows account credentials using password-based SSH authentication (most secure, but requires supported, SSH-enabled target system).
- **Windows Proxy Connector:** Functions similar to this Windows Remote Connector but you must install the connector on a remote server in your target domain. See [Add a Windows Proxy Connector](#).

This connector uses Samba commands and remote Windows API calls to make updates to the account, services, and scheduled tasks passwords. To complete discovery and password changes for services and scheduled tasks, the connector might incur extra overhead.

To add the target connector using the CLI, see the [Windows Remote Target Connector CLI Configuration](#).

To add the target connector using the external API, see [Windows Remote Target Connector External API Configuration](#).

### Prerequisites for Using the Windows Remote Connector

Complete the following prerequisite steps to prepare your environment to support the Windows Remote Connector:

1. To configure Windows Remote target accounts, first [create a device](#) (target server) that is assigned a device type of Password Management.

**NOTE**

Use the private IP address of an AWS or Azure Windows device. Some features do not function properly when you use the public IP address.

2. Prepare the target server for using the Windows Remote Connector with the following information:
    - **Ports Used by the Connector**  
The Windows Remote Connector requires these ports to be open in the firewall:
      - SMB: port 445
      - WMI: port 135 and port range from 49152 through 65535 or 1024 through 4999
    - **Disable the Guest Account**  
If the guest account in the domain or on the target server is enabled, the connector tries to verify its password, which does not exist. Disable this account to prevent a false password verification
    - **User Access Control workaround**  
If User Access Control is enabled on the target server and the account for password management is a local administrator, the connector needs access to perform SMB and WMI operations. To give the connector access, add the LocalAccountTokenFilterPolicy registry setting to remove remote restrictions:
 

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System
\LocalAccountTokenFilterPolicy = dword:00000001
```
- NOTE**  
WMI traffic is encrypted. When a password is updated through WMI, the password is encrypted.
- **Review Group or Local Policy Security Options**  
The default values for network security on Windows systems allow the Windows Remote Connector to function. However, if certain settings are set too restrictive, Windows Remote password management fails. To ensure that Windows Remote operates effectively, verify the following settings in the Group or Local Policy Security Options. Go to Start, Administrative Tools, Local Security Policy, Local Policies, Security Options.
    - **Network security: Restrict NTLM: Incoming NTLM traffic**  
Allow all, or Not Defined
    - **Network security: Restrict NTLM: NTLM authentication in this domain**  
Disable, Not Defined, or Deny for domain accounts
  - **Set the Local System Context**  
The Windows Remote Connector can be run in the context of a local system. This scenario allows successful management and updates of the local Windows accounts, service passwords, and scheduled task passwords. The Windows Remote Administrator account that you add to the appliance must be part of the Local Administrator group on the target server.
3. To use a Windows Domain account

**Add the Target Application and Connector****Follow these steps in the UI:**

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Fill in the following fields:
  - **Host Name:** The hostname of the target server.
  - **Device Name:** The name of the target device.
  - **Application Name:** The name must be unique.
4. In the **Application Type** field, select **Windows Remote**.
5. (Optional) Select a password composition policy.

**NOTE**

If you do not select a password composition policy, a default policy is used. This policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.

6. If you are using target groupings, add Descriptors.
7. Select the **Windows Remote** tab.
8. For the **Account Type**, select one of the following options:
  - **Local Account:** Manage local accounts on target servers.
  - **Domain Account:** Manage Windows Domain accounts. We recommend using the [Active Directory connector](#) to manage Domain Accounts.

If you set the **Domain Account** option, select one of the following options from the drop-down list that becomes active:

  - **Target Server is Domain Controller:** (For domain administrator accounts only) Use the target server as the domain controller.
  - **Domain Controllers are on servers:** Specify the IP address or addresses (comma-separated) of domain controllers in the **Specify Servers** text field. If there are multiple entries, PAM uses the first reachable domain controller. Enter one or more servers, which are separated by commas.

**NOTE**

To support Kerberos authentication (see **Use Kerberos** later in this topic), you must specify the FQDNs of domain controllers instead of IP addresses.

- **Lookup Domain Controllers in DNS:** Use the first reachable DNS server that is configured in the [PAM server network settings](#) to look up the domain controller.
  - **Lookup Domain Controllers in specified:** Specify the IP address or (comma-separated) addresses of one or more DNS servers to use to look up the domain controller in the **Specify DNS** text field. If there are multiple entries, PAM uses the first reachable DNS server in the list to look up the domain controller.
  - **Use Kerberos:** (Optional) Set this option to enable authentication using the Kerberos protocol. The name of the Kerberos realm is displayed in the **Realm Name** field that appears below the **Domain Name** field lower on the dialog.
- Kerberos verifies user identities using a Key Distribution Center (KDC), which is a service that runs on Windows domain controllers. PAM uses the KDC on the domain controller which is determined by the previously configured **Domain Account** setting.

**NOTE**

If an existing Windows Remote target application has the same domain name but a different Domain Controller lookup option than the one specified in this definition, a popup appears stating that you should use the Domain Controller lookup option. However, you can override this suggestion and keep the Domain Controller lookup specified here.

- Complete the following fields in the **DNS Servers** section:
    - **Domain Name:** Specify the Windows domain of the managed account.
    - **Active Directory Site:** (Optional) Specify an Active Directory directory site name to narrow the search for domain controllers. If the field is empty, PAM searches for all domain controllers who are identified by the DNS server. (This field is Inactive if the "Target Server is Domain Controller" **Domain Account** option is specified.)
    - **DC replication time (in ms):** Enter the frequency of replication in milliseconds.
  - **Active Directory Connect Timeout:** Enter the timeout for connecting to AD, in milliseconds.
  - For **Active Directory Read Timeout:** Enter the timeout for reading from AD, in milliseconds.
9. If you enabled [Account Discovery](#), complete the following settings on the **Account Discovery** tab:

**NOTE**

**Account Discovery** is only supported for **Local Accounts**.

- **Account Filter:** (Optional) Specify a filter to limit the accounts that are discovered from the Windows server.

**NOTE**

The only valid wildcard character in filters is an asterisk (\*).

- **Discover Services:** Set this option to also discover services.
- **Discover Tasks:** Set this option to also discover tasks.

10. Select **OK** to save the application.

**NOTE**

Next step: [Configure Windows Remote Target Accounts](#).

**Windows Remote Target Connector CLI Configuration**

This topic contains the parameters for adding a Windows Remote target application and target account:

**Windows Remote Target Connector CLI Parameters**

To add a Windows Remote target application and connector using the CLI, use the `addTargetApplication` command and the following command parameters:

***Attribute.extensionType***

Specify the type of account to use.

Required	Default Value	Valid Values
yes	N/A	windowsRemoteAgent

***Attribute.accountType***

The type of account being managed.

Required	Default Value	Valid Values
yes	domain	domain, local

***Attribute.domainName***

The Windows domain for the managed accounts.

Required	Default Value	Valid Values
Required if <code>Attribute.accountType</code> is set to domain (the default).	none	Domain name (a text string)

***Attribute.domain***

The Windows domain for the managed accounts. This attribute exists only for backwards compatibility. We recommend using `Attribute.domainName` instead.

Required	Default Value	Valid Values
Required if <code>Attribute.accountType</code> is set to domain (the default).	none	Domain name (a text string)

***Attribute.useDNS***

Determine the level to which DNS is used.

Required	Default Value	Valid Values
Required if <code>Attribute.accountType</code> is set to domain (the default).	none	<ul style="list-style-type: none"> <li><code>noDNS</code> : DNS is not used</li> <li><code>retrieveDNS</code> : Retrieve the DNS server that the Credential Manager server uses</li> <li><code>specifiedDNS</code> : Use the DNS server that is specified by the <code>dnsServer</code> attribute</li> </ul>

### ***Attribute.dnsServer***

The host names of the DNS servers to use.

Required	Default Value	Valid Values
Required if <code>Attribute.useDNS</code> is set to <code>specifiedDNS</code> .	none	Comma separated list of DNS server host names.

### ***Attribute.specifiedServersList***

Provide a comma separated list of domain controllers.

Required	Default Value	Valid Values
Required if <code>Attribute.useDNS</code> is set to <code>specifiedServers</code> .	none	Comma separated list of valid domain controllers

### ***Attribute.adSite***

The Active Directory site. This parameter is only used if `Attribute.useDNS` is set to `retrieveDNS` or `specifiedDNS`. If a value is given, Credential Manager uses the value to narrow the search for domain controllers, using the specified name.

Required	Default Value	Valid Values
no	none	String

### ***Attribute.enableKerberos***

Determines whether Kerberos authentication is enabled for a target application.

Required	Default Value	Valid Values
no	false	<ul style="list-style-type: none"> <li><code>true</code> - Kerberos authentication is enabled.</li> <li><code>false</code> - Kerberos authentication is not enabled.</li> </ul>

### ***Attribute.overrideDnsType***

If Kerberos is enabled, specifies whether to allow a different DNS lookup type for this target application than for others in the same domain.

Required	Default Value	Valid Values
no	false	<ul style="list-style-type: none"> <li>true - a different DNS lookup type is allowed for this target application.</li> <li>false - a different DNS lookup type is not allowed for this target application.</li> </ul>

### Windows Remote Target Account CLI Parameters

To add a Windows Remote target account that uses the target connector, use the `addTargetAccount` command and the following parameters:

#### ***Attribute.extensionType***

Specify the extension type to use.

Required	Default Value	Valid Values
yes	N/A	windowsRemoteAgent

#### ***Attribute.accountType***

Specify the type of account to use.

Required	Default Value	Valid Values
yes	user	user, admin

#### ***Attribute.useOtherAccountToChangePassword***

Specify whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false

#### ***Attribute.otherAccount***

Specify which other account to use to perform password change requests.

Required	Default Value	Valid Values
Required if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	A valid target account ID.

**Note:** The Target Account ID can be found using the `searchTargetAccount` command.

#### ***Attribute.serviceInfo***

List of services.

Required	Default Value	Valid Values
no	N/A	Add the following code for each service: <code>hostname: servicename:restart</code> <code>hostname: servicename:norestart</code> <code>hostname</code> is the server hosting the service Delimit multiple services with the   (pipe) character. An empty string means no services.

### ***Attribute.tasks***

List of scheduled tasks.

Required	Default Value	Valid Values
no	none	For each task, add the string: <code>hostname: taskname</code> Delimit multiple services with the   (pipe) character. <code>hostname</code> is the name of the server where the scheduled task is hosted An empty string means no tasks.

### ***Attribute.forcePasswordChange***

This parameter specifies whether Credential Manager updates passwords that fail verification during an initial synchronization. The default value is false. To update passwords that fail initial synchronization, set the attribute value to true.

Required	Default Value	Valid Values
no	false	true, false

### **Windows Remote CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myWindowsRemote TargetApplication.type=windowsRemoteAgent
Attribute.extensionType=windowsRemoteAgent Attribute.accountType=domain Attribute.domainName=testDomain
Attribute.enableKerberos=true

cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com TargetApplication.name=myWindowsRemote
TargetAccount.userName=admin TargetAccount.password=P@ssw0rd TargetAccount.privileged=true
Attribute.extensionType=windowsRemoteAgent Attribute.accountType=admin
Attribute.useOtherAccountToChangePassword=false Attribute.forcePasswordChange=false
Attribute.serviceInfo=HostA:servicename:restart|HostB:ServiceName:norestart Attribute.tasks=HostA:taskName|
HostB:taskName
```

## **Windows Remote Target Connector External API Configuration**

This topic describes the required and supported Attributes used when adding or updating Windows Remote target applications using the External API.

## Windows Remote Target Application External API Attributes

To add or update a Windows Remote target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call.

### ***accountType***

The type of account being managed.

Required	Default Value	Valid Values
yes	domain	domain, local

### ***domainName***

The Windows domain for the managed accounts.

Required	Default Value	Valid Values
Required if <code>accountType</code> is set to domain (the default).	none	Domain name (a text string)

### ***domain***

The Windows domain for the managed accounts. This attribute exists only for backwards compatibility. We recommend using `domainName` instead.

Required	Default Value	Valid Values
Required if <code>accountType</code> is set to domain (the default).	none	Domain name (a text string)

### ***useDNS***

Determine the level to which DNS is used.

Required	Default Value	Valid Values
Required if <code>accountType</code> is set to domain (the default).	none	<ul style="list-style-type: none"> <li><code>noDNS</code> : DNS is not used</li> <li><code>retrieveDNS</code> : Retrieve the DNS server that the Credential Manager server uses</li> <li><code>specifiedDNS</code> : Use the DNS server that is specified by the <code>dnsServer</code> attribute</li> </ul>

### ***dnsServer***

The host names of the DNS servers to use.

Required	Default Value	Valid Values
Required if <code>useDNS</code> is set to <code>specifiedDNS</code> .	none	Comma separated list of DNS server host names.

### ***specifiedServersList***

Provide a comma separated list of domain controllers.

Required	Default Value	Valid Values
Required if <code>useDNS</code> is set to <code>specifiedServers</code> .	none	Comma separated list of valid domain controllers

### ***adSite***

The Active Directory site. This parameter is only used if `useDNS` is set to `retrieveDNS` or `specifiedDNS`. If a value is given, Credential Manager uses the value to narrow the search for domain controllers, using the specified name.

Required	Default Value	Valid Values
no	none	String

### ***enableKerberos***

Determines whether Kerberos authentication is enabled for a target application.

Required	Default Value	Valid Values
no	false	<ul style="list-style-type: none"> <li>t - Kerberos authentication is enabled.</li> <li>f - Kerberos authentication is not enabled.</li> </ul>

### ***overrideDnsType***

Determines whether a Kerberos-enabled application supports a different domain controller lookup type than an existing Kerberos-enabled Windows Remote target application in the same domain.

Required	Default Value	Valid Values
no	false	<ul style="list-style-type: none"> <li>t - A different domain controller lookup type is supported.</li> <li>f - A different domain controller lookup type is not supported.</li> </ul>

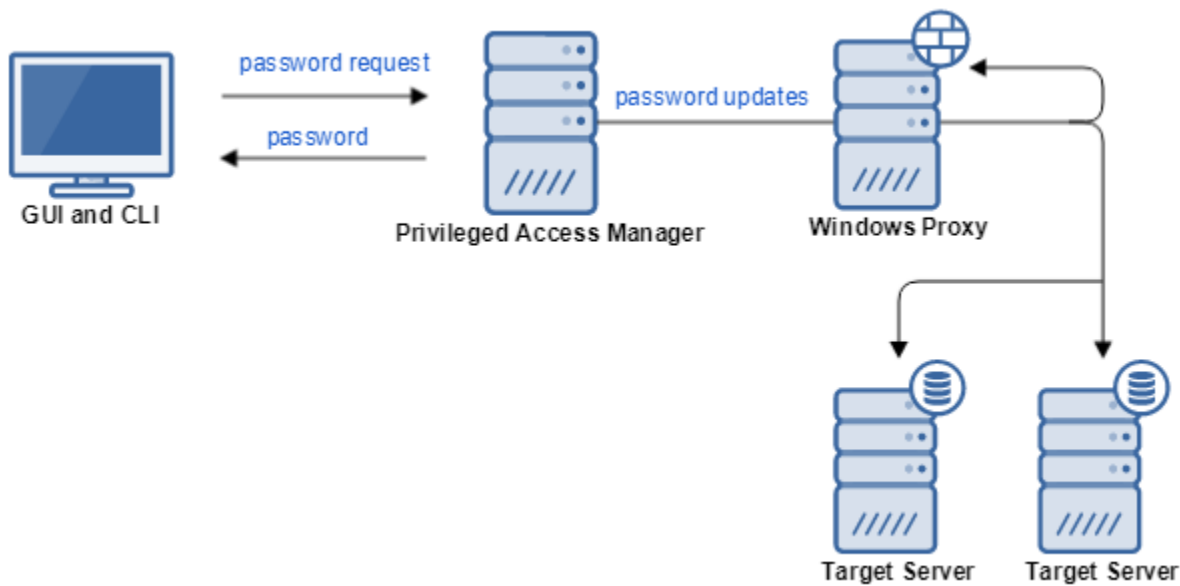

### **Windows Remote External API Example**

```
{
  "applicationName": "myWindowsRemote",
  "applicationType": "windowsRemoteAgent",
  "attributes": {
    "accountType": "domain",
    "domainName": "testDomain",
  }
}
```

## **Add a Windows Proxy Connector**

The Windows Proxy connector manages Windows accounts. To use the Windows Proxy connector, you must install the connector on a remote server in your target domain.

The following graphic shows where the Windows Proxy resides in your environment.

**Figure 25: Windows Proxy architecture****TIP**

Two other Windows connectors are available:

- Windows Remote Target Connector - functions similar to the Windows Proxy but it does not require you to install any component in your target domain. See [Windows Remote Target Connector](#).
- Active Directory Connector - manages passwords of Active Directory accounts. See [Active Directory Target Connector](#).

Use the Windows Proxy connector to manage passwords for:

- Active Directory accounts
- Local Windows accounts
- Windows services
- Windows scheduled tasks

The Windows Proxy Connector uses Windows APIs to make updates to these passwords. The connector queries one or more DNS servers to find domain controllers. The Windows Proxy connector uses HTTPS and AES encryption for secure communications.

The permissions that are required for the Windows Proxy are affected by several architectural deployment decisions:

- The type of accounts being managed by the proxy: local, domain, or both.

**NOTE**

**Account Discovery** is only supported for **Local Accounts**.

- Whether passwords on services and scheduled tasks are also being managed
- Whether the proxy is deployed on each server, or whether one proxy is deployed for the domain.

To manage only local accounts, you deploy the proxy on each managed server and run the proxy in the "local system" context. This scenario allows successful updates to the local accounts, services, and scheduled tasks.

If you deploy a proxy to manage multiple servers, it must operate under an account with privileges to manage the accounts, services, and scheduled tasks. If you use the Active Directory connector to manage the domain accounts, then the proxy must run with a domain account that has those privileges.

As a result, the service account that is used for the proxy can limit its privileges to a Domain User. To enable "local system" management, the service account must be a member of the Local Administrator group on the managed Target Account server.

To use the Windows Proxy to manage Domain accounts, add the service account to the domain Account Operators group. The proxy can then reset passwords in Active Directory.

### **Next Steps**

- [How to Install a Windows Proxy for Credential Manager](#)
- [Add Windows Proxy Target Applications and Accounts](#)
- [Windows Proxy Target Connector CLI Configuration](#)
- [View Windows Proxy Logs](#)

## **How to Install a Windows Proxy for Credential Manager**

The Windows Proxy is a software component of Privileged Access Manager Credential Manager. Install it to enable updating Windows-based account passwords, and updating Windows service and scheduled task login account passwords. For basic information about the Windows Proxy, see [Add a Windows Proxy Connector](#).

The sections in this topic describe how to install a Windows Proxy.

### **About Windows Accounts**

The following table describes the various Windows user accounts. Windows service accounts allow system administrators to control the permission level that is granted to a Windows service. Windows services that access network resources might require a restart when the associated user account password is changed.

Windows account types	Who can change the password?	Description
Local user	Local user Local administrator account	An account with local system privileges on a Windows system that a user accesses.
Domain user	Domain user Domain administrator	A network-based user account. Domain user accounts provide users with access to network resources. A domain user account is authenticated against Active Directory.
Local administrator	Local administrator	A local administrator account has administrator privileges on the local system, but does not have Network Administrator privileges. A local administrator cannot change domain user account passwords.
Domain administrator	Domain administrator	A domain administrator account has administrator privileges throughout the domain. A domain administrator requires local administrator privileges to update local accounts.  By default, when a system joins the domain, the domain administrator is given local administrator access.

### **Windows Proxy Configuration**

The configuration of the Windows Proxy depends on the type of accounts you are managing and whether your network is part of a domain.

You can install as many Windows Proxies as you need. You must install a minimum of one Windows Proxy for each domain or workgroup. The Windows Proxy service must run as a domain administrator or local administrator. By default, the Windows Proxy installs with local service permissions. You must update the local service permissions to manage passwords over a network connection.

The following table lists the target host and target account registration notes associated with the various Windows Proxy installation options.

Windows Proxy service runs as:	Target user account type	Target host configuration notes	Target Account Registration notes
Domain administrator	Domain	The domain administrator must have local administrator privileges on the target host.	When adding the target account, select the option Use Proxy credentials to change password.
Domain administrator	Local (target host)	The account being managed (on the target host) must have Log in local user rights.	When adding the target account, the account that is selected to manage passwords must have Local Administrator privileges.
Local administrator (Proxy host)	Domain	Not recommended	Not recommended
Local administrator (Proxy host)	Local (target host)	None	When adding the target account, the account that is selected to manage passwords must have local administrator privileges.

## WARNING

If Privileged Access Manager manages the administrator account that the Windows Proxy service runs as, do *not* configure this account to change its own password. The Windows service cannot restart itself after a password change. Instead, use a second Windows Proxy running as a different account to manage the service account. Use a separate target application that only uses the remote proxy. When you configure the Windows target account for the Windows Proxy, discover the proxy service and set the **Start/Restart** option. This option allows Privileged Access Manager to restart the service on a password change.

The accounts that are associated with the two Windows Proxy services must be in the Administrators group on their proxy hosts. The proxies can then manage other accounts on either host, or on remote hosts with target applications that have selected both proxies for high availability.

When verifying the passwords of Windows Proxy target applications, Credential Manager connects to target servers using the Windows Proxy.

When adding a domain controller target server, use the domain controller NetBIOS name as the target server host name.

You can register the Windows Proxies in Credential Manager manually or automatically. Upon receipt of the Windows Proxy login, the server automatically adds the Windows Proxy in an inactive state and flags the request in the UI.

A Windows Proxy is not configured as a managed object device, so the proxy does not appear in the Device list. However, this same host can still be the target of a Privileged Access Manager managed object. The same host can be used for access or password management as a device.

When the Privileged Access Manager server sends sensitive information to a Windows Proxy, that information is encrypted using the Windows Proxy key. The key is unique for each Windows Proxy. The UI provides a button to update the Windows Proxy key.

## **Windows Proxy Requirements**

This section details the hardware and software requirements for the Windows Proxy.

### ***Hardware Requirements***

The Windows Proxy requires 128 MB of RAM and 180 MB of hard drive space. The Windows Proxy log file requires 50 MB.

### ***Operating System Requirements***

For a list of Windows operating system versions that support the Windows Proxy, see [Supported Environments](#).

## **Prepare for Windows Proxy Installation**

Complete the following tasks to prepare to install the Windows Proxy:

- Verify that firewalls do not block necessary communication ports. See [Default Ports for Credential Manager](#).
- Verify that DNS resolution of the Windows Proxy host succeeds on the Privileged Access Manager server. If DNS resolution of the server fails on the Windows Proxy host, the Windows Proxy hosts file (C:\Windows\System32\drivers\etc\hosts) requires an entry for the server.
- Verify that DNS resolution of the Privileged Access Manager server succeeds on the Windows Proxy host.
- Disable Windows Simple File Sharing on all Windows servers that have accounts being managed through the Windows Proxy.  
Follow these steps:
  - a. Select **Start**.
  - b. Select **My Computer**.
  - c. Select **Organize** or **View**, depending upon your Windows version.
  - d. Select **Options** and **Folder and Search Options**, depending upon your Windows version.
  - e. Select the **View** tab.
  - f. At the bottom of **Advanced Settings**, disable **Use Sharing Wizard (Recommended)**.  
If you enable the sharing wizard, the Windows Proxy cannot synchronize and update accounts, and the Windows Proxy error log returns a 1326-ERROR\_LOGON\_FAILURE message.
- If the Guest account in the domain or on the target server is enabled, the Windows Proxy Connector appears to verify the password. However, that target account password does not exist on the target server. Disable the guest account in the domain or on the target server to avoid this false password verification.

You can install the Windows Proxy and an A2A Client on the same Windows host. Do not use the same installation folder for both the Windows Proxy and the A2A Client. The installation of either component overwrites the Credential Manager component that is already installed in that folder.

The default values for Network Security on Windows systems allow Windows Proxy to function. If certain settings are set too restrictively, the Windows Proxy can fail. Verify these settings in the Group or Local Policy Security Options:

- **Network security: Restrict NTLM: Incoming NTLM traffic**  
Allow all, or Not Defined
- **Network security: Restrict NTLM: NTLM authentication in this domain**  
Disable, Not Defined, or Deny for domain accounts

## **Download the Windows Proxy Software**

Download the Windows Proxy software (WindowsProxy-X.x(x).zip) from the Broadcom Support site. For information on how to download the software, see [Download PAM Installation Media](#).

## **Install the Windows Proxy Software**

The wizard installs the Windows Proxy software.

### **NOTE**

Installing more than one Windows Proxy on the same host is not supported. Installing into the same directory overwrites the Windows Proxy already installed in that directory. Always uninstall an existing Windows Proxy before installing a newer version.

### **NOTE**

The wizard fails when you execute it from an account that contains special characters. To avoid this error, start the installation by right-clicking on the executable file and selecting the **Run As** option. The **Run As** dialog opens and prompts for an alternate username and password to use for the installation. Specify the account credentials and continue with the installation.

### **Follow these steps:**

1. Navigate to the location where you unzipped the installation package.
2. Start the `setup_windows_agent.exe` installation wizard.
3. In the Introduction window, select **Next**.
4. In **Choose Install Folder** window, enter, or select the folder where you want to install the proxy, and select **Next**. We recommend that you do not use a space character in the root folder, the name of the installation location, or the folder name.
5. In the **Server Information** window, enter the Fully Qualified Domain Name (FQDN) of the Privileged Access Manager server in the **Server Name** field. If you want the Windows Proxy Agent to communicate to the PAM appliance using an IPv6 address, select **IPv6 Enabled**.

### **NOTE**

If the **IPv6 Enabled** option is set, verify that both the Agent and PAM are configured with IPv6 addresses.

6. Select **Next** to confirm your choices and display the **Pre-Installation Summary** window.
7. In the **Pre-Installation Summary** window, validate the installation information then select **Install**.
8. When the installation finishes and the Install Complete window appears, select **Done**.

## **Start the Windows Proxy Service**

To start the Windows service (`PAM Proxy`) on a Windows server, complete *one* of the following procedures:

- Open a command window and enter the following text: `net start "PAM Proxy"`
- Start the **PAM Proxy** service using the Services Administrative tool:  
The steps to start the service using the Windows Services Administrative tool depend on your Windows platform. For example, to start the service with Windows 7, select Start, Control Panel, Administrative Tools, Services. Then select **PAM Proxy** in the Services list and then select **Start**.

## **Activate the Windows Proxy**

After the Windows service is running on the Windows server, active the Windows Proxy from the PAM UI.

### **Follow these steps:**

1. From the UI, go to Credentials, Manage Targets, Proxies.
2. Select the new proxy entry and select **Update**.
3. Select the **Active** checkbox then select OK.

## **Stop the Windows Proxy**

Do *one* of the following steps:

- Stop the **PAM Proxy** service using the Services Administrative tool.  
Stopping the service using the Windows Services Administrative tool depends on your Windows platform. For example, to stop the service with Windows 7, select Start, Control Panel, Administrative Tools, Services, select **PAM Proxy** in the Services list, and then select Stop.
- Open a command line window and type the following command: `net stop "PAM Proxy"`

### Related Topics

- [Add Multiple Windows Proxies](#)
- [Configure a Windows Proxy to Use a Windows Domain Account](#)
- [Modify the Windows Proxy Configuration File](#)
- [Uninstall a Windows Proxy](#)

## Add Multiple Windows Proxies

You add multiple proxies in Privileged Access Manager to support managing multiple domains, improve load balancing and redundancy of your network.

For general information about Windows Proxies, see [Configure a Windows Proxy Connector](#).

### WARNING

Install the Windows Proxy software on a Windows host before adding a proxy to Credential Manager. See [Install a Windows Proxy for Credential Manager](#). The Windows Proxy runs as service on the Windows host. During the installation process:

1. Identify the Privileged Access Manager appliance with which the proxy registers.
2. Access the proxy list by selecting Targets, Proxies.
3. Activate the proxy by opening the proxy record in that list and changing its Status to "Active".

Use the following procedure to add a proxy manually and register it automatically.

### Follow these steps:

1. Select **Credentials, Manage Targets, Proxies**. The Proxy List page appears.
2. Select **Add**.  
The Proxy Details page appears.
3. In the **Host Name** field, enter the DNS host name or IP address where the proxy software resides.
4. In the **Device Name** field, assign a name to the Device.
5. In the **IP Address** field, enter the IP address of the host.
6. To activate the proxy, select the **Active** checkbox. Otherwise, clear the box.
7. To prevent the host name from being overwritten each time the client registers, set the **Preserve Host Name** option. Otherwise, clear the option.  
The default option for this setting is determined on the **Settings, Credential Manager** page. See the **Preserve Client/Proxy Host Names** checkbox on the **Request Server Settings** tab.
8. If you are using target groupings, enter the proxy descriptor information in the **Descriptor** fields.
9. Select **OK** to save.

## Configure a Windows Proxy to Use a Windows Domain Account

You might want the Windows Proxy to use a Windows Domain account to provide the privileges necessary to manage Windows Proxy Target Accounts. You must have local administrator privileges to change the Windows Proxy settings.

**Follow these steps on the device that hosts the Windows Proxy:**

1. Select **Start, Control Panel, Administrative Tools, Services**.
2. Right click on **PAM Proxy** and select **Properties**.
3. Select on the **Log On** tab.
4. Select **This Account** radio button.
5. Enter the Domain and Windows account names for the account. For example: NT-01\joedoe or joedoe@ca.com

**Modify the Windows Proxy Configuration File**

You can modify the Windows Proxy configuration file to address certain scenarios, such as:

- Changing a configuration that is not included in the installer, for example, port numbers.
- Applying a configuration change after installation such as changing the log file location.
- Modifying the logging level to debug a problem.

The Windows Proxy configuration file is located here:

```
C:\<install_home>\cloakware\cspmclient\config\cspm_client_config.xml
```

Where `<install_home>` is the location and name of your installation folder, for example Program Files \cspm\_agent.

The following table describes the XML tags in the Windows Proxy configuration file.

XML Tag	Description
<code>&lt;applicationtype&gt;</code>	Valid value is <code>cspm_agent</code> . If this value is set to <code>cspm_agent</code> , the Credential Manager client starts with Windows Proxy functionality. <code>cspm_agent</code> is supported only on Windows platforms.
<code>&lt;cacheallow&gt;</code>	Enables or disables caching for the Credential Manager client. The default value is <code>true</code> .
<code>&lt;loglevel&gt;</code>	Specifies the log level. Valid values are <code>severe</code> , <code>warning</code> , <code>info</code> , <code>fine</code> and <code>off</code> . Entry is case insensitive. The default value is <code>warning</code> . The <code>off</code> setting means log messages are not generated.
<code>&lt;cspmserver&gt;</code>	Specifies the host name of the Privileged Access Manager appliance. This value is set by the installer.
<code>&lt;cspmserver_port&gt;</code>	The default port on which the Privileged Access Manager appliance listens. The default is blank. For HTTPS, the default is 443. If the server port is changed from 443, you must modify this value
<code>&lt;daemonserver1_port&gt;</code>	The Windows Proxy uses this port to listen for requests from the Privileged Access Manager appliance. For the Windows Proxy, the default value is 27077.
<code>&lt;daemonserver2_port&gt;</code>	This port is not used by the Windows Proxy.
<code>&lt;logfile&gt;</code>	Specifies the location of the log file that is used by the daemon. The installer sets this value.

<c_logfile>	The log file that is used by the service and stateless client interface stubs. The default is: C:\WINDOWS\TEMP\cspm_c_client_log.txt on Windows Server 2008 R2. The log file must be in a directory to which all users of the Windows Proxy have write access.
<operation>	For internal use only.

## Uninstall a Windows Proxy

You can uninstall a Windows Proxy from a Windows client when it is no longer needed.

### Follow these steps:

1. Stop the Windows Proxy using one of the following steps:
  - Stop the **PAM Proxy** service using the Windows Services tool.
  - Open a Command Prompt window and enter the following command:  
net stop "PAM Proxy"
2. Use one of the following methods to launch the uninstall executable:
  - Use the Control Panel Add/Remove Programs option: Select the **Windows Proxy** entry
  - Navigate to C:\cspm\_agent\Cloakware\cspmclient\Uninstall\_Password\_Authority\_Windows\_Proxy and double-click Uninstall PAM Proxy.exe .
  - Open a Command Prompt window and run the uninstall script:  
C:\cspm\_agent\Cloakware\cspmclient\Uninstall\_Password\_Authority\_Windows\_Proxy  
\"Uninstall PAM Proxy.exe"

Ensure that you enclose the file name within double quotes.  
The greeting window appears followed by the **Uninstall Windows Proxy** window.
3. Select **Uninstall**.  
The **Uninstall Windows Proxy** status window appears.  
When the uninstall finishes, the **Uninstall Complete** window appears. You might need to remove files manually. If so, the uninstaller identifies the files that must be manually removed.
4. Select **Done**.
5. (Optional) Remove the empty cspm\_agent folder.

## Add Windows Proxy Target Applications and Accounts

You can manage credentials for Windows Proxy accounts. For introductory information about the Windows Proxy, see [Add a Windows Proxy Connector](#).

To configure Windows Proxy target applications and accounts, follow these procedures:

### Prerequisites for Windows Proxy Accounts

To register Windows Proxy target accounts, including Windows services, verify that the following prerequisites are met.

- [Install a Windows Proxy for Credential Manager](#) on the target server or another server in the domain that the target server can access.
- Create a Device (target server) of type Password Management or A2A.
- Verify that you have control of an account with Administrator rights on the target server.
- If the Windows Remote target account is of Administrator account type, the account requires Administrator rights on the Windows server.

**NOTE**

If your target account is to be used as a service account (that is, it is to be used to rotate passwords of other target accounts), we recommend that you prevent this account from being able to login interactively. To do this, assign the following User Rights to the Windows account:

- Deny log on locally
- Deny log on through Remote Desktop Service

**Create a Windows Target Application****Follow these steps:**

1. Select **Credentials, Manage Targets, Applications**. The Application List page appears.
2. Select **Add**. The Add Target Application page appears.
3. Select the **Host Name** magnifying glass to find an existing target server.
4. Enter a unique **Application Name**.
5. Select "Windows Proxy" as the **Application Type**.  
The Windows Proxy and Account Discovery tabs appear.
6. (Optional) Select a **Password Composition Policy**.
7. If you are using target groupings, add **Descriptors**.
8. On the **Windows Proxy** tab, select the **Account Type**.  
If you select **Local Account**, go to the next step. If you select **Domain Account**, you select from further options.
  - **Local Account** is only able to manage local accounts on target servers.
  - **Domain Account** is able to manage Windows Domain accounts. We recommend using the [Active Directory connector](#) to manage Domain Accounts.  
For the Domain Account, a drop-down list becomes active, with the following options:
    - **Target Server is Domain Controller** (For domain administrator accounts only)
    - **Domain Controllers are on servers** (with **Specify Servers** text field)  
Enter one or more servers, which are separated by commas.
    - **Lookup Domain Controllers in DNS**
    - **Lookup Domain Controllers in specified** (with **Specify DNS** text field)  
Enter one or more DNS servers, which are separated by commas
 For DNS Servers, complete the following fields:
    - **Domain Name**: Specify the Windows domain of the managed account
    - **Active Directory Site**: This field is not active for the Target Server is Domain Controller option. If you enter a value, it is used to narrow the search for domain controllers, using the specified name. If the field is empty, we search for all domain controllers in DNS.
    - **DC replication time (in ms)**: Enter the frequency of replication in milliseconds.
  - For **Active Directory Connect Timeout**, enter the timeout for connecting to AD, in milliseconds.
  - For **Active Directory Read Timeout**, enter the timeout for reading from AD, in milliseconds.
9. Select one or more **Available Proxies** and add them to the **Selected Proxies** list.
10. On the Account Discovery tab, select **Discover Services** and **Discover Tasks**. Specify an optional **Account Filter**.

**NOTE**

If you do not specify a filter, all accounts are discovered from the Windows server. Use only the \* character in filters. Example: User\*

11. Select **OK**.

The new Windows target application is added to the list of applications on the Target Applications page.

## Create a Windows Target Account and Target Alias

### Follow these steps:

1. Select **Credentials, Manage Targets, Accounts**. The Account List page appears with a list of existing accounts.
2. Select **Add**. The Add Target Account page appears.
3. On the Account tab, select the magnifying glass to find an existing **Application Name** on the host server, or select + to create a target Application. Select or create a Windows Proxy type application.  
The **Host Name** field is filled. The Windows Proxy tab appears on the Add Target Account page.
4. Enter the **Account Name**. The Account Name must be unique for a given target application and must be the account name that is used by the target system.

### NOTE

This target account requires Administrator rights on the Windows server.

5. Select the **Password View Policy** for the account.
6. Select whether the **Account Type** is A2A (application-to-application) or privileged account. This choice is only possible if your license allows for A2A accounts.
7. (Optional) Enter an **Access Type**. Access type is a reference field for customer convenience. Access Type is not used by Credential Manager.
8. If you select A2A Account Type, more fields appear:
  - a. If you are using target groupings, enter **Descriptors** for the target Account.
  - b. Enter target **Aliases**. A target alias name must be unique across Credential Manager.
  - c. Enter the appropriate settings for password **Cache Behavior** for the A2A Client:
    - **Use Cache First:** The A2A Client looks for the password in local cache first. If there is no password or if the password is not the most recent, the A2A Client contacts Credential Manager.
    - **Use Server First:** The A2A Client contacts Credential Manager to get the most recent password. If a password is unavailable, the A2A Client looks in the local cache.
    - **No Cache:** The password is never stored in the local cache. The A2A Client always contacts Credential Manager for the password.
  - d. For A2A accounts that use caching, set the cache duration in **Cache Expiry Days**.
9. Enter an initial account **Password** or select the blue Generate Password icon to generate a default password. The Generate Password icon is to the right of the Password field, and looks like a ring with a set of keys.
10. On the Password tab, select **Discovery Allowed** to discover accounts from the Windows Proxy system.
11. Select the appropriate synchronization option (for example, update both Credential Manager and the target system). The **Synchronized** option is not available for the Generic application type.
  - **Update only the Password Authority Server:** Passwords are updated only in Credential Manager. Credential Manager and target system passwords can differ.
  - **Update both the Password Authority Server and the target system:** Password updates are performed both in Credential Manager and on the target system to maintain consistency.
12. If you use multiple target accounts, add the target servers on the Compound Servers tab. For more information, see the Compound Target Accounts section in [Add Target Accounts and Aliases](#).
13. (Optional) If you are adding or updating an account and you do not know the existing password, select the **Force password change** checkbox. The existing password gets changed, even though the account is not in sync.
14. Select **OK** to save changes.

Your new Windows Proxy Account is added to the Target Accounts page.

## Use An Alternate Account to Change Passwords

You can specify an account that has the authority to change passwords. On the Windows Proxy tab, the Change Process option lets you determine which account manages password changes. The options for this setting are:

- **Account can change own password.** To allow the existing target account to change its own password, keep the default option, **Account can change own password**, selected. The initial password that you enter must be the same as the target account password. The exception is a user with more privileges, who can update the password.
- **Use proxy credentials to change password.** Select this option for domain accounts. For this option to work:
  - Configure the Windows Proxy server on a Domain member.
  - Configure the service to run with credentials for a domain account that Windows Proxy connector can use to change passwords.
- **Use the following account to change password.** Select this option to specify a master account that can change password. For most target accounts, a blank field appears below the radio button. Select the magnifying glass and search for the target account to use as the alternate. Avoid using the current target account as the alternate. To show the target accounts that are defined in the system, filter by account name or host name. You can also show all target accounts. Typically, the other account is an account of the same application.

### **Discover Windows Proxy Target Account Services and Scheduled Tasks**

You can use account discovery to manage credentials of multiple Windows services and scheduled tasks. PAM can use the target account to manage changes and updates for any services and scheduled tasks that use this account. You do not have to update the password on an individual service or scheduled task basis.

#### **NOTE**

This procedure is for local Windows accounts. To discover services and scheduled tasks for Active Directory accounts, see [Discover Services and Scheduled Tasks for AD Accounts](#).

#### **Prerequisite**

Before you run account discovery, go to the Account Discovery tab of the Windows Proxy Target application. Select the discover option for services or tasks. You can select both.

#### **Discover Services and Tasks**

To discover new tasks and services on Windows Proxy accounts, follow these steps:

1. Select **Credentials, Discovery**.
2. On the Scan Profiles tab, select **Run** for the profile of the account you want to update.  
If a profile does not exist, follow these steps:
  - a. Select **Add**.
  - b. Give the profile a **Name**.
  - c. On the Servers tab, select the Server that is associated with the remote account.
  - d. Select **Run**.
3. Select the **Discovered Accounts** tab.  
Windows Proxy accounts that have updates available display a green checkbox under the Updates Available column.
4. Select the **Update** button for the Windows Proxy account with updates available.  
The Update Discovered Accounts window appears. Available Services and Scheduled Tasks appear on their respective tabs.
5. Select **OK**.
6. Select **Yes** when you are prompted to Update Selected Accounts.
7. To see a list of services and scheduled tasks:
  - a. Select **Credentials, Manage Targets, Accounts**.
  - b. Select the Services and Scheduled Tasks tabs to display the list accounts.

To remove tasks and services from a Windows Proxy Target Accounts, follow these steps:

1. Select **Credentials, Manage Targets, Accounts**.
2. Select the account that you want to modify.

3. Select **Update**.
4. Select the Services or Scheduled Tasks tab.
5. To delete a service or task, select the **X** next to the entry.

**NOTE**

**More Information:** [Account Discovery](#)

## Windows Proxy Target Connector CLI Configuration

This section describes using the Credential Manager command-line interface (CLI) to add Windows Proxy applications and accounts. For introductory information about the Windows Proxy, see [Configure the Windows Proxy Connector](#).

### Windows Proxy Add Target Application CLI Parameters

To add a Windows Proxy target application and connector using the CLI, use the [addTargetApplication](#) command and the following command parameters:

#### ***Attribute.extensionType***

Specify the type of account to be used.

Required	Default Value	Valid Values
yes	N/A	windows

#### ***Attribute.agentId***

The identifiers for the Windows Proxies used to manage passwords.

Required	Default Value	Valid Values
yes	N/A	Comma separated list of Windows Proxy IDs. Each ID is a numeric.

#### ***Attribute.accountType***

The type of account being managed.

Required	Default Value	Valid Values
no	domain	domain, local

#### ***Attribute.domainName***

The Windows domain for the managed accounts.

Required	Default Value	Valid Values
Required if Attribute.accountType is set to domain (the default)	none	Domain name (a text string)

#### ***Attribute.domain***

The Windows domain for the managed accounts. This setting exists only for backwards compatibility. We recommend using `Attribute.domainName` instead.

Required	Default Value	Valid Values
Required if <code>Attribute.accountType</code> is set to domain (the default)	none	Domain name (a text string)

### ***Attribute.useDNS***

Determine the level to which DNS is used.

Required	Default Value	Valid Values
Required if <code>Attribute.accountType</code> is set to domain (the default)	none	One of: <ul style="list-style-type: none"> <li><code>noDNS</code> : DNS is not used</li> <li><code>retrieveDNS</code> : Retrieve the DNS server that is used by the Credential Manager server</li> <li><code>specifiedDNS</code> : Use the DNS server that is specified by the <code>dnsServer</code> attribute</li> </ul>

### ***Attribute.dnsServer***

The host names of the DNS servers to use.

Required	Default Value	Valid Values
Required if <code>Attribute.useDNS</code> is set to <code>specifiedDNS</code>	none	Comma separated list of DNS server host names.

### ***Attribute.specifiedServersList***

Provide a comma separated list of domain controllers.

Required	Default Value	Valid Values
Required if <code>Attribute.useDNS</code> is set to <code>specifiedServers</code>	none	Comma separated list of valid domain controllers.

### ***Attribute.adSite***

The Active Directory site. This parameter is only used if `Attribute.useDNS` is set to `retrieveDNS` or `specifiedDNS`. If a value is given, Credential Manager uses the value to narrow the search for domain controllers using the specified name.

Required	Default Value	Valid Values
no	none	String.

## **Windows Proxy Add Target Account CLI Parameters**

To add a Windows Proxy target account that uses the target connector, use the [addTargetAccount](#) command and the following parameters:

### ***Attribute.extensionType***

Specify the type of account to be used.

Required	Default Value	Valid Values
yes	N/A	windows

#### ***Attribute.useOtherAccountToChangePassword***

Specify whether to use the target account or a different account to perform password change requests.

Required	Default Value	Valid Values
yes	N/A	true, false, agent

#### ***Attribute.otherAccount***

Specify which other account to use to perform password change requests.

Required	Default Value	Valid Values
Required if <code>Attribute.useOtherAccountToChangePassword</code> is true.	N/A	String. A valid target account ID.

#### ***Attribute.serviceInfo***

List services.

Required	Default Value	Valid Values
no	N/A	<code>&lt;empty string&gt;</code> no services Add the following attribute for each service: <code>&lt;hostname&gt;:&lt;servicename&gt;:restart</code> or <code>&lt;hostname&gt;:&lt;servicename&gt;:norestart</code> Multiple services are delimited by the   character. <code>&lt;hostname&gt;</code> is the name of the server where the service is hosted.

#### ***Attribute.tasks***

List scheduled tasks.

Required	Default Value	Valid Values
no	none	<code>&lt;empty string&gt;</code> no tasks Add the following attribute for each task: <code>&lt;hostname&gt;:&lt;taskname&gt;</code> Multiple services are delimited by the   character. <code>&lt;hostname&gt;</code> is the name of the server where the scheduled task is hosted.

#### ***Attribute.forcePasswordChange***

This parameter specifies whether Credential Manager updates passwords that fail verification during an initial synchronization. The default value is false. To update passwords that fail initial synchronization, set the attribute value to true.

Required	Default Value	Valid Values
no	false	true, false

### **Windows Proxy CLI Example**

```
cmdName=addTargetApplication TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=myWindows

TargetApplication.type=windows Attribute.extensionType=windows Attribute.agentId=1

Attribute.accountType=domain Attribute.domainName=testDomain
```

```
cmdName=addTargetAccount TargetServer.hostName=myhostname.mydomain.com
TargetApplication.name=mywindows

TargetAccount.userName=admin TargetAccount.password=P@ssw0rd
TargetAccount.cacheAllow=true

TargetAccount.cacheDuration=19 Attribute.extensionType=windows
Attribute.useOtherAccountToChangePassword=false

Attribute.forcePasswordChange=false Attribute.serviceInfo=HostA:serviceName:restart|
HostB:ServiceName:norestart

Attribute.tasks=HostA:taskName|HostB:taskName
```

## **Windows Proxy Target Connector External API Configuration**

This topic describes the required and supported Attributes used when adding or updating Windows Proxy target applications using the External API.

### **Windows Proxy Target Application External API Parameters**

To add or update a Windows Proxy target application using the External API, use the following properties as members of the "attributes" associative array included in the 'body' parameter of the REST call.

#### ***agentId***

The identifiers for the Windows Proxies used to manage passwords.

Required	Default Value	Valid Values
Required if agentHostname is not set	N/A	Comma separated list of Windows Proxy IDs. Each ID is a numeric.

### ***agentHostname***

The host names of the Windows Proxies used to manage passwords.

Required	Default Value	Valid Values
Required if agentId is not set	N/A	Comma separated list of Windows Proxy Hostnames

### ***accountType***

The type of account being managed.

Required	Default Value	Valid Values
no	domain	domain, local

### ***domainName***

The Windows domain for the managed accounts.

Required	Default Value	Valid Values
Required if accountType is set to domain (the default)	none	Domain name (a text string)

### ***domain***

The Windows domain for the managed accounts. This setting exists only for backwards compatibility. We recommend using `domainName` instead.

Required	Default Value	Valid Values
Required if accountType is set to domain (the default)	none	Domain name (a text string)

### ***useDNS***

Determine the level to which DNS is used.

Required	Default Value	Valid Values
Required if accountType is set to domain (the default)	none	One of: <ul style="list-style-type: none"> <li><code>noDNS</code> : DNS is not used</li> <li><code>retrieveDNS</code> : Retrieve the DNS server that is used by the Credential Manager server</li> <li><code>specifiedDNS</code> : Use the DNS server that is specified by the <code>dnsServer</code> attribute</li> </ul>

***dnsServer***

The host names of the DNS servers to use.

Required	Default Value	Valid Values
Required if <code>useDNS</code> is set to <code>specifiedDNS</code>	none	Comma separated list of DNS server host names.

***specifiedServersList***

Provide a comma separated list of domain controllers.

Required	Default Value	Valid Values
Required if <code>useDNS</code> is set to <code>specifiedServers</code>	none	Comma separated list of valid domain controllers.

***adSite***

The Active Directory site. This parameter is only used if `useDNS` is set to `retrieveDNS` or `specifiedDNS`. If a value is given, Credential Manager uses the value to narrow the search for domain controllers using the specified name.

Required	Default Value	Valid Values
no	none	String.

**Windows Proxy CLI Example**

```
{
  "applicationName": "MyWindows",
  "applicationType": "windows",
  "attributes": {
    "agentId": "1",
    "accountType": "domain",
    "domainName": "testDomain"
  }
}
```

**View Windows Proxy Logs**

You can view Windows Proxy logs with the UI, so you can troubleshoot client issues.

**Follow these steps:**

1. Select **Credentials, Manage Targets, Proxies**.
2. Select the host name of the server where the proxy whose logs you want to view is installed and select **Update**.

**NOTE**

You can only request the most recent log file. Previously rotated files are excluded.

3. Select the **Get Logs** button.

A zip file containing the Windows Proxy logs directory is downloaded to your browser. The default maximum file size is 20 MB. You can configure the maximum file size using the `getLogsMaxSize`

`{SystemProperty.SYSTEM_PROPERTY_MAX_LOG_SIZE}` property setting. For further details, see the description of the [setSystemProperty](#) CLI command.

## API Key Target Connector

This target connector is for the Privileged Access Manager External API. This connector does not map to any device, but it is available as an application type so an administrator can view the password. The API Key connector supports rollover of the target account, but there is no external device that needs its password rolled over.

The connector does not introduce any additional parameters when using the CLI to add a target application or target account.

## Develop Custom Connectors for Remote Targets

The out-of-the-box application types and target connectors that the appliance provides might not be sufficient for your remote systems and applications. For remote targets that are not available out-of-the-box, you can build custom target connectors. Privileged Access Manager offers a Custom Connector framework, which provides the necessary components to develop custom target connectors.

The process to build a custom target connector includes the following tasks:

- [Deploy the Custom Connector Software](#)
- [Try Out the Sample Custom Connectors](#)
- [Learn How to Use the Custom Connector Components](#)
- [Build Your Custom Connector](#)
- [Configure Custom Connectors Using the CLI](#)
- [Troubleshoot Custom Connector Issues](#)

Before you begin these tasks, familiarize yourself with the target connector framework.

### Target Connector Framework Functions

The *target connector framework* (TCF) and a custom connector enable users with the necessary privileges to view and update remote account passwords.

#### **NOTE**

The target connector framework is referred to as the **TCF** going forward in this guide.

The TCF communicates with the appliance and the custom target connector for the following functions:

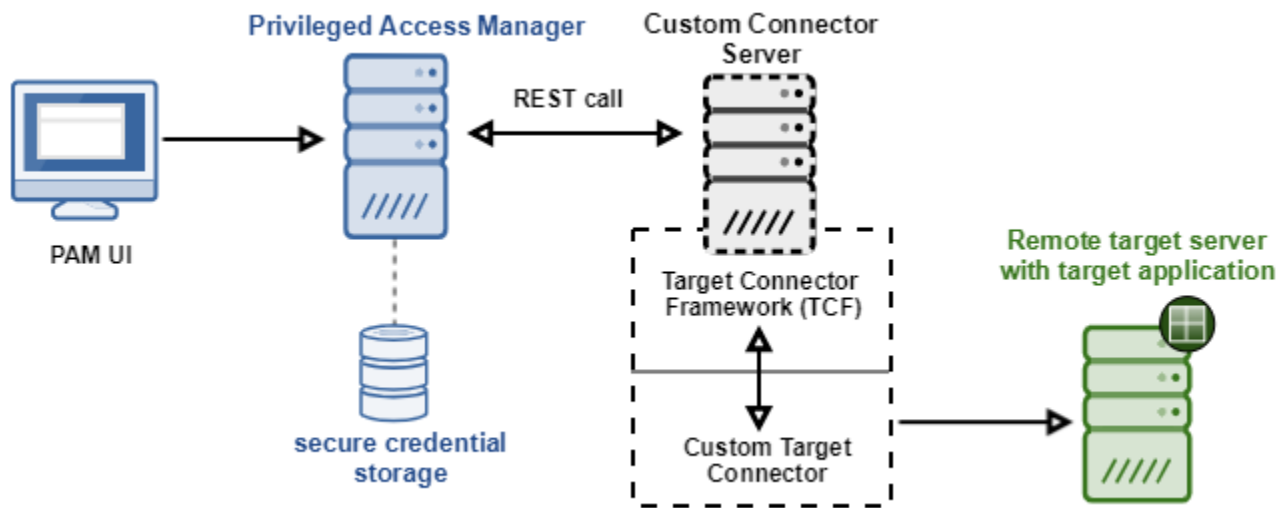

- Sends the appliance information about the custom connector and the remote target.
- Sends information about the target application and target account to the UI.
- Exchanges data between the appliance and the custom target connector to change and view the target account passwords.

The TCF and the custom target connector are installed on a *Custom Connector server*. The Custom Connector server is a Tomcat server.

#### **NOTE**

Any reference to the **Custom Connector server** implies a Tomcat server where the TCF and custom target connector are installed.

The following graphic shows where the TCF and custom connector reside in a PAM deployment.

**Figure 26: Custom Target Connector in a Network**

### **TCF Communication with PAM and Custom Connectors**

The TCF has the following main components:

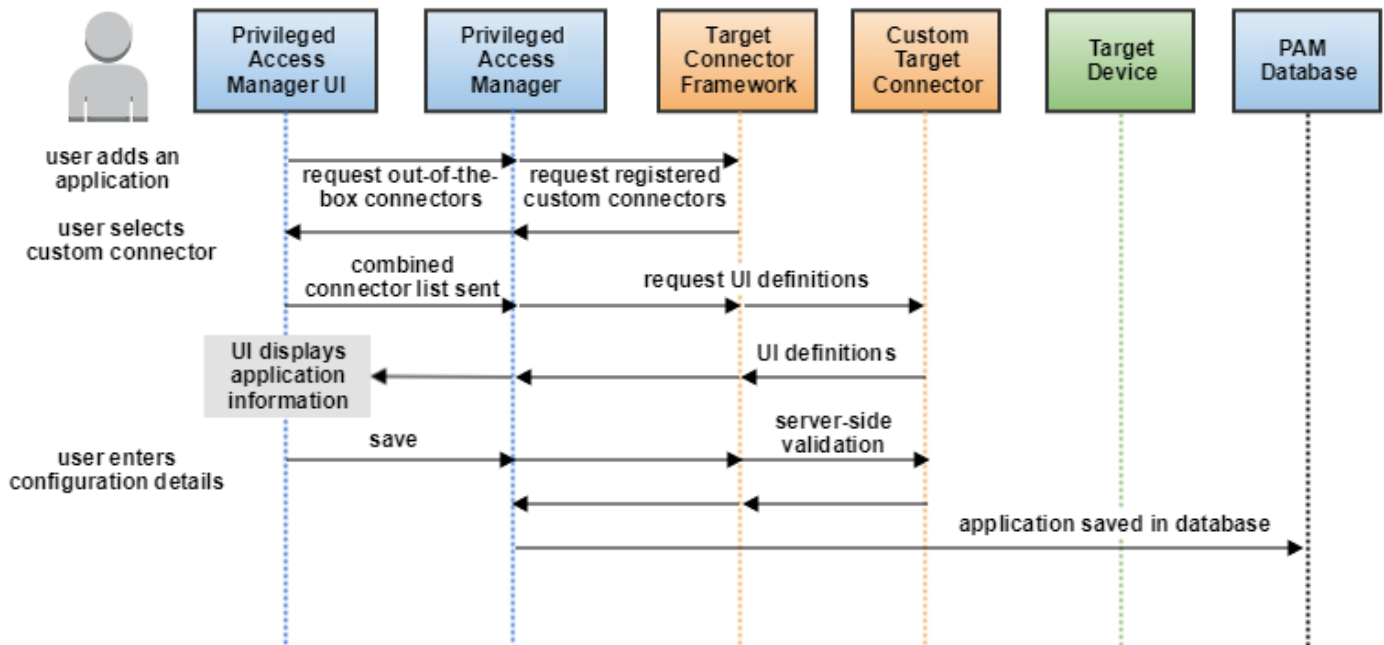

- TCF web application
- UI schema to define the custom UI fields and controls
- A TCF SDK

The TCF web application acts as a proxy between PAM and the custom target connectors. When the appliance sends a request for available target connectors, the TCF calls the custom target connectors. The TCF then sends the list of deployed connectors back to the appliance. The UI elements are then rendered on the appliance. The TCF also handles tasks that are related to verifying and changing account passwords. The TCF sends a request to the target connector to perform these tasks.

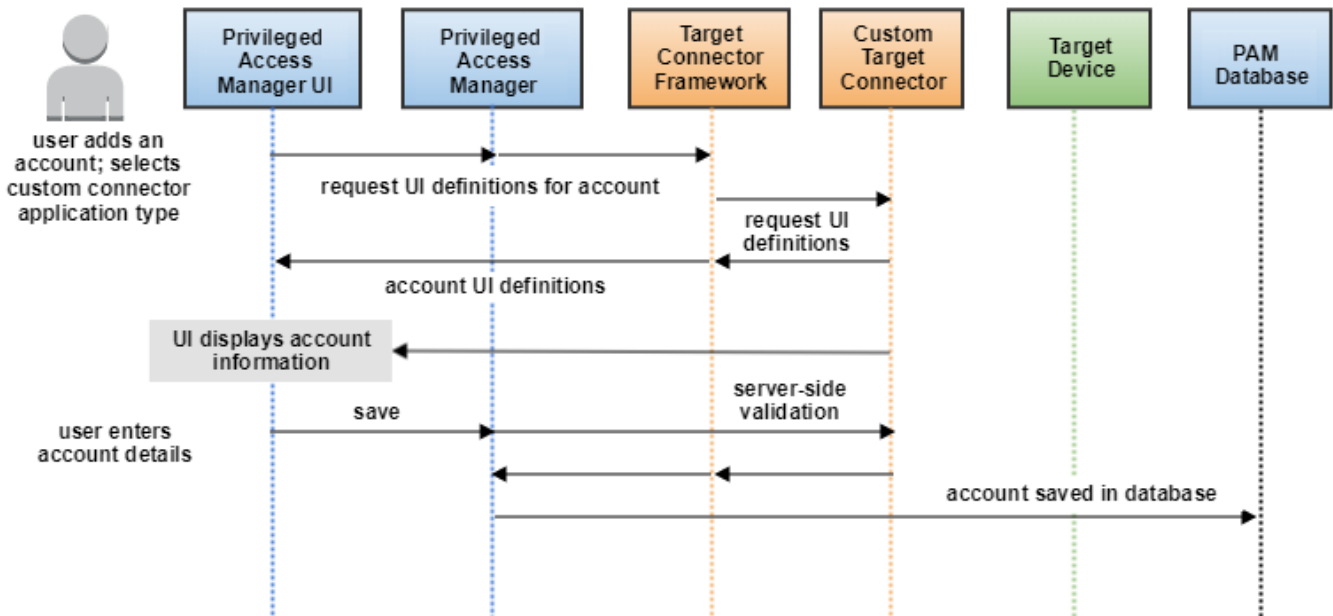

When a custom target connector starts up, it registers with the TCF. The connectors themselves manage the UI fields and controls for target accounts and applications.

### ***Data Flow for a Target Application***

The following graphic shows the data flow between Privileged Access Manager, the TCF, the target connector, and the target application:

**Figure 27: Target Connector Framework Data Flow****Data Flow for a Target Account**

The following graphic shows the data flow between PAM, the TCF, the target connector, and the target account:

**Figure 28: Target Connector Framework Account Data Flow**

## **Customer Responsibilities for Custom Connectors**

If you build custom target connectors that are based on the TCF, you are responsible for the operation between the custom target connector and the target endpoint. These responsibilities include:

- Writing log messages from the target connector to the TCF server catalina.out log
- Writing any log messages that the target connector returns to PAM.
- Obfuscating passwords when log messages are written into the catalina.out file on the TCF server.
- Providing for secure information transfer between the target connector and the target endpoint.

CA Technologies is responsible for operation up to the point where the TCF passes information to the custom target connector. After that point, you are responsible for how the custom connector handles communication, operationally and securely.

### **NOTE**

**Begin the first task:** [Deploy the Custom Connector Software](#).

## **Deploy the Custom Connector Software**

This topic explains how to install and deploy the Custom Connector software. The procedures apply to development and production systems, with one more step for the production system. After deployment on a production system, you remove two folders.

### **NOTE**

In this topic, example file paths are for UNIX systems and use a forward slash (/). For Windows systems, the paths are similar but use a backward slash (\).

## **Required Software for the Custom Connector Server**

The Custom Connector Server (Tomcat) server needs the following software:

- Apache Tomcat 9
- Java 8 or Java 11 (In a deployed production environment, you only need the JRE)

## **Minimum System Requirements**

- 2 CPUs are recommended but 1 CPU is sufficient
- 4-GB RAM
- 32-GB Disk space

## **Install Tomcat**

Install Tomcat 9 on a Windows or Linux system. If you install Tomcat on a Linux system, run Tomcat as a service. For installation instructions, see the [Apache Tomcat 9 documentation](#).

### **WARNING**

Use a dedicated Tomcat server for the Custom Connector installation.

## **Download the Custom Connector Software**

Download the Custom Connector software from the Broadcom Support site to the Tomcat server that you created. For information on how to download the software, see [Download PAM Installation Media](#).

### **NOTE**

The Tomcat server is referred to as the *Custom Connector Server* throughout the rest of the documentation.

## ***Extract the Custom Connector Files***

Unzip the Custom Connector archive to a directory, such as **/tmp/tcf**. The subdirectories and files that are shown in the following table are created under that directory:

Directory	Content
<b>application</b>	<code>capamef.war</code> : The TCF web application.
<b>conf</b>	<ul style="list-style-type: none"> <li><code>capamef_messages.properties</code> : Contains messages for the framework to report in tomcat log and potential back to when problems occur</li> <li><code>extension_framework.properties</code> : A set of configuration properties the framework uses to communicate with the core pieces of the extension framework running in Tomcat and PAM.</li> </ul>
<b>samples</b>	<ul style="list-style-type: none"> <li><code>exampleTargetConnector.war</code> : Sample target connector for Linux devices</li> <li><code>echoTargetConnector.war</code> : Sample target connector which logs received requests.</li> </ul>
<b>sdk</b>	<ul style="list-style-type: none"> <li><code>lib</code> : Contains the library <code>caextensionscore-x.xx.x.jar</code> and its dependencies. The <code>x.xx.x</code> represents the version of the JAR.</li> <li><code>customConnectorTemplate</code> : Contains project metadata files that are related to the tools Gradle, Maven, and the source code.</li> <li><code>exampletargetconnector</code> : Contains the source code for the Example Target Connector.</li> <li><code>echotargetconnector</code> : Contains the source code for the Echo Target Connector.</li> <li><code>createTCProject</code> : A shell script for UNIX platforms to create the custom connector project.</li> <li><code>createTCProject.cmd</code> : A batch script for Windows systems to create the custom connector project.</li> <li><code>tcProjectGenerator.jar</code> : The library that generates the custom connector project.</li> </ul>
<b>configTCF</b>	<p>Tools for various TCF encryption tasks:</p> <ul style="list-style-type: none"> <li><code>capamextensionstcfCryptoUtil-x.xx.x.jar</code> : A library that encrypts and decrypts the keystore password. The library uses the Machine ID of the system where the Custom Connector server is installed. The <code>x.xx.x</code> represents the version of the JAR.</li> <li><code>configTCF</code> : The UNIX utility for creating a keystore for encryption and decryption tasks.</li> <li><code>configTCF.cmd</code> : The Windows utility for creating a keystore for encryption and decryption tasks.</li> </ul>

### **Deploy the Custom Connector WAR Files**

To deploy the Custom Connector WAR files on the Custom Connector Server, the directories and WAR files must have the right owners and permissions. The required file and directory ownership and permissions are listed by platform:

#### **Linux Platforms**

- **File and Directory Ownership:** Set the owner to the Tomcat user and group. For example, to set the ownership of the `capamef.war` enter:

```
chown tomcat:tomcat capamef.war
```

- **File Permissions:** Give the Tomcat user read/write permissions. For example, to set the permissions for capamef.war, enter:

```
chmod 600 capamef.war
```

- **Directory Permissions:** Give the Tomcat user Read/Write/Execute (rwx) permissions. Give the group Read/Execute (rx) permissions. For example, to assign rx permissions to the webapps\_targetconnectors directory, enter:

```
chmod 750 webapps_targetconnectors
```

## Windows Platforms

- **File and Directory Ownership:** The Windows Administrator must be the owner
- **File and Directory Permissions:** Only the Administrator user from the group Administrators has write access. No other user has write permissions.

## Deploy the WAR files

### Follow these steps:

1. Copy the **capamef.war** file to the directory */CATALINA\_HOME/webapps*, where *CATALINA\_HOME* is the installed location of the server.
2. Under the *CATALINA\_HOME*, create a directory that is named **webapps\_targetconnectors**.
3. Copy the **exampleTargetConnector.war** file and the **echoTargetConnector.war** file to the **webapps\_targetconnectors** directory.
4. Configure the Custom Connector server, as instructed in the next section.

## Configure the Custom Connector Server

After you deploy the software, complete the following tasks at the Custom Connector server:

1. Create a keystore for HTTPS communication
2. Modify the server.xml file

In the following procedures, *CATALINA\_HOME* is the installed location of the server.

### Create a Keystore for HTTPS Communication

For secure communication between PAM and the TCF, configure the Tomcat server to use TLS. This step is optional but recommended. For TLS support, create a keystore with a keystore password. The keystore holds the X.509 key/certificate pair for securing communication. For complete instructions about configuring TLS, see the Apache Tomcat documentation.

To secure the keystore, encrypt the keystore password. Use the Custom Connector server utility, named **configTCF**, to encrypt the keystore password. The password is encrypted with the Machine ID of the system on which the Custom Connector server is installed. Each system has a unique Machine ID.

The following procedure uses the keytool utility as an example. You can create a keystore using other tools.

### To create a keystore and encrypt the password, follow these steps:

1. Create a PKCS12 keystore by entering the following keytool command. The keystore must contain an X.509 private key and certificate pair in PEM format.

```
keytool -genkey -alias pam -keyalg RSA -keysize 2048 -storetype PKCS12 -dname
"CN=capamtcf,OU=PAM,O=Organization,L=City,ST=State,C=Country" -keypass keystore_password -
storepass keystore_password -keystore keystore_file -validity 360
```

*Organization* is the name of the organization. For example, "Broadcom".

*City* is the name of city in which the keystore is located. For example, "Burlington".

*State* is the code for the state or province in which the keystore is located. For example, "MA".

*Country* is the code for the state or province in which the keystore is located. For example, "US".

*keystore\_password* is the password that you want to assign to the keystore.

*keystore\_file* is full path and file name of the location that you want to generate the keystore.

2. Give the user running the Tomcat process **read** permission to the keystore file.
3. Extract the certificate from the keystore that you generated in step 1 by executing the following command:

```
keytool -exportcert -alias pam -keystore keystore_file -keypass keystore_password -storepass keystore_password -rfc -file tcf.crt
```

Keep the file tcf.crt. This certificate is required when you configure the PAM Custom Connector settings later.

4. Navigate to the location of the extracted TCF zip file and find the **configTCF** folder.
5. Encrypt the keystore password by executing the command for your operating system:

– **Windows:**

```
configTCF.cmd -Dcommand=encryptPassword -Dpassword=keystore_password
```

– **Unix/Linux:**

```
configTCF -Dcommand=encryptPassword -Dpassword=keystore_password
```

*keystore\_password* is a password value that you assigned.

The configTCF command output is an encrypted keystore password that is displayed on the command prompt.

6. Copy the encrypted password to a temporary file.
7. From the configTCF folder, copy the **capamextensionstcfCryptUtil.jar** file to *CATALINA\_HOME/lib*. *CATALINA\_HOME* is the location where the Tomcat server is installed.
8. Navigate to *CATALINA\_HOME/conf* and open the **catalina.properties** file.
9. Copy the following line from this document and paste it at the end of the **catalina.properties** file:

```
org.apache.tomcat.util.digester.PROPERTY_SOURCE=com.ca.pam.extensions.tcfcryptoutil.TCFPropertySource
```

*encrypted\_keystore\_password* is the encrypted password that is generated in the previous step.

The encrypted keystore password is unique to the system where it is generated. You cannot generate the password on one server then copy the encrypted information to another server. On each production server, run the configTCF to encrypt the keystore password. After the password is encrypted, delete the configTCF utility from the system.

## NOTE

An alternate method to secure the keystore is to use the PAM A2A functionality. For instructions, see [Use A2A to Secure the Keystore for HTTPS \(Optional\)](#).

## Modify the Tomcat server.xml File

Modify the server.xml file to:

- Add a connector service that uses port 18080 (required)
- Add a connector service that uses port 8443 for HTTPS communication (required only for TLS support)

## Follow these steps:

1. Navigate to */CATALINA\_HOME/bin* and enter values for the required variables in the catalina.sh script.
2. Navigate to */CATALINA\_HOME/conf*.
3. Copy the **server.xml** file then rename the *original* file. Give the original file a unique name.
4. Open the server.xml file in a text editor.
5. Add a connector service that uses port 18080. **This port uses loopback address 127.0.0.1 for IPv4 and ::1 for IPv6.** The following file excerpt shows an example of the added connector service (CatalinaTC):

```
<Service name="CatalinaTC">
  <Connector port="18080" protocol="HTTP/1.1" connectionTimeout="30000"
    URIEncoding="UTF-8" address="127.0.0.1" />
  <!-- Define an AJP 1.3 Connector on port 8009
    <Connector port="18009" protocol="AJP/1.3" redirectPort="18443" />
  <Engine name="CatalinaTC" defaultHost="targetconnectors">
    <Host name="targetconnectors" appBase="webapps_targetconnectors"
```

```

    unpackWARs="true" autoDeploy="false" deployOnStartup="true">
    <Valve className="org.apache.catalina.valves.AccessLogValve" directory="logs"
    prefix="localhost_access_log" suffix=".txt"
    pattern="%h %l %u %t &quot;%r&quot; %s %b" />
  </Host>
</Engine>
</Service>

```

For an IPv6 IP address, the third line below should be used:

```

<Service name="CatalinaTC">
  <Connector port="18080" protocol="HTTP/1.1" connectionTimeout="30000"
  URIEncoding="UTF-8" address="::1" />
  ...

```

6. Keep port 8080 open for the local host at least. To ensure port 8080 is open, verify that *one* of the following entries is in the server.xml file, under:

If you enabled TLS for the Custom Connector, ensure that the following entry exists:

```

<Connector port="8080" protocol="HTTP/1.1" connectionTimeout="30000" URIEncoding="UTF-8"
address="127.0.0.1" />

```

If you did not enable TLS, ensure that the following entry exists:

```

<Connector port="8080" protocol="HTTP/1.1" connectionTimeout="30000" URIEncoding="UTF-8"/>

```

7. If you enable TLS for the Custom Connector, add a connector service that uses port 8443 (HTTPS port). Add this connector under the default Catalina service (<Service name="Catalina">) section. Port 8080 is in the server.xml file by default; but use port 8443 for secure TCF communication.

The following code excerpt shows how to add port 8443:

```

<Connector protocol="org.apache.coyote.http11.Http11NioProtocol"
port="8443" maxThreads="200"
scheme="https" secure="true" SSLEnabled="true"
keystoreFile="keystore_file_path" keyAlias="unique_key_identifier" keystorePass="${tomcat.keystore.pwd}"
clientAuth="false" sslProtocol="TLS" xpoweredBy="false"/>

```

Ensure that you specify the full keystore file path, including the name of the keystore.

#### TIP

Enter the string `keystorePass="${tomcat.keystore.pwd}"` exactly as shown. This string is an alias for the encrypted password. Use the `keyAlias` attribute to uniquely identify the key to avoid identification issues when there are multiple keys in the keystore.

8. Save the server.xml file.
9. Restart the Tomcat server.
10. Verify that the Tomcat server is set up correctly. Navigate to `CATALINA_HOME/logs` and look for the following messages:

```

INFO [main] org.apache.coyote.AbstractProtocol.start Starting ProtocolHandler ["http-nio-8080"]
INFO [main] org.apache.coyote.AbstractProtocol.start Starting ProtocolHandler ["https-jsse-nio-8443"]
INFO [main] org.apache.coyote.AbstractProtocol.start Starting ProtocolHandler ["http-nio-127.0.0.1-18080"]
INFO [main] org.apache.coyote.AbstractProtocol.start Starting ProtocolHandler ["http-
nio-0:0:0:0:0:0:0:1-18080"]
INFO [main] org.apache.catalina.startup.Catalina.start Server startup in <duration_to_start_server>

```

If the Tomcat server does not start up, see [Troubleshoot Custom Connector Issues](#) for possible solutions.

## Secure the Custom Connector Server

We recommend that you harden, that is, secure the Custom Connector server. Securing the server reduces its vulnerability to attacks. For instructions on how to [secure the Tomcat server](#), see the Tomcat documentation. See also the [sample server.xml file](#), which has entries for securing the server.

## Configure Custom Connector Settings at PAM

The Custom Connector configuration page has settings to identify the Custom Connector server. The page also has settings to secure communication between PAM and the Custom Connector server.

### Follow these steps at the PAM UI:

1. Log in to the PAM UI and navigate to **Configuration, Custom Connectors**.
2. Identify the Custom Connector server by entering values for the following fields:
  - **Server Address**: Enter the IP address of the Tomcat server
  - **Server Port**: Enter the port on which Tomcat listens for HTTP traffic
3. Specify the timeout settings:
  - **Connect Timeout (sec)**: This timeout specifies how long PAM waits for a response from the TCF. Default: 3 seconds
  - **Read Timeout (sec)**: This timeout specifies how long PAM waits for a response from TCF. This timeout is for requests other than credential management operations, such as requests for data to construct and validate the UI content. Default: 3 seconds.
  - **Update Timeout (sec)**: This timeout specifies how long PAM waits for a response from the TCF about credential management operations. Operations can include a password verification or a password rollover. Default: 30 seconds
4. (Optional but recommended) Enable TLS to secure the communication channel:
  - a. Obtain the server certificate (**tcf.crt file**) from the Custom Connector server keystore. You extracted the tcf.crt file after you [created a keystore for HTTPS communication at the Tomcat server](#).
  - b. Confirm that the **Use TLS** checkbox is selected. We recommend using TLS over HTTPS port 8443.
  - c. For the **Certificate Filename** field, select **Choose File** next to the field. Browse to the server certificate on your local system and select it. The file name displays in the **Current Certificate File** field.
5. Generate an encryption key. The key encrypts the authentication token and the payload that PAM sends with each REST call to the Custom Connector server.
  - a. Next to the **Encryption Key** field, select **Generate Key**. The appliance creates a key and puts the value in the field. For example: **em6/C5X7GxBZiGt9QF4Z56SBjxOM2jvmwoacGjUAXvk=**
  - b. Copy the encryption key value and save it to a file.
  - c. For the **Authentication Token Validity (sec)** field, determine how long you want the authentication token to be active. The default value (120 seconds) allows for any timing delays between PAM and the Custom Connector server. The PAM and Custom Connector servers clocks must be synchronized.
6. Select **Save**. A message indicates that the appliance is connected to the Custom Connector server.

### WARNING

The **Clear** button returns the settings on the page to the factory defaults. The Clear button also deletes your configuration from the UI and the PAM database. To reestablish your configuration, you must regenerate the encryption key. Finally, copy the new values over to the `extension_framework.properties` file on the Custom Connector server.

## Create a Keystore at the Custom Connector Server

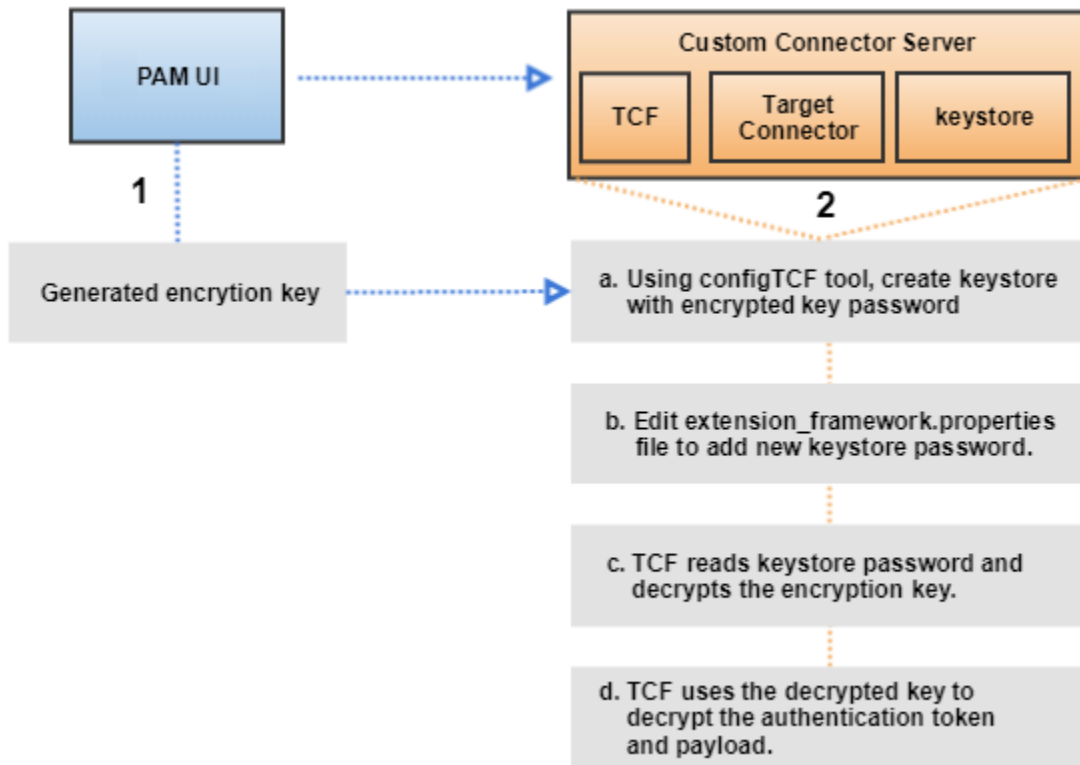

During a REST call to the Custom Connector server, PAM sends an encrypted authentication JWT token in the header and an encrypted payload. Store the encryption key in a keystore at the Custom Connector server. To authenticate a request, the TCF decrypts the JWT token using the stored encryption key. If the TCF cannot decrypt the token, it rejects the request. If decryption is successful, it then uses the key to decrypt the payload.

To generate a keystore, run a configuration utility at the Custom Connector server.

**NOTE**

The keystore that holds the encryption key is unique from the keystore that holds X.509 key/certificate pair for HTTPS communication.

The following graphic illustrates the PAM payload encryption process:

**Follow these steps:**

1. Create a directory named **tcf** in the location `/$CATALINA_HOME/tcf`. The tomcat user should own this directory. Permissions to access this directory should be and have Read/Write/Execute (rwx) for the Tomcat user and Read/Execute (rx) for users in the Tomcat group.
2. Create a keystore. Use the **configTCF** command (UNIX) or **configTCF.cmd** (Windows) and the PAM-generated encryption key. The command syntax is:

```
configTCF -Dcommand=createKeyStore -DkeyStoreFile=keystore_path_and_name -
DkeyStorePW=user_assigned_password -Dkey=CAPAM_encryption_key
keystore_file: file path and name of the keystore.
```

**keystore\_path\_and\_name:** The location and name of the keystore on the Tomcat server.

**user\_assigned\_password:** The password that you specify for the keystore **CAPAM\_encryption\_key:** The key that is generated at the PAM UI and copied to this command

**Windows example:**

```
configTCF.cmd -Dcommand=createKeyStore -DkeyStoreFile="%CATALINA_HOME%\tcf\keyStore -
DkeyStorePWD=keypwd -Dkey=em6/C5X7GxBZiGt9QF4Z56SBjxOM2jvmwoacGjUAXvk=
```

**UNIX example:**

```
configTCF -Dcommand=createKeyStore -DkeyStoreFile=/$CATALINA_HOME/tcf/keyStore -DkeyStorePWD=keypwd -
Dkey=em6/C5X7GxBZiGt9QF4Z56SBjxOM2jvmwoacGjUAXvk=
```

After this configTCF command executes, the file `keyStore` is created in the directory `CATALINA_HOME/tcf/keyStore` and the key password (`keypwd`) is encrypted. The encrypted value of the password `keypwd` is `PIdadRtvyRGPOlCSU7lSxWGgbpnyadRMA5q6cMagx2U=`.

#### NOTE

If you do not specify a file path, the keystore file is created in the directory from where you execute the `configTCF` command.

3. Copy and save the encrypted key store password.
4. Give the user running the Tomcat process **read** permission to the keystore file.
5. Navigate to the **extension\_framework.properties** file at `CATALINA_HOME/webapps/capamef/WEB-INF/classes/extension_framework.properties`.
6. Edit the properties file and add the following entries:
  - `extension.encrypted.pwd`: copy the new password that was generated by the configTCF tool.
  - `extension.keystore.file`: specify the path of the keystore.

If Tomcat's `server.xml` uses `::1` as a loopback address, then modify the `extension.url.prefix` as follows:  
`extension.url.prefix=http://[::1]:18080`
7. If tomcat's `server.xml` uses `::1` as a loopback address, then navigate to `CATALINA_HOME/conf` and open the `catalina.properties` file. Copy the following line from this document and paste it at the end of the `catalina.properties` file:  
`tomcat.tcf.ipv6.preferred=true`
8. The following example shows the new properties in bold. The values of these properties are from the executed configTCF command.

```
Connector.name=TargetConnectorRegistry
extension.url.prefix=http://127.0.0.1:18080
extension.connection.timeout=100000
extension.read.timeout=100000
extension.encrypted.pwd=PIdadRtvyRGPOlCSU7lSxWGgbpnyadRMA5q6cMagx2U=
extension.keystore.file=/home/tcf/keyStore
```

#### WARNING

On Windows and UNIX platforms, always use forward slashes (/) for file paths in the properties file.

9. Save the properties file.
10. Restart the Tomcat server.

To decrypt the token and payload, the TCF reads the **extension.encrypted.pwd** value from the `extension_framework.properties` file. The TCF uses the password to open the keystore and retrieve the encryption key. The key itself is decrypted, then TCF uses it to decrypt the token and payload. Finally, TCF sends the payload to the custom connector.

### Test the Deployment

To test the **communication between PAM to Custom Connector server**:

1. Log in to the UI and navigate to **Configuration, Custom Connectors**.
2. Select **Test** to verify that you can connect to the Custom Connector server.

If the connection is not working, you can also see a message at the top of the **Dashboard Overview Tab**.

**To verify that all files and sample target connectors are deployed correctly:**

1. Log in the PAM UI as a Global Administrator or Configuration Manager.
2. Select **Configuration** on the top menu.
3. Verify that you see the **Custom Connectors** option in the left pane.
4. Select **Credentials, Manage Targets, Application**.

5. Select **Add**.
6. In the **Application Type** field, confirm that the pull-down list includes the Echo Target Connector and Example Target Connector.
7. If you select either of the sample application types, a new tab displays for the application, such as **Example – Application**.
8. Exit from the UI.
9. Log in to the Custom Connector server where the TCF is deployed. Open the **catalina.out** file and look for a message that reads:

```
Registering client of type, targetConnectors, with name: echoTargetConnector
```

If you see the prior message, the deployment is successful.

### **Remove Unused Folders from the Production Systems**

After you deploy the Custom Connector on a production server, remove the following folders that are not required for use in production:

- sdk folder
- configTCF folder

### **Sample server.xml File**

The following code shows an example server.xml file, which has entries for securing a PAM server that can be used as a basis for securing the custom connector server.

```
<?xml version="1.0" encoding="UTF-8"?>

## Use an Alternate Custom Connector Server for Disaster Recovery

In a multi-site cluster environment, you can configure an alternate Custom Connector Server to be used if your primary site fails and a secondary site is promoted to be the new primary. The alternate Custom Connector Server configuration is replicated to all other members of the cluster but ignored until the **Use Alternate Server** option is set.

### NOTE

Although the alternate Custom Connector Server configuration is replicated to all other members of the cluster, the value of the **Use Alternate Server** setting, which controls whether the alternate Custom Connector Server is used, is not replicated. You must configure it independently on each node in the cluster.

Because credential management work with the Custom Connector Servers is done by the primary site, the Custom Connector Server specified on the secondary nodes (with the **Use Alternate Server** setting) is ignored until the secondary site becomes a primary site.

Also, because this setting is not replicated, you can select **Use Alternate Server** on the secondary site nodes in preparation for a potential secondary site promotion to primary site in the future. Credential management work with the Custom Connector Servers is done by the primary site. In that sense, the Custom Connector Server chosen on the secondary nodes ( the Use Alternate Server setting ) does not come into play until the secondary site becomes a primary site.

In a single-site environment, you can set up an alternate Custom Connector Server as a backup server. The alternate Custom Connector server uses a different TCF instance from the first instance that the main server uses. If your main server becomes inoperative for any reason, you can enable the already configured alternate Custom Connector Server for communication with your custom target connectors and applications.

### NOTE

All target connectors must be configured for each Custom Connector server instance.

### To configure an alternate server for disaster recovery (multi-site cluster):

1. At the primary site, navigate to **Configuration, Custom Connector**.
2. On the **Connector Server** panel, complete the settings then save the configuration.
3. Log in to a secondary site member.
4. On the **Connector Server** panel, set the **Use Alternate Server** option.
5. Select the **Alternate Connector Server** tab.
6. Configure the settings then save the configuration.
7. Repeat this procedure for each member of the secondary site.

If you promote the secondary site to become the primary, the configuration of the alternate Custom Connector Server is used.

### To configure an alternate server for manual backup (non-clustered environment):

1. From the UI, navigate to **Configuration, Custom Connector**.
2. Complete *one* of the following procedures:
  - If the Connector Server is not configured:**
    - a. Complete the settings then save the configuration.
    - b. Set the **Use Alternate Server** option then select the **Alternate Connector Server** tab.
    - c. On the **Alternate Connector Server** panel, configure the settings then save the configuration.
    - d. Return to the Connector Server
    - e. Unset the **Use Alternate Server** checkbox then save the configuration. Saving the changes updates the configuration to use the primary server.
  - If the Connector Server is configured:**
    - a. Set the **Use Alternate Server** option.
    - b. Select the **Alternate Connector Server** tab, configure the settings then save the configuration.

- c. Return to the Connector Server
- d. Unset the **Use Alternate Server** checkbox then save the configuration. Saving the changes updates the configuration to use the primary server.

If the Connector Server fails in production, log in to this server and set the **Use Alternate Server** option. This action makes the configured alternate server active and the first server inactive.

## Use A2A to Secure the Keystore and Password (Optional)

The Custom Connector keystore contains the TLS key/certificate pair for HTTPS communication. You can configure PAM to encrypt and store the keystore password. The Custom Connector server securely retrieves the password using the PAM A2A feature.

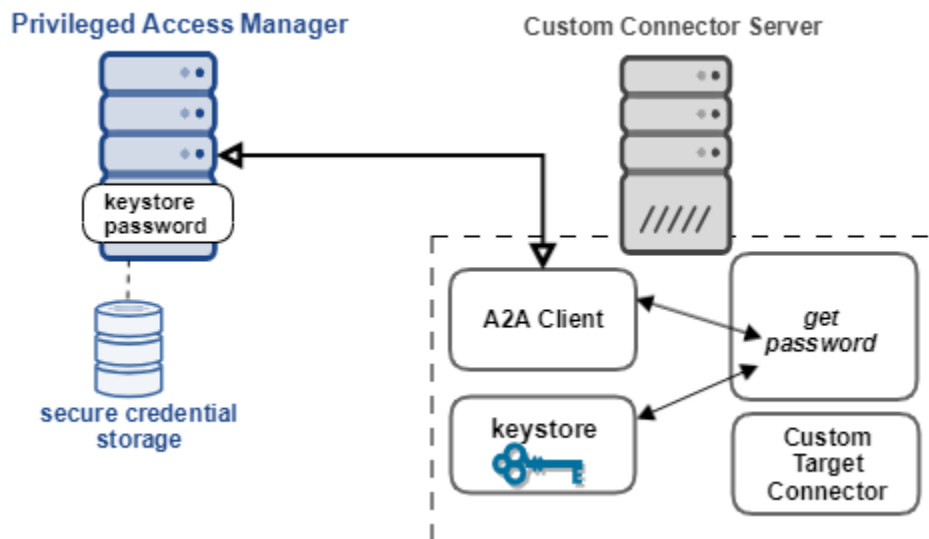

To implement the A2A method, configure specific target applications and associated A2A target accounts. The target accounts represent the password for accessing the keystore, a call stack hash, and a file list hash. These mechanisms work together to secure the keystore password. PAM can randomly generate the keystore password, which is used when you create the keystore at the Custom Connector server. The call stack and file list hashes ensure that the Custom Connector server, running in a trusted environment, retrieves the keystore password from PAM.

### NOTE

This A2A method is an alternative to using the `tcfCryptoUtil` utility to encrypt the keystore password. The A2A method provides file integrity validation, which `tcfCryptoUtil` does not. To use `tcfCryptoUtil`, see the instructions in [Deploy the Custom Connector Toolkit](#), in the section "Create a Keystore for HTTPS Communication."

The following picture illustrates the A2A setup:

**Figure 29: A2A Keystore Password Encryption**

To set up A2A for securing the keystore password, complete the following tasks:

### Install the A2A Client

Install the A2A Client on the Custom Connector server and register the Client with PAM. For instructions, see [Install an A2A Client for Credential Management](#).

When you install the A2A Client, it sends a registration request to PAM. As part of the registration process, PAM creates a device, unless it finds an existing one. The device name is the fully qualified domain name or IP address of the host where the client is installed. The device type, which is set to A2A, is used later in this procedure.

**NOTE**

Edit the `cspmclient.xml` file, and remove the `preserveCacheBetweenRestarts` parameter. A2A Client does not need to cache credentials.

**Configure PAM Components for A2A**

Configure the following PAM components to secure the keystore with A2A:

- A2A device configuration
- Two password composition policies
- Two target applications, one for the keystore and one for both hash values
- Three target accounts, one for the key store, one for the call stack hash, and one for the file list hash
- An A2A script, which gets credentials from PAM
- An A2A target group (optional)
- A2A mappings for the target accounts

The following sections explain how to configure these components. The procedures list only the fields requiring configuration, including sample values. For step-by-step A2A configuration procedures, see [Add and Run Credential Manager A2A Requestors](#).

***Modify the A2A Device Configuration***

A device record is required for the appliance to establish a relationship between the Tomcat server and the A2A target accounts.

Select the A2A device for the registered A2A Client. For this procedure, assume that the A2A device has the following values:

- **Name:** `tcf.tomcat.host`  
Specify the host name of the Tomcat server where the TCF and A2A Client is installed.
- **Address:** `tcf.tomcat.host`  
The address field uses the same value as the Name field, whether the value is an IP address or a fully qualified domain name.

For the device to manage credentials for the keystore, add Password Management to the Device Type setting.

**Follow these steps:**

1. Go to **Devices, Manage Devices**.
2. From the list, select the A2A device record and select **Update**.
3. For the **Device Type** setting, select **Password Management**. The Device Type now is set to Password Management and A2A.
4. Select **OK** to save the changes.

***Create Two Password Composition Policies***

To specify the characteristics of the keystore password, the call stack and the file list hash values, configure two password composition policies. Create one policy for the keystore password. Create a second policy for the hash values.

Navigate to Credentials, Manage Targets, Password Composition Policies and configure the policies with the following values:

**Keystore Password Policy:** Configure a policy to generate a password for the keystore. The password for the keystore is kept only in memory, but make it a strong password of sufficient length.

- **Name:** Assign a descriptive name to the policy, such as KeyStorePCP.
- **Minimum Length** and **Maximum Length:** Set to 64 characters
- **Must Contain** and **First Must Contain:** Include uppercase, lowercase, and numeric characters. Avoid using special characters.

**Hashes Password Policy:** Configure a policy that defines the requirements for the call stack and file list hash values. The Custom Connector server calculates these hash values. Before the server requests the keystore password, it compares these hashes with the hashes that are stored in the target accounts at PAM.

- **Name:** Assign a descriptive name to the policy, such as TCFHashPCP.
- **Minimum Length** and **Maximum Length:** Set to 64 characters
- **Must Contain** and **First Must Contain:** Use only lowercase and numeric characters. Avoid using special characters.

### **Configure Two Target Applications**

Configure two target applications (Credentials, Manage Targets, Applications). One application is for the keystore password and one application is for the call stack and file list hash values.

**Keystore Target Application:** Specify the following values for the keystore application:

- **Host Name:** Enter the name of the A2A device (tcf.tomcat.host)
- **Device Name:** Enter the name of the A2A device (tcf.tomcat.host).
- **Application Name:** Enter a name to indicate that this target application is for the keystore (TCFKeyStoreApplication).
- **Application Type:** Generic
- **Password Composition Policy:** Specify the keystore password policy that you created (KeyStorePCP)

**Hashes Target Application:** Specify the following values for the hash values application:

- **Host Name:** Enter the name of the A2A device (tcf.tomcat.host)
- **Device Name:** Enter the name of the A2A device (tcf.tomcat.host).
- **Application Name:** Enter a name to indicate that this target application is for the hashes, such as TCFHashApplication.
- **Application Type:** Generic
- **Password Composition Policy:** Specify the hashes password policy that you created (TCFHashPCP).

### **Create Three Target Accounts**

Configure three target accounts—one for the keystore password, one for the file list hash and one for the call stack hash. The Custom Connector server calculates the hash values. You copy these values to the target accounts. Before the Custom Connector server requests the keystore password, it compares its calculated hashes with the target account hashes. The values must match.

**Keystore Target Account:** When you configure the keystore target account, you generate a password. This password gets encrypted and stored in the PAM database. Use this generated password for the keystore that you create at the Custom Connector server.

Specify the following values for the account and save the account:

- **Host Name:** Enter the name of the A2A device (tcf.tomcat.host)
- **Device Name:** Enter the name of the A2A device (tcf.tomcat.host).
- **Application Name:** Enter the name of the keystore target application (TCFKeyStoreApplication).
- **Account Name:** Enter a name indicating that this target account is for the keystore, such as TCFKeystore
- **Password View Policy:** Default
- **Account Type:** A2A Account
- **Aliases:** We recommend that you enter the same name as the target account name, TCFKeystore. You can specify a different value.
- **Cache Behavior:** No Cache
- **Password:** Select the key ring icon and generate a password.

In the Target Accounts list:

1. Select the keystore account that you created.
2. Under Action, select the eye icon to view the password.
3. Copy this password and save it. This value is required when you create a keystore at the Custom Connector server.

**Call Stack Hash Target Account:** Specify the following values for the account:

- **Host Name:** Enter the name of the A2A device (tcf.tomcat.host)
- **Device Name:** Enter the name of the A2A device (tcf.tomcat.host).
- **Application Name:** Enter the name of the target application you created for the hashes (TCFHashApplication).
- **Account Name:** Enter a name indicating that this target account is for the call stack hash, such as TCFCallStackHash.
- **Password View Policy:** Default
- **Account Type:** A2A Account
- **Aliases:** We recommend that you enter the same name as the target account name, TCFCallStackHash. You can specify a different value.
- **Cache Behavior:** No Cache
- **Password:** Select the key ring icon and generate a password. After the Custom Connector server generates the call stack hash, update this field with that hash value.

**File List Hash Target Account:** Specify the following values for the account:

- **Host Name:** Enter the name of the A2A device (tcf.tomcat.host)
- **Device Name:** Enter the name of the A2A device (tcf.tomcat.host).
- **Application Name:** Enter the name of the target application you created for the hashes (TCFHashApplication).
- **Account Name:** Enter a name indicating that this target account is for the file list hash, such as TCFFileListHash.
- **Password View Policy:** Default
- **Account Type:** A2A Account
- **Aliases:** We recommend that you enter the same name as the target account name, TCFFileListHash. You can specify a different value.
- **Cache Behavior:** No Cache
- **Password:** Select the key ring icon and generate a password. After the Custom Connector server generates the file list hash, update this field with that hash value.

### ***Identify the A2A Script that Retrieves the Keystore Password***

The A2A script, which is a Java class, runs on the Tomcat server. This script uses the A2A Client to fetch the keystore password from PAM. PAM calculates the script hash when one of the following requests occur:

- You select Get Script Hash when you add an A2A Script in the UI.
- The A2A Client uses the script to send a password request.

At PAM, identify the A2A script:

1. In the UI, select **Credentials, Manage A2A, Scripts**.
2. Select Add and specifying the following values:
  - **Client:** tcf.tomcat.host
  - **Device Name:** tcf.tomcat.host
  - **Script/App Name:** Enter the class name that calls the A2A Client. In this context, the class name is **com.ca.pam.extensions.tcfcryptoutil.TCFPropertySource**
  - **Execution Path:** Specify the directory where the Tomcat server is installed on Custom Connector server. Note: If the Execution Path check is enabled in the mapping, then paths that include soft links result in failure. Example: In the path /example/linkdir/test, if linkdir is a soft link to reldir, then the Execution Path should be /example/reldir/test.
  - **File Path:** Specify the location of the class. For example, the location is the /lib directory on the Tomcat server and the CryptoUtil JAR file name. For example: C:\DevTools\apache-tomcat-9.0.13\lib\capamextensionstcfCryptoUtil-4.16.0.jar
  - **Type:** Java
3. Select **OK**.

#### NOTE

The JAR file is determined by the version of the Tomcat server.

#### **Configure a Target and Request Group to Reduce A2A Mappings (Optional)**

PAM must authorize requesters who want to retrieve the keystore password. An A2A mapping is the mechanism that PAM uses to verify a request script and before releasing the requested credentials.

You can use a target group to organize the accounts for the keystore password, call stack hash, and file list hash. Using this target group requires only one A2A mapping. Without a target group, you have to configure individual mappings for each account. If several Custom Connector servers are deployed, use an A2A request group for A2A mappings.

#### **Create a Target Group**

A target group lets you organize target accounts. A target group can use filters on host servers, applications, and accounts. By using a target group for the keystore password and two hash target accounts, you can more easily manage authorization policies between clients and scripts.

#### **Follow these steps:**

1. From the UI, select **Credentials, Manage Targets, Target Groups**.
2. Add a group.
3. Complete the following settings:
  - **Name:** Enter a descriptive name, such as TCFTargetGroup
  - **Server** section: Select the Filter column for the Host Name. Filter on a string that is contained in the name of the Tomcat servers.
  - **Application** section: Select the Filter column for the **Application Name** field. Add a string that applies to all the relevant TCF target applications that you configured earlier. For example, for the Application Name, use this filter:

- **Account** section: Select the Filter column for the **Account Name** field. Add a string that applies to all the relevant TCF target accounts that you configured earlier.

#### **Create an A2A Request Group**

If you deploy two Custom Connector servers, a request group is useful. Both servers in the group need access to the keystore credentials.

**Follow these steps:**

1. From the UI, select **Credentials, Manage A2A, Request Groups**.
2. Add a group.
3. In the Client section, select the Filter column for the **Host Name** field. Filter on a string that is contained in the name of the Tomcat servers. Add a second host for the other Custom Connector server. Ensure both servers use the same A2A script.
4. In the Script section, select the Filter column for the **Name** field. Filter on the name of the A2A script you created previously. The following graphic shows how to configure the Script section of the A2A request group page:

Fields	Filters
<b>Client</b>	
Host Name	<a href="#">Not Specified</a>
Device Name	<a href="#">Not Specified</a>
IP Address	<a href="#">Not Specified</a>
Descriptor 1	<a href="#">Not Specified</a>
Descriptor 2	<a href="#">Not Specified</a>
<b>Script</b>	
Name	<b>WHERE</b> Script.Name <a href="#">beginswith 'com.ca.pam.extensions.tfcryptout</a>

5. Continue to the next section and create an A2A mapping.

**Create an A2A Mapping for Requester Authorizations**

The final configuration step at PAM is to configure an A2A mapping for requester authorizations. Create a mapping between the A2A script running on the Tomcat server and the individual target account or A2A target group. This mapping tells the appliance to authorize the A2A script, the requester, and grant access to credentials.

A mapping to a target group includes aliases for all accounts in the group. A mapping from a request group includes all Custom Connector servers in the group.

If your environment has only one Custom Connector server, add an A2A authorization mapping for a single client.

To map the script to a single Tomcat server, specify the following values:

- **Target:** Select **Group** and specify the TCFTargetGroup
- **Request:** Select **Client** and enter the IP address of the A2A Client
- **Script:** Select **Individual** and specify the name of the script, com.ca.pam.extensions.tfcryptoutil.TCFPropertySource
- **Check Execution User/Execution User:** Select this checkbox and specify the user administering the Tomcat server.
- **Check Execution Path:** Select this checkbox
- **Check File Path:** Select this checkbox
- **Perform Script Integrity Validation:** Select this checkbox

To map the script to multiple Tomcat servers, specify the following values:

- **Target:** Select **Group** and specify the Tomcat keystore
- **Request:** Select **Group** and select the name of the request group you created previously.
- **Check Execution User/Execution User:** Select this checkbox and specify the user administering the Tomcat server.
- **Check Execution Path:** Select this checkbox
- **Check File Path:** Select this checkbox
- **Perform Script Integrity Validation:** Select this checkbox

### **Configure the Custom Connector to Obtain the Keystore Password**

After you set up the A2A components at PAM, set up the Custom Connector server to retrieve the keystore password. Some of the appliance configuration settings are required to create and secure the keystore.

#### ***Create a Keystore and Encrypt the Keystore Password***

To secure communication between PAM and the Custom Connector, create a PKCS12 keystore. The keystore must contain an X.509 private key and certificate pair in PEM format. When you generate the keystore, the keystore password is in plain text. Encrypt the password using a TCF-provided utility, configTCF.

#### **NOTE**

The keystore that holds the X.509 key/certificate pair is separate from the keystore to secure the payload from PAM.

#### **Example: Keystore Set Up Using Keytool**

Many tools are available to create a keystore. The following procedure uses the keytool utility as an example.

#### **TIP**

The keys expire after the number of days that are specified by the `-validity` command argument. In the following procedure, the keys expire after 360 days. To regenerate the keys after they expire, repeat this procedure.

#### **Follow these steps to create a keystore and encrypt the password:**

1. Create a PKCS12 keystore by entering the following keytool command. If you created a keystore when you initially deployed the Custom Connector, do not create a new one. Move on to step 2.

```
keytool -genkey -alias pam -keyalg RSA -keysize 2048 -storetype PKCS12 -dname
"CN=capamtcf, OU=PAM, O=CA, L=Burlington, ST=MA, C=US" -keypass password-
storepass password -keystore <keystore_file> -validity 360
```

*password* is the password that you assigned when you created the [keystore target account](#).

*keystore\_file* is path and file name where you want to generate the keystore

This command output is an encrypted keystore password that is displayed on the command prompt.

2. Continue to the next procedure.

#### ***Add the Keystore Location to the server.xml File***

Specify the location of the keystore:

1. Edit the server.xml file in %CATALINA\_HOME%\conf\.
2. Locate the connector for HTTPS scheme
3. Add the following lines:

```
<Connector
  protocol="org.apache.coyote.http11.Http11NioProtocol"
  port="8443" maxThreads="200"
  scheme="https" secure="true" SSLEnabled="true"
```

```
keystoreFile="keystore_file" keystorePass="${tomcat.keystore.pwd}"
clientAuth="false" sslProtocol="TLS"/>
```

*keystore\_file* is the file path and name of the PKCS12 keystore you created previously.

4. Continue to the next section.

### **Enable Tomcat to Read the TCF Properties**

Modify the catalina.properties file to enable Tomcat to read the TCF properties:

#### **Follow these steps:**

1. Navigate to the file %CATALINA\_HOME%\conf\catalina.properties .
2. Edit the file by adding the following lines to the end of it:

```
org.apache.tomcat.util.digester.PROPERTY_SOURCE=com.ca.pam.extensions.tcfcryptoutil.TCFProperties
tomcat.keystore.pwd.usea2a=true
tomcat.keystore.pwd=TCFKeyStore
tomcat.callstack.hash.alias=TCFCallStackHash
tomcat.file.list.hash.alias=TCFFileListHash
```

The entries provide the following information:

- The line beginning `org.apache.tomcat` : Overrides the default behavior to read the properties.
- `tomcat.keystore.pwd.usea2a=true`: Instructs Tomcat to retrieve the keystore password from PAM. With this set to true, the following lines are required:
  - `tomcat.keystore.pwd=TCFKeyStore` : Alias for the keystore password target account that is stored at PAM.
  - `tomcat.callstack.hash.alias=TCFCallStackHash` : Alias for the call stack hash target account
  - `tomcat.file.list.hash.alias=TCFFileListHash` : Alias for the file list hash target account

### **Enable the Custom Connector Server to Retrieve Credentials**

For the Custom Connector server to retrieve credentials from PAM, add the A2A Client API libraries and TCF libraries to its class paths.

In the following procedure:

- The directory paths and place holders reflect a UNIX/LINUX system. Windows paths use backward slashes and placeholders use % signs.
- `cspmclient/lib` is located under `CSPM_CLIENT_HOME`, the installed location of the A2A Client on your system
- `CATALINA_HOME` is the installed location of the Tomcat server

#### **Follow these steps:**

1. Copy the following A2A JAR files from `CSPM_CLIENT_HOME/cspmclient/lib` to `$CATALINA_HOME/lib`
  - `cspmclient.jar`
  - `cwjcafips.jar`
2. Copy the appropriate A2A Client libraries for your platform:
  - UNIX/Linux platforms:
    - a. Copy the following libraries from `$CSPM_CLIENT_HOME/cspmclient/lib` to `$CATALINA_HOME/lib`
      - `libcpaspiffadaptor64.so`
      - `libcspminterface64.so`
      - `libcwjcafips.so`
    - b. For Tomcat to recognize these libraries, set the `LD_LIBRARY` path in the `setenv.sh` script. This script is located in `$CATALINA_HOME/bin/`.  
 Example path: `export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/$CATALINA_HOME/lib`
  - Windows platforms: copy the following DLL files from `%CSPM_CLIENT_HOME%\cspmclient\lib` to `%CATALINA_HOME%\bin`:

- • cpaspiffadaptor64.dll
  - cspminterface64.dll
  - cwjcafips.dll
3. Copy the capamextensionstcfCryptoUtil-4.16.0.jar file from `TCF_HOME/configTCF` to `$CATALINA_HOME/lib`. `TCF_HOME` is where you extracted the Custom Connector Framework zip file.

### Create a File List for Verifying Deployed Files

Before the Custom Connector server fetches the keystore password, it verifies the integrity of its files. The Custom Connector server adds all the file hashes together and calculates one consolidated hash value of its files. The server compares this hash with the hash of the file list target account, which is retrieved from PAM. The hash values must match.

To generate the hash, the server needs a list of all the deployed target connector files.

#### Follow these steps:

1. Create a file and name it **pam.filelist**. This name is the required file name.
2. In the pam.filelist file, include the:
  - full path of the pam.filelist file itself
  - full path of the capamef.war file
  - full path for all the files that are extracted from the .war files in the **webapps** and **webapps\_targetconnectors** folders
  - full path of all custom target connectors that are deployed on the Custom Connector server.
  - Optionally, the full path of libraries in the **lib** directory under `%CATALINA_HOME%`

All paths and file names are case-sensitive.
3. Save the file.
4. Copy the file to `%CATALINA_HOME%\conf`.
5. Restart the Tomcat server.

The following example is a simple file list. An actual file list contains more files, such as the files extracted from the .war files in the **webapps** and **webapps\_targetconnectors** folders.

```
C:\DevTools\apache-tomcat-9.0.13\conf\pam.filelist
C:\DevTools\apache-tomcat-9.0.13\webapps\capamef.war
C:\DevTools\apache-tomcat-9.0.13\webapps_targetconnectors\exampleTargetConnector.war
C:\DevTools\apache-tomcat-9.0.13\webapps_targetconnectors\echoTargetConnector.war
```

### Copy the Hash Values to Target Accounts

When the Custom Connector requests the keystore password, it calculates the call stack and file list hash values. The server then compares these values to the target account hashes. The values must match before PAM responds with the keystore password.

For the hashes to match, you must copy the calculated values to the target accounts at PAM.

#### To compare hashes, follow these steps:

1. Start the Custom Connector server but expect startup to fail.  
At startup, the server calls PAM and fetches the hash values. Startup fails because the hashes obtained from PAM do not match the values that are calculated by the Custom Connector server.
2. Open the catalina.log file in `%CATALINA_HOME%\logs` directory.
3. Look for the following two messages in the log file:
 

```
Computed callstack hash: callstack_hash does not match the retrieved call stack
hash: CA_PAM_call_stack_hash
```

Computed filelist hash: *filelist\_hash* does not match the retrieved filelist hash: *CA\_PAM\_file\_list\_hash*

4. Copy the hashes from these log messages and paste them into the **Password** tab of the associated target accounts at PAM.
  - *callstack\_hash*: The computed value from the call stack target account
  - *filelist\_hash*: The computed value from the file list target account
5. Restart the server.

When the Custom Connector server restarts, it requests the hashes from PAM, which are verified successfully. Finally, the Custom Connector server retrieves the keystore password from PAM.

## Troubleshooting

If exceptions are logged during startup of the Tomcat server, look at the catalina log file. If the exception stack trace looks like the following graphic, the server cannot start the HTTPS connector.

```
01-Nov-2018 14:59:46.063 INFO [main] org.apache.coyote.AbstractProtocol.init
  Initializing ProtocolHandler ["https-openssl-nio-8443"]
01-Nov-2018 14:59:46.401 SEVERE [main]
  org.apache.catalina.util.LifecycleBase.handleSubClassException Failed to initialize
  component [Connector[HTTP/1.1-8443]]
org.apache.catalina.LifecycleException: Protocol handler initialization failed
at org.apache.catalina.connector.Connector.initInternal(Connector.java:935)
at org.apache.catalina.util.LifecycleBase.init(LifecycleBase.java:136)
at org.apache.catalina.core.StandardService.initInternal(StandardService.java:533)
at org.apache.catalina.util.LifecycleBase.init(LifecycleBase.java:136)
at org.apache.catalina.core.StandardServer.initInternal(StandardServer.java:852)
```

The reasons for this problem are:

**Problem:** The keystore password is incorrect.

The password is retrieved from PAM, but it is incorrect. Verify the retrieval by checking the catalina.log for the message:

A2A Client Status Code: 400

Examine the following stack trace in the catalina.log file:

```
Caused by: java.io.IOException: keystore password was incorrect
at sun.security.pkcs12.PKCS12KeyStore.engineLoad(PKCS12KeyStore.java:2015)
at sun.security.provider.KeyStoreDelegator.engineLoad(KeyStoreDelegator.java:238)
at sun.security.provider.JavaKeyStore$DualFormatJKS.engineLoad(JavaKeyStore.java:70)
at java.security.KeyStore.load(KeyStore.java:1445)
at org.apache.tomcat.util.net.SSLUtilBase.getStore(SSLUtilBase.java:179)
at
  org.apache.tomcat.util.net.SSLHostConfigCertificate.getCertificateKeystore(SSLHostConfigCertificate.java:144)
at org.apache.tomcat.util.net.jsse.JSSEUtil.getKeyManagers(JSSEUtil.java:203)
```

**Solution:** In the PAM UI, verify that the password in keystore target account is correct. Also, verify that the Tomcat keystore has the same password.

**Problem:** The A2A Client is not started. The catalina.log file contains the message: A2A Client Status Code: 402

**Solution:** Start the A2A client daemon (UNIX)/service (Windows).

**Problem:** The keystore password alias in the catalina.properties file is not found in PAM. The catalina.log shows the message: `A2A Client Status Code: 405` **Solution:** In the PAM UI, look at the name of the keystore target account. At the Tomcat server, look at the catalina.properties file. Confirm that the `tomcat.keystore.pwd.alias` property has the same name as the target account.

#### NOTE

If the call stack or filelist hash alias is not found in PAM, the error and solution are the similar. Look in the UI and the catalina.properties file and ensure that the aliases match.

**Problem:** Unauthorized Script Name. The A2A mapping uses an incorrect script name. The catalina.log contains the message: `A2A Client Status Code: 409` **Solution:** Fix the A2A script to match the mapping and script program.

**Problem:** Unauthorized execution path. The A2A mapping does not have the correct execution path for the script. The catalina.log contains the message: `A2A Client Status Code: 410`

**Solution:** Verify the execution path. In the PAM UI, navigate to **Credentials, Reports, Activities**. Select **Configure** to set up the activities report. Add an entry using the **+** sign then select the **Failed A2A Client Requests in Last 30 days** item. After the report runs, look for the entry with the 410 error code. That entry includes the execution path for the A2A client request. Specify this execution path in the A2A script.

**Problem:** Unauthorized execution user. The A2A mapping does not specify the correct user. The catalina.log includes the message: `A2A Client Status Code: 411` **Solution:** Change A2A mapping to use the same user that is running the Tomcat server.

**Problem:** Incorrect script hash value. The hash value of the Custom Connector Java class file is incorrect or the wrong script is specified. The catalina.log includes the message: `A2A Client Status Code: 436`

**Solution:** If the Custom Connector Java class file is changed intentionally, recalculate the hash. Select the **Get Script Hash** button on the script panel PAM UI.

## Try Out the Sample Custom Connectors

To help you develop your own connectors, the Custom Connector software comes with two sample target connectors:

- **Echo target connector (echoTargetConnector.war)** – This sample connector displays the requests that are sent from the appliance to the TCF. Use this sample to verify the UI definitions and the data flow for the connector.
- **Example target connector (exampleTargetConnector.war)** – This sample lets you view and update passwords on a Linux target device.

The .war files for these sample connectors are in the **samples** folder.

Use one or both of them to help you understand how custom target connectors work.

#### WARNING

Do not use the Example Target Connector in a production environment.

The steps for configuring a custom target connector are no different from the out-of-the-box connectors. When trying out the sample connectors, follow this procedure, which is shown in the following graphic:

**Figure 30: Credential Manager target configuration tasks**

**NOTE**

In a typical production environment, an access policy is configured. This policy lets a user or administrator to view and update credentials from the Access page in the UI. To test the sample target connectors, these procedures use an alternative method. You view and update credentials from the target account page.

**Use the Echo Target Connector to Follow Requests to the TCF**

The Echo Target Connector demonstrates the requests that are sent from the appliance to the TCF. Information from the Echo Target Connector connector is echoed to the catalina.out log file on the Custom Connector server. By examining the log, you can see all of the available UI fields and controls from the uiDefinitions.json file. You can also see the information that the target connector extracts from the payload that is sent by the TCF.

Complete the following procedures to configure the Echo Target Connector and view the catalina.out file on your Custom Connector server:

1. Specify a remote target server.
2. In the UI, add the Echo Target Connector application
3. Add an account to the echo target connector application
4. Update the password and view the catalina.out log file.

Each procedure is explained in the next sections.

***Specify a Remote Target Server***

You do not need an actual target server when using the echo target connector. This connector only tests communication between the appliance and the TCF. However, you must specify a target server, even a fake entry, for the configuration in the UI.

**Follow these steps:**

1. Log in the Privileged Access Manager UI.
2. In the UI, select **Devices, Manages Devices**.
3. From the Devices page, select **Add**.
4. In the Add Device dialog, complete the required fields in the Basic Info tab.
5. For the **Device Type**, select the **Password Management** checkbox. Keep the Access checkbox selected.
6. Go to the **Access Methods** tab and specify an access protocol, such as SSH. The appliance uses the access method to contact the remote target server.
7. Select **OK** to complete the configuration.

Now, add the target application as instructed in the next procedure.

***Add the Echo Target Connector Application***

Configure the Echo Target Connector application.

**Follow these steps:**

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Select or enter values for the following fields:
  - Host Name: Select the magnifying glass to pick the target server you defined in the previous procedure.
  - Device Name: Enter the name for the target server you added.
  - Application Name: Specify an application name, such as echoapp. Application names must be unique for a given target server.
4. In the **Application Type** field, select **Echo Target Connector**.  
A new tab labeled **Echo - Application** displays.

5. On the **Echo - Application** tab, change the default settings on this page. If you change the settings, you can see the new values in the Tomcat catalina.out file when you validate the credentials.
6. Select **OK**.

Continue on and add a target account for the echo target application.

### **Add the Target Account**

Add a target account that you want to associate with the target application. When you configure a target account, identify a target application for that account. Target account user names must be unique for a given target application.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**.
2. Select **Add**.
3. Complete the following fields:
  - **Host Name:** Enter the IP address of the remote target server you defined.
  - **Device Name:** Enter the name for the target server.
  - **Application Name:** Select the Echo Target Application name that you configured in the previous procedure.
  - **Account Name:** Assign a unique account name for a given target application. The Echo Target Connector does not connect to a target server, so you can enter any name. Suggestion: echo
  - **Password View Policy:** Accept the default password view policy.
  - **Protocol:** This field is filled-in automatically after you specify a device.
  - **Password:** The password of the user account at the remote target server. For testing the Echo Target Connector, we recommend that you select the Generate Credential icon (keys on a ring).  
The generated password follows the password composition policy, and it updates automatically at the target server.
  - **Account Type:** Accept the default, Privileged Account.
4. Select **OK** to save the account.
5. Keep the account page open and go to the next procedure.

### **Update Credentials and Examine the Log File**

1. From the account page you created, select the Generate Credential icon (keys on the ring) and generate a new password.
2. Select **OK** to save the new password.
3. Select the Verify Credential icon (person with a green checkmark) and select **OK**.
4. Log in to the Tomcat system where you deployed the TCF.
5. Open the catalina.out file and look for the contents of the REST web service. Review the entries for the updated credential.

The log file entries illustrate the exchanges between the appliance and the TCF. The file also includes the UI definitions that render the Echo Target Connector application and account tabs in the UI.

### **Use the Example Target Connector to View and Update a Password**

The Example Target Connector demonstrates an end-to-end communication flow. Beginning at the appliance, the connector shows the request to the TCF, through to the target connector, and ending at the remote target server.

#### **WARNING**

Do not use the Example Target Connector in a production environment.

Before you can use the Example Target Connector:

- Complete the prerequisites
- Install an SSH Utility on the Custom Connector Server
- Follow the procedures to configure the target server, target application, and target account on the appliance.

After you complete these tasks, try viewing and updating a password.

### **Prerequisites**

- Set up a remote Linux target server
- Set up a user account whose password you can change.  
Verify that you can log in to the Linux system as that user. Use SSH to connect to the Linux system. If the user can log in, the Example Target Connector can communicate to the target.

### **Install an SSH Utility on the Custom Connector Server**

The Example Target Connector lets you verify and update passwords on a UNIX target device. To use the Example Target Connector, install the utility on the Custom Connector server where the TCF is installed:

- [Install the sshpass utility \(UNIX\)](#)
- [Install PuTTY Link \(Plink\) \(Windows\)](#)

#### **NOTE**

You can install the Custom Connector server on a UNIX or Windows system. However, the Example Target Connector is for use only with a UNIX target device.

You do not have to execute any commands with these utilities. The example target connector executes commands automatically.

#### **Install sshpass on the UNIX System Running Tomcat**

If the Custom Connector server is running on a UNIX platform, install the **sshpas** utility. The sshpass utility lets you run keyboard interactive authentication in non-interactive mode. The command to install sshpass differs depending on the type of UNIX system you are using.

Installation command examples:

- On a Linux system, enter the following command:

```
$ sudo yum install sshpass
```

- On a Debian/Ubuntu system, enter the following command:

```
$ sudo apt-get install sshpass
```

#### **Install the PuTTY Link Utility on the Windows System Running Tomcat**

If the Custom Connector server is running on a Windows system, download and install the PuTTY SSH client. The client includes the Plink utility, which you can use to run non-interactive SSH sessions. The Example Target Connector uses Plink.

### **Specify the Remote Linux Target Server**

Add the Linux target server as a target device.

#### **Follow these steps:**

1. Log in the Privileged Access Manager UI.
2. In the UI, select **Devices, Manages Devices**.

3. From the Devices page, select **Add**.
4. In the Add Device dialog, complete the required fields in the **Basic Info** tab.
5. For the **Device Type**, select the **Password Management** checkbox. Keep the Access checkbox selected.
6. Go to the Access Methods tab and specify an access protocol, such as SSH. The appliance uses the access method to contact the remote target server.
7. Select **OK** to complete the configuration.

Now, add the Example Target Application.

### ***Add the Example Target Connector Application***

Configure the Example Target Connector application.

#### **Follow these steps in the UI:**

1. Select **Credentials, Manage Targets, Applications**.
2. Select **Add**.
3. Complete the following fields:
  - Host Name: Select the magnifying glass to pick the target server.
  - Device Name: Enter the name for the Linux target server.
  - Application Name: Specify an application name, such as exampleapp. Application names must be unique for a given target server.
4. In the **Application Type** field, select **Example Target Connector**.  
A new tab labeled **Example - Application** displays.
5. On the Example - Application tab, we recommend that you change the settings. If you change the settings, you can see the new values in the Tomcat catalina.out file when you validate the credentials.
6. Select **OK**.

Now add the example target account.

### ***Add the Example Target Account***

Add the Linux user account as a target account. Target account user names must be unique for a given target application.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**.
2. Select **Add**.
3. Complete the following fields:
  - **Host Name:** Select the remote Linux system from the drop-down list.
  - **Device Name:** Enter the name of the remote Linux system.
  - **Application Name:** Select the example application that you configured in the previous procedure. An **Example - Account** tab displays. On this tab, optionally add an account description and select a master account with privileges to log in on behalf of the user.
  - **Account Name:** Assign a unique account name for a given target application. The account name that you enter must match the account name that is used by the target system. For example, on a Linux system, account names are the user ID (userid).
  - **Password View Policy:** Use the default password view policy.
  - **Protocol:** This field is filled-in automatically after you specify a device.
  - **Password:** For this example, we recommend that you select the Generate Password icon (keys on a ring). The generated password follows the password composition policy, and it updates automatically at the target server.
  - **Account Type:** Accept the default, Privileged Account.
4. Select **OK** to save the account.
5. Keep the account page open and go to the next procedure.

## View and Update the Password

After you specify the Example - Application and the target account, you can verify and change the password.

### Follow these steps:

1. Select the target account and then select Update.
2. Select the **Password** tab.
3. Select the option **Update both the Credential Manager System and the target server**.
4. Select **OK**.  
The appliance verifies the password at the target system. If the verification is successful, a green checkmark is placed in the Verified column for the target account entry.
5. Select the target account entry again and select Update.
6. View the current password by selecting the View Credential icon (the eye) next to the **Password** field.
7. Select the **Generate Password** icon (keys on a ring).
8. Select **OK**. The password is updated.
9. Select the **Verify Credential** icon (person with a green checkmark) the select **OK**.  
After successful verification, view the password again to see that it has changed.

### NOTE

Continue by reading [Learn How to Use the Custom Connector Components](#). Review this information carefully before building your own target connector.

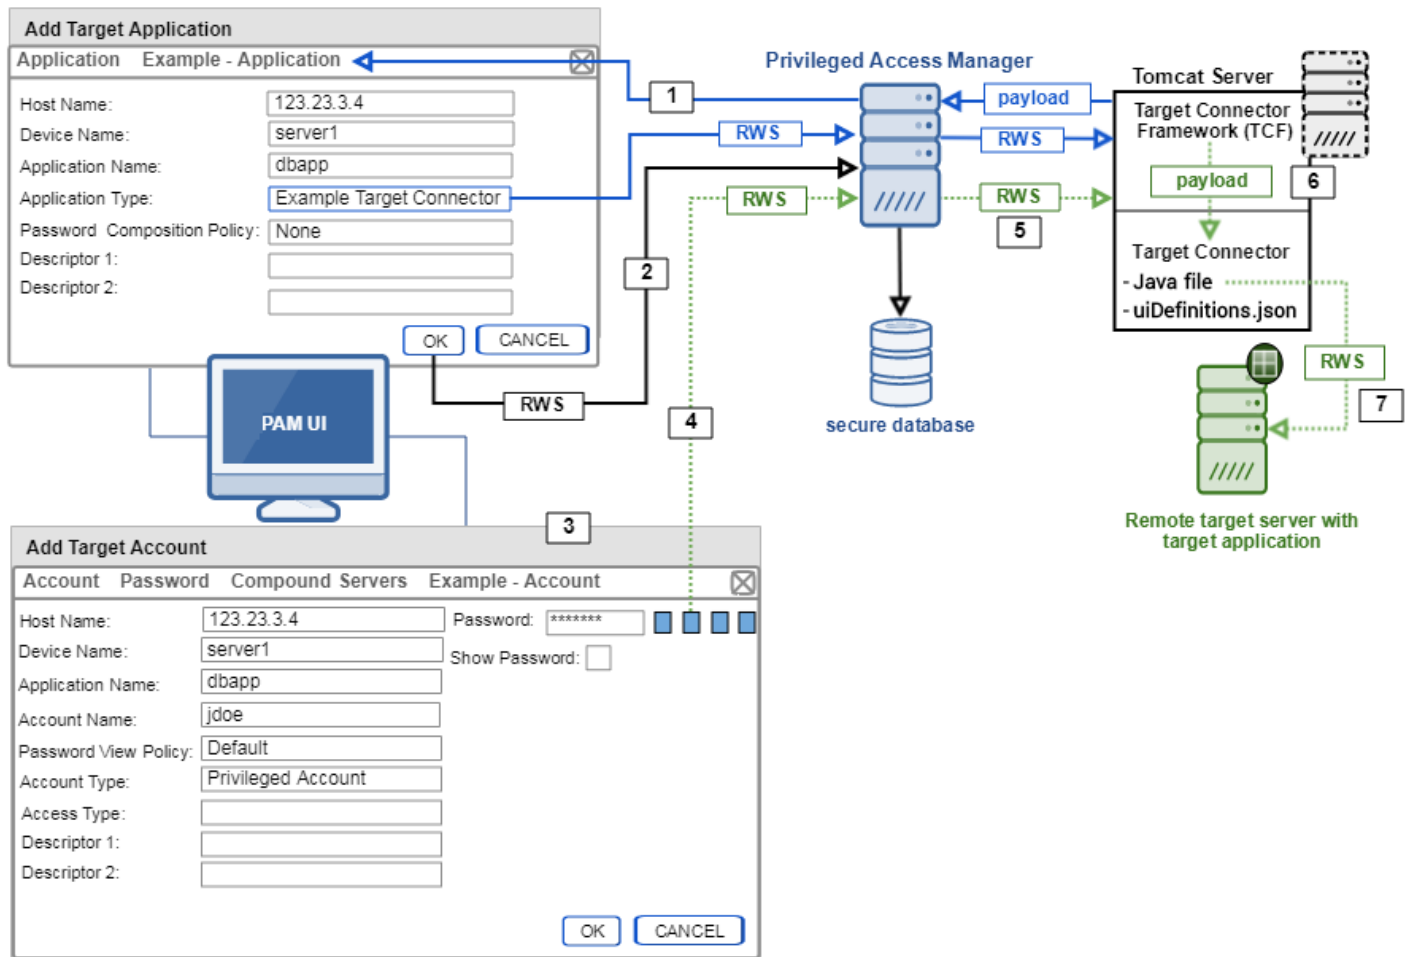

## Learn How to Use the Custom Connector Components

Before you build your own custom target connectors, familiarize yourself with the major components and how these components are used at runtime.

A custom target connector uses the following components to work with the TCF:

- **uiDefinitions.json file** –This JSON file includes the custom target connector fields that are displayed in the UI. This file also determines the attributes that are saved in the appliance database. To customize the UI for your applications and accounts, you define attributes in the uiDefinitions.json file.
- **REST web service endpoints (RWS)** – The Java code that you write for the custom target connector must support three REST web service endpoints: UI definitions, validations, and credentials. Each service provides a unique function for the TCF and target connector operation.

The following diagram illustrates how the appliance and the TCF use the uiDefinitions.json file and the Java code at runtime:

**Figure 31: Runtime flow of a TCF Transmission**

After a custom target connector is deployed, the custom application type and account are available in the UI.

When an administrator adds a target application and selects a custom application type, such as Example Target Application the following runtime sequence occurs:

1. The appliance contacts the TCF, which returns a JSON payload to the appliance and the UI. The tab for the custom application is rendered.
2. The administrator completes the settings on the custom application tab and selects **OK** to save this entry. The UI makes a REST web service call to the appliance.
3. The appliance stores the attributes that are sent from the UI in its database.
4. The administrator adds a target account that is associated with the custom application type.
5. When the View Password icon or the Validate Credential icon on the account page is selected, the UI sends another REST call to the appliance.
6. The appliance recognizes the call as a request for an external resource, and sends a REST call to the TCF.
7. The TCF sends a REST call with a payload to the target connector to complete the view or validate credential request. The payload is determined by the attributes in the uiDefinitions.json file. The Java code parses the payload and extracts the data that it needs. The Java code uses the "field" attribute of each entry in the JSON file to identify and extract the necessary data.
8. The target connector now has access to the application on the target server.

To learn about the `uiDefinitions.json` and the web service endpoints in detail, go to the following topics:

- [UI Fields and Controls for Configuring Connectors](#)
- [Web Service Endpoints for the Custom Connector](#)

After you are familiar with these two components, you can edit them when you go to [build your own custom connectors](#).

## UI Fields and Controls for Configuring Connectors

The PAM UI must be able to render the tabs and input controls for the target application and account. The UI fields and controls are defined in a JSON file named **uiDefinitions.json**. When an administrator selects a custom connector, the appliance contacts the TCF. The TCF then returns the JSON payload to the appliance and the UI. The UI displays the tabs and settings that are defined in the JSON file.

This topic provides reference information that describes the `uiDefinitions.json` file. The contents of this file determines how UI panels and controls for your custom target connector are displayed. When you are ready to build a custom target connector, modify the `uiDefinitions.json` file and then validate your changes with the UI validator utility. These tasks are explained in the topic [Build Your Custom Connector](#).

### Structure of the uiDefinitions.json File

The `uiDefinitions.json` file is organized into three main sections:

- **account** – specifies the target account at the appliance  
A single "account" attribute definition that contains a single child "uiDefinition" attribute are required.
- **application**– specifies the target application at the applianceA single "application" attribute definition that contains a single child "uiDefinition" attribute are required.
- **locale** – specifies the language of the field labels when the UI controls are shown in different languages. See [Define the Locale for UI Field Labels](#) later in this topic.

### **Account and Applications Sections**

The account and applications sections can include one or more tabbed panels. Each panel can contain groups of related target application or target account attributes. For example, the `uiDefinitions.json` file for the Example Target Connector contains an "application" section. This section defines a panel with an **Example - Application** tab and a series of fields that define the UI controls. The controls identify details about the connector. The JSON file also has an "account" section with a tab **Example - Account**, a description field and a target account drop-down list.

#### **WARNING**

The JSON file must include an "account" and "application" section.

The following two panels are rendered by the `uiDefinitions.json` file that follows the panels.

## Add Target Account

Account Password Compound Servers Example - Account

Description:

Master Account:

OK

CANCEL

## Update exampleapp

          "value": 60000
        }, {
          "type": "NUMBER",
          "field": "readTimeout",
          "label": "Read Timeout",
          "minValue": 1,
          "value": 5000
        }, {
          "type": "NUMBER",
          "field": "sshPort",
          "label": "SSH Port",
          "minValue": 0,
          "maxValue": 65535,
          "value": 22
        }, {

```

```

        "type": "RADIO",
        "field": "connector_protocol",
        "label": "Connector Protocol",
        "value": "TLS_1.2",
        "values": [{
            "label": "TLS 1.0",
            "value": "TLS_1"
        }, {
            "label": "TLS 1.2",
            "value": "TLS_1.2"
        }, {
            "label": "TLS 1.3",
            "value": "TLS_1.3"
        }]
    }, {
        "type": "COMBOBOX",
        "field": "additionalEncryption",
        "label": "Additional Encryption",
        "value": "AES",
        "values": [{
            "label": "Triple DES",
            "value": "TRIPLEDES"
        }, {
            "label": "RSA",
            "value": "RSA"
        }, {
            "label": "Blowfish",
            "value": "BLOWFISH"
        }, {
            "label": "Twofish",
            "value": "TWOFISH"
        }, {
            "label": "AES",
            "value": "AES"
        }]
    }, {
        "type": "CHECKBOX",
        "field": "useCertificate",
        "label": "Use Certificate",
        "value": false
    }, {
        "type": "TEXTAREA",
        "field": "certificate",
        "label": "Certificate"
    }]
}]

```

```

    }

}

}

```

## How the Web Service Java Code Uses the UI Definitions

The "account" and "application" sections of the uiDefinitions.json file have a "uiDefinitions" attribute with a single "tabs" attribute. The tabs attribute allows you to define high-level tabs to group related fields together. Each tab contains a "fields" section, which defines all the individual configurable settings and controls for all connector-relevant data. Under the "fields" section are the individual connector-specific attributes, one of which is named "field".

The "field" attribute is used in the following ways:

- Each field serves as a unique identifier that allows the TCF to access data values.
- For all field attributes in the uiDefinitions.json file, validation of field values occurs automatically based on the definitions file. To execute any custom validation, such as cross-field validation for fields dependent on one another, you must add validation logic to the **Validations.java** file. In the topic [Build Your Custom Connector](#), see the section, "Edit Web Service Endpoints" for instructions about adding validation logic.
- If you remove a field from the uiDefinitions.json file, edit your Java code so it no longer references the field. This instruction applies to the Credentials.java file and the Validations.java file.
- All field values are defined as strings in the JSON payload. You might need to do some data type conversions in your Java code.

The remainder of this topic describes the different attributes and constraints for each field type.

## UI Tabs and Controls for Target Applications and Accounts

The following table describes the characteristics of the UI tabs and controls for the custom target connector-specific settings that you see in PAM UI. Specific details for each type are described later in this topic.

Attribute	Description
type	<p>(Required) Identifies the kind of field and the type of data value entry and validation options are allowed.</p> <p>Options:</p> <ul style="list-style-type: none"> <li>• TEXT – plain text entries for fields like user names</li> <li>• TEXTAREA – displays a block of text, such as a certificate</li> <li>• NUMBER – for integer data, such as port numbers</li> <li>• PASSWORD – for passwords that are entered in plain text that are masked in the UI.</li> <li>• CHECKBOX – provides a selectable box next to each option so a user can make a binary true or false choice.</li> <li>• COMBOBOX – provides a drop-down list for selecting only one of a predefined set of mutually exclusive options</li> <li>• RADIO – provides a radio button for selecting only one of a predefined set of mutually exclusive options</li> <li>• TARGETACCOUNT – provides a drop-down list of configured target accounts from which to select an account.</li> </ul>

field	(Required) Unique identifier for referencing the field and accessing data values. Identifiers must be unique for the defined target application or account. Every identifier must begin with a letter or underscore, followed by one or more letters, underscores or digits. You can follow an initial underscore with another underscore. Valid entries for this attribute are case-sensitive. A field value cannot contain embedded spaces.
label	(Required) Labels the control, such as the field name, the radio button label, or the checkbox label. If the value of the label is an identifier from the "locale" section of the file, the language-specific string is used. If a locale identifier is not specified, the literal string value is used. For more details, see <a href="#">Define the Locale for UI Field Labels</a> later in this topic.
value	(Optional) Designates the initial default value for new records.
values	(Required) An array of objects which contain a label and a value. This attribute is used by the RADIO and COMBOBOX attribute types.

### Constraints for Specific Field Types

For many of the attribute types, you can specify certain constraints for the field values. Pattern constraints let you require and restrict what values can be entered by the user. If the value provided does not meet the constraints, the UI displays a message with the valid entry criteria.

The following table lists the constraints that are allowed in the uiDefinitions.json file:

Constraint	Description	Used by Field Type
required	(Optional) Specifies whether a field value must be provided. A red asterisk displays next to the field label, indicating the field required. Valid entries: <ul style="list-style-type: none"> <li>false (default value). The field value is not required</li> <li>true. The field value is required for basic field validation</li> </ul>	TEXT, TEXTAREA, PASSWORD, NUMBER, TARGETACCOUNT
maxLength	(Optional) Maximum length for the field value	TEXT, TEXTAREA, PASSWORD
minLength	(Optional) Minimum length for the field value	TEXT, TEXTAREA, PASSWORD
minValue	(Optional) Minimum field value allowed	NUMBER
maxValue	(Optional) Maximum field value allowed	NUMBER
patternConstraint	(Optional) Specifies a regular expression that the connector tests against the field value during validation. If the test fails, the UI marks the field invalid when the user enters or saves the invalid entry.	TEXT, TEXTAREA, PASSWORD

patternConstraintMessage	(Optional) Contains the error message that the connector displays when a patternConstraint is used and the validation test fails. By default, this attribute is set to: "The value in this field is invalid"	TEXT, TEXTAREA, PASSWORD
--------------------------	---	--------------------------

### Examples of pattern constraints:

```
"patternConstraint": "^(today|tomorrow|yesterday)$"
"patternConstraintMessage": "Enter today, tomorrow or yesterday"
"patternConstraint": "^(?: (25[0-5]|2[0-4][0-9]|1[0-9][0-9]|1[0-9][0-9]|1[0-9][0-9]|1[0-9][0-9]) (\. (?!$) |$) ) {4}$"
"patternConstraintMessage": "Enter a valid IPV4 address 12.22.111.132"
"patternConstraint" = "^\\((?([0-9]{3})\\)?[-. ]?(?([0-9]{3})[-. ]?(?([0-9]{4}))$";
"patternConstraintMessage" = 'Enter a valid phone number 555-555-5555 or (555)555-5555';
"patternConstraint": "^(5[0-9]{3,4}|[1-4]\\d{3,4}|[6-9]\\d{3})?$"
"patternConstraintMessage": - "Enter integer in the range [5000..59999]"
```

To see pattern constraint examples within a JSON file, go to [Create a TEXT, TEXTAREA, and PASSWORD Attributes](#).

### Review UI Definitions using an Example JSON File

To show how the UI definitions render the UI panels, examine the JSON file for the Example Target Connector. One "application" section and one "account" section are in the file.

#### NOTE

To explain each attribute type, this topic uses the **Example - Application** panel. However, all the UI definition guidelines apply to the "account" and the "application" sections of the file.

On the Application tab, there is an **Application Type** field. When you select the Example Target Connector for the application type, the **Example - Application** tab becomes available.

The following screen image shows the **Example - Application** tab:

## Update exampleapp

Application	Example - Application
Connect Timeout:	<input type="text" value="60000"/>
Read Timeout:	<input type="text" value="5000"/>
SSH Port:	<input type="text" value="22"/>
Connector Protocol:	<input type="radio"/> SSL <input type="radio"/> TLS 1.0 <input checked="" type="radio"/> TLS 2.0
Additional Encryption:	<input type="text" value="AES"/>
Use Certificate:	<input type="checkbox"/>
Certificate:	<input type="text"/>

How to define the tabs and fields is described in these topics:

- [Define Required uiDefinition and Tabs Sections](#)
- [Define Custom Connector Tabs](#)
- [Create a Number Field](#)
- [Create a Text, Text Area, and Password Attributes](#)
- [Display a Field with Radio Buttons](#)
- [Use a Checkbox to Select an Option](#)
- [Create a Field with a Drop-down List of Values](#)
- [Define the Locale for Field Labels](#)
- [Create a Target Account Selection Field](#)

### **Define Required uiDefinition and Tabs Attributes**

Each application and accounts section requires a "uiDefinitions" attribute followed by a single "tabs" attribute. These attributes designate the following information:

- **uiDefinition** - For each application and account section, this attribute is the parent for the "tabs" definition.
- **tabs** - This section lists an array of tab objects that contain the tab identifier, label, and corresponding "fields" displayed on each tab. This attribute lets you define high-level tabs to group related fields.

The following code example shows these two sections:

```
"application": {
  "uiDefinition": {
    "tabs": [{
      "id": "ExampleAppDetail",
```

```
"label": "Example - Application",

"fields": [{...}]
```

### Define Custom Connector Tabs

A tab contains all the target application or target account attributes for your target connector. To group related attributes, create one or more tabs as needed.

The following graphic shows the Example - Application tab.

Each tab must have the following attributes:

Attribute	Description
id	Unique identifier for the tab. This identifier must be unique on the UI panel where the tab is rendered. Every identifier must begin with a letter or underscore, followed by one or more letters, underscores or digits. You can follow an initial underscore with another underscore. Valid identifiers are case-sensitive. Tab identifiers cannot contain embedded spaces.
label	The text on the tab itself, such as Example - Application, which is shown in the previous graphic. If the value of the label is an identifier from the "locale" section of the file, the language-specific string is used. If a locale identifier is not specified, the literal string value is used. For more details, see <a href="#">Define the Locale for UI Field Labels</a> later in this topic.
fields	Specifies an array of field objects to display on the tab panel.

To add a target application tab that is labeled Example - Application, use the following JSON syntax:

```
"application": {
  "uiDefinition": {
    "tabs": [{
      "id": "ExampleAppDetail",
      "label": "Example - Application",

      "fields": [{...}]
```

To add the two tabs, **Example - Application** and **User Information**, use the following JSON syntax:

```
"application": {  
  "uiDefinition": {  
  
    "tabs": [{  
  
      "id": "ExampleAppDetail",  
  
      "label": "Example - Application",  
  
      "fields": [{  
  
        "type": "NUMBER",  
  
        "field": "connectTimeout",  
  
        "label": "Connect Timeout",  
  
        "required": false,  
  
        "minValue": 1,  
  
        "value": 60000  
  
      }]  
  
    }, {  
  
      "id": "ExampleAppUserInfo",  
  
      "label": "User Information",  
  
      "fields": [{  
  
        "type": "TEXT",  
  
        "field": "firstName",  
  
        "label": "First Name",  
  
        "required": true  
  
      }], {  
  
        "type": "TEXT",
```

```

        "field": "lastName",

        "label": "Last Name",

        "required": true

    }, {

        "type": "NUMBER",

        "field": "age",

        "label": "Age",

        "required": false,

        "minValue": 1,

        "value": 1

    }]

}

}

```

### Create a Number Field

To display fields that require numerical entries, such as ports, timeouts, add a `NUMBER` field type. You can restrict `NUMBER` fields by specifying a minimum (`minValue`) or maximum (`maxValue`) constraint.

The following JSON syntax creates the Connect Timeout, Read Timeout, and SSH Port fields in the Example - Application panel. Based on the JSON, this panel includes initial default values for each field. The example shows how to provide minimum and maximum restrictions on the specified values. Also, the example has the `required` attribute set to `true`, which indicates that you must specify a value. You cannot leave the attribute blank.

```

"fields": [{
    "type": "NUMBER",
    "field": "connectTimeout",
    "label": "Connect Timeout",
    "required": true,
    "minValue": 1,
    "value": 60000
}, {
    "type": "NUMBER",
    "field": "readTimeout",
    "label": "Read Timeout",
    "required": true,

```

```

        "minValue": 1,
        "value": 5000
    }, {
        "type": "NUMBER",
        "field": "sshPort",
        "label": "SSH Port",
        "required": true,
        "minValue": 0,
        "maxValue": 65535,
        "value": 22
    }
]

```

### Create a Text, Text Area, and Password Attributes

The following excerpt shows the definition for the following field types:

- TEXT: A field that requires text.
- TEXTAREA: A field that can accommodate a large amount of text.
- PASSWORD: A field for a user password.

The TEXT type use pattern constraints. The TEXT type sets the **required** attribute to true, indicating that the field cannot be left blank. The TEXTAREA does not have any pattern constraints.

```

{

    "type": "TEXT",

    "field": "userName",

    "label": "User Name",

    "required": true,

    "minLength": 1,

    "maxLength": 200

}, {

    "type": "TEXT",
    "field": "admin",
    "label": "Administrator",
    "required": true,
    "maxLength": 16,
    "patternConstraint": "^[A-Za-z0-9]+$",
    "patternConstraintMessage": "Administrator name consists of letters and numbers
only",

```

```

    "value": "admin"

  }, {

    "type": "TEXTAREA",

    "field": "certificate",

    "label": "Certificate"

  }, {

    "type": "TEXT",

    "field": "occurance",

    "label": "Activity from",

    "patternConstraint": "^(today|tomorrow|yesterday)$",

    "patternConstraintMessage": "Enter today, tomorrow or yesterday"

  }, {

    "type": "PASSWORD",

    "field": "user_password",

    "label": "User Password"

  }

```

### ***Display a Field with Radio Buttons***

The **RADIO** attribute type displays a control for selecting only one option from a set of a predefined and mutually exclusive option. The **RADIO** type is recommended for a configuration setting with only a few options. The **RADIO** type requires a "values" attribute followed by two or more unique "label" and "value" options for the control.

The following JSON syntax creates the Connector Protocol setting with three options: TLS 1.0, 1.2. and 1.3. When you create a Target Application or Account, the TLS 1.2 option is set by default. If no initial value is specified, the first option, in this example TLS 1.0, is selected by default.

```

{
  "type": "RADIO",
  "field": "connector_protocol",
  "label": "Connector Protocol",
  "value": "TLS_1.2",

```

```

    "values": [{
      "label": "TLS 1.0",
      "value": "TLS_1"
    }, {
      "label": "TLS 1.2",
      "value": "TLS_1.2"
    }, {
      "label": "TLS 1.3",
      "value": "TLS_1.3"
    }
  ]
}

```

### ***Use a Checkbox to Select an Option***

To display a field with a checkbox for a true or false choice, use the CHECKBOX parameter type.

The following JSON syntax creates the Use Certificate field in the Example - Application panel. By default, this panel has the option set to true (selected) by default. If no initial value is provided, the control is false (not selected).

```

{
  "type": "CHECKBOX",
  "field": "certificate",
  "label": "Use Certificate",
  "value": true
}

```

### ***Create a Field with a Drop-down List of Values***

To display a field with values selectable from a drop-down list, add a COMBOBOX parameter type.

The following JSON syntax creates the Additional Encryption field in the Example - Application panel. When creating a target application or account, this example shows AES set as the default value. If no initial value is specified, the first item, in this example Triple DES, is selected by default.

```

{
  "type": "COMBOBOX",
  "field": "additionalEncryption",
  "label": "Additional Encryption",
  "value": "AES",
  "values": [{
    "label": "Triple DES",

```

```

        "value": "TRIPLEDES"
    }, {
        "label": "RSA",
        "value": "RSA"
    }, {
        "label": "Blowfish",
        "value": "BLOWFISH"
    }, {
        "label": "Twofish",
        "value": "TWOFISH"
    }, {
        "label": "AES",
        "value": "AES"
    }
  ]
}

```

### Create a Target Account Selection Field

To create a field where a user can select a target account, use the TARGETACCOUNT field type. This field displays a field with a drop-down list from which to select an account. The field also lets a user search and select a target account. In the following example, on the Example - Account panel, there are two fields, one labeled Description and the other field labeled Master Account.

```

"fields": [{
    "type": "TEXT",
    "field": "description",
    "label": "Description",
    "maxLength": 60
  }, {
    "type": "TARGETACCOUNT",
    "field": "anotherAccount",
    "label": "Master Account"
  }
]

```

### Define the Locale for UI Field Labels

To localize how field labels display in a web browser, add a **locale** section to the uiDefinitions.json file. The locale attribute interacts only with the browser locale. The only supported locale values are **en** (English) and **ja** (Japanese).

Guidelines for the locale section:

- There can be only one locale section in the file
- Under the locale section you can have multiple subsections, one for each language. For example, under locale you can list an "en" subsection and a "ja" subsection.
- For each field label that you want in a specific language, add a corresponding string in the relevant language subsection.
- If you have a label that you cannot localize, such as a proper name, do not include a string in the locale section.

The following table explains how the browser locale and the locale section work together to render UI pages:

Browser Locale	Specified Locale Section in the uiDefinitions.json File	Language Displayed in the PAM UI
English	en	English. All other locale sections in the file are ignored. If the <code>label</code> for a field does not have a corresponding string in the <code>en</code> section, the UI uses the literal value of the label. This value can be any language.
Japanese	ja	Japanese. All other locale sections in the file are ignored. If the <code>label</code> for a field does not have a corresponding string in the <code>ja</code> section, the UI uses the literal value of the <code>label</code> . This value can be any language.
<b>Note:</b> If there is no locale section, the UI displays the literal value of the <code>label</code> for a control. For example, if a label is in Japanese, the field name displays in Japanese even if the browser is set to English.		

You can enter strings in the locale section in two formats. You can mix both formats in the same locale section. The format options are:

- Regular string values. **JSON example:** "AccountTabLabel" : "Account Tab"
- Unicode hexadecimal character. This format begins with a backslash and the letter u (\u), followed by a four-value hexadecimal constant. This format is required for multi-byte languages, such as Japanese.

**JSON Example:** "AccountTabLabel" : "\u30a8\u30b3\u30fc\u30a2\u30ab\u30a6\u30f3\u30c8"

The browser locale determines whether "Account Tab" is rendered in English or rendered in Kanji characters.

The following example is an abbreviated sample JSON file with a locale attribute. The example shows a section for English and Japanese and the regular string and Unicode hexadecimal formats that you can use. The locale section renders four UI panels—an Account Tab in English and Japanese and an Application Tab in English and Japanese. For illustration purposes, the two Account Tab panels are shown.

```

{
  "account": {
    "uiDefinition": {
      "tabs": [{
        "id": "AccountTab",
        "label": "AccountTabLabel",
        "fields": [{
          "type": "TEXT",
          "field": "AccountNameField",
          "label": "AccountNameFieldLabel"
        }]
      }]
    },
  },
  "application": {
    "uiDefinition": {
      "tabs": [{
        "id": "ApplicationTab",
        "label": "ApplicationTabLabel",
        "fields": [{
          "type": "TEXT",
          "field": "ApplicationNameField",
          "label": "ApplicationNameFieldLabel"
        }]
      }]
    },
  },
  "locale" : {
    "en" : {
      "AccountTabLabel" : "Account Tab",
      "AccountNameFieldLabel" : "Account Name",

      "ApplicationTabLabel" : "Application Tab",
      "ApplicationNameFieldLabel" : "Application Name"
    },
    "ja" : {
      "AccountTabLabel" : "\u30a8\u30b3\u30fc\u30a2\u30ab\u30a6\u30f3\u30c8",
      "AccountNameFieldLabel" : "\u30c6\u30ad\u30b9\u30c8\u30d5\u30a3\u30fc",

      "ApplicationTabLabel" : "\u30a8\u30b3\u30fc\u0020\u002d\u0020\u30a2\u30d5\u30c8",
      "ApplicationNameFieldLabel" : "\u756a\u53f7\u30d5\u30a3\u30fc\u30ab\u30c8\u30c9"
    }
  }
}

```

The following screens show the Account Tab in English and Japanese:

Validate TCF Definition

TCF Definition JSON Account Tab

Account Name:

CLOSE

除済みサー

ワードを エコーアカウント

テキストフィールド:

閉じる

### Localization for the Server

The language for request and error messages from PAM and the Custom Connector server is determined by the PAM server. Messages include log and error messages about the TCF and the custom connector, and UI validation errors. If the appliance locale is English, then all error messages that the TCF returns to PAM are in English. If the appliance locale is Japanese, then all the error messages that the TCF returns are in Japanese.

When you update a target connector configuration, the validation request goes to the TCF server. If there are errors, the language that the error messages are displayed is based on the locale of the PAM server.

#### NOTE

Continue by reading about the required [web services endpoints](#).

### Web Service Endpoints for the Custom Connector

Each target connector must support three web service classes:

The Custom Connector software comes with a project named `customConnectorTemplate`. This project includes all three services, which are defined in `com/ca/pam/customConnectorTemplate/api`. Before you develop your own target connector, read about each service class in detail. Then use the `customConnectorTemplate` as a basis to write your own Java code.

### **Credentials Service**

The Credentials service verifies and updates the credentials for an account at the remote target device.

#### **URLs for the Credentials service:**

- `http://tomcat_host:port/capamef/targetConnectors/target_connector_name/credentials/validate`
- `http://tomcat_host:port/capamef/targetConnectors/target_connector_name/credentials/update`

**Method supported:** POST

**Sample REST call:** HTTP POST `http://112.22.30.111:8443/capamef/targetConnectors/exampleTargetConnector/credentials/validate`

The following sample code includes requests to update and verify credentials. The extended attribute sections are based on the account and application attributes defined in `uiDefinitions.json` file.

Figure 32: sample credentials.java

    "accessType": null,
    "privileged": true,
    "password": "xxxxxxx",

```

## UIDefinitions Service

The UIDefinitions service returns UI definitions in JSON format for a specified field type. This service determines how the Java code and the JSON file work together.

**URL for the uiDefinitions service:** `http://tomcat_host:port/capamef/targetConnectors/target_connector_name/uiDefinitions/{uiDefinitionType}`

In the uiDefinitions service URL:

- `tomcat_host:port` values are not case-sensitive.
- `target_connector_name` must be in lower camel case. For example, `customTargetConnector`.
- `uiDefinitionType` must be **account** or **application**

**Method supported:** GET

**Sample REST call:** HTTP GET `http://112.22.30.111:8443/capamef/targetConnectors/exampleTargetConnector/uiDefinitions/application`

**Sample Response from the TCF:**

```
{ "_data": { "application": { "uiDefinition": { "tabs": [ { "label": "Example -
Application", "id": "ExampleAppDetail",

"fields": [ { "type": "NUMBER", "field": "connectTimeout", "minValue": "1", "label": "Connect
Timeout", "required": false, "value": "60000" },

{ "type": "NUMBER", "field": "readTimeout", "minValue": "1", "label": "Read
Timeout", "required": false, "value": "5000" },

{ "type": "NUMBER", "field": "sshPort", "minValue": "0", "label": "SSH
Port", "required": false, "value": "22", "maxValue": "65535" },

{ "type": "RADIO", "field": "connectorProtocol", "label": "Connector
Protocol", "required": false, "value": "TLS_1.2",

"values": [ { "label": "TLS 1.0", "value": "TLS_1" }, { "label": "TLS 1.2", "value": "TLS_1.2" },
{ "label": "TLS 1.3", "value": "TLS_1.3" } ] },

{ "type": "COMBOBOX", "field": "additionalEncryption", "label": "Additional
Encryption", "required": false, "value": "AES",

"values": [ { "label": "Triple DES", "value": "TRIPLEDES" }, { "label": "RSA", "value": "RSA" },
{ "label": "Blowfish", "value": "BLOWFISH" },

{ "label": "Twofish", "value": "TWOFISH" }, { "label": "AES", "value": "AES" } ] },

{ "type": "CHECKBOX", "field": "useCertificate", "label": "Use
Certificate", "required": false, "value": "false" },

{ "type": "TEXTAREA", "field": "certificate", "label": "Certificate", "required": false } ] ] ] ] } }, "_meta": {
"_success": "true" } }
```

## Validations Service

The Validations service verifies account and application data before saving it into the Privileged Access Manager database.

**URL for the Validations service:** `http://tomcat_host:port/capamef/targetConnectors/target_connector_name/validations/{validationType}`.

- If the *validationType* is **account**, this service validates data for target account creation and update.
- If the *validationType* is **application**, this service validates data target application creation and update.

**Methods supported:** POST, PUT

**Sample REST call:** HTTP POST `http://112.22.30.111:8443/capamef/targetConnectors/exampleTargetConnector/validations/application`

The following sample request payload includes requests to the Validations service. The extended attributes in the payload are defined in the previous sample response for the uiDefinitions service.

### Sample Request Payload:

```
"application": {
  "targetServer": {
    "hostName": "114.20.50.111",
    "ipaddress": "114.20.50.111",
    "deviceName": "UnixDevice"
  },
  "name": "UnixApp",
  "type": "exampleTargetConnector",
  "extendedAttributes": {
    "sshPort": "22",
    "additionalEncryption": "AES",
    "connectorProtocol": "TLS_1.2",
    "readTimeout": "5000",
    "useCertificate": "false",
    "connectTimeout": "60000",
    "certificate": ""
  }
}
```

A `ValidationManager` class is distributed in the core library. This class validates data based on the constraints in the `uiDefinitions` JSON file. In additions to these standard validations, you can add custom validations to this class. If a validation fails, the `ValidationManager` class throws an `ExtensionException` with a list of messages.

To see sample code, look at the `Validations.java` class in the `customConnectorTemplate` project.

### NOTE

Now that you are familiar with the components for creating a custom target connector, [Build Your Custom Connector](#).

## Build Your Custom Connector

Now that you are familiar with the UI definitions and the web service endpoints, you can build your own connector.

Follow these steps in order:

### NOTE

All custom target connectors must be installed on every instance of the Custom Connector server. You can install the Custom Connector server on a Windows or Linux system as long as the Tomcat server is installed on that system. If your custom target connector code is using native operating system calls, then all target connectors must make calls to that same operating system. Do not write one target connector that makes native Windows calls and another target connector that makes native Linux calls. One of the connectors fails because they are operating on one server

### Deploy the Custom Connector Software

Before you build a custom connector, complete the steps in [Deploy the Custom Connector Software](#). Ensure that you configured the settings on the Custom Connector page (**Configuration, Custom Connectors**).

### Obtain the Required Software

- JDK 8 Update 201 (minimum version) or JDK 11
  - Java build tool: Apache Maven or Gradle
  - Core library `com.ca.pam:capamexternsionscore:4.16.0`, included with the SDK, in the directory `sdk/lib`.
  - Repository for Maven or Gradle
- Maven and Gradle rely on a repository to manage library dependencies. To create a connector project, first set up a repository with the following dependencies:

JDK 8	JDK 11
<ul style="list-style-type: none"> <li>• <code>javax.ws.rs:javax.ws.rs-api:2.0.1</code></li> <li>• <code>org.glassfish.jersey.containers:jersey-container-servlet:2.25.1</code></li> <li>• <code>org.glassfish.jersey.media:jersey-media-json-jackson:2.25.1</code></li> <li>• <code>org.codehaus.jettison:jettison:1.3.8</code></li> <li>• <code>io.swagger:swagger-jersey2-jaxrs:1.5.19</code></li> <li>• <code>org.slf4j:slf4j-api:1.8.0-beta2</code></li> <li>• <code>org.apache.logging.log4j:log4j-api:2.11.0</code></li> <li>• <code>org.apache.logging.log4j:log4j-core:2.11.0</code></li> <li>• <code>org.apache.logging.log4j:log4j-slf4j-impl:2.11.0</code></li> </ul>	<ul style="list-style-type: none"> <li>• <code>org.glassfish.jersey.containers:jersey-container-servlet:2.27</code></li> <li>• <code>org.glassfish.jersey.core:jersey-common:2.27</code></li> <li>• <code>org.glassfish.jersey.inject:jersey-hk2:2.27</code></li> <li>• <code>org.glassfish.jersey.media:jersey-media-multipart:2.27</code></li> <li>• <code>javax.xml.bind:jaxb-api:2.3.1</code></li> <li>• <code>javax.activation:activation:1.1.1</code></li> <li>• <code>org.glassfish.jersey.media:jersey-media-json-jackson:2.27</code></li> <li>• <code>org.codehaus.jettison:jettison:1.4.0</code></li> <li>• <code>io.swagger:swagger-jersey2-jaxrs:1.5.21</code></li> <li>• <code>javax.servlet:javax.servlet-api:4.0.1</code></li> </ul>

### Create a Project for the Custom Connector

The first step before building the custom target connector is to create a project for the connector. The Custom Connector zip includes a command-line script to create a project for your custom connector:

**Windows:** `createTCProject.cmd`

**UNIX:** `createTCProject`

When you run the `createTCProject` script, it uses the `custom ConnectorTemplate` to build the project. The `customConnectorTemplate` contains metadata files for the Maven and Gradle source code. The template also contains example source code for creating the input validation service and the credentials verification and update services.

**NOTE**

If you set the JAVA\_HOME environment variable on the system where you run the createTCProject script, the script reads the JDK path from this variable. Ensure that the script is pointing to the correct JDK version and update.

**To create a project:**

Go to the directory that contains the script, then execute the following command:

```
createTCProject -Dworkspace=workspace_location -DgroupId=group_id -
DartifactId=project_id -Dversion=version -DbuildTool=build_tool
```

The command example is for UNIX platforms. For Windows systems, other than the command extension, the command is the same.

Alternatively, specify an absolute or relative path to the script. For example, if you are at the directory C:\CAPAM\customconnectors and the file is in \CAPAM\sdk, the command using the absolute path is:

```
C:\CAPAM\sdk\createTCProject -Dworkspace=workspace_location -DgroupId=group_id -
DartifactId=project_id -Dversion=version -DbuildTool=build_tool
```

The command using the relative path is:

```
..\sdk\createTCProject -Dworkspace=workspace_location -DgroupId=group_id -
DartifactId=project_id -Dversion=version -DbuildTool=build_tool
```

The place holders in italicized text get replaced with the following information:

- *workspace\_location*: The location where the target connector project is generated. This path can be a relative or absolute path. If this folder does not exist, the tool creates it.
- *group\_id*: The group Identifier for the target connector project, like the Maven or Gradle group identifier. This ID is also used as the package prefix for the project Java source files.
- *artifact\_id*: The name of the target connector project. A folder with this name is created in the workspace. All the source files and project files for target connector are generated in this folder. This ID is also used in the generated package name.
- *version*: The version of the target connector project.
- *build\_tool*: Indicates which build tool (Maven or Gradle) to use for the target connector project.

**Create a project – Gradle Example:**

```
createTCProject -Dworkspace=tcworkspace -DgroupId=com.company.tc -
DartifactId=myconnector -Dversion=1.0 -DbuildTool=gradle
```

**Create a project – Maven Example:**

```
createTCProject -Dworkspace=tcworkspace -DgroupId=com.company.tc -
DartifactId=myconnector -Dversion=1.0 -DbuildTool=maven
```

After you create a project, the following directory structure is created from where you ran the command:

**Figure 33: custom connector gradle project structure****tcworkspace**

```

| ..... application
|   | ..... gradle
| ..... src
|   | ..... main
|       | ..... java
|           | ..... com/company/tc/myconnector/api
|               | ..... credentials.java
|               | ..... UIDefinitions.java
|               | ..... Validations.java
|           | ..... resources
|               | ..... extension_messages.properties
|               | ..... extensions.properties
|               | ..... TargetConnectorMessages_en_US.properties
|               | ..... TargetConnectorMessages_ja.properties
|               | ..... uiDefinitions.json
|           | ..... webapp
|               | ..... WEB-INF
|                   | ..... web.xml
|               | ..... META-INF
|               | ..... index.html
| ..... build.gradle
| ..... gradlew.bat
| ..... gradlew

```

After you create a project, build a custom target connector.

## **Build the Custom Connector using a Build Script**

The Custom Connector zip includes scripts for building a custom connector.

Build the connector, following the instructions for one of the following build scripts:

- [Run the Gradle Build Script](#)
- [Run the Maven Build Script](#)

### **Run the Gradle Build Script**

The template includes a **build.gradle** build script. This file includes repositories, dependencies, and plug-in configurations. A sample of the build.gradle script is shown after the procedure.

Modify the script as instructed:

1. Modify the `repositories` section and include your repository.  
The `repositories` section includes the Maven central repository. The `mavenCentral` repository can remain in the script or you can remove it.
2. List dependencies in the `dependencies` section. The list must include dependencies on the target connector core library and on any other third-party libraries that the core library requires. All the dependencies that you add in this section must be installed in your repository so that the libraries are available to Gradle build script.

The default build.gradle script is shown in the following graphic:

```
buildscript {
    repositories {
        mavenCentral()
    }
}

apply plugin: 'war'
apply plugin: 'eclipse-wtp'
apply plugin: 'idea'
sourceCompatibility = 1.8
targetCompatibility = 1.8

repositories {
    mavenCentral()
}

dependencies {
    compile ('javax.ws.rs:javax.ws.rs-api:2.0.1')
    compile ('org.glassfish.jersey.containers:jersey-container-servlet:2.25.1')
    compile ('org.glassfish.jersey.media:jersey-media-json-jackson:2.25.1')
    compile ('org.codehaus.jettison:jettison:1.3.8')
    compile ('io.swagger:swagger-jersey2-jaxrs:1.5.19')
    compile ('org.slf4j:slf4j-api:1.8.0-beta2')
    compile ('org.apache.logging.log4j:log4j-api:2.11.0')
    compile ('org.apache.logging.log4j:log4j-core:2.11.0')
    compile ('org.apache.logging.log4j:log4j-slf4j-impl:2.11.0')
    compile ('com.ca.pam:capamextensionscore:4.16.0')
}

file('build').mkdirs()

war {
    archiveName 'projectTemplate.war'
}
```

3. After you finish modifying the Gradle build script, run the script using the following command:

```
gradlew.bat build
```

If the build is successful, a **.war** file is created in the build directory. If there is a problem with the build, error messages display in the console. Make the necessary corrections and rerun the script.

4. Import the Gradle project into your integrated development environment (IDE), such as Eclipse or IntelliJ.
5. Go to the next task, [Modify the uiDefinitions.json File](#).

### **Run the Maven Build Script**

The template includes a **pom.xml** file. This file includes repositories, dependencies, and plug-in configurations.

Modify the script as instructed:

1. Modify the `repositories` section and include your repository.  
The `repositories` section includes the Maven central repository. The `mavenCentral` repository can remain in the script or you can remove it.
2. List dependencies in the `dependencies` section. The list must include dependencies on the target connector core library and on any other third-party libraries that the core library requires. All the dependencies that you add in this section must be installed in your repository so that the libraries are available to maven build script.

The default Maven `pom.xml` file is shown in the following graphic:

```
<?xml version="1.0" encoding="UTF-8"?>
<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance"
  xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/
maven-4.0.0.xsd">
  <modelVersion>4.0.0</modelVersion>
  <groupId>com.ca.pam</groupId>
  <artifactId>customConnectorTemplate</artifactId>
  <version>1.0</version>
  <repositories>
    <!-- Define corporate repository here.-->
  </repositories>
  <dependencies>
    <dependency><groupId>javax.ws.rs</groupId><artifactId>javax.ws.rs-api</
artifactId><version>2.0.1</version></dependency>
    <dependency><groupId>org.glassfish.jersey.containers</groupId><artifactId>jersey-
container-servlet</artifactId><version>2.25.1</version></dependency>
    <dependency><groupId>org.glassfish.jersey.media</groupId><artifactId>jersey-media-
json-jackson</artifactId><version>2.25.1</version></dependency>
    <dependency><groupId>org.codehaus.jettison</groupId><artifactId>jettison</
artifactId><version>1.3.8</version></dependency>
    <dependency><groupId>io.swagger</groupId><artifactId>swagger-jersey2-jaxrs</
artifactId><version>1.5.19</version></dependency>
    <dependency><groupId>org.slf4j</groupId><artifactId>slf4j-api</
artifactId><version>1.8.0-beta2</version></dependency>
    <dependency><groupId>org.apache.logging.log4j</groupId><artifactId>log4j-api</
artifactId><version>2.11.0</version></dependency>
    <dependency><groupId>org.apache.logging.log4j</groupId><artifactId>log4j-core</
artifactId><version>2.11.0</version></dependency>
```

```

    <dependency><groupId>org.apache.logging.log4j</groupId><artifactId>log4j-slf4j-impl</artifactId><version>2.11.0</version></dependency>
    <dependency><groupId>com.ca.pam</groupId><artifactId>capamextensionscore</artifactId><version>4.16.0</version></dependency>
    <!-- Add additional dependencies -->
</dependencies>
<plugins>
    <plugin>
        <artifactId>maven-war-plugin</artifactId>
        <version>2.3</version>
    </plugin>
</plugins>
</project>

```

3. After you finish modifying the Gradle build script, run the script using the following command:

```
mvmw.cmd package
```

If the build is successful, a **.war** file is created in the target directory. If there is a problem with the build, error messages display in the console. Make the necessary corrections then rerun the script.

4. Import the Maven project into your integrated development environment (IDE), such as Eclipse or IntelliJ.
5. Go to the next task, [Modify the uiDefinitions.json File](#)

### **Modify the uiDefinitions.json File**

In the project you created, add, or modify the tab and field attributes to render all the necessary UI elements for your custom target connector.

#### **Follow these steps:**

1. In your project, navigate to the directory **/src/main/resources/** and locate the uiDefinitions.json file.
2. Open the file in a JSON editor and modify the entries for your custom connector.
3. Define an "application" section and "account" section. The application extended attributes enable communication to the target device. The account section extended attributes verify or update account credentials at the target device.

For detailed information about valid UI attributes, see [UI Fields and Controls for Configuring Connectors](#).

### **Test and Validate the UI Definitions**

The UI provides a mechanism for testing and validating the attributes in the uiDefinitions.json file. The validation mechanism can also test the creation and modification of the target application and account user interface controls. The facility verifies whether the syntax and structure of the JSON entries are correct. If there are any errors with a definition, error messages are displayed from the UI. These messages can indicate problems with syntax or other issues in the uiDefinitions.json file. You can also define custom validation rules. Custom validation can contain field validation criteria, which verifies UI data when users update or can save the target application or account.

The facility also has a preview option. After you modify the uiDefinitions.json file, you can see the resulting UI panels and controls for the target application and account.

#### **NOTE**

Only administrators with the Target Connector Validator role can use the validation facility. The Target Connector Validator role is assigned the Validate Target Connector UI privilege.

#### **To validate the UI definitions, follow these steps:**

1. Log in to the UI as an Administrator with the **Target Connector Validator** role, such as an Operational Administrator.

You must be assigned a role with the Validate Target Connector UI privilege to see the Validate TCF Definition option under the **Settings** menu.

2. Select **Settings, Validate TCF Definition**.

The Validate UI Definition page displays with a **TCF Definition JSON** page.

3. Copy and paste the content from a uiDefinitions.json file to the page.

Alternatively, you can manually enter the JSON for the application and account tabs and other UI elements. Follow the JSON syntax and expected field attributes, as described earlier in this topic.

4. After you put content on the page, select **Validate**.

The syntax of the definitions is examined. If the JSON has any errors, the facility reports these errors to the user.

### NOTE

Correct any errors that are detected. If any UI definition errors exist, the preview does not display.

5. Preview the application and account panels:

- a. To display the target application panel, select **Show TCF Application**. The panel displays next to the TCF Definition JSON page. The controls reflect what you defined in the application section of the JSON file.
- b. To display the target account panel, select **Show TCF Account**. The panel displays next to the TCF Definition JSON page. The controls reflect what you defined in the account section of the JSON file.

6. To view and update the JSON entries, edit them in the TCF Definition JSON page.

7. After the JSON is complete, copy the text and paste into the **uiDefinitions.json** file.

## Edit the Web Service Endpoints

In the project you created, modify the web service classes that define the endpoints for a custom target connector.

### Follow these steps:

1. In your project, navigate to the directory **/src/main/java/com/company/tc/project\_name/api**. This folder contains three web service classes. Modify only the following two classes:
  - **Credentials.java** - this code provides the business logic that the TCF uses to verify and change passwords at remote endpoints.
  - **Validations.java** - this code validates any field types against the application and account constraints in the uiDefinitions.json file.

Do not modify the UDefinitions.java web service.

2. Edit the **Credentials.java** file. This class provides two stub methods for adding credential verification and update logic for a target connector.

Add your credential verification logic to this stub method:

```
private void processCredentialVerify () throws ExtensionException {
    add credential verification logic here
}
```

Add your credential update logic to this stub method:

```
private void processCredentialUpdate () throws ExtensionException {
    add credential update logic here
}
```

If any of the verifications or updates fail, these methods must throw an ExtensionException.

### NOTE

The data that is required to perform verifications and updates is available as instance variables. These variables are listed in the Credentials.java class.

3. Optionally, modify the **Validations.java** file. This service class validates target application and account data based on the constraints in the uiDefinitions.json file. This class provides the following stub method for adding custom validations.

If you want to add more validations, add your validation logic to this stub method:

```
private void performCustomValidation(Map<String,String> extendedAttributes, String
    validationType) throws ExtensionException {
    add custom validation logic here
}
```

This method takes two arguments:

- **extendedAttributes**: Represents the "field" attribute and its value in the uiDefinitions.json file. The values are the inputs that the user provides in the PAM UI.
- **validationType**: Indicates whether the data is for a target application or a target account. The value can be "account" or "application." The value for the validationType comes from the request URL that is sent by the appliance to the TCF.

If any of the validations fail, this method must throw an ExtensionException.

Here is an example of server-side validation. The following code adds custom validation for a Checkbox control on the Echo - Application panel.

```
private void customValidation(String json, String validationType)
    throws ExtensionException {
    if (validationType.equals("application")) {
        try {
            JSONObject jsonObj = new JSONObject(json);
            JSONObject jobject = jsonObj.getJSONObject(validationType);
            JSONObject jsonObject = jobject.getJSONObject("extendedAttributes");

            if(jsonObject.get("checkboxControl").equals("true")) {
                String str = jsonObject.get("textareaControl").toString();
                if(str.isEmpty() || str.equals("")) {
                    buildException(EchoMessageConstants.TEXTAREA_CONTROL_MISSING, false,
                        "textareaControl");
                }
            }
        } catch (JSONException e) {
            LOGGER.log(Level.SEVERE, "Custom validation failed " + e.toString());
            buildException(MessageConstants.INVALID_JSON, false);
        }

        if(exception != null) {
            throw exception;
        }
    }
}
```

If the validation fails, the following message displays:

For detailed information about the web service endpoints, see [Web Service Endpoints for the Custom Connector](#).

### **Establish Logging for the Custom Connector**

To monitor activity and troubleshoot problems between the appliance and the Custom Connector server, set up logging. The TCF and the example target connectors use the standard

```
java.util.logging
```

package and write messages to the catalina.out file.

When you write log statements, add the following two TCF-specific attributes to the standard log message format. Include these two attributes in all the log statements from the Custom Connector server and custom target connectors so you can debug any issues.

- **request ID**—When PAM generates a request to the Custom Connector server, this auto-generated attribute gets added to the header of every REST web service call. The request ID enables you to track the transaction to and from the Custom Connector server, which helps troubleshoot errors.
- **context name**—When the Custom Connector server writes a message to the log file, the context name identifies whether the source of the message is the TCF or the custom target connector. The context name is configurable. To change the name, go to *Tomcat\_home*\src\main\webapp\WEB-INF\ and edit the name in the web.xml file. The context name is only for logs that the Custom Connector server generates, not PAM.

The following graphic shows the format of log statement. The request id and the context name are preceded and followed by the custom strings that you specify:

```
day-month-year time log_level [url_custom_connector_server] tcf_java_class [request_id]
[context_name]
Forward the request to UIDefinitions
```

For example:

```
01-Nov-2018 13:15:20.735 INFO [http-nio-8080-exec-1]
com.ca.pam.extensions.framework.api.TargetConnectors.targetConnectorUIDefinitions
```

```
[7dc53df5-703e-49b3-8670-b1c468f47f1f] [targetconnector] Forward the request to
UIDefinitions
```

### Add Log Statements to Your Java Code

To add log statements for your custom target connectors, call the `java.util.logging` API. Before calling this API, call the `LoggerWrapper` class to add the request ID and context name to the log messages. For example:

```
LOGGER.log(Level.INFO, LoggerWrapper.logMessage("<message>"));
```

In this example, `LOGGER` is an instance of the `java.util.logging.Logger` class.

#### NOTE

No instance of the `LoggerWrapper` class is required because `logMessage` is a static method. The custom message can be passed as a parameter to the `logMessage` method. The method constructs the log statement by adding the request id and the context name.

### Set Log Levels

When log messages are displayed in the `catalina.out` file, the messages are ordered based on the log level hierarchy. You can change log levels for your messages depending on the level of detail you want reflected in each log message. To modify the log levels, go to the Tomcat server directory `/conf/logging.properties`.

If a particular log level is required for only certain classes in the package, then add the package name to the `logging.properties` file.

### Configure Error Handling for a Custom Connector

The Custom Connector SDK includes error messages that are related to TCF operation. If an error occurs, the TCF sends back to PAM. TCF error messages are in the **`extension_messages.properties`** and the **`extension_messages_ja.JP.properties`** files.

#### NOTE

Do not modify the `extension_messages.properties` files.

For your custom target connectors, you can set up custom error handling specifically for target connector operation. If an error occurs, the target connector sends messages to the TCF which forwards them back to PAM.

Custom error handling reads the error messages from one of the following properties files:

- `artifact_ID_messages.properties` file (English messages)
- `artifact_ID_messages_ja_JP.properties` file (Japanese messages)

When you run the command to create a TCF project, the command automatically creates these two custom properties files in the directory `tomcat_home/src/main/resources`. Any custom message that you write must be added to the message properties file.

### How to Add Custom Error Messages

When you add error messages to the properties file, begin each message with a unique numbered identifier, for example PAM-TC-1001. As you add messages, we recommend using the next number in consecutive order.

#### TIP

Use a different numbering scheme from the numbering in the **`extension_messages.properties`** and the **`extension_messages_ja.JP.properties`** files so the identifiers do not override one another. For example, if the numbering in the `extension_message.properties` file begins with PAM-EF-001, use xxx-xx-1001 for your custom properties file.

You might want comment on the numbering scheme in the custom properties file so the pattern is clear to anyone modifying the file. For example:

```
// Resource Bundle for Custom Target Connector Messages
// Please start the message codes at 1001 (i.e. PAM-TC-1001) to avoid message number
// collisions
// Example: PAM-TC-1001=Text area control must not be empty when checkbox is selected.
```

For error messages related to the TCF and the custom target connector, the locale setting of the PAM appliance determines the language. If the appliance locale is English, then all error messages are in English. If the appliance locale is Japanese, then all messages are in Japanese. In general, any data that is stored in the appliance database is impacted by the appliance locale and not the browser.

### **Complete the Build Process**

1. After you complete all the tasks to build the connector, rebuild your project by entering the Gradle or Maven build command:  
 - gradlew.bat build  
 - mvnw.cmd package  
 An updated *project\_name*.war file is generated.
2. Deploy the *project\_name*.war file by copying the file to the directory */tomcat\_home/webapps\_targetconnectors*. The .war file automatically deploys. The Tomcat server does not have to be restarted.
3. To verify a successful deployment, log in to the Tomcat server where the TCF is deployed. Open the **catalina.out** file and look for a message that reads:  
 Registering client of type, targetConnectors, with name: *project\_name*
4. Log in to the PAM UI as a Global Administrator, Configuration Manager.
5. Select **Configuration** on the top menu.
6. Verify that you see the **Custom Connectors** option in the left pane.
7. Select **Credentials, Manage Targets, Application**.
8. Select **Add**.
9. In the **Application Type** field, confirm that the drop-down list includes the project name of your custom connector.
10. Exit from the UI.

### **Configure Remote Targets with Your Custom Connector**

Now that you have built and deployed your own target connector, you can use the connector to manage privileged account credentials. The procedure for configuring target applications and accounts using a custom connector is the same procedure as it is for out-of-the-box connectors. For instructions, see [Protect Privileged Account Credentials](#).

## **Configure Custom Connectors Using the CLI**

Custom target connectors can be configured using any existing CLI commands that are related to target applications and target accounts. For a list of CLI commands, see [Credential Manager CLI Commands](#).

To execute these types of commands using a custom target connector, add the value of the **field** attribute from the uiDefinitions.json file to the command. The field attribute must match the entry in the JSON file. For each attribute you want to specify, add the string **Attribute.field\_string="value"** separated by a space.

### **TIP**

Use the value of the "field" attribute, not the "label" attribute.

For example, if the uiDefinitions.json file has the following entries in the application section, the CLI command must contain the strings `Attribute.connectTimeout="1 Attribute.sshPort="22"`

```

}, {
    "type": "NUMBER",
    "field": "connectTimeout",
    "label": "Connection Timeout",
    "required": true,
    "minValue": 1,
    "value": 60000

}, {
    "type": "NUMBER",
    "field": "sshPort",
    "label": "SSH Port",
    "minValue": 0,
    "maxValue": 65535,
    "value": 22

```

### Follow this process to use the CLI:

1. Complete *all* the tasks for developing a custom connector.

#### NOTE

To use the CLI commands, you must still define the UI elements in the uiDefinitions.json file.

2. Configure your custom target application and account using the relevant CLI command. The following examples show how to use the addTargetApplication and addTargetAccount commands to add the Example Target Connector.

#### Add a target application:

```

capam_command capam=11.323.23.130 adminUserID=admin cmdName=addTargetApplication
    TargetServer.hostName=myhost.mydomain.com

TargetApplication.name=exampleapp TargetApplication.type=exampleTargetApplication
    Attribute.descriptor1="headquarters"

Attribute.descriptor2="lab" Attribute.sshPort="22" Attribute.connectTimeout="1"

```

#### Add a target account:

```

capam_command capam=11.323.23.130 adminUserID=admin cmdName=addTargetAccount
    TargetServer.hostName=myhost.mydomain.com

TargetApplication.name=exampleapp TargetApplication.type=exampleTargetConnector
    TargetAccount.userName=sysop1 TargetAccount.password=sys0p2

```

```
Attribute.descriptor1="headquarters"
Attribute.descriptor2="lab" Attribute.description="customconnector"
Attribute.anotherAccount="1"
```

3. Follow the same pattern for any other target application or account CLI commands.
4. Verify that your changes with the CLI are working:
  - a. Log in the UI.
  - b. Navigate to **Credentials, Manage Targets, Target Applications**. Select the drop-down list in the **Application Type** field and confirm that you can see the new custom target applications and accounts.
  - c. Navigate to **Credentials, Manage Targets, Target Accounts**. Verify that your custom target account is in the accounts list.

## Troubleshoot Custom Connector Issues

The two components that might require troubleshooting are the Custom Connector Server, where the TCF is running, and the PAM appliance. If there are communication problems between these two components, those issues might also require problem solving.

The following topics offer solutions for common Custom Connector Server and TCF problems:

### Custom Connector (Tomcat) Server Startup Issues

The Custom Connector (Tomcat) server might not start up cleanly or fails to start services. To determine the problem, look for errors in the Tomcat catalina.out log.

Potential reasons for a startup issue include:

- [Property source error](#)
- [Connector is not initializing](#)
- [Authentication header cannot be decrypted](#)
- [Network port issues](#)
- [TLS connection issues](#)

#### ***Problem Loading the Property Source***

The TCF uses its own property source to read the encrypted keystore password from the catalina.properties file. The TCF decrypts the password before giving it to the Tomcat server to access the TLS keystore.

**Error:** If you see the following exception:

```
25-Apr-2019 13:37:57.382 SEVERE [main] org.apache.tomcat.util.digester.Digester.<clinit>
Error loading property source [com.ca.pam.extensions.tcfcryptoutil.TCFPropertySource]
java.lang.ClassNotFoundException: com.ca.pam.extensions.tcfcryptoutil.TCFPropertySource
```

**Action:** Verify that you copied the capamextensionstcfCryptoUtil-x.x.x.jar file to \$CATALINA\_HOME/lib.

#### ***Server Cannot Initialize the Connector Component***

**Error:** If you see the following exception:

```
25-Apr-2019 14:46:50.353 SEVERE [main]
org.apache.catalina.util.LifecycleBase.handleSubClassException Failed to initialize
component [Connector[HTTP/1.1-8443]]
org.apache.catalina.LifecycleException: Protocol handler initialization failed
```

**Actions:** Examine the server.xml file. Verify that the file is showing the correct full path to the TLS keystore on the Custom Connector server. Also, ensure that the keystore password correct. The keystore password must be set to the `#{tomcat.keystore.pwd}` property, which is specified the catalina.properties file.

### **Authorization Header Cannot be Decrypted**

**Error:** If you see the following exception:

```
25-Apr-2019 14:52:48.157 SEVERE [https-jsse-nio-8443-exec-6]
com.ca.pam.extensions.framework.util.ExtensionAuthenticationFilter.validateAuthToken
[5435a4b9-9c8c-4e6a-b1d8-eef45857569b] [PAMTargetConnector] Authorization header cannot
be decrypted:
org.jose4j.lang.InvalidKeyException: The key must not be null.
```

### **Actions:**

- Verify that the extension.encryption.pwd is set in the extension\_framework.properties file
- Verify that the extension.keystore.file is set in the extension\_framework.properties. Ensure that the file path is correct.
- Ensure that a keystore exists on the Custom Connector server and ensure that the encryption key is in the keystore.

### **Network Port Issues**

See if the Custom Connector Server is listening on the following network ports:

- Port 8080 for any address
- Port 18080 for loopback address (127.0.0.1:18080)
- If TLS enabled, port 8443 for any address

To determine which processes are bound to the network ports, run the following command for your platform:

**Linux:** `netstat -tulpn`

**Windows:** `netstat -aon`

This Windows command requires administrative privileges.

The ports that are specified in the server.xml file must display in the `netstat` command output. If the ports are not displayed, verify that the Custom Connector Server is running. Also ensure that the services that are associated with the ports have started. If the Tomcat server is using non-default ports, ensure that these non-default ports are listed in the `netstat` output. If the ports are not, ensure that they are defined in the server.xml file.

### **TLS Connection Issues**

If you enabled TLS for the Custom Connector configuration, verify that the catalina.properties file has the correct values for the appropriate properties. The appropriate properties are:

- `org.apache.tomcat.util.digester.PROPERTY_SOURCE`
- `tomcat.keystore.pwd`

If you see the following exception in the PAM Tomcat log `java.net.NoRouteToHostException: No route to host (Host unreachable)`, run the `tracert` command. The `tracert` command determines whether the

appliance has line-of-site to the Custom Connector Server. If the server is reachable, then the TLS properties are the issue. Verify these properties.

### **Custom Connector Server Operational Issues**

All Custom Connector Framework diagnostic information in tomcat log (catalina.out). The level of diagnostic and Java package-specific diagnostics are defined in the logging.properties file. This file is in the directory \$CATALINA\_HOME/conf. The default log level is INFO.

For example: com.ca.pam.extensions.framework.level = INFO

When reviewing the log, knowledge of Tomcat and Java logging is helpful.

### **PAM Appliance Issues**

At PAM, the two main areas to focus on for troubleshooting are the PAM Tomcat server and the UI.

#### ***Review the Tomcat Log***

To review operation at the appliance, look at the PAM Tomcat log, catalina.out. Most of the diagnostic information is in this log. If you suspect communication problems, this log is also where you can look. The appliance initiates all communication, except for A2A transactions.

You can control the **Tomcat Log Level** from the UI. Select to **Configuration, Diagnostics, Diagnostic Logs**. The default level is Warning.

The screenshot shows the 'Log Levels' tab in the PAM UI. A dropdown menu is open for 'Tomcat Log Level', displaying the following options: Warning (highlighted), Severe, Info, Config, Fine, Finer, Finest, and Off. Other log level settings listed on the left include CA PAM as SAML RP Log Level, CA PAM as SAML IdP Log Level, Web Services Log Level, LDAP Sync Log Level, and Applet Log Level.

Most TCF-specific diagnostics are from the classes CustomConnectorUtil and CustomConnectorResult.

### ***UI Issues***

**Issue:** You are seeing JavaScript errors when rendering the UI.

#### **Actions**

- Enable UI Logging. Select **Configuration, Diagnostics, UI Log** and configure the UI Log Settings. To see the log results, select the **UI Log Entries** tab.
- Verify the integrity of the uiDefinitions.json file. Select **Settings, Validate TCF Definition** to use the validator utility. For more instructions, see [Build Your Custom Target Connector](#), and read the section **Test and Validate the UI Definitions**.

**Issue:** Building target applications or target accounts for custom connectors can produce errors. The errors are displayed as popup messages on the target application or target account UI page. Errors can range from the target connector not being registered to a custom error message coded by a connector developer.

**Action:** Look at the popup message for information about the source of the problem. If the popup is from a message from the TCF, the address of the Custom Connector server is included. Look at the logs and the configuration of the Custom Connector server.

**Issue:** Testing the Custom Connector connection fails. You used the **Test** button on the Configuration, Custom Connector page, and the test failed.

**Actions:**

- Verify the configuration settings on the Custom Connector page.
- Examine the PAM Tomcat catalina.log for communication errors, such as timeouts and connection refused
- Look at the Custom Connector Server Tomcat catalina.log. Determine if the request from the appliance was received.

**Issue:** The list of target applications does not include the custom connectors.

**Actions:**

- Verify that the appliance can communicate with the Custom Connector server. Use the **Test** button on the Configuration, Custom Connector page.
- Examine the PAM Tomcat catalina.log for communication errors, such as timeouts and connection refused
- Look at the Custom Connector Server Tomcat catalina.log. Determine if the request from the appliance was received and is being serviced.

## **Credential Management Issues**

**Issue:** Potential password management problems.

The TCF is tied to the PAM Credential Manager functions. The appliance can try to verify or change passwords using the custom connector. Any issues are recorded in the session logs.

**Action:** Messages in the session logs are labeled to indicate which side of the communication is having a problem:

- Messages that start with **PAM-CF** are appliance-side connector that is related.
- Messages that start with **PAM-EF** are Custom Connector server and TCF related.
- Messages that are from the Custom Connector server itself include address, and possibly a host name

## **Configure SSH Key Pair Policies**

Configure SSH key policies to specify the characteristics that PAM uses to generate SSH key pairs, specifically the cryptographic algorithm to use, and the length of the key.

Use the following procedure to configure PAM SSH key policies for UNIX and Windows SSH Key target connectors.

**Follow these steps:**

1. Select **Credentials, Manage Targets, SSH Key Pair Policies**.
2. Select **Add**.
3. Provide a unique **Name** for the policy.
4. (Optional) Provide a **Description** for the policy.
5. Select the **SSH Key Type**:
  - **UNIX**: ECDSA, RSA, or DSA
  - **Windows SSH Key**: ECDSA or RSA (Windows does not accept DSA keys)
6. Specify the **SSH Key Length**:

- **For ECDSA keys:** 256 bytes, 384 bytes, or 521 bytes
- **For RSA keys:** 1024 bytes, 2048 bytes, or 4096 bytes
- **For DSA keys:** 512 bytes or 1024 bytes

7. Select **OK**.

#### NOTE

For information about target connectors that require SSH key pair policies, see:

- [Add a UNIX Target Connector](#)
- [Add a Windows SSH Key Target Connector](#)

## Add Target Accounts to Target Applications

After you configure a target application and connector, add a target account. The target account identifies an account at the remote server for which PAM can view, and change passwords or certificates.

#### WARNING

Before you add a target account, verify that an account exists on the remote target system. For example, create an Oracle account on the remote Oracle database before you add Oracle as a target account. Make sure that each credential only has one target account.

### Add a Target Account Using the UI

On the **Account** tab, follow these steps to add a target account:

1. Select **Credentials, Manage Targets, Accounts**.
2. Select **Add**.
3. On the **Account** tab, complete the following fields:
  - **Host Name:** Enter the IP address of the remote target system
  - **Device Name:** Enter the name of the remote target system.
  - **Application Name:** Select an existing target application. The application corresponds to an application installed on the remote target server. Complete any additional fields and tabs that might appear.

#### NOTE

For details about target application-specific settings, see [Configure Settings Specific to Individual Target Application Types](#).

- **Account Name:** Assign a *unique* account name for a given account. The account name that you enter must match the account name that is used by the target system. For example, on a UNIX system, account names are the UNIX user ID (userid).

#### NOTE

If the **Provisioned Account** option is set, a search icon (  ) that is used for JIT provisioning appears beside the **Account Name** field.

- **Password View Policy:** The default password view policy is always assigned. Use the magnifying glass to select other defined view policies.
- **Protocol (only for UNIX targets):** This field appears when you select a UNIX target application. From the drop-down list, select the appropriate authentication protocol.

#### NOTE

**SSH-2 Certificate Authentication** cannot be used with the A2A account type.

If you select **SSH-2 Certificate Authentication**, see the [Add the SSH Certificate Target Account and Add Target Accounts to Target Applications](#) section in the [SSH Certificate Authentication for Accessing UNIX/LINUX Targets](#) topic.

If you select **SSH-2 Public Key Authentication**, see the [Add the SSH Key Pair to a Target Account](#) section in the [SSH Key Authentication for Accessing UNIX/LINUX Targets](#) topic.

- **Credential:** The credential of the user account at the remote target server. These credentials must match. Enter a credential or select the **Generate Credential** icon (). The generated credential follows the credential composition policy, and it updates automatically at the target server. For accounts that use the **Generic** application type, manually change the credential on the target system so it matches the one in the secure database.
- **Account Type:** Accept the default, **Privileged Account**, unless you are adding an A2A target. For A2A devices, select **A2A Account**. A2A is only available if your license allows for A2A devices. If you select an SSH certificate authentication for your **Application Name**, this field grays out with a value of Privileged Account. The **Password** and **Compound Servers** tabs also disappear, and the **Certificate** tab appears. See Step 5 for more information on applications that use SSH certificate authentication
- **Access Type (Optional):** The Access type is only for reference. This field is not used by Credential Manager. Use the Access Type value to define dynamic target groups. If you are using target groupings, enter descriptors for the target account.
- **Descriptor 1 and 2 (Optional):** If you are using target groupings, you can enter descriptors for the target account.
- **Provisioned Account (Optional):** Set this option to configure the account as a template for dynamically creating user accounts to support Just in Time (JIT) provisioning.

#### NOTE

Setting the **Provisioned Account** option activates a search icon () beside the **Account Name** field that is used to select an identity template for JIT provisioning.

For more information, see [Create a Target Account for the MSSQL JIT Provisioned Account](#) and [Create a Target Account for the Azure SQL Managed Instance JIT Provisioned Account](#).

4. For A2A target accounts, the following fields are optional:
  - **Aliases:** A target alias enables an A2A requestor to request credentials from a specific account without transmitting the account user name and password. Enter a target alias name for the account. The target alias name must be unique across the Credential Manager.
  - **Cache Behavior:** Controls password caching on the A2A Client. Select one of the following options:
    - Use Cache First: The A2A Client looks for the password in the local cache first. If there is no password or if the password is not the most recent, the A2A Client contacts the appliance.
    - Use Server First: The A2A Client contacts the product appliance to get the most recent password. If a password is unavailable, the A2A Client looks in the local cache.
    - No Cache: The password is never stored in the local cache. The A2A Client always contacts the product appliance for the password.
  - **Cache Expiry Days:** Specify how long the password remains in the cache.
5. If you select **SSH-2 Certificate Authentication** for your **Protocol**, the following fields and tabs appear:
  - **Principal:** Optionally, enter a comma-separated list of strings to use as authentication principals. If this field is blank, the **Account Name** is used as a principal. The principals that are defined here should match the principals that are defined on the SSH server.
  - **Certificate Details:** Lists the details of the selected SSH certificate authentication policy that is associated with the target application. For more information about SSH certificate policies, see [Create an SSH Certificate Policy with the UI](#).
  - **Certificates Tab:** This tab appears when you select **SSH-2 Certificate Authentication** for your **Protocol**. This tab displays the following options:
    - **Last Generated:** Displays the most-recent time and date that the certificate was generated. A new certificate is generated and sent to the sshd server on the UNIX system every time a user logs in using MindTerm or an SSH proxy service. **Last Generated** is equivalent to the last time that a user attempted to log in with this target account.
    - **Account Created:** Displays the time and date that the certificate was created.

6. Select **OK**. Your new target account is added to the list of accounts on the Account List page.

### **WARNING**

When you update target account information other than the password, you must manually perform password verification. To verify the password manually, select the **Verify Password** icon on the Account tab for the target account.

### ***Specify AWS Target Account Information***

If the target account is an AWS account, there are more fields that you must configure.

Before doing this procedure, ensure that you have downloaded from AWS the **EC2 Private Key** file. The key file has a `.pem` extension.

### **Follow the steps for adding an AWS target account:**

1. In the **Application Name** field, select **AWS Access Credential Accounts**.  
The Host Name and Device Name fields are populated with the `xceedium.aws.amazon.com` entry.
2. For AWS Access Credential Type, select the **EC2 Private Key** option button.
3. Enter the EC2 Instance User Name, such as `ec2-user` (for Amazon Linux), or `root` (for Red Hat Linux), or other full permission account.
4. Browse and upload the EC2 Private Key file.
5. In Key Pair Name, enter the file name of the EC2 Private Key you uploaded, but without the extension.
6. (Optional) Enter a passphrase to use with the EC2 private key in the Passphrase field.

### **Add a Target Account using the CLI**

To use the CLI, see [Add Target Accounts using the CLI](#).

### **Configure Password Synchronization and Account Discovery**

From the Password tab of a target account, you can view information about a target account password, such as:

Regardless of whether the password has been used, you can also configure account discovery and password synchronization. These two features are documented in the following topics:

- [Account Discovery](#)
- [Password Synchronization](#)

### **Add a Compound Target Account (Optional)**

A compound account consists of several accounts on a cluster of servers, all having the same account name. When the password of a compound account is updated, it is changed on all the cluster members. If the password cannot be changed on all cluster members, roll back the password to the previous value.

The Compound Servers tab shows the status of an update:

- If a password update fails but the subsequent rollback succeeds, the Verified column displays a warning symbol next to the server.
- If a password update fails *and* the subsequent rollback fails, the Verified column displays a red **X** next to the server name. The password on this server is now out of sync.

Compound accounts respect existing target account functions such as, workflow, scheduled jobs, auto-connect, and target group membership.

You can create a compound target account from the Compound Servers tab.

### **NOTE**

You cannot add the host target server as a compound server.

**Follow these steps:**

1. Add a target account or update an existing target account.
2. Select the **Compound Servers** tab.
3. Use the + sign to add servers. The number of servers is not limited, but the recommendation is 20 servers.

**Configure Settings Specific to Individual Target Application Types**

When you add a target account, one or more tabs are added to the Target Account configuration page. The tabs are specific to the target application associated with the target account. Many of these settings are for features unique to one or more target accounts. The following table lists where you can find information about these additional tabs.

For information about target accounts for service desk applications, see [Integrate with Your Service Desk Solution](#).

Application Type for Target Account	UI Setting or Tab	Instructions
Multiple application types	<b>Change Process</b> setting	See <a href="#">Use an Alternate Account to Change Passwords (Optional)</a>
Active Directory	<b>Services</b> and <b>Scheduled Tasks</b> tabs	See <a href="#">Add Services and Scheduled Tasks for Windows Accounts</a>
Cisco	<b>Cisco SSH</b> tab	See <a href="#">Cisco SSH Target Account Configuration</a>
LDAP	<b>DN</b> setting	Enter the distinguished name for the account
MSSQL	<b>MSSQL</b> tab	<a href="#">Configure MSSQL Target Accounts</a>
MSSQL Azure Managed Instance	<b>MSSQL Azure Managed Instance</b> tab	See <a href="#">Configure MSSQL Azure Managed Instance Target Accounts</a>
MYSQL	<b>Database</b> setting	Enter the name of the database on the target system
Oracle	<b>Oracle</b> tab	See <a href="#">Oracle Internet Directory Target Account Settings</a>
Palo Alto	<b>Palo Alto</b> tab	See <a href="#">Palo Alto Account Configuration</a>
SPML v2.0	<b>Database Name</b> setting	Specify the name of the SPML 2.0-compliant database
UNIX	<b>Privilege Elevation</b> setting	See: <a href="#">UNIX Privilege Elevation Setting</a> <a href="#">SSH Access to UNIX Targets</a>
VMware NSX Manager	<b>Access Privileged mode using</b> setting	See <a href="#">Use an Alternate Account to Change Passwords (Optional)</a> The function of this field is the same as the Change Process setting.
Windows SSH Key	Public and private key settings <b>SSH</b> tab	See <a href="#">Add a Windows SSH Key Target Connector</a>
Windows SSH Password	<b>SSH</b> tab	See <a href="#">Add a Windows SSH Password Target Connector</a>
Windows Proxy	Windows Proxy settings	See <a href="#">Register Windows Proxy Target Accounts</a>
Windows Remote	Services and Scheduled Tasks tabs	See <a href="#">Configure Windows Remote Target Accounts</a>

## Add Target Accounts using the CLI

To add a target account using the CLI, use the `updateTargetAccount` commands.

Follow these instructions:

### Encode Complex Passwords with Special Characters

When you define targets (servers, applications, accounts) with the CLI, certain complex passwords, and SSH private keys can be difficult to input with CLI commands. The keys and passwords can contain special characters such as spaces, line feeds, and carriage returns. If the password contains these special characters, the shell (Windows and UNIX) can corrupt the information that Credential Manager receives.

To avoid this issue, perform base-64 encoding on the password *before* adding a target account with the `addTargetAccount` command.

The following utilities can perform base-64 encoding:

- For Windows, use the `b64` utility available at: <http://sourceforge.net/projects/base64/>
- For Linux and UNIX, use the `base64` built-in command.
- For OS X, use the `base64` built-in command.

The following utilities can verify file hashes:

- For Windows, use the Penteract File Checksum Integrity Verifier utility, [available free from Microsoft.](#)
- For Linux, use the `sh1sum` command.
- For OS X, use the `shasum` command.

When you use the `addTargetAccount` command, use the `passwordIsBase64Encoded` parameter and set it to true. If you set this parameter to true, the specified password is Base64-encoded and Credential Manager must decode the password before storing it.

### Add a Target Account with the CLI

This procedure includes the commands for adding all required target objects, that is, a server, an application and an account. For details on the parameters of each command, see [Windows Remote Target Connector CLI Configuration](#) for parameters unique to Windows Remote.

#### 1. Add a target server:

Windows:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetServer ^
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetServer.ipAddress=11.1.0.3 ^
Attribute.descriptor1=Vienna Attribute.descriptor2=Lab
```

Linux:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetServer \
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetServer.ipAddress=11.1.0.3 \
Attribute.descriptor1=Vienna Attribute.descriptor2=Lab
```

#### 2. Enter your password at the prompt. Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetServer>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
```

```

<ID>1</ID>
<createDate>Mon Nov 12 15:35:14 EST 2007</createDate>
<updateDate>Mon Nov 12 15:35:14 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>XhMAD33ITheWuMB1L89Zsxfdxsg=</hash>
<hostName>Vienna-Lab3.cloakware.com</hostName>
<IPAddress>11.1.0.3</IPAddress>
</TargetServer>
</cr.result>
</CommandResult>

```

### 3. Add a target application:

#### Windows:

```

capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetApplication ^
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetApplication.type=Generic ^
TargetApplication.name='Generic Application Type' Attribute.descriptor1=Vienna ^
Attribute.descriptor2=Lab

```

#### Linux:

```

capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetApplication \
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetApplication.type=Generic \
TargetApplication.name='Generic Application Type' Attribute.descriptor1=Vienna \
Attribute.descriptor2=Lab

```

### 4. Enter your password at the prompt. Credential Manager returns the following XML command string.

```

<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetApplication>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1</ID>
<createDate>Mon Nov 12 15:38:32 EST 2007</createDate>
<updateDate>Mon Nov 12 15:38:32 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>kvSzMfnFi2iCIihAVt85+N2jzpc=</hash>
<targetServerID>1</targetServerID>
<type>Generic</type>
<name>Generic</name>
<policyID>0</policyID>
</TargetApplication>
</cr.result>
</CommandResult>

```

### 5. Add a target account:

#### Windows:

```

capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetAccount ^
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetApplication.name='Generic Application Type' ^
TargetAccount.userName=account1 TargetAccount.password=123456 ^
passwordIsBase64Encoded=true TargetAccount.cacheBehavior=useCacheFirst TargetAccount.privileged=false ^
TargetAccount.cacheDuration=20 TargetAccount.accessType='A generic system account' ^

```

```
TargetAccount.synchronize=false Attribute.changePasswordAfterViewing=true ^
Attribute.descriptor1=Vienna Attribute.descriptor2=Lab
```

**Linux:**

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetAccount \
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetApplication.name='Generic Application Type' \
TargetAccount.userName=account1 TargetAccount.password=123456 \
passwordIsBase64Encoded=true TargetAccount.cacheBehavior=useCacheFirst TargetAccount.privileged=false \
TargetAccount.cacheDuration=20 TargetAccount.accessType='A generic system account' \
TargetAccount.synchronize=false Attribute.changePasswordAfterViewing=true \
Attribute.descriptor1=Vienna Attribute.descriptor2=Lab
```

**6. Enter your password at the prompt. Credential Manager returns the following XML command string.**

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetAccount>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.changePasswordAfterViewing>true
</Attribute.changePasswordAfterViewing>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1</ID>
<createDate>Mon Nov 12 15:42:43 EST 2007</createDate>
<updateDate>Mon Nov 12 15:42:43 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>q3/BaUy9uPvtbUkKgIrXvgseGt8=</hash>
<targetApplicationID>1</targetApplicationID>
<userName>account1</userName>
<password>l4adc6a1a720e58ee52032364b98f95b</password>
<accessType>A</accessType>
<cacheAllow>true</cacheAllow>
<cacheBehavior>useCacheFirst</cacheBehavior>
<cacheDuration>20</cacheDuration>
<privileged>false</privileged>
<synchronize>false</synchronize>
<passwordVerified>false</passwordVerified>
<lastVerified>
</lastVerified>
</TargetAccount>
</cr.result>
</CommandResult>
```

**7. If the account type is A2A (only possible if your license allows for A2A accounts), add a target alias:****Windows:**

```
Windows:
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetAlias ^
TargetAlias.name=ViennaAlias5 TargetServer.hostName=Vienna-Lab3.cloakware.com ^
TargetApplication.name='Generic Application Type' TargetAccount.userName=account1
```

**Linux:**

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetAlias \
TargetAlias.name=ViennaAlias5 TargetServer.hostName=Vienna-Lab3.cloakware.com \
```

```
TargetApplication.name='Generic Application Type' TargetAccount.userName=account1
```

**8. Enter your password at the prompt. Credential Manager returns the following XML command string.**

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetAlias>
<ID>1</ID>
<createDate>Mon Nov 12 15:43:24 EST 2007</createDate>
<updateDate>Mon Nov 12 15:43:24 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>iB6pR3X7E8yP8p4RemqsChneEQc=</hash>
<name>ViennaAlias5</name>
<accountID>1</accountID>
</TargetAlias>
</cr.result>
</CommandResult>
```

### **Add a Compound Account (Optional)**

To add multiple servers that have the same account, you can specify compound servers.

**Follow these steps:**

1. Add a target server as shown in the previous example in this topic
2. Enter your password at the prompt.
3. Add one or more servers:

**Windows:**

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetServer ^
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetServer.ipAddress=11.1.0.3 ^
Attribute.descriptor1=Vienna Attribute.descriptor2=Lab
```

**Linux:**

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetServer \
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetServer.ipAddress=11.1.0.3 \
Attribute.descriptor1=Vienna Attribute.descriptor2=Lab
```

**4. Enter your password at the prompt. Credential Manager returns the following XML command string.**

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetServer>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>2</ID>
<createDate>Mon Nov 12 15:35:14 EST 2007</createDate>
<updateDate>Mon Nov 12 15:35:14 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>XhMAD33ITheWuMB1L89Zsxfdxsg=</hash>
<hostName>Vienna-Lab3.cloakware.com</hostName>
```

```
<IPAddress>11.1.0.4</IPAddress>
</TargetServer>
</cr.result>
</CommandResult>
```

Repeat step 3 and 4 for each compound server you want to add. Each `addTargetServer` operation returns a new ID value.

5. Add a target application as shown in the previous example in this topic.
6. Enter your password at the prompt.
7. Add a compound target account:

For the `TargetAccount.compoundServerIDs` parameter, list each `<ID>` value that is returned in steps 3 and 4, separated by commas.

**Windows:**

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetAccount ^
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetApplication.name='Generic Application Type' ^
TargetAccount.userName=account1 TargetAccount.password=123456 ^
TargetAccount.cacheBehavior=useCacheFirst TargetAccount.privileged=false ^
TargetAccount.cacheDuration=20 TargetAccount.accessType='A generic system account' ^
TargetAccount.synchronize=false Attribute.changePasswordAfterViewing=true ^
TargetAccount.isCompound=true TargetAccount.compoundServerIDs=1,2 Attribute.descriptor1=Vienna ^
Attribute.descriptor2=Lab
```

**Linux:**

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addTargetAccount \
TargetServer.hostName=Vienna-Lab3.cloakware.com TargetApplication.name='Generic Application Type' \
TargetAccount.userName=account1 TargetAccount.password=123456 \
TargetAccount.cacheBehavior=useCacheFirst TargetAccount.privileged=false \
TargetAccount.cacheDuration=20 TargetAccount.accessType='A generic system account' \
TargetAccount.synchronize=false Attribute.changePasswordAfterViewing=true \
TargetAccount.isCompound=true TargetAccount.compoundServerIDs=1,2 Attribute.descriptor1=Vienna \
Attribute.descriptor2=Lab
```

8. Enter your password at the prompt. Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetAccount>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.changePasswordAfterViewing>true
</Attribute.changePasswordAfterViewing>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1</ID>
<createDate>Mon Nov 12 15:42:43 EST 2007</createDate>
<updateDate>Mon Nov 12 15:42:43 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>q3/BaUy9uPvtbUkKgIrXvgseGt8=</hash>
<targetApplicationID>1</targetApplicationID>
<userName>account1</userName>
<password>14adc6a1a720e58ee52032364b98f95b</password>
<accessType>A</accessType>
<cacheAllow>true</cacheAllow>
```

```

<cacheBehavior>useCacheFirst</cacheBehavior>
<cacheDuration>20</cacheDuration>
<privileged>false</privileged>
<synchronize>false</synchronize>
<passwordVerified>false</passwordVerified>
<lastVerified>
</lastVerified>
</TargetAccount>
</cr.result>
</CommandResult>

```

## Use Account Discovery to Add Target Accounts

A subset of out-of-the-box target applications offers the Account Discovery feature. Account Discovery is a mechanism to add target accounts easily. You can use it as an alternative to manually adding target accounts.

The following application types offer Account Discovery:

- [UNIX/LINUX](#)
- [Active Directory](#)
- [LDAP](#)
- [Windows Remote](#)
- [Windows Proxy](#)

### NOTE

If you discover accounts using Amazon AWS integration, the **Address** field of the device must include the fully qualified domain name or IP address. If a device using AWS integration has already been discovered, recreate the device.

### Account Discovery Prerequisites

Before you can use Account Discovery, you must configure the targets that the appliance searches for discovery. For any managed target, configure the following items:

1. Target servers. See [Device Discovery](#).
2. Target Applications. Configure one of the target applications that support Account Discovery.
3. Target Accounts for each target application that supports Account Discovery.

When you add a target account, the **Discovery Allowed** option is available. Selecting this option indicates that the account is available for discovery. Select this option only for accounts that you want to scan for discovery.

### NOTE

You can use an account to scan only for other accounts that support the same target application. For example, use a Windows domain account that is configured with an Active Directory target application to scan for other accounts that use the Active Directory application type. You cannot use the Windows domain account to scan for local accounts that are configured with a Windows Proxy target application.

For UNIX accounts, selecting Discovery Allowed also adds the checkbox **Allow multiple server discovery for this type of application**. This checkbox indicates that the account is a discovery account for any server and application of this type. For example, if you have 20 servers with a common account and password, use one account and select this box. Then for any discovery job with this application type selected, this account is used as a credential for discovery.

## Discover Accounts Using a Scan

To discover accounts, follow these steps:

1. Go to **Credentials, Discovery**.
2. Select **Discovery** from the Targets Menu.
3. Create a Scan Profile:
  - a. From the Scan Profiles tab, select **Add**.
  - b. On the Profile tab, complete the fields.
  - c. On the Servers tab, move Available Servers to Selected Servers with the arrow button. The listed available servers are managed devices.
  - d. The Purge Interval field sets the number of days that discovered devices are deleted, unless the devices are discovered by another profile. The Purge Interval default is set on the Global Settings page, under Basic Settings, as Scan Purge Interval.
4. Run the scan.
  - a. Create a schedule to run the scan or run it on demand.
    - Use the Schedule tab to create an optional schedule. Once you select a frequency, other fields appear. Select the appropriate time intervals. Select OK to save the Scan Profile.
    - To run the scan on demand rather than on a schedule, select OK to save it. Select the Scan Profile from the Scan Profiles list, and select the Run button above the list.
  - b. Once a scan is running, monitor its progress on the Scan Profile Jobs tab. You can also cancel the job on this panel by selecting Cancel Job. Once it is complete, view a summary of its results on the Scan Profile History tab. The Scan Profile Jobs and other tables are refreshed according to the default setting on the Global Settings page. Table Refresh Interval is in the Basic Settings section, and defaults to 60 seconds.

### NOTE

Selecting **Delete** for a highlighted profile deletes its Scan Profile History. **Delete** also deletes any Accounts that are associated with that Profile unless they are associated with another Profile.

After a scan is complete, you can:

- [View the scan results](#)
- [Export results to a CSV file](#)
- [Bring discovered accounts under management.](#)
- [Update discovered accounts.](#)

## View the Scan Results

Select the Scan Profile History tab to view the results of the account discovery scans. Each row shows a Scan Profile, its latest Discovery time, and a summary of the scan results. The summary shows a count of discovered accounts, how many are new, and not found. "Not found" Accounts were discovered by a previous run of the same Scan Profile, but are now missing. The Summary shows the same information about SSH Keys. See [SSH Key Discovery](#) for more information. The Summary also shows a count of any errors that were encountered. These numbers refer only to the latest run of this scan profile.

Use the **Filter** button to filter the display on the page. You can use asterisks and percent signs as multiple-character wildcards.

### View Summary Details

The View Summary Details button opens the Scan Results window. The Scan Information tab displays the Scan Profile name and the Job Time. The Discovered Accounts, New Accounts, and Not Found Accounts tabs list the Account Names in each respective category. For information about the Discovered Keys, New Keys, and Not Found Keys, see [SSH Key Discovery](#). The Logs tab displays a table including each action that is taken regarding this scan.

To see all scans that have run for a given Profile, select the View Scans button above the Summary. Clicking the Summary numbers lists the accounts or keys that are discovered in the same panel as View Summary Details. You can also select the View Summary Details button to get to this panel.

### **View Account Scan Results**

To see information about the discovered accounts, go to the Scan Profile History panel and select **Scan Profile, View Account Scan Results**. The account name, the device where it was found, the application, and a timestamp are displayed. A checkbox indicates whether Credential Manager manages the account.

On the history panel, are the following controls:

- **Filter:** Filter the display on the page by column values. You can use asterisks and percent signs as multiple-character wildcards.
- **Export:** Create a CSV file with a row for each Discovered Account listed.
- **View:** Show the data for one row whose Account Name box is checked. In the Logs tab, it displays log information that is not shown in the Account Scan results panel.
- **Manage:** Bring an account under management. To manage accounts, select one or more accounts names. Then select **Manage**. The Manage Discovered Accounts window opens.

### **View All Scans**

To see all discovered accounts rather than only the accounts for a given scan, select the **Discovered Accounts** tab. The displayed table lists each Account Name, Device Name, Application Name, Latest Discovery Time, and whether it Is Managed.

On this tab are the following controls:

- **Filter:** Filter the display on the page by column values. You can use asterisks and percent signs as multiple-character wildcards.
- **Export:** Create a CSV file with a row for each Discovered Account listed.
- **View:** Show the data for one row whose Account Name box is checked. In the Logs tab, it displays log information that is not shown in the Account Scan results panel.
- **Manage:** Bring an account under management. To manage accounts, select one or more account names then select **Manage**. The Manage Discovered Accounts window opens.

### **Bring Discovered Accounts Under Management**

To manage an account from the Discovered Accounts window, follow these steps:

1. From the Discovered Accounts tab, select **Manage**. The Manage Discovered Accounts window opens.
2. Select a synchronization option. This option is not available if the application type is **Generic**.
  - **Update only the Password Authority Server.** Passwords are only updated in Credential Manager. Credential Manager and target system passwords can differ.
  - **Update both the Password Authority Server and the target system.** Password updates are performed in both Credential Manager and the target system to maintain consistency.

#### **NOTE**

For the Windows Proxy and Windows Remote application types, the discovered accounts have the **Force password change** option enabled automatically.

3. For most target account types, a **Password Change Process** option is available. This option lets you select whether the managed account can change its own password or whether another, higher-privilege account must do that. If you select **Use the following account to change the password**, a field appears below the legend so that you can select the password-changing account.

Some application types allow an account password to be updated from another account (for example, root). If this situation applies, select that account. The account that is used to change the password must already be registered in Credential Manager.

4. To generate a random password for each account, select the **Generate credential for each account** checkbox.
5. Select whether the account type is Privileged Account or an A2A account (A2A is available only with a license). If you select A2A, more fields appear. You can set the Cache Behavior to use the Cache or the Server first, or not use a cache. You can also set the Cache Expiry in days.
6. **Password View Policy** allows you to select a policy, including a Default policy. Access Password View Policies from the Workflow menu.
7. Enter a **Password**. The Account Details page (Accounts option on the Targets menu) has more options that are not presented here. Once an Account is managed, you can access it from the Accounts page.
8. (Optional) For or customer convenience, enter a value for the **Access Type** to define dynamic target groups. This field is only for reference and is not used by Credential Manager.
9. (Optional) If you are using target groupings, enter **Descriptors**.
10. Select **OK** to save.

### **Update Discovered Accounts (Windows Proxy or Windows Remote Accounts Only)**

To add new tasks and services to Windows Proxy or Windows Remote Accounts, follow these steps:

1. Select **Credentials, Discovery**.
2. On the Scan Profiles tab, select **Run** for the Profile with the account you want to update. If a Profile does not exist, select **Add**. Give it a **Name**. On the Servers tab, select the Server that is associated with the Proxy or Remote Account. Select **Run**.
3. Select the **Discovered Accounts** tab.  
Windows Proxy or Windows Remote accounts that have updates available display a green checkbox under the Updates Available column.
4. Select the **Update** button for the Windows Proxy or Windows Remote account with updates available.  
The Update Discovered Accounts windows appears. Available Services and Scheduled Tasks appear on their respective tabs.
5. Select **OK**.
6. Select **Yes** when you are prompted to Update Selected Accounts.  
The managed Services and Scheduled Tasks appear on their tabs on the Account, under Credentials, Manage Targets, Accounts.

To remove tasks and services from Windows Proxy or Windows Remote Target Accounts, follow these steps:

1. Select **Credentials, Manage Targets, Accounts**.
2. Select the account that you want to modify.
3. Select **Update**.
4. Select the Services or Tasks tab.
5. Select the service or task you want to delete. Select the **Delete** icon.

#### **NOTE**

- Discover Linux or UNIX SSH keys for auditing: See [SSH Key Discovery](#) for more information.
- Discover Windows services and scheduled tasks for AD accounts: See [Discover Services and Scheduled Tasks for AD Accounts](#).

## **Synchronize Target Account Passwords**

Synchronization ensures that password updates that are made in the Credential Manager database are also made to passwords stored at the remote target system. When passwords are synchronized, the appliance pulls credentials from

the Credential Manager database and then it sends the credentials to the target system. The target system then verifies whether the credentials are accurate.

#### NOTE

Password synchronization needs an associated [password composition policy](#). When Credential Manager generates a password, it meets the criteria of the composition policy.

You can synchronize passwords for individual accounts and for a group of target accounts. For compound account groups, synchronization updates a series of replicated databases with the same password and keeps the passwords that are synchronized with each other.

You can configure password updates at the following times:

- Immediately
- After a password is viewed
- When it attains a certain age
- On a configured schedule

There is no limit to how many previous passwords PAM stores or to how long passwords are kept.

### **Enable Password Synchronization**

When you add a target account or you update an existing account, you can enable password synchronization.

#### **Follow these steps:**

1. In the UI, go to **Credentials, Manage Targets, Accounts**.
2. Select **Add** or double-click an account in the Target Accounts list.
3. Select the **Password** tab.
4. For the **Synchronized** option, select the behavior that you want between the Credential Manager database and the target system:
  - Update only the Credential Manager Server. This option allows the PAM and target system passwords to differ.
  - Update both the Credential Manager Server and the target system

#### NOTE

Synchronization is not available for accounts that use the Generic application type.

5. In the **Owner User Name** field, select the Credential Manager user
6. Select **OK**.

If a target account is a Windows Proxy account, Credential Manager directs the Windows Proxy to verify the password and update it.

To learn more about password synchronization, review the following topics:

- [Verify Synchronized Target Account Passwords](#)
- [Schedule Password Updates and Verifications](#)

### **Verify Synchronized Target Account Passwords**

On the Target Accounts page (**Credentials, Manage Targets, Accounts**), accounts are displayed with many details, including whether they are verified. The **Verified** column displays only when synchronization is enabled.

Some operations, such as Account Discovery, require an account to be verified.

#### **Verify Account Passwords using the UI**

Use the following procedure to verify a synchronized target account password from the UI.

**Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**. A list of target accounts appears.
2. Double-click the target account whose password you want to verify.
3. Select the Verify Credential icon (a blue person with green checkmark), located to the right of the Password field. A message indicating successful password verification appears.

**Verify Account Passwords using the CLI**

To verify synchronized target account passwords with the CLI, use the `verifyAccountPassword` command.

**Follow these steps:**

1. Search target accounts to retrieve the target account ID:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=searchTargetAccount
TargetAccount.userName=account1
```

2. Enter your password at the prompt. Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success</cr.statusDescription>
<cr.result>
<TargetAccount>
<Attribute.descriptor2>Lab</Attribute.descriptor2>
<Attribute.changePasswordAfterViewing>true</Attribute.changePasswordAfterViewing>
<Attribute.descriptor1>Vienna</Attribute.descriptor1>
<ID>1233</ID>
<createDate>Mon Nov 12 15:42:43 EST 2007</createDate>
<updateDate>Mon Nov 12 15:42:43 EST 2007</updateDate>
<createUser>admin</createUser>
<updateUser>admin</updateUser>
<hash>q3/BaUy9uPvtbUkKgIrXvgseGt8=</hash>
<targetApplicationID>1</targetApplicationID>

<cacheDuration>20</cacheDuration>
<privileged>false</privileged>
<synchronize>false</synchronize>
<passwordVerified>false</passwordVerified>
<lastVerified>Mon Nov 12 15:42:43 EST 2007</lastVerified>
</TargetAccount>
</cr.result>
</CommandResult>
```

3. Run the following command:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=verifyAccountPassword TargetAccount.ID=1233
```

4. Enter your password at the prompt. Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
```

```

<TargetAccount>
<privileged>true</privileged>
<aliases></aliases>
<password>{1}8ae8e633c1fa6020bfb7695e17f83f18</password>
<lastUsed></lastUsed>

</TargetAccount>
</cr.result>
</CommandResult>

```

If the password is not verified, the attribute `passwordVerified` returns a "false" value; for example, `<passwordVerified>false</passwordVerified>`.

## Schedule Password Updates and Verifications

For synchronized target accounts, you can schedule:

- Regular password updates: Scheduled password updates use automatically generated passwords that conform to your specified password composition policies. If the passwords in the appliance database and at the remote target match, the scheduled job updates both passwords.
- Password verifications: Verifications ensure whether passwords are in sync.

For password updates or verifications, you can schedule jobs on a per account basis or per target group basis. When a job is scheduled for a group, the appliance performs the update or verification on each synchronized target accounts in that group. If a single update or verification fails, the job status is marked as failed. However, the job continues to process the remaining updates or verifications.

This topic explains how to:

### Schedule an Update or Verification

Follow these steps:

1. Select **Credential, Manage Targets, Scheduled Jobs**.

2. Select **Add**.  
The Add Scheduled Job page appears.
3. Enter the **Job Name**. Use a text description for the job, up to 80 characters long.
4. In the **Recurrence** field, select the frequency. You can select **Run Once**, **Daily**, **Weekly**, **Monthly**, **Yearly**, and **Every N Days**.
5. The **Date/Time** option changes to correspond with your **Recurrence** selection:
  - a. For **Run Once**, use the **Date/Time** option to select the date and time to run one instance.
  - b. For **Daily**, use the **Time** option to select the time to run a daily instance. The **Repeat Only On Weekdays** option excludes a daily run on any weekend day (Saturday and Sunday).
  - c. For **Weekly**, use the **Time** option to select the time and the days of the week to run the instance.
  - d. For **Monthly**, you have two options:
    - **Run on day <number> of the selected month(s)**: Select a date (1 to 31), or **Last** for the last day of the month to run the job. You can select one or more months to run the job using the corresponding checkbox beneath this option.
    - **Run on the <number><day> of the selected month(s)**: Select First, Second, Third, Fourth, or Last day to run the job. This option allows you to specify a particular day instead of a particular date. You can select one or more days and months to run the job.
  - e. For **Yearly**, use the **Date/Time** option to select the date and time to run the annual instance.
  - f. For **Every N Days**, use the **Date/Time** option to select the start date and time, and then how long to wait before running another instance. For example, you could select a start date, and set the time to 1 AM every four days, by setting the **Time** to 01:00:00 and the **Days** to 4.
6. On the **Account Details** tab, select one of the following entries from the **Command** drop-down list:
  - **Update Target Account Password** for password updates
  - **Verify Account Password** for password verification.
7. Select whether you want this job to apply to a target group or individual account.
8. Specify either the target group or individual target account for this job.

#### NOTE

Account updates or verifications proceed sequentially within a job. However, scheduled jobs can run concurrently. Therefore, having more jobs that are shorter performs better and faster than having fewer jobs that are long.

9. For the "Update Target Account Password" command:
  - Select whether Credential Manager generates the new password. If you select No, extra fields appear so you can supply the new password.
  - For Credential Manager generated passwords, select whether to apply the same new password to all accounts in the group.
10. Select **OK**.

### View the Progress of Scheduled Jobs

To view the status of scheduled jobs, generate the Scheduled Jobs Report. See [Generating Reports](#).

## Use an Alternate Account to Change Passwords (Optional)

For specific application types, Credential Manager can use an alternate master account with sufficient privileges to update a specific target account password. When a user does not have permission to change their own passwords, this alternate account lets Credential Manager synchronize user accounts. If a user changes a password on the target system, Credential Manager can use the master account to override the change and update the password.

When you add a target account, a tab for the associated application type becomes available. On that application tab, there is a **Change Process** setting. The following page is an example for an LDAP application type:

To allow the existing target account to change its own password, keep the default option, **Account can change own password**, selected. The initial password that you enter must be the same as the target account password. The exception is a user with more privileges, such as root, who can update the password.

To use an alternate master account:

1. Select **Use the following account to change password**. For most target accounts, a blank field appears below the radio button.
2. Select the magnifying glass and search for the target account to use as the alternate. Avoid using the current target account as the alternate.  
To show the target accounts that are defined in the system, filter by account name or host name. You can also show all target accounts. Typically, the other account is an account of the same application. For example, the password for an Oracle database account is changed by a privileged account on the same database. You can use another account that is associated with a different application. Select compatible combinations.

#### NOTE

The only supported dissimilar account combination is the use of an LDAP or Active Directory account to change the password of a UNIX account.

3. Some target accounts require additional information:  
MYSQL: Identify the account by specifying the user name and the hostname of the database. Enter the hostname in the **host-Name Qualifier** field.

## Configure Windows Remote Target Accounts

This section describes the configuration steps for Windows Remote target accounts.

### Prerequisites for Windows Remote Target Accounts

To configure Windows Remote target accounts, including Windows services, ensure that the following tasks are completed:

- Add a device (target server) with Password Management as the device type.

#### NOTE

If you are adding an AWS Windows device, use the private IP address in the Address field of the account. Some features do not function properly when you use the public IP address.

- Add a target application for the target server. This step includes associating Windows Remote with the host on which the Windows account resides. See [Add a Windows Remote Target Connector](#).
- If the Windows Remote target account is of the Administrator account type, the account requires Administrator rights on the Windows server.

#### NOTE

If your target account is to be used as a service account (that is, it is to be used to rotate passwords of other target accounts), we recommend that you prevent this account from being able to log in interactively. To do this, assign the following User Rights to the Windows account:

- **Deny log on locally**
- **Deny log on through Remote Desktop Service**
- If the Windows Remote target account is a domain account, log in to the target system using that account. Logging in establishes the Windows user environment for the domain account, which is required for the Windows remote target connector to function.

### **Create a Windows Remote Target Account**

Use this procedure to create a Windows Remote target account using the PAM UI.

To add a Windows Remote Target account using the CLI, see [Windows Remote Target Connector CLI Configuration](#).

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**. The Target Account page appears with a list of existing accounts.
2. Select **Add**. The Add Target Account page appears.
3. Select the **Host Name** magnifying glass to find an existing target server, filling the Host Name and **Device Name**.
4. Select the **Application Name** magnifying glass to find an existing target application on the target server, or select **+** to create a target application. Select or create a Windows Remote type of target application. The Windows Remote appears on the Add Target Account page.
5. Enter the **Account Name**. The account name must be unique for a given target application and must be the account name that the target system uses.
6. Select the **Password View Policy** for the account.
7. Enter an initial account **Password** or select the Generate Credential key icon to generate a default password.
8. On the **Password** tab, Select **Discovery Allowed** to discover accounts on the Windows remote system. Select the appropriate synchronization option:
  - Update only the Credential Manager Server: Passwords are updated only in Credential Manager. Credential Manager and target system passwords can differ.
  - Update both the Credential Manager Server and the target system: Password updates are performed both in Credential Manager and on the target system to maintain consistency.
9. On the **Windows Remote** tab, select the **Account Type**:
  - User: If you select a regular User account, select "Use the following account to change password" for the **Change Process**.
  - Administrator: If you select Administrator, use either **Change Process** option.
10. If you select the magnifying glass next to "Use the following account to change password" for the **Change Process**, a Target Account dialog appears. Select an account that is of Administrator account type from the same Windows Remote application.
11. (Optional) If you are adding or updating an account and you do not know the existing password, select the **Force password change** checkbox. The existing password gets changed, even though the account is not in sync.
12. Select **OK** to save.  
Your new Windows target account is added to the list of accounts on the Target Accounts page.

### **Discover Windows Services and Scheduled Tasks**

You can use account discovery to manage the credentials of multiple Windows services and scheduled tasks. PAM can use the target account to manage changes and updates for any services and scheduled tasks that use this account. You do not have to update the password on an individual service or scheduled task basis.

#### **NOTE**

This procedure is for local Windows accounts. To discover services and scheduled tasks for Active Directory accounts, see [Discover Services and Scheduled Tasks for AD Accounts](#).

#### **Prerequisite**

Before you run account discovery, go to the Account Discovery tab of the Windows Remote Target application. Select the discover option for services or tasks. You can select both.

### **Discover Services and Tasks**

To discover new tasks and services on Windows remote accounts, follow these steps:

1. Select **Credentials, Discovery**.
2. On the Scan Profiles tab, select **Run** for the profile of the account you want to update.  
If a profile does not exist, follow these steps:
  - a. Select **Add**.
  - b. Give the profile a **Name**.
  - c. On the Servers tab, select the Server that is associated with the remote account.
  - d. Select **Run**.
3. Select the **Discovered Accounts** tab.  
Windows Remote accounts that have updates available display a green checkbox under the Updates Available column.
4. Select the **Update** button for the Windows Remote account with updates available.  
The Update Discovered Accounts window appears. Available Services and Scheduled Tasks appear on their respective tabs.
5. Select **OK**.
6. Select **Yes** when you are prompted to Update Selected Accounts.
7. To see a list of services and scheduled tasks:
  - a. Select **Credentials, Manage Targets, Accounts**.
  - b. Select the Services and Scheduled Tasks tabs to display the list of accounts.

To remove tasks and services from a Windows Remote Target Accounts, follow these steps:

1. Select **Credentials, Manage Targets, Accounts**.
2. Select the account that you want to modify.
3. Select **Update**.
4. Select the Services or Scheduled Tasks tab.
5. To delete a service or task, select the **X** next to the entry.

#### **NOTE**

**More Info:** [Use Account Discovery to Add Target Accounts](#)

## **Configure MSSQL Target Accounts**

This topic describes how to configure MSSQL target accounts.

### **Follow these steps:**

1. Navigate to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.
3. Complete the following fields on the **Account** tab of the **Add Target Account** pane that opens:
  - **Host Name:** The IP address or FQDN of the MSSQL host.
  - **Device Name:** The name of the MSSQL device.
  - **Application Name:** The name of the MSSQL target application.
  - **Account Name:** Assign a *unique* account name for each account. The account name that you enter must match the account name that is used by the target system. For example, on a UNIX system, account names are the UNIX user ID (userid).

**NOTE**

If the **Provisioned Account** option is set, you can use the search icon (🔍) that appears to specify the account name from the **Extended Identity Templates** dialog that opens. For more information, see [Create a Target Account for the MSSQL JIT Provisioned Account](#).

- **Password View Policy:** The name of the password view policy that you created for the account.
- **Password:** Any text that matches the password composition policy for the target account (provisioned account passwords are not managed within PAM).
- **Provisioned Account** (Optional): Set this option to configure the target account as a template for dynamically creating user accounts to support MSSQL Just in Time (JIT) provisioning.

**NOTE**

Setting the **Provisioned Account** option activates a search icon (🔍) beside the **Account Name** field that is required to select an identity template for JIT provisioning.

For more information, see [Create a Target Account for the MSSQL JIT Provisioned Account](#).

4. On the **MSSQL** tab, select one of the following options and complete any associated configuration:
  - **Account can change own password**
  - **Use the following account to administer changes**

Complete the following steps to select the account to use to administer changes

  1. Select the Search icon (🔍) beside the text field that appears.
  2. Choose the required account from the **Target Accounts** dialog that opens as shown in the following example

**Target Accounts**

Column: 

Application Type

Value: 

MSSQL

Account Name	Application Name	Application	Host Name	Device Nam	Account Ty	Owner User	Verified
\${User.userPrincipalName}	MSSQL JIT	MSSQL	10.252.5...	MSSQL	Privileged		
sa	MSSQL DB	MSSQL	10.252.5...	MSSQL	Privileged		<div></div>

screenshot:

**NOTE**

When a user performs checkout and check-in operations using a provisioned account, their account name is replaced with the RDP User Name set in the User Information (Provisioned Account, *MYLDAP\TestUser1*) on the **Access** page.

3. Select **OK**.

## Configure MSSQL Azure Managed Instance Target Accounts

This topic describes how to configure MSSQL Azure Managed Instance target accounts for Azure SQL Managed Instances.

### Follow these steps:

1. Navigate to **Credentials, Manage Targets, Accounts**.
2. Select the **Add** button.
3. Complete the following fields on the **Account** tab of the **Add Target Account** pane that opens:

- **Host Name:** The IP address or FQDN of the Azure SQL managed instance.
- **Device Name:** The name of the Azure SQL managed instance.
- **Application Name:** The name of the Azure SQL Managed Instance target application.
- **Account Name:** Assign a *unique* account name for each account. The account name that you enter must match the account name that is used by the target system. For example, on a UNIX system, account names are the UNIX user ID (userid).

**NOTE**

If the **Provisioned Account** option is set, you can use the search icon (🔍) that appears to specify the account name from the **Extended Identity Templates** dialog that opens. For more information, see [Create a Target Account for the Azure SQL Managed Instance JIT Provisioned Account](#).

- **Password View Policy:** The name of the password view policy that you created for the provisioned account.
- **Password:** Any text that matches the password composition policy for the target account (provisioned account passwords are not managed within PAM).
- **Provisioned Account** (Optional): Set this option to configure the target account as a template for dynamically creating user accounts to support Azure SQL Managed Instance Just in Time (JIT) provisioning.

**NOTE**

Setting the **Provisioned Account** option activates a search icon (🔍) beside the **Account Name** field that is used to select an identity template for JIT provisioning.

For more information, see [Create a Target Account for the Azure SQL Managed Instance JIT Provisioned Account](#).

4. On the **MSSQL Azure Managed Instance** tab, select one of the following options and complete any associated configuration:
  - **Account can change own password**
  - **Use the following account to administer changes**

Complete the following steps to select the account to use to administer changes

1. Select the Search icon (🔍) beside the text field that appears.
2. Choose the required account from the **Target Accounts** dialog that opens as shown in the following example

### Target Accounts

Column:	Application Type	Value:	MSSQL Azure Manager				
Account N	Application Name	Application Type	Host	Device Na	Account T	Owner Use	Verifie
sa	Azure SQL MI DB	MSSQL Azure Managed Instance	bosto...	Azure ...	Privileg...		✓
\${User...	Azure SQL MI JIT	MSSQL Azure Managed Instance	bosto...	Azure ...	Privileg...		
\${User...	Azure SQL MI JIT	MSSQL Azure Managed Instance	bosto...	Azure ...	Privileg...		

screenshot:

OK

Cancel

**TIP**

- Accounts from the Azure SQL Managed Instance have an Application Type of "MSSQL Azure Managed Instance" and are listed by default.
- Accounts from an Azure AD have an Application Type of "Azure Access Credentials." To view such accounts, change the selection filter value to "Azure Access Credentials."
- To list all accounts, select the **Reset** icon (  ).

3. Select **OK**.

## Configure IBM i Target Accounts

This section describes the configuration steps for IBM i (formerly AS/400) target accounts.

### Prerequisites for IBM i Target Accounts

To configure IBM i target accounts, ensure that the following tasks are completed:

- Add a device (target server) with Password Management as the device type.

**NOTE**

If you are adding an AWS IBM i device, use the private IP address in the Address field of the account. Some features do not function properly when you use the public IP address.

- Add a target application for the target server. This step includes associating IBM i with the host on which the account resides. See [Add an IBM i Target Connector](#).

To add an IBM i Target account using the CLI, see [IBM i Target Connector CLI Configuration](#).

### Create an IBM i Target Account

Follow these steps:

1. Select **Credentials, Manage Targets, Accounts**. The Target Account page appears with a list of existing accounts.
2. Select **Add**. The Add Target Account page appears.
3. Select the **Host Name** magnifying glass to find an existing target server, filling the Host Name and **Device Name**.
4. Select the **Application Name** magnifying glass to find an existing target application on the target server, or select **+** to create a target application. Select or create an IBM i type of target application.  
The IBM i appears on the Add Target Account page.
5. Enter the **Account Name**. The account name must be unique for a given target application and must be the account name that the target system uses.
6. Select the **Password View Policy** for the account.
7. Enter an initial account **Password** or select the Generate Credential key icon to generate a default password.
8. On the **Password** tab, Select **Discovery Allowed** to discover accounts on the IBM i system. Select the appropriate synchronization option:
  - Update only the Credential Manager Server: Passwords are updated only in Credential Manager. Credential Manager and target system passwords can differ.
  - Update both the Credential Manager Server and the target system: Password updates are performed both in Credential Manager and on the target system to maintain consistency.
9. On the **IBM i** tab, do the following steps:
  - a. Select the **Account Type**:
    - **User**: Use a regular user account.
    - **Administrator**: Use an administrator account.
  - b. Select the Change Process:

- If you selected **User** as your **Account Type**, select **Use the following account to change password** and type the name of or use the magnifying glass icon to specify an account that is of the Administrator account type for the same IBM i application.
- If you selected **Administrator** as your **Account Type**, use either **Change Process** option.
- (Optional) If you are adding or updating an account and you do not know the existing password, select the **Force password change** checkbox. The existing password gets changed, even though the account is not in sync.

c. Select **OK** to save.

Your new IBM i target account is added to the list of accounts on the Target Accounts page.

### **Configure PAM to Allow Non-Administrative Users to Unlock IBM i Target Accounts Without Administrative Privileges.**

#### **WARNING**

This feature provides self-service password unlock for privileged users who are inadvertently locked out of an account whose password they have permission to view. However, we strongly recommend that administrators that provision privileged account access consider the security and compliance policy implications of configuring this functionality. Self-service unlock events are included in the session log for auditing purposes.

This procedure describes how to configure PAM to enable local non-administrative user to unlock an IBM i target account that has been locked for some reason, such as in the following example scenario:

1. A user logs into PAM and accesses a target account for an IBM i system and checks out the credentials. The target account is assigned a password view policy with the following options set:
  - Check-out / Check-in
  - Change Password on View
2. Later on, the user attempts to login to the IBM i system from an external terminal emulator using the password they checked out earlier but it is no longer valid for one of the following reasons:
  - The **Force check-in after** period configured in the password view policy has expired and the password has been rotated
  - A local administrator has changed the password on the IBM i system.
3. The user reattempts to use the password until they exceed the maximum number of allowed failed login attempts configured on the IBM i system and the account is locked.

### **Discover IBM i Services and Scheduled Tasks**

You can use account discovery to manage credentials of multiple IBM i services and scheduled tasks. PAM can use the target account to manage changes and updates for any services and scheduled tasks that use this account. You do not have to update the password on an individual service or scheduled task basis.

#### **NOTE**

This procedure is for local IBM i accounts. To discover services and scheduled tasks for Active Directory accounts, see [Discover Services and Scheduled Tasks for AD Accounts](#).

#### ***Prerequisite***

Before you run account discovery, go to the Account Discovery tab of the IBM i Target application. Select the discover option for services or tasks. You can select both.

#### ***Discover Services and Tasks***

To discover new tasks and services on IBM i accounts, follow these steps:

1. Select **Credentials, Discovery**.
2. On the Scan Profiles tab, select **Run** for the profile of the account you want to update.

If a profile does not exist, follow these steps:

- a. Select **Add**.
- b. Give the profile a **Name**.
- c. On the Servers tab, select the Server that is associated with the remote account.
- d. Select **Run**.
3. Select the **Discovered Accounts** tab.  
IBM i accounts that have updates available display a green checkbox under the Updates Available column.
4. Select the **Update** button for the IBM i account with updates available.  
The Update Discovered Accounts window appears. Available Services and Scheduled Tasks appear on their respective tabs.
5. Select **OK**.
6. Select **Yes** when you are prompted to Update Selected Accounts.
7. To see a list of services and scheduled tasks:
  - a. Select **Credentials, Manage Targets, Accounts**.
  - b. Select the Services and Scheduled Tasks tabs to display the list accounts.

To remove tasks and services from an IBM i Target Accounts, follow these steps:

1. Select **Credentials, Manage Targets, Accounts**.
2. Select the account that you want to modify.
3. Select **Update**.
4. Select the Services or Scheduled Tasks tab.
5. To delete a service or task, select the **X** next to the entry.

#### NOTE

**More Info:** [Use Account Discovery to Add Target Accounts](#)

## Discover Active Directory Services and Scheduled Tasks

You can use account discovery to manage credentials of multiple Windows services and scheduled tasks. To configure discovery for AD required the combination of an AD target account and a windows Proxy or Windows remote account. Using the combination that you can discover and manage updates for any services and scheduled tasks that use the AD account. You do not have to update the password on an individual service or scheduled task basis.

Discovery of services and scheduled tasks that are associated with AD accounts is based on AD domains and groups.

To configure this feature, complete the following topics:

### Complete the Prerequisites

Before you use service or scheduled task discovery, ensure that the following prerequisites are met:

- The target server and Active Directory target application are configured.
- A Windows Remote or Windows Proxy target application and administrative account is configured. You must use one of these accounts to discover the services and scheduled tasks.
- If the Windows Remote or Windows Proxy target account is of Administrator account type, the account requires Administrator rights on the Windows server.

#### NOTE

If your target account is to be used as a service account (that is, it is to be used to rotate passwords of other target accounts), we recommend that you prevent this account from being able to login interactively. To do this, assign the following User Rights to the Windows account:

- Deny log on locally
- Deny log on through Remote Desktop Service
- The administrative account to be used for discovery has been verified in Credential Manager.

### **Discover Services that Use AD Accounts**

Use service discovery to speed the process of adding services that are associated with an Active Directory target account. Discovered services are typically added to synchronized accounts so Credential Manager can manage them.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**. The Target Accounts page appears.
2. Select a Target Account of the Active Directory **Application Type** to use for service discovery. The account that you select must be **Verified** (with a checkmark in the Verified column).
3. Select **Update**.
4. Ensure that the data in the fields are specified according to your requirements.
5. For Service discovery, select the **Services** tab.
6. For **Change Services Using**, select the credentials to use for changing Services:
  - **Change Process Credentials:** Use the credentials for this AD account.
  - **Proxy or Windows Remote Credentials:** Use the credentials for the Proxy or Windows Remote selected in the next step.
7. For **Discover Services**, select Windows Remote or Proxy:
  - **Using Proxy:** Select the **Proxy Host** from the drop-down list. Enter the **Host to Search** on which the services reside.
  - **Using Windows Remote Credentials:** Select the magnifying glass icon to select a target account that is an Administrator on the target server.
8. For **Login Using**, select the credentials for logging in:
  - **Change Process Credentials:** Use the credentials for this AD account.
  - **Proxy or Windows Remote Credentials:** Use the credentials for the Proxy or Windows Remote selected in the previous step.
9. Select the **Discover Services** button. The procedure returns a list of services for the account. The discovered services are added to the table on the Services tab.
10. To allow Credential Manager account to start or restart a service, select its check box in the Restart column. To disallow this feature, clear the check box.
11. Select **OK** if you want to update credentials for all the discovered services whenever the target account password changes.

#### **To add a service to the account manually, follow these steps:**

1. Select the **+** icon in the Services table.
2. In the new row, select a Proxy or Windows Remote Credential.
3. Enter the **Service Host** on which the service resides, and enter the Service name.
4. To allow Credential Manager account to start or restart a service, select its check box in the Restart column. To disallow this feature, clear the check box.
5. Select **OK** if you want to update credentials for all the listed services whenever the target account password changes.

To remove any services that are not required, select the **X** delete icon corresponding to the service in the Services table. The deleted service retains its current login credentials and is not updated when the target account password changes.

## Discover Scheduled Tasks that Use AD Accounts

Use scheduled tasks discovery to speed the process for adding the scheduled tasks that are associated with an Active Directory target account. Discovered scheduled tasks are typically added to synchronized accounts so Credential Manager can manage them.

### Follow these steps:

1. Select **Credentials, Manage Targets, Accounts**. The Target Accounts page appears.
2. Select a Target Account of the Active Directory **Application Type** to use for Scheduled Tasks discovery. The account that you select must be **Verified** (with a checkmark in the Verified column).
3. Select **Update**.
4. Ensure that the data in the fields are specified according to your requirements.
5. For Scheduled Tasks discovery, select the **Scheduled Tasks** tab.
6. For Change **Tasks** Using, select the credentials to use for changing Scheduled Tasks:
  - **Change Process Credentials:** Use the credentials for this AD account.
  - **Proxy or Windows Remote Credentials:** Use the credentials for the Proxy or Windows Remote selected in the next step.
7. For **Discover Tasks**, select Proxy. Select the **Proxy Host** from the drop-down list. Enter the **Host to Search** on which the tasks reside.
8. For **Login Using**, select the credentials for logging in:
  - **Change Process Credentials:** Use the credentials for this AD account.
  - **Proxy or Windows Remote Credentials:** Use the credentials for the Proxy or Windows Remote selected in the previous step.
9. Select the Discover **Tasks** button. The procedure returns a list of tasks for the account. The discovered tasks are added to the table on the Scheduled Tasks tab.
10. Select **OK** if you want to update credentials for all the discovered scheduled tasks whenever the target account password changes.

### To add a scheduled task to the account manually, follow these steps:

1. Select the **+** icon in the Scheduled Tasks table.
2. In the new row, select a Windows Remote Credential.
3. Enter the **Task Host** on which the scheduled task resides, and enter the Task name.
4. Select **OK**.
5. Manually synchronize the task password with the account password.

**To remove any scheduled tasks:** In the Scheduled Tasks tables, select the **X** (delete) icon corresponding to the task. The deleted scheduled task retains its current login credentials and is not updated when the target account password changes.

### NOTE

To discover Windows Proxy services and scheduled tasks for local accounts, see [Register Windows Proxy Target Accounts](#).

To discover Windows Remote services and scheduled tasks for local accounts, see [Configure Windows Remote Target Accounts](#).

## Cisco SSH Target Account Configuration

If you configure a target account for a Cisco target application, the Cisco SSH tab is added to the Target Account page.

### NOTE

PAM supports only Cisco IOS and ASA IOS devices.

To enable the appliance to manage passwords, follow the procedure [Manage Local Accounts on Cisco IOS or ASA IOS Devices](#).

**On the Cisco SSH tab, complete the following fields:**

- **Protocol:** Select whether the connection to the target is using SSH-2 or Telnet.
- **Account Type:** Select one of the following two options. The selected option indicates which account PAM uses to change the password.
  - **Login (User EXEC):** To restrict the target account to only User EXEC permissions, select this option. Configure any other active settings on the page.
  - **TACACS+:** If the user account resides on a TACACS+ server, select this option.

#### NOTE

Do not select the **Enable (Privileged EXEC)** option. The appliance cannot manage passwords using this option.

- **Change Password for Lines:** Select which type of line on the Cisco router for which this user account can change passwords. The choices are:
  - VTY (virtual terminal) lines
  - AUX (auxiliary) port
  - Console (CTY) line for a console terminal
- **Connect As** (Available for accounts of type Login (User EXEC) only): Specify whether to use the target account or a different account. Accept the default, **This account**, to use the target account. To specify another account, select **The following account** radio button and then enter the account name.
- **Verify Through Other Account** (Available for accounts of type Login (User EXEC) only): If you specify an account other than the target account for password management, verify the user access configuration. Select one of the following options:
  - **Verify using own credentials**
  - **Verify using other account's credentials**
- **Access Privileged EXEC As** (Available for accounts of type Login (User EXEC) only): To elevate permissions to the Privileged EXEC level, select this option and specify a fake target account that holds the Enable mode password.

### Manage Local Account Passwords on Cisco Devices

To manage passwords on a Cisco IOS or ASA IOS device, the account that connects to the Cisco device must be elevated to Privileged EXEC mode. The Enable command promotes an account to Privileged EXEC mode so a user can execute privileged tasks, such as changing passwords. PAM must initially log in to the Cisco device using an account with only User EXEC permissions. That account must then be elevated to Privileged EXEC mode.

To elevate the connection to Privileged EXEC mode, configure two accounts:

- **Enable password account.** This account stores the password for the Enable command which is used to execute Privileged EXEC level tasks. You must know the Enable password to create this account.
- **Standard User EXEC account.** This account initially logs in to the Cisco device.

The following procedures explain how to configure these two accounts.

#### **Configure the Enable Password Account**

Set up an account that holds the Enable command password. This account is a fake account that does not exist at the Cisco device. After you create this account, you can use it for any standard user account that you want to promote to Privileged EXEC level.

**Follow these steps:**

1. Create a target account that is associated with the Cisco target application.
2. On the Account tab:

- For the Account Name field, assign a name that indicates the purpose of this account, such as enableacct.
- In the Password field, enter the Enable password.

### Update enableacct

Account
Password
Compound Servers
Cisco SSH

Host Name: *	<input type="text" value="111.11.1.12"/>	<input type="text" value="Password: *"/>
Device Name: *	<input type="text" value="Cisco"/>	<input type="checkbox"/> Show Password:
Application Name: *	<input type="text" value="ciscoswitch"/>	
Account Name: *	<input type="text" value="enableacct"/>

Descriptor 1:	<input type="text"/>	
Descriptor 2:	<input type="text"/>	

- On the Password tab, ensure that the Synchronized setting is using the **Update only the Credential Manager Server** option.
- On the Cisco SSH tab, use the following settings:
  - Account type: Login (User EXEC)
  - Connect As: This account
  - Access Privileged EXEC As: This account

## Update enableacct

Account Password Compound Servers **Cisco SSH**

Protocol:
☒ SSH-2 Password or Keyboard-Interactive Authentication
☐ Telnet

Account Type:
☒ Login (User EXEC)
☐ Enable (Privileged EXEC)
☐ TACACS+

Change Password for Lines:
☐ VTY  Maximum VTY Number
☐ AUX
☐ Console

Connect As:
☒ This account
☐ The following account

Access Privileged EXEC As:
☒ This account
☐ The following account

5. Select OK.

### Configure Standard User Account

After creating the Enable password account, create an account with User EXEC permissions. This account uses the Enable account to elevate its permissions. This user can then update passwords.

#### Follow these steps:

1. In the UI, create a Cisco target account that is associated with the Cisco target application. For this example, the account name is ciscouser.
  2. On the Account tab, enter the current password for the account at the Cisco device.
  3. On the Password tab, change the Synchronized setting to **Update both the Credential Manager Server and the target system.**
  4. On the Cisco SSH tab, use the following settings:
    - **Account type:** Login (User EXEC)
    - **Connect As:** This account
    - **Access Privileged EXEC As: The following account:** Select the Enable account. In this example, that account is enableacct.
  5. Select **OK** to save the account
- The following picture shows an example:

## Update ciscouser

Change Password for Lines:	<input type="checkbox"/> VTY <input type="text" value="1"/> Maximum VTY Number <input type="checkbox"/> AUX <input type="checkbox"/> Console		
Connect As:	<input checked="" type="radio"/> This account <input type="radio"/> The following account		
Access Privileged EXEC As:	<input type="radio"/> This account <input checked="" type="radio"/> The following account		
<input type="text" value="enableacct"/>			

PAM can now use this standard user account (ciscouser) to manage passwords for other Cisco accounts, both standard and privileged.

If you configure more accounts, you can use this standard user account to manage passwords. For those other accounts:

- For the **Connect As** option, select **This following account** and specify the standard user account.
- Leave the **AccessPrivileged EXEC As** option set to **This account**

## SSH Key Authentication for Accessing UNIX/LINUX Targets

For SSH access to a UNIX/Linux target server, you can use SSH key pairs instead of a password to authenticate a client to an SSH server.

To configure SSH key authentication, you must:

1. Create an SSH key pair policy using the UI or generate a key pair using a third-party utility. If you use a utility, copy the key pair to a local system from which you can upload them into the credential database.
2. Create a UNIX target application and select the SSH Key pair policy that you created.
3. Configure a target account that is associated with the UNIX target application. For the account, set the Protocol field to SSH-2 Public Key Authentication.
4. Create an access policy that uses the SSH key pair.

Complete the following procedures:

## **Create an SSH Key Pair Policy with the UI**

For the appliance to generate an SSH key pair, configure an SSH key policy. The key policy specifies the characteristics for the key pair, specifically the cryptographic algorithm, and the key size. When you update the target account that uses the key pair, the appliance pushes the public key to the target device.

### **Follow these steps:**

1. Select **Credentials, Manage Targets, SSH Key Pair Policies**.
2. Select **Add**.
3. Provide a unique **Name** for the policy.
4. (Optional) Provide a **Description** for the policy.
5. Select the **Key Type**: ECDSA or RSA or DSA.
6. Specify the **Key Length**. The drop-down list shows the options available for the key type.
7. Select **OK**.

After you create a key pair, you can select it when you configure a target application.

## **Select the SSH Key Policy for the UNIX Target Application**

Remember to configure a UNIX/LINUX target device before you create a target application.

### **Follow these steps:**

1. Select **Credentials, Manage Targets, Applications**
2. Select **Add**.
3. In the Add Target Application dialog, complete the fields, selecting **UNIX** for the **Application Type**. Several more tabs populate the page.
4. Select the **SSH-2** tab.
5. In the **SSH Key Pair Policy** field, select the key pair policy.
6. Select **OK**.

## **Add the SSH Key Pair to a Target Account**

### **Follow these steps:**

1. Select **Credentials, Manage Targets, Accounts**.
2. Select **Add**.
3. Complete the fields, noting the following specific entries:
  - **Application Name**: Search and select the UNIX target application that you created.
  - **Account Name**: Enter a valid account name on the target device
  - **Protocol**: Select SSH-2 Public Key Authentication
4. Do *one* of the following tasks:
  - For the appliance to generate the key pair, select the keys icon next to the Private key box.
  - To upload keys that are generated by a utility, select **Choose File** next to the Private and Public key boxes. Browse to the relevant file on your local system.
5. Select the **Password** tab and for the **Synchronized** setting, select **Update both the Password Authority Server and the target system**.
6. Select **OK**.  
In the list of target accounts, a green checkmark in the Verified column next to the specific account indicates that the keys were verified.

## **Create an Access Policy that Uses the SSH Keys**

After you configure your target components, can now manage access to the target server by creating a policy.

### **Follow these steps:**

1. Select Policy, Manage Policies.
2. Select Add.
3. On the Association tab, select the user.
4. on the Access tab, select **SSH:22**.
5. For that access method, search for the target account you created earlier.
6. Select **OK**.

## **Test SSH Access using SSH Key Authentication**

The appliance can now authenticate to the UNIX target using the SSH key pair. The target server uses the public key to authenticate. When the appliance connects to the target using SSH, it uses the private key. The target server authenticates the access request using the public key.

### **Follow these steps:**

1. As the user, log in to the UI and select the Access page.
2. Select the SSH icon for the target server to launch an SSH session.
3. When the command window opens, view the public key by entering:

```
cat .ssh/authorized_keys
```

## **Securing Privileged Accounts that use SSH Keys**

Privileged Access Manager secures privileged accounts by preventing users from knowing the account passwords. When you initially deploy the appliance in your environment, you configure the appliance to change the passwords for those accounts. If SSH keys for those privileged accounts exist before you deploy the appliance, changing the passwords does not prevent the existing SSH keys from working. So, those privileged accounts are not fully secure.

SSH key discovery allows you to seek out these keys so you can remove them. Once removed, the privileged accounts are truly secured; you can only use them through the appliance. Learn how to use SSH key discovery by reading [Use SSH Key Discovery to Find Key Pairs](#).

## **Use SSH Key Discovery to Find Key Pairs**

An administrator can install SSH keys to protect access to privileged accounts. When you initially deploy the appliance in your network, you configure the appliance to change your privileged account passwords. However, if you deploy the appliance *after* SSH keys are installed, changing the passwords does not stop the SSH keys from working. So, those privileged accounts are not fully secure.

SSH key discovery allows you to find these keys so you can remove them. Once removed, the privileged accounts are truly secure, and only the Privileged Access Manager can manage these privileged accounts. SSH key discovery does not manage private keys of privileged users.

### **NOTE**

SSH key discovery only occurs for application types Linux and UNIX.

The following topics explain how to run SSH key discovery:

## Prerequisites

Before you perform SSH key discovery, complete the following prerequisites:

- Enable Account Discovery at the target application and target account
- Grant sudo permissions to the administrative account
- Edit the sudoers file to disable password authentication

### **Enable Account Discovery at the Target Application and Target Account**

SSH key discovery requires that you set up account discovery. For configuration instructions, see [Account Discovery](#).

1. Select a target application type that supports account discovery, such as UNIX.
2. Optionally, configure the options on the **Account Discovery** tab. This tab does not enable account discovery but it defines other options. Account Discovery is enabled at the target account, by selecting the Discovery Allows checkbox. The options on the tab differ depending on the application type. For example, a UNIX application provides the UID and GID values or ranges, which limit the number of discovered accounts. The UID and GID settings are used in conjunction, so that the targets must satisfy *both* criteria to be discovered.
3. Configure a target account to allow discovery. Add a target account, select the Password tab, and select the **Discovery Allowed** checkbox.

The appliance uses only those accounts with Discovery Allowed enabled as credentials for discovery.

If **Discovery Allowed** is checked, the "Allow multiple server discovery for this type of application" checkbox is also displayed for UNIX accounts. This checkbox lets the account act as a global discovery account for any server and application of this type. For example, if you have 20 servers with a common account and password, use one account and select this box. Then for any discovery job with this application type selected, this account is used as a credential for discovery.

### **Grant sudo Permissions to the Administrative Account**

Grant sudo permissions to the administrative account doing the discovery on the remote target system. SSH key discovery skips any accounts with inadequate permissions.

An administrator can create SSH keys for specific privileged accounts. For SSH key discovery, the administrative account uses sudo with the following commands:

- test
- cat
- date
- ssh-keygen

To test whether an account has sufficient access, issue one of these commands while logged on using that account. For example:

```
sudo -l ssh-keygen
```

Successful commands echo the full command name, while failures report insufficient access:

```
Sorry, user user may not run sudo on [server].
```

### **Edit the sudoers File to Disable Password Authentication**

If the administrative account uses only SSH key pairs instead of a password, configure the target server not to ask for a password.

To prevent the administrator from being prompted for a password, edit the **sudoers** file by adding a NOPASSWD entry for the account. For example:

```
jdoe ALL=(ALL) NOPASSWD: ALL
```

#### Follow these steps:

1. On the remote target server, edit the sudoers file in the */etc* directory.
2. Find the entry for the administrative account.
3. Add NOPASSWD to its entry. For example:

```
jdoe ALL=(ALL) NOPASSWD: ALL
```

4. Repeat for each server that is targeted for SSH key discovery.

### Process to Discover Keys

To perform discovery of SSH keys, follow these steps:

1. Create a scan profile.
2. Run the scan and view results.
3. View the scan results in the scan profile history.
4. (Optional) Export the results to a CSV file.

### Add and Run a Scan Profile

Start by adding a Scan Profile. Follow these steps:

1. Select **Credentials, Discovery**.
2. Select the **Scan Profiles** tab and select the **ADD** button.  
On the **Profile** tab, name the profile, and give it an optional description. Purge Interval sets the number of days after which devices that are discovered by this scan are deleted. Devices that have also been discovered by another profile are not deleted. The Purge Interval default is set on the Global Settings page, under Basic Settings, as Scan Purge Interval.
3. On the **Servers** tab, move **Available Servers** to the **Selected Servers** column. The Available Servers list is populated by managed devices.
4. Optionally, create a schedule to run the scan. Otherwise, skip to the next step to run the scan on demand.
  - Select the **Schedule** tab.
  - Select a **Frequency**. Other fields appear.
  - Select the appropriate time intervals.
  - Select **OK** to save the scan profile.
5. Select **OK** to save the scan profile and return to the Device Scan Profiles list. Select the scan profile from the list and select **RUN**.

#### NOTE

Selecting **Delete** for a highlighted Scan Profile deletes its scan profile history. It also deletes any accounts that are associated with that profile, unless they are associated with another profile.

### **Monitor the Scan**

You can monitor the progress of a scan on the **Scan Profile Jobs** tab. You can also cancel the job on this panel by selecting **CANCEL JOB**. Once a job is complete, view a summary of its results on the Scan Profile History tab.

Tables in the Discovery area allow filtering by column values. You can use asterisks and percent signs as multiple-character wildcards.

### NOTE

The Scan Profile Jobs and other tables are refreshed according to the value of the **Table Refresh Interval** field. This field is on the first tab of the Global Settings page. The default refresh time is 60 seconds.

### View the Scan Results

Select the **Scan Profile History** tab to view the results of the discovery scans. Each row shows a Scan Profile, its latest Discovery time. You can also select the buttons to view different aspects of a scan. The Summary also displays the number of errors encountered. These numbers refer only to the latest run of this scan profile.

For account discovery scans, see [Account Discovery](#).

### View Summary Details Display

The View Summary Details button opens the scan results window. The summary shows the following information:

- A count of discovered keys, how many are new, and not found. "Not found" keys were discovered by a previous run of the same scan profile, but are now missing.
- Scan Information tab displays the scan profile name and the job time.
- The Discovered Keys, New Keys, and Not Found Keys tabs list the Account Names and SSH key fingerprints in each respective category.

The Logs tab displays a table including each action that is taken regarding this scan.

### View Key Scan Results

To view key scan results, select a profile on the Scan Profile History page then select the **View Key Scan Results** button. The following information about the discovered keys is available:

Field	Description
Account Name	One or more accounts that are associated with an SSH key. If you export the results to a CSV file, this field is named userIds.
Fingerprint	Shows the public key fingerprint as hex pairs separated by colons.
Key File Age	The number of days when the key file was last modified. This number of days might not be the age of the key itself.
Key Size	The size (or length) of the SSH key in bits
Device Name	The server where the key was discovered. If you export the results to a CSV file, this field is the targetServerName.
Authorized Key File Name	The location of the <code>authorized_keys</code> file. The names of the SSH keys are stored in this file.
Is Managed (read only)	If the appliance manages the SSH key, this checkbox is selected. To enable the appliance to manage a key, the existing keys at the remote target must first be revoked manually. Then, generate a new key pair with the appliance. Only SSH keys that are generated and deployed with Credential Manager are managed.

The **Export** button creates a CSV file with a row for each discovered account that is listed.

The **View** button opens the View Discovered Keys dialog for the Account Name whose box is checked. The dialog has a **Basic Info** and **Advanced Info** tab. The Advanced Info tab displays log information that is not shown in the Account Scan results panel.

## Discovered Keys

The Discovered Keys tab contains the same information as the [View Key Scan Results](#). From this tab, you can select accounts and view details about discovered keys.

### View Discovered Keys

To open the View Discovered Key page for an account, select the account entry on the Discovered Keys page then select **View**. The **Basic Info** tab of the page contains the same information as the Discovered Keys tab.

The **Advanced Info** tab provides the following additional information:

Field	Description
Key	Displays the entire public key, including the modulus or base64 key. For SSH protocol 1, only RSA is supported (rsa1). For SSH-2, base64 is displayed.
Key Instance	It is possible to duplicate the <code>authorized_keys</code> text file so this field maintains data consistency. Any duplicate keys have an incremented integer here, typically 1.
Key Type	Displays the type of SSH key.
Comment	SSH key generation allows inclusion of comments in the key file, which are displayed in this field if present.
Revoked	Some systems are configured to allow an SSH key to be revoked. Key discovery tests each key to see if it was revoked using the command <code>"ssh-keygen -Q"</code> . If so, that is saved as a property.
Bubble Babble	Bubble Babble is an encoding method for binary data fingerprints. The bubble babble format renders the hexadecimal digits into pseudowords that can be pronounced more easily than a series of hexadecimal digits.

### Export Discovered Keys to a File

You can export information about discovered SSH keys to a CSV file for use in spreadsheets and databases. To export all SSH keys, select the Discovered Keys tab. Select the Export button above the displayed list to generate a CSV file. To export data from a specific scan, select the Scan Profile History tab. Select a Scan Profile, then select View Key Scan Results. The Export button appears above the list of keys.

The exported CSV file contains more information than is displayed in the UI. In addition to what is found in the UI, the following fields are included:

- **targetApplicationName:** The name of the target application
- **protocolVersion:** SSH Protocol 1 or 2
- **options:** Login options as included in the SSH key file
- **exponent:** Part of SSH protocol 1 (RSA1) key, with values such as 65527
- **modulus:** Part of SSH protocol 1 (RSA1) key, a long integer
- **base64Key:** Part of SSH protocol 2 key, a long base64 representation of the public key
- **authorizedKeyFileTimestamp:** The timestamp of the authorized key file, used to determine Key File Age field
- **lastLogin:** Displays the last time that this key was used to log in, as determined by its last log entry. If the log file does not go far back enough, this field might be blank

## SSH Certificate Authentication for Accessing UNIX/LINUX Targets

When connecting to target devices using SSH protocol, PAM can be configured to use Certificate Authentication as an alternative to password or public key authentication. SSH Certificate Authentication establishes a chain of trust through the PAM SSH User Certificate Authority. This certificate-based approach requires a public key for the certificate authority to be added to the target system **TrustedUserCAKeys** file.

Certificate authentication reduces the administrative burden of maintaining authorized keys or passwords on target devices therefore providing zero standing privileges for the Target systems. Also, certificates that are issued by PAM can specify a validity period providing Just-In-Time access. Combine this with the ability to control authorized activities by specifying options for the certificate user and SSH Certificates provide an excellent contribution to an organization's Zero Trust strategy.

To configure SSH certificate authentication, complete the following procedures:

### 1. Configure PAM as an SSH Certificate Authority

As a Configuration, Super, or Global administrator, you can use PAM as an SSH certificate authority (CA) to provide your organization members with the ability to authenticate using signed SSH certificates.

#### NOTE

**Prerequisite:** PAM's SSH Certificate Authentication capability depends on SSH Certificates that are generated at login time and have a brief validity interval. As a result, your PAM instances and your Unix Target Devices **must** have their system clocks synchronized. We recommend, but do not require use of NTP on your PAM instances and your UNIX Target Devices so that their system clocks are always synchronized. For more information about clock synchronization, see [Configure Date/Time Settings](#).

#### Follow these steps:

1. Select **Configuration, Security, SSH Certificate Authority** to display the **SSH Certificate Authority** page. The first time this page appears, it displays only one button that is labeled **Enable SSH Certificate Authority**.
2. Select the **SSH Certificate Authority** button to enable PAM to function as an SSH Certificate Authority. Configure the following options as desired.
3. In the **Algorithm** drop-down, select either **ECDSA** or **RSA**. This choice determines corresponding the **Key Size** options: **ECDSA** supports 256 and 384, and 521. **RSA** supports 2048 and 4096.
4. In the **Key Size** drop-down, select the key size.
5. Select **Save and Generate**. The **Public Key** textbox displays the generated public key. You can copy the public key to the UNIX and Linux target devices, as shown in the following section.

### 2. Copy the Public Key from the Certificate Authority to the Target UNIX/Linux Systems

As root user, you must copy the public key from created in the Certificate Authority page in the previous step to the **TrustedUserCAKeys** file on the target device to establish trust. You have two options when using deciding how to distribute the public key:

- [Use the Manual Method to Distribute the Key](#)
- [Use a Scripted Method to Distribute the Key](#)

#### Use the Manual Method to Distribute the Key

Use these manual steps to distribute the public key. For more information about OpenSSH Server configuration, see [https://man.openbsd.org/sshd\\_config](https://man.openbsd.org/sshd_config).

#### Follow these steps:

1. On the target device, modify the sshd configuration file `/etc/ssh/sshd_config` to set the **TrustedUserCAKeys** parameter to a local file (`/etc/ssh/ca.pub` for example).

2. As the root user, copy the public key from the PAM SSH Certificate Authority created in the previous section to the `/etc/ssh/ca.pub` local file.
3. Restart `sshd` on the target device by entering the following command: `$ /bin/systemctl restart sshd.service`
4. Repeat these steps for every target UNIX/Linux device.

### ***Use a Scripted Method to Distribute the Key***

As an administrator, you can also use a script to retrieve the current SSH Certificate public key from the specified PAM instance, and apply it to the local SSHD service. The script downloads the public key from the PAM SSH Certificate Authority using a public, unauthenticated REST API call. Comments within the script itself give well-documented instructions on how to use it.

#### **NOTE**

You must copy the script and must run it on each UNIX machine.

#### **Follow these steps to use a script to distribute public key:**

1. To access the script, select [this link](#) to download a zip file that contains the script.
2. Unzip the file to access the script.
3. Follow the comments in the script for more instructional information.

### **3. Create an SSH Certificate Policy**

As a System Administrator for UNIX and Linux devices, you can configure SSH Certificate Authentication options and extensions to further control the use of managed devices. The options and extensions themselves are described in the OpenSSH Certificate man page, which is defined [here](#). A subset of the defined options and extensions can be configured using the SSH-Certificate Policy UI which can then be attached to a UNIX target application.

#### **NOTE**

There is a default SSH Certificate Policy named "Default". If you had an existing policy named "Default" before upgrading, that policy becomes the default. Also note that you cannot delete the default policy, but you can modify it.

#### **Follow these steps:**

1. Select **Credentials, Manage Targets, SSH Certificate Policies**.
2. Select **Add** to display the **Add SSH Certificate Policy** window.
3. Provide a unique **Name** for the policy.
4. (Optional) Provide a **Description** for the policy.
5. (Optional) In the **Force Command** field, enter a force command string. This value forces the execution of the command that is entered in this field instead of opening a shell.
6. Select the desired **Extensions**. You can select the following optional extensions, and then select **OK** to confirm and exit this window:
  - **X11 Forwarding**: X11 forwarding is a mechanism that allows a user to start up remote applications and forward the application display to your local system display.
  - **Port Forwarding**: SSH port forwarding creates a secure connection between a local computer and a remote machine through which services can be relayed.
  - **Pseudo Terminal**: This setting allows Pseudo Terminal (aka PTY) to be allocated.
  - **User Run Commands**: Allows execution of the user `~/.ssh/rc` file at login time.

### **4. Create a UNIX Device**

Create a device, as described in [Device Setup](#), with these options:

- On the **Basic Info** tab: Select **Password Management**, and set the Name and **Address** for a UNIX device.
- On the **Access Method** tab, select **SSH** if you want PAM to use MindTerm. Select **X11** if you want to use X11.
- You can also [Create an SSH Service to Access a Device](#) with the **Protocol** set to **TCP**, the **Application Protocol** as **SSH**, and set the **Client Application** to (for example, for PuTTY)

```
C:\Progra~1\PuTTY\PuTTY.exe -ssh -l <User> <Local IP> <First Port>
```

#### NOTE

If you want to use X11 Forwarding, you must set the **X11** option and you must modify your PuTTY Client Application command to include the “-X” switch.

- If you do use a service, make sure to add the service to the device. For more information, see the [Select Services](#) section of the [Device Setup](#) topic.

### 5. Add a UNIX Target Connector

Use the UNIX target connector to manage UNIX-based privileged accounts.

Create a UNIX Target Connector, as described in [Add a UNIX Target Connector](#), with these options:

- On the **Application** tab, in the **Application Type** field, select **UNIX**.
- Select the **Host Name** corresponding to the Device that you created earlier.
- On the **SSH-2** tab, select the desired **Key Pair Policy** and **Certificate Policy**. For information about key pair policies, see [SSH Key Authentication for Accessing UNIX/LINUX Targets](#).

#### NOTE

DSA key types are incompatible with SSH-2 Certificate Authentication.

### 6. Add the SSH Certificate Target Account and Add Target Accounts to Target Applications

After you configure a Unix Target Connector, you can add corresponding target accounts. Target accounts identify accounts at the remote server for which PAM can authenticate users using SSH-2 certificate authentication. This section follows the [Add Target Accounts to Target Applications](#) topic with the same exceptions for SSH-2 certificate authentication configuration items.

#### Follow these steps:

1. Select **Credentials, Manage Targets, Accounts**.
2. Select **Add**. On the **Account** tab, complete the fields, noting the following specific entries:
3. In the **Application Name** field, search for and select the UNIX target application that you created.
4. In the **Account Name** field, enter a valid account name for the target device.
5. In the **Protocol** field, select **SSH-2 Certificate Authentication**. This option displays the following fields:
  - a. **Principal**: Optionally, enter a comma-separated list of strings to use as authentication principals. If this field is blank, the **Account Name** is used as the principal. The principals that are defined here should match the principals that are defined on the SSH server.
  - b. **Certificate Details**: Lists the details of the selected SSH certificate authentication policy that is associated with the target application.
6. The **Certificates** tab appears when you select **SSH-2 Certificate Authentication** for your **Protocol**. This tab displays the following options:
  - a. **Last Generated**: Displays the most-recent time and date that the certificate was generated. A new certificate is generated and sent to the SSHD server on the UNIX system every time a user logs in using MindTerm or an SSH proxy service. **Last Generated** is equivalent to the last time that a user attempted to log in with this target account.
  - b. **Account Created**: Displays the time and date that the account was created.
7. Select **OK** to confirm and exit this page, and add the new target account to the list of accounts on the **Account List** page.

## 7. Create an Access Policy that Uses the SSH Certificate

After you configure your target components, can now manage access to the target server by creating a policy.

**Follow these steps:**

1. Select **Policy, Manage Policies**.
2. Select **Add**.
3. Complete the fields, noting the following specific entries:
4. On the **Association** tab, select the **User** and **Device**.
5. On the **Access** tab, select the SSH Access Method if one was configured in the **Device**.
6. For the **Selected Access** method, search for and add the target account that you created earlier.
7. Select **OK**.

### Special Considerations For SSH Access Method Sessions Using SSH-2 Certificate Authentication

When using the SSH-2 Certificate Authentication protocol, the SSH Access Method autologin behavior differs from autologin using the SSH-2 Password or SSH-2 Public Key protocols. When using SSH-2 Certificate Authentication, the applet connects to an SSH Proxy Service in the PAM appliance that performs go-between actions including SSH-2 certificate authentication, session recording, command filtering and socket filtering. The SSH-2 Password or SSH-2 Public Key protocols do not require this additional layer of processing.

As a result, using the SSH-2 Certificate Authentication protocol reduces the number of simultaneous SSH Access Method applets per PAM Appliance that can be run due to increased load on the PAM server. Also, the cryptography settings governing connections to Target Devices via the SSH-2 Certificate Authentication protocol will be configured on the **Configuration, Security, Cryptography** page under the **SSH Proxy** tab, versus the **SSH MindTerm** tab for the SSH-2 Password or SSH-2 Public Key protocols.

### Troubleshooting

#### Using X11 with Certificates

If you want to use X11, be sure to select it in the certificate, during device setup, and to select X11 and enter the correct syntax for X11 in the **Client Application** text box.

## Create an SSH Certificate Policy with the UI

As a System Administrator for multiple UNIX and Linux devices, you configure Certificate Authentication options and SSH certificate extensions to control the permitted activities, commands, and validity period of Users connecting to managed devices. This configuration improves the ability to define roles and limit User activities to that authorized. Such options are shown in the openSSH Certificate man page, defined [HERE](#), and are available to establish a SSH-Certificate policy to apply to accounts used to connect to target systems by users.

### NOTE

There is a default policy named Default. If you have an existing policy named default, that policy becomes the default. Also note that you cannot delete a policy named default.

**Follow these steps:**

1. Select **Credentials, Manage Targets, SSH Certificate Policies**.
2. Select **Add** to display the **Add SSH Certificate Policy** window.
3. Provide a unique **Name** for the policy.
4. (Optional) Provide a **Description** for the policy.

5. (Optional) In the **Force Command** field, enter a force command string. A force command forces (or overrides) the execution of the command entered in this field instead of any shell or command specified by the user when using the certificate for authentication.
6. Select the desired **Extensions**. You can select the following optional extensions:
  - **X11 Forwarding**: X11 forwarding is a mechanism that allows a user to start up remote applications but forward the application display to your local system display.
  - **Port Forwarding**: SSH port creates a secure connection between a local computer and a remote machine through which services can be relayed. When you use port forwarding, the client still thinks that it connects to the hostname/IP address of the gateway. When the SSL certificate is used to verify the host name, as you do with https, the SSL certificate you serve from the server should be valid for the host name of the forwarding gateway.
  - **Pseudo Terminal**: A Pseudo Terminal (aka pseudoterminal) is a pair of virtual character devices that provide a bidirectional communication channel.
  - **User Run Commands**: Allows execution of `~/.ssh/rc`
7. Select **OK** to conform and exit this window.

After you create an SSH Certificate Policy, you can select it when you configure UNIX and Linux target application.

## Set the Privilege Elevation for UNIX Target Accounts

For target accounts associated with UNIX target applications, you can configure the **Privilege Elevation** setting. This setting determines which privilege elevation capabilities the account has on the target server. How you configure this setting impacts whether password synchronization works.

On the UNIX tab of the target account, select one of the following options for the given account.

### NOTE

The descriptions assume that the privilege elevation command is **sudo** and the password change command is **passwd**.

- **Do not use elevated privileges**: Select this option for an account that is not allowed to run sudo commands on the target server. When the user of the account tries to change its own password, the user must provide the current password first. Accounts without privilege elevation cannot update passwords of other accounts.
- **Use elevated privileges**: Select this option for an account that is allowed to run sudo commands without providing its own password to sudo. This use case applies for an account with the "NOPASSWD" flag set in the `/etc/sudoers` file. The NOPASSWD flag is considered insecure and not recommended. Such accounts can change passwords of other accounts, including the root account.
- **Use elevated privileges with authentication**: Select this option for accounts that can run sudo commands but must provide a password. Before a command is executed, the sudo command prompts the account user for a password. This behavior is the recommended sudo option. Such accounts can change passwords of other accounts, including root.
- **This account is a root account**: Select this option for accounts that need no privilege elevation. Such accounts can change their own password without having to provide the current password first. These accounts also can change passwords of other accounts without the use of the sudo command. Beginning with release 3.0.3, if you select this option, the default script does not invoke the sudo command.

## Oracle Target Account Configuration

The Oracle target connector can communicate with an Oracle database and Oracle Internet Directory (OID) server.

If you create a target account for an Oracle target application, there are more settings that you must configure, as shown in the following screen:

## Add Target Account ? X

Account Password Compound Servers **Oracle**

Use OID:

☒ JDBC Thin  
☐ JDBC Thin using OID

Schema: \*

Schema is a RAC Service Name:

☐

Change Process:

☒ Account can change own password  
☐ Use the following account to change password

This is a SYSDBA Account:

☐

Use REPLACE Syntax:

☐

The configuration settings include:

**Use OID**—Specifies whether PAM connects to an Oracle database or an Oracle Internet Directory (OID) server. The options are:

- **JDBC Thin**: To connect to an Oracle database, accept this default option
- **JDBC Thin using OID**: To connect to an Oracle Internet Directory server, select this option and enter values for the following fields:
  - **SID/Service** – Specifies the System Identifier (SID) of the Oracle Internet Directory database instance. Enter the SID specified during the installation of the OID software.
  - **CN** – Specifies the Common Name (CN) of an Oracle context. The default value is cn=OracleContext.

**Schema**: Enter the schema name for the database account.

**Schema is a RAC Service Name** (for JDBC Thin only): If the target is an Oracle RAC, select this checkbox.

**Change Process**: Select one of the options:

- **Account can change own password**: Select this option when a user account can change the password. The assumption is that the user knows the original password.
- **Use the following account to change password**: Select this option to use a *master account*. A master account has privileges to change any account password, such as an administrator with maximum privileges.

For more information about this setting, see [Use an Alternate Account to Change Passwords \(Optional\)](#).

**This is a SYSDBA Account**: If the target account is a SYSDBA database administrator, select this checkbox.

**Use REPLACE Syntax**: The Oracle REPLACE function lets you replace one text string with another. By default, this option is not enabled. Accept the default if the account that is specified to change an account password does not know the original password.

Follow these guidelines:

- For a standard user who knows the original account password, select this checkbox. For this account, the **Account can change own password** option is also selected.
- For an account with the ALTER USER privilege, such as an Oracle administrator, acting as a master account, keep this checkbox unselected. A master account can change any account password without knowing the original password for the target account. To use a master account, select the **Use the following account to change password** setting and enter the privileged account.

## Palo Alto Account Configuration

If you configure a target account for a Palo Alto target application, the Palo Alto tab is added to the Target Account page. Select the type of account that PAM uses to manage passwords on a Palo Alto device:

**Account type:** This setting indicates whether the account is a standard user account or an administrator account.

- **User (Configuration access is disabled)** - The account is a standard user account.
- **Privileged (Configuration access is enabled)** - The user is a privileged administrator with permissions to manage other account passwords

**Connect As:** If you select User for the Account type field, select one of the following options:

- To use the specified target account, accept the default, **This account**.
- To enter an account other than the target account, select **The following account** and enter the account name.

If you change the account type from User to Privileged, the information for the Connect As setting is removed because it is no longer relevant.

## Configure Windows SSH Key Target Accounts

Learn how to configure target accounts for PAM Windows SSH Key target applications.

This topic describes how to configure Windows SSH Key target accounts.

**Follow these steps:**

1. Select **Add**.
2. Select **Credentials, Manage Targets, Accounts**. The **Target Accounts** page opens with a list of existing accounts.
3. Select **Add**. The **Add Target Account** page appears.
4. Select the **Host Name** magnifying glass icon and select the required target server from the Target Servers dialog that opens. The **Host Name** and **Device Name** fields are populated appropriately.
5. Select the **Application Name** magnifying glass icon and select the required Windows SSH Key or Windows SSH Password target application from the **Target Applications** dialog that opens. The **Application Name** field is populated appropriately.
6. Complete the following fields:
  - **Account Name:** Enter a valid account name on the target device.
  - **Password View Policy:** The default password view policy is always assigned. Use the magnifying glass icon to select other defined view policies.
7. Use *one* of the following methods to populate the public and private keys:
  - To have PAM generate the key pair, select the key icon next to the **Private Key** box. The **Public Key** and **Private Key** fields are populated using the generated values.

### TIP

To configure PAM to generate the key pair when creating a target account, select the **Use a different account to change credentials** option on the **SSH** tab.

- To upload keys that you have generated using a utility, select the Upload icons beside the **Public Key** and **Private Key** fields and select the required files to upload. The corresponding fields are populated using the uploaded keys.
8. Optionally, on the **Password** tab, change the **Synchronized** value to specify a different password synchronization option:
    - **Update only the Credential Manager Server:** Passwords are updated only in Credential Manager. Credential Manager and target system passwords can differ.
    - **Update both the Credential Manager Server and the target system** (Default): Password updates are performed in Credential Manager and on the target system to maintain consistency.

9. Select the **SSH** tab and specify the account that has the authority to change passwords using one of the following **Change Process** options:
  - **Account can change own credentials:** (Default) Allow the target account to change its own password. The initial password that you enter must be the same as the target account password.
  - **Use a different account to change credentials:** Select the magnifying glass icon next to the **Account to change credentials with** field and select the account to use to change passwords from the **Target Accounts** dialog that opens. Select an account of application type "Windows SSH Password" or "Windows SSH Key." Do not select the current target account.

**NOTE**

In the list of target accounts, a green checkmark in the Verified column next to the specific account indicates that its keys are verified.

10. Select **OK**.

**NOTE**

For information about the associated target application, see [Add a Windows SSH Key Target Connector](#).

## Configure Windows SSH Password Target Accounts

Learn how to configure target accounts for PAM Windows SSH Password target applications.

This topic describes how to configure Windows SSH Password target accounts.

### Follow these steps:

1. Select **Add**.
2. Select **Credentials, Manage Targets, Accounts**. The **Target Accounts** page opens with a list of existing accounts.
3. Select **Add**. The **Add Target Account** page appears.
4. Select the **Host Name** magnifying glass icon and select the required target server from the Target Servers dialog that opens. The **Host Name** and **Device Name** fields are populated appropriately.
5. Select the **Application Name** magnifying glass icon and select the required Windows SSH Password target application from the **Target Applications** dialog that opens. The **Application Name** field is populated appropriately.
6. Complete the following fields:
  - **Account Name:** Enter a valid account name on the target device.
  - **Password View Policy:** The default password view policy is always assigned. Use the magnifying glass icon to select other defined view policies.
7. Specify the SSH password in the **Credential** field.
8. Select the **SSH** tab and specify the account that has the authority to change passwords using one of the following **Change Process** options:
  - **Account can change own credentials:** (Default) Allow the target account to change its own password. The initial password that you enter must be the same as the target account password.
  - **Use a different account to change credentials:** Select the magnifying glass icon next to the **Account to change credentials with** field and select the account to use to change passwords from the **Target Accounts** dialog that opens. Select an account of application type "Windows SSH Password" or "Windows SSH Key." Do not select the current target account.

**NOTE**

In the list of target accounts, a green checkmark in the Verified column next to the specific account indicates that its keys are verified.

9. Optionally, on the **Password** tab, change the **Synchronized** value to specify a different password synchronization option:

- **Update only the Credential Manager Server:** Passwords are updated only in Credential Manager. Credential Manager and target system passwords can differ.
- **Update both the Credential Manager Server and the target system (Default):** Password updates are performed in Credential Manager and on the target system to maintain consistency.

10. Select **OK**.

#### NOTE

For information about the associated target application, see [Add a Windows SSH Password Target Connector](#).

## Set Up Password Composition and View Policies

Privileged Access Manager is the master password `pwd` repository that pushes password changes to the configured target accounts. You can manage privileged account passwords with the following types of password policies:

- **Password composition policies:** These policies define the rules to which passwords must conform. When passwords are updated at the target, they must comply with the composition policies.
- **Password view policies:** These policies specify how the [appliance](#) behaves when someone wants to view a password. Password view policies can also control the actions that take place after a password is viewed.

In addition to privileged accounts, you can also [manage A2A passwords](#), provided you have the correct license.

**Table 1: Test**

Policy	Definition	Use Case
Password Composition	© self-evident #	Govern password content
Password View	© self-evident #	Govern password usage

To set up password policies, see the following topics:

- [Construct Password Composition Policies](#)
- [Establish Password View Policies](#)

## Construct Password Composition Policies

Password composition policies define the rules to which target account passwords must conform. Credential Manager allows you to define various password composition policies to ensure that passwords meet the unique security needs of your organization.

If no policy is set, the default password composition policy is applied. The default policy specifies a minimum length of four characters and a maximum length of 16 characters, with no character restrictions.

You assign password composition policies to target applications. When a user enters a password, the password is validated against the composition policy. Credential Manager also uses the password composition policy to generate random passwords.

#### WARNING

Ensure that policies meet or exceed the minimum password composition policy that is required by the target account. Also, validate that the use of special characters in the policy is allowed by the target system. The policy must follow the password requirements of the target system. If not, a password update can fail because the target system prevents the update.

Review the following topics before configuring password composition policies:

## Password Composition Rules

Password composition policies characteristics define the minimum requirements for passwords. Configurable password composition policies characteristics include:

**Remote Password Generation:** Indicates that the policy applies to remotely generated credentials. If selected, the only other rules that apply to the policy are Maximum Password Age Enforcement and Maximum Password Age Days. Other rules are hidden. Currently, only the AWS Access Credentials connector supports Remote Password Generation.

**Password Prefix:** A fixed sequence of characters that must start the password string.

**Minimum Length:** Password length must be greater than or equal to this value. Limits: 1-2048 characters.

**Maximum Length:** Password length must be less than or equal to this value. Limits: 1-2048 characters.

### NOTE

Although PAM supports a maximum password length of 2048 characters, target systems may have lower limits. For example, the maximum password length on a Linux system is 511 characters. Therefore, if you want PAM to manage accounts on a Linux system as synchronized accounts, set the **Maximum Length** value to no more than 511.

**Minimum Iterations Before Reuse:** This rule dictates a previous number of passwords are available for reuse. For example, if you enter 3, then the current password and the previous password cannot be reused. However, the third previous password and older passwords can be reused. Entering 0 means that there are no restrictions; this password can always be reused. Use this setting with the **Minimum Days Before Reuse** setting to prevent the same password from being used twice. Credential Manager checks this setting only when updating a target account password.

**Minimum Days Before Reuse:** This option prevents the reuse of any password that was used within the last specified number of days.

**Maximum Password Age Enforcement:** A password expires after this many days. The password is then considered expired. If you enable Automatically Update Expired Passwords (Settings, Credential Manager), Credential Manager updates the password. Use this setting with the **Minimum Iterations Before Reuse** setting to prevent the same password from being used twice. Credential Manager checks this setting only when updating a target account password.

**Maximum Password Age Enforcement:** This setting determines whether Credential Manager adheres to the specified password age. If disabled, the password for the target account never expires.

**Maximum Password Age Days:** This parameter specifies the maximum number of days a password is valid. The default value is 90 days. The password age is reset each time that the password is updated.

### NOTE

The **Password Expiry** date indicates the number of days from the last password update to the maximum password age. If the password expires at least one day in the future, the indicator is green. If the password expires on the current day, the indicator is yellow. If the password is already expired, the indicator is red.

**Must Contain:** This setting indicates the types of characters that a password must contain.

- At least one ASCII character set item
- Each type of character that is selected must be included in the password
- Each type of character that is not selected must be excluded in the password

**First Must Contain:** This rule specifies the first character of each password from one of the types selected. Exactly one of the options is used.

**Must Not Contain Rules:** This rule Identifies character patterns that the password must *not* contain. Options include:

- **Disallow Repeating Characters:** Do not allow any adjacent matching characters. However, duplicate characters that are not adjacent are allowed.  
Example: ABCCDECFC. The letters that are crossed out are not allowed.
- **Disallow Duplicate Characters:** Do not allow any matching characters.

Example: **ABC CDECFC**. The letters "C" after the first one are not allowed.

- **Disallow Max Class Repeat:** Do not allow consecutive characters of the same class type. If enabled, the minimum allowed is 2 and the maximum is less than the maximum password length. Example: When the Max Class Repeat is set to 2, then ABcc12#% is allowed and ABCc12#% is not allowed.
- **Characters to Exclude:** Do not allow any character from a list that you specify

In addition to the configurable options, passwords cannot begin with the following characters:

- **{n}** where *n* is any integer value; non-integer values are acceptable. For example, Credential Manager cannot manage {1}mypassword, {999}anotherpassword but can manage {104.1}okpassword.
- Passwords cannot begin or end with a space character. Credential Manager ignores a space character and does not save it.

### **Suggested Password Composition Policies**

Password composition policies must comply with password requirements of the remote applications. For the following types of targets, we suggest the following password composition policies:

- **Databases and Windows systems:**
  - Alpha and numeric characters, plus a special character, such as [!#\_-\$@\*]
  - A minimum length of six characters and a maximum length of 12 characters.
- **UNIX:** Alphabetic characters (no mixed or numeric characters) with a length of eight characters.

### **Configure Password Composition Policies**

You can create password composition policies with the UI or the CLI. Once you create password composition policies, you can then apply them to target applications.

- [Create a Password Composition Policy with the GUI](#)
- [Create a Password Composition Policy with the CLI](#)

## **Create a Password Composition Policy with the UI**

### **Create a Password Policy**

Follow these steps to create a policy in the UI:

1. Select **Credentials, Manage Targets, Password Composition Policies**. The Password Composition Policies page appears.
2. Select **Add**.
3. In the Add Password Composition Policy page, complete the fields, and select the policy rules that you want to apply. See the [descriptions of the composition rules](#).
  - Assign a unique name for the policy.
  - Select at least one of the **Must Contain**, **First Must Contain**, or **Last Must Contain** rules.
  - Do not enter same characters in **Must Contain** and **Must Not Contain** fields.
4. Select **Test**. The test lets you see the generated sample password. The test also verifies the following conditions:
  - Whether the password can be generated with the options you set
  - Whether the generated password suits your requirement
  - The complexity of the password to avoid it being figured out
5. Select **OK**.

## Automatically Update Expired Passwords

You can enable or disable the automatic updating of expired passwords globally. If it is enabled, the password for a synchronized account is automatically updated after it expires. Passwords for unsynchronized accounts remain expired until manually updated.

### Follow these steps:

1. Select **Settings, Credential Manager, General Settings**.
2. Set the **Automatically Update Expired Passwords** option. This option automatically updates synchronized accounts that have expired passwords with a new password.

See also the [Accounts with Expired Passwords](#) report.

## Create a Password Composition Policy with the CLI

To create a password composition policy from the CLI using the `addPasswordPolicy` command. You can use this command for the following tasks.

### Create a Password Composition Policy

#### Follow these steps:

1. Specify the password composition policy:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addPasswordPolicy
PasswordPolicy.name=MaximumPasswordAgePolicy
PasswordPolicy.description=PasswordCompositionPolicy
Attribute.passwordPrefix=pas
Attribute.composedOfUpperCaseCharacters=True
Attribute.composedOfLowerCaseCharacters=True
Attribute.composedOfNumericCharacters=True
Attribute.composedOfSpecialCharacters=true
Attribute.specialCharacters=!#$%()*+,-./:;=?[\\]^_{|}~
Attribute.firstCharacterUpperCase=true
Attribute.firstCharacterLowerCase=true
Attribute.firstCharacterNumeric=true
Attribute.firstCharacterSpecial=true
Attribute.firstCharacterSpecials=!#$%()*+,-./:;=?[\\]^_{|}~
Attribute.lastCharacterUpperCase=true
Attribute.lastCharacterLowerCase=true
Attribute.lastCharacterNumeric=true
Attribute.lastCharacterSpecial=true
Attribute.lastCharacterSpecials=!#$%()*+,-./:;=?[\\]^_{|}~
Attribute.mustNotContainConsecutiveDuplicateCharacters=true
Attribute.mustNotContainAnyDuplicateCharacters=true
Attribute.mustNotContainCharacters=true
Attribute.composedOfMustNotContainCharacters=XYZ
Attribute.minLength=6
Attribute.maxLength=16
Attribute.minIterationsBeforeReuse=2
Attribute.minDaysBeforeReuse=3
```

2. Enter your password at the prompt. Credential Manager returns the following XML command string:

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
```

```

<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<PasswordPolicy>
<minLength>6</minLength>
<maxLength>16</maxLength>
<minDaysBeforeReuse>3</minDaysBeforeReuse>
<minIterationsBeforeReuse>2</minIterationsBeforeReuse>
<firstCharacterSpecialCharacters>!#$%()*+,-./:;=?[\\]^_{}~</firstCharacterSpecialCharacters>
<mustNotContainCharacters>true</mustNotContainCharacters>
<passwordPrefix>pas</passwordPrefix>
<specialCharacters>!#$%()*+,-./:;=?[\\]^_{}~</specialCharacters>
<composedOfLowerCaseCharacters>true</composedOfLowerCaseCharacters>
<composedOfMustNotContainCharacters>>false</composedOfMustNotContainCharacters>
<composedOfNumericCharacters>true</composedOfNumericCharacters>
<composedOfSpecialCharacters>true</composedOfSpecialCharacters>
<composedOfUpperCaseCharacters>true</composedOfUpperCaseCharacters>
<firstCharacterLowerCase>true</firstCharacterLowerCase>
<firstCharacterNumeric>true</firstCharacterNumeric>
<firstCharacterSpecial>true</firstCharacterSpecial>
<firstCharacterUpperCase>true</firstCharacterUpperCase>
<mustNotContainDuplicateCharacters>true</mustNotContainDuplicateCharacters>
<mustNotContainRepeatingCharacters>true</mustNotContainRepeatingCharacters>
<name>NewPasswordPolicy</name>
<type>passwordPolicy</type>
<description>PasswordCompositionPolicy</description>
<ID>1006</ID>
<Attribute.composedOfNumericCharacters>true</Attribute.composedOfNumericCharacters>
<Attribute.mustNotContainCharacters>true</Attribute.mustNotContainCharacters>
<Attribute.composedOfSpecialCharacters>true</Attribute.composedOfSpecialCharacters>
<Attribute.firstCharacterNumeric>true</Attribute.firstCharacterNumeric>
<Attribute.mustNotContainAnyDuplicateCharacters>true</Attribute.mustNotContainAnyDuplicateCharacters>
<Attribute.firstCharacterSpecial>true</Attribute.firstCharacterSpecial>
<Attribute.firstCharacterSpecials>!#$%()*+,-./:;=?[\\]^_{}~</Attribute.firstCharacterSpecials>
<Attribute.firstCharacterLowerCase>true</Attribute.firstCharacterLowerCase>
<Attribute.composedOfLowerCaseCharacters>true</Attribute.composedOfLowerCaseCharacters>
<Attribute.maxLength>16</Attribute.maxLength>
<Attribute.passwordPrefix>pas</Attribute.passwordPrefix>
<Attribute.composedOfMustNotContainCharacters>>false</Attribute.composedOfMustNotContainCharacters>
<Attribute.firstCharacterUpperCase>true</Attribute.firstCharacterUpperCase>
<Attribute.minLength>6</Attribute.minLength>
<Attribute.minDaysBeforeReuse>3</Attribute.minDaysBeforeReuse>
<Attribute.specialCharacters>!#$%()*+,-./:;=?[\\]^_{}~</Attribute.specialCharacters>
<Attribute.composedOfUpperCaseCharacters>true</Attribute.composedOfUpperCaseCharacters>
<Attribute.minIterationsBeforeReuse>2</Attribute.minIterationsBeforeReuse>
<Attribute.mustNotContainConsecutiveDuplicateCharacters>true</
Attribute.mustNotContainConsecutiveDuplicateCharacters>
<createDate>Wed Nov 24 07:13:03 UTC 2010</createDate>
<createUser>admin</createUser>
<extensionType />
<hash />
<updateDate>Wed Nov 24 07:13:03 UTC 2010</updateDate>
<updateUser>admin</updateUser>
</PasswordPolicy>

```

```
</cr.result>
</CommandResult>
```

### **Set the Maximum Password Age**

The maximum password age specifies the maximum number of days a password is valid. The default value is 90 days. The password age is reset each time that the password is updated.

#### **Follow these steps:**

##### **1. Specify the new policy:**

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addPasswordPolicy
PasswordPolicy.name=MaximumPasswordAgePolicyNew
PasswordPolicy.description=PasswordCompositionPolicy
Attribute.composedOfUpperCaseCharacters=True
Attribute.composedOfLowerCaseCharacters=True
Attribute.composedOfNumericCharacters=True
Attribute.firstCharacterUpperCase=true Attribute.minLength=6
Attribute.maxLength=16 Attribute.minIterationsBeforeReuse=2
Attribute.minDaysBeforeReuse=3 Attribute.maxPasswordAge=true
Attribute.maxPasswordAge=12
```

##### **2. Enter your password at the prompt.**

Credential Manager returns the following XML command string:

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<PasswordPolicy>
<minLength>6</minLength>
<maxLength>16</maxLength>
<maxPasswordAge>0</maxPasswordAge>
<minDaysBeforeReuse>3</minDaysBeforeReuse>
<minIterationsBeforeReuse>2</minIterationsBeforeReuse>
<firstCharacterSpecialCharacters>!#$%()*+,-./:;=?@[\\]^_`{|}~&#38;
</firstCharacterSpecialCharacters>
<mustNotContainCharacters></mustNotContainCharacters>
<passwordPrefix></passwordPrefix>
<specialCharacters>!#$%()*+,-./:;=?@[\\]^_`{|}~&#38;</specialCharacters>
<composedOfLowerCaseCharacters>true</composedOfLowerCaseCharacters>
<composedOfMustNotContainCharacters>>false</composedOfMustNotContainCharacters>
<composedOfNumericCharacters>true</composedOfNumericCharacters>
<composedOfSpecialCharacters>>false</composedOfSpecialCharacters>
<composedOfUpperCaseCharacters>true</composedOfUpperCaseCharacters>
<enableMaxPasswordAge>>false</enableMaxPasswordAge>
<firstCharacterLowerCase>>false</firstCharacterLowerCase>
<firstCharacterNumeric>>false</firstCharacterNumeric>
<firstCharacterSpecial>>false</firstCharacterSpecial>
<firstCharacterUpperCase>true</firstCharacterUpperCase>
<mustNotContainDuplicateCharacters>>false</mustNotContainDuplicateCharacters>
<mustNotContainRepeatingCharacters>>false</mustNotContainRepeatingCharacters>
<name>MaximumPasswordAgePolicyNew</name>
<type>passwordPolicy</type>
```

```

<description>PasswordCompositionPolicy</description>
<ID>1004</ID>
<Attribute.composedOfNumericCharacters>true</Attribute.composedOfNumericCharacters>
<Attribute.mustNotContainCharacters></Attribute.mustNotContainCharacters>
<Attribute.composedOfSpecialCharacters>false</Attribute.composedOfSpecialCharacters>
<Attribute.firstCharacterNumeric>false</Attribute.firstCharacterNumeric>
<Attribute.maxPasswordAge>0</Attribute.maxPasswordAge>
<Attribute.enableMaxPasswordAge>false</Attribute.enableMaxPasswordAge>
<Attribute.firstCharacterSpecial>false</Attribute.firstCharacterSpecial>
<Attribute.firstCharacterSpecials>!#$%()*+,-./:;=?@[\\]^_`{|}~&#38;
</Attribute.firstCharacterSpecials>
<Attribute.mustNotContainAnyDuplicateCharacters>false
</Attribute.mustNotContainAnyDuplicateCharacters>
<Attribute.firstCharacterLowerCase>false</Attribute.firstCharacterLowerCase>
<Attribute.composedOfLowerCaseCharacters>true</Attribute.composedOfLowerCaseCharacters>
<Attribute.maxLength>16</Attribute.maxLength>
<Attribute.passwordPrefix></Attribute.passwordPrefix>
<Attribute.composedOfMustNotContainCharacters>false
</Attribute.composedOfMustNotContainCharacters>
<Attribute.firstCharacterUpperCase>true</Attribute.firstCharacterUpperCase>
<Attribute.minLength>6</Attribute.minLength>
<Attribute.minDaysBeforeReuse>3</Attribute.minDaysBeforeReuse>
<Attribute.specialCharacters>!#$%()*+,-./:;=?@[\\]^_`{|}~&#38;</Attribute.specialCharacters>
<Attribute.composedOfUpperCaseCharacters>true</Attribute.composedOfUpperCaseCharacters>
<Attribute.minIterationsBeforeReuse>2</Attribute.minIterationsBeforeReuse>
<Attribute.mustNotContainConsecutiveDuplicateCharacters>false
</Attribute.mustNotContainConsecutiveDuplicateCharacters>
<createDate>Thu Dec 01 11:17:28 UTC 2011</createDate>
<createUser>admin</createUser>
<updateDate>Thu Dec 01 11:17:28 UTC 2011</updateDate>
<updateUser>admin</updateUser>
<extensionType></extensionType>
<hash></hash>
</PasswordPolicy>
</cr.result>
</CommandResult>

```

## Configure Automatic Updating of Expired Passwords

You can enable or disable automatic updating of expired passwords globally using the `targetAccountPasswordExpirationEnabled` command. For example:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=setSystemProperty
propertyName=targetAccountPasswordExpirationEnabled propertyValues=true
```

The default value is false.

## Establish Password View Policies

Password view policies determine what actions Credential Manager takes when a password is viewed or used. In the UI, users can view target account passwords for synchronized and non-synchronized target accounts.

A password view policy can control many tasks, including:

- Automatically change the account password for synchronized accounts once it is viewed
- Automatically change the account password when a connection is ended
- Ensure that only one person at a time can view an account password
- Ensure that an account password is only revealed after a specific approver has authorized it

Each time a user views a password, Credential Manager generates a log entry. You can then view each time that a user tried to view an account password in a report.

#### NOTE

Password view policies apply only to password administration with the GUI, CLI, or Java API. Requests from A2A clients are not affected by password view policies.

The following topics describe how to work with password view policies:

- [Create a Basic Password View Policy](#)
- [Modify the Default Password View Policy](#)
- [Configure Password View Policies That Require Approval of Requests](#)
- [Require an Account Check-Out to View the Password](#)
- [Enable Email Notifications for Viewed Passwords](#)
- [Track Account Movement Across Active Directory OUs](#)
- [See a List of Password View Requests](#)

## Create a Basic Password View Policy

Each target account is associated with a password view policy, whether it is the default policy or a policy that you create. Use this procedure to create a password view policy with the UI.

To use the CLI to create a password view policy, see [Create a Password View Policy with the CLI](#).

### Configure a Password View Policy

Follow these steps:

1. Select **Credentials, Workflow, Password View Policies**. The Password View Policies page appears.
2. Select **Add**.
3. On the **Basic Info** tab, enter a policy **Name** and **Description** and specify the properties of the policy using the following controls:

#### NOTE

Use the radio buttons to display applicable and available options: either **Show All Options**, or **Show SSH Certificate Options**. Accounts that use an SSH certificate for authentication do not use a password. This means password-specific options do not apply to these accounts that use an SSH certificate for authentication.

You can still associate any password view policy option with accounts that use SSH certificates. For such accounts, viewing credentials is disabled, thus any password-view options do not apply. Also note that the options related to password rotation also do not apply. Specifically, the **Change Password On Auto Connect**, **Change Password on Connection End**, **Change Password on Session End** options will not trigger password rotation.

- **Re-authenticate for View:** If set, a dialog appears when a user tries to view a password. To continue, the user enters their password.
- **Re-authenticate for Auto-Connect:** If set, a dialog appears when a user tries to auto-connect to an application through Access. To continue, the user enters their password.
- **Reason Required for View:** If set, a dialog appears when a user tries to view an Account password. The user selects a Reason and enters a Description and Reference Code to view the password. Select the View Credential (eye icon) for an Account on the Account List page or on the Account Details page.
- **Reason Required for Auto-Connect:** If set, a dialog appears when a user tries to auto-connect. The user selects a Reason and enters an optional Description and optional Reference Code to auto-connect.
- **Change Password on View:** Viewed password on synchronized and non-synchronized accounts is automatically changed after the delay specified (in minutes) in the **Change Password Interval** field. If you also select Dual Authorization, this interval is disabled and ignored. Dual Authorization has its own Default Request Interval, which takes precedence.  
The password view policy can also require that the user check out the password to view it. For password check-out, the password is changed only when it is checked back in, regardless of the number of times the user displays the password. For compound accounts, even if only one account is accessed, the password is changed on all servers.
- **Automatic Password Change (Optional):** Set *one* of the following options to change passwords that are used in remote sessions (not "viewed" passwords):
  - **Change Password On Connection End.** A password is automatically changed when the user SSH or RDP connection to a target server ends. The connection can end because the connection times-out, the user terminates the connection, or the connection is lost. This option does not apply to "View Password."
  - **Change Password on Session End.** All passwords that are used to log in to target servers are changed when the user session in Privileged Access Manager ends. The connection can end because the user logs out, a session times out, or connectivity is lost. This option does not apply to "View Password."
- **Change Password on Auto-Connect:** If set, the password is changed a configurable number of minutes after each successful automatic connection using the credential.  
**Note:** This setting might not be suitable for environments where multiple sessions are initiated simultaneously using the same credential.
- **Password View Request Banner:** Optional. Displayed when the Reason Required for View or Reason Required for Auto-Connect is checked. If displayed, enter the text for a banner that is displayed on Password View Requests. This banner can contain information about what users need to enter in the Reason Description and Reason Code fields when they attempt to view a password for an account. You can also set this banner on the Credential Manager General Settings page. The setting in the Password View Policy takes priority over the General Setting.
- **Change Password Interval** (appears only if one or both of the **Change Password on View** or **Change Password on Auto-Connect** options are selected): Specifies an interval (in minutes) between the password view or auto-connect operation (as applicable) until Credential Manager changes the password.  
If the **Check-out/Check-in** option is also set, the Change Password Interval setting is ignored. Instead, the password is changed when the account is checked in.
- **Check-out/Check-in:** If selected, this option specifies how long Credential Manager waits (in minutes) before automatically checking in the account password.  
The Check-in/checkout interval must be less than or equal to the Dual authorization interval. When you enable check-out/check-in and dual authorization, the check-out/check-in expiry time becomes less than or equal to the dual authorization expiry time.  
For more information, see [Require an Account Check-Out to View the Password](#).
- **Exclusive Check-out On Auto Connect:** If selected, this option specifies that credentials are checked in if all connections are closed.

#### NOTE

If you select this option, all view properties and the Check-out/Check-in property are unavailable.

If Exclusive Check-out On Auto Connect is selected with service desk integration, the Reason Required for View option is selected but disabled. Even though it is selected, the functionality of view password does not work, as exclusive checkout takes precedence. Viewing of a password is disabled when the account is associated with exclusive checkout on auto connect.

4. The Dual Authorization tab is optional. **Dual Authorization** requires a person with an Approver role to grant access to the account password before a person can view the password. If you configure dual authorization, you can also enable *One-click approval*. One-click approval allows identified approvers to approve or deny the password view request without logging in to Privileged Access Manager. For more information about configuring the Dual Authorization option, see [Make a Request to View a Password](#).

**Retrospective Approval** allows immediate "break glass" access to account credentials. When these credentials are viewed, a notification is sent to administrators with an approver role for after-the-fact approval. Use this functionality to provide emergency access to accounts that would typically require *prior* authorization by an administrator with an approver role. For more information, see [Configure Password View Policies That Require Approval of Requests](#).

5. The Email Notification tab is optional. This option allows certain users to receive email notifications when another user views an account password. Emails are sent only for successful initial password view requests. See [Enable Email Notification](#) for more information.
6. The Service Desk tab is optional. To use this capability, you have to have a Service Desk integration set up already. See [Integrate with Your Service Desk Solution](#) for more information.

### **How View Policy Changes are Applied**

Any change to an existing password view policy applies to all future attempts to view a password. However, any ongoing view attempts are governed by the previous policy. For example, if you disable the Check-out/Check-in option while a password is checked out, the password remains checked out. A user checks the password back in or the check-out time expires. Therefore, if there are outstanding password view requests for an account, do not change the password view policy.

Changes that are made to the list of request approvers take effect immediately. For example, a new approver is able to receive the relevant email notification and approve or deny the request. Similarly, approver that is removed from the list can no longer receive the email or, approve or deny the request.

#### **NOTE**

For information about advanced password view policy features, see the following topics:

- [Configure Password View Policies That Require Approval of Requests](#)
- [Enable Email Notifications for Viewed Passwords](#)
- [Integrate with Your Service Desk Solution](#)

### **Create a Password View Policy with the CLI**

To create a password view policy from the CLI, use the `addPasswordViewPolicy` command.

#### **Follow these steps:**

1. Specify the Password View policy. For example:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=addPasswordViewPolicy
PasswordViewPolicy.name=PasswordViewPolicy
PasswordViewPolicy.description=Test
PasswordViewPolicy.changePasswordOnView=true
PasswordViewPolicy.checkinCheckoutRequired=true
PasswordViewPolicy.authenticationRequired =true
PasswordViewPolicy.checkinCheckoutInterval=60
PasswordViewPolicy.dualAuthorization=true
```

```

PasswordViewPolicy.passwordViewRequestMaxDays=7
PasswordViewPolicy.passwordViewRequestMaxInterval=60
PasswordViewPolicy.dualAuthorizationInterval=60
PasswordViewPolicy.changePasswordOnConnectionEnd=true
PasswordViewPolicy.changePasswordOnSessionEnd=false
PasswordViewPolicy.enableOneClickApproval=true
PasswordViewPolicy.approvers=approver1,approver2
PasswordViewPolicy.emailNotificationRequired=true
PasswordViewPolicy.emailNotificationToDualAuthApprovers=false
PasswordViewPolicy.emailNotificationToActiveUsers=true
PasswordViewPolicy.emailNotificationUsers=user1,user2

```

## 2. Enter your password at the prompt.

Credential Manager returns an XML command string. For example:

```

<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<PasswordViewPolicy>
<name>PasswordViewPolicy</name>
<readOnly>>false</readOnly>
<description>Test</description>
<enableOneClickApproval>true</enableOneClickApproval>
<changePasswordOnView>true</changePasswordOnView>
<emailNotificationRequired>true</emailNotificationRequired>
<dualAuthorizationRequired>true</dualAuthorizationRequired>
<passwordViewRequestMaxDays>14</passwordViewRequestMaxDays>
<passwordViewRequestMaxInterval>60</passwordViewRequestMaxInterval>
<dualAuthorizationInterval>60</dualAuthorizationInterval>
<changePasswordOnConnectionEnd>true</changePasswordOnConnectionEnd>
<changePasswordOnSessionEnd>>false</changePasswordOnSessionEnd>
<approvers>approver1,approver2</approvers>
<approverIDs>[]</approverIDs>
<emailNotificationUserIDs>[]</emailNotificationUserIDs>
<checkinCheckoutRequired>true</checkinCheckoutRequired>
<checkinCheckoutInterval>60</checkinCheckoutInterval>
<passwordChangeInterval>60</passwordChangeInterval>
<emailNotificationForDualAuthApprovers>>false</emailNotificationForDualAuthApprovers>
<authenticationRequired>true</authenticationRequired>
<emailNotificationForActiveUsers>true</emailNotificationForActiveUsers>
<emailNotificationUsers>user1,user2</emailNotificationUsers>
<ID>1016</ID>
<createDate>Wed Nov 17 07:46:45 UTC 2010</createDate>
<createUser>admin</createUser>
<extensionType />
<hash>u09WfJd7m5RNv2N/3ZgIqVGU00M=</hash>
<updateDate>Wed Nov 17 07:46:45 UTC 2010</updateDate>
<updateUser>admin</updateUser>
</PasswordViewPolicy>
</cr.result>
</CommandResult>

```

The previous example creates a policy that is named `PasswordViewPolicy`. This new policy specifies:

- An account password must be changed once it is viewed.
- Only one person at a time can view an account password.
- The person must authenticate before viewing an account password.
- After a password is checked out, a password is automatically checked in after 60 minutes.
- After a connection is established, that password is automatically changed after that session is closed or times out.
- When the password is viewed, an email must be sent to the list of identified approver.
- The email sent to list of approvers must contain two URLs (one to approve and another to deny the password view request).
- When the password is viewed, an email is sent to the list of identified users.

### **Customize Reasons for Viewing Password**

Use the `setPasswordViewReasons` CLI command to customize the list of reasons for viewing a password that is displayed to GUI users. See [setPasswordViewReasons](#) for details.

## **Modify the Default Password View Policy**

You can edit the default password view policy to customize it for your requirements. The customized policy becomes the default policy.

### **NOTE**

Do not change the name of the default policy. Leave the name as **Default**.

Use the following procedure to modify the default password view policy.

### **Follow these steps:**

1. Select **Credentials, Workflow, Password View Policies**.
2. Select the **Default** option and select **Update**.
3. Modify the options on the various tabs, as required.  
For more information about the settings, see [Create a Basic Password View Policy](#).
4. select **OK**.

## **Configure Password View Policies That Require Approval of Requests**

To require that password view requests be approved by another administrator, enable one of the following options in the Password View Policy:

- **Dual Authorization:** Requires an administrator with an *approver* role to authorize access *before* the requester can access account credentials.
- **Retrospective Approval:** Provides immediate access to account credentials and sends a notification to administrators with an approver role for retrospective (after-the-fact) approval. Use this functionality (often referred to as "break glass") to provide emergency access to accounts that would typically require *prior* authorization by an administrator with an approver role.

This content contains the following information:

To configure dual authorization or retrospective approval using the CLI, see [Password View Requests in the CLI](#).

### **Who Can Be An Approver?**

Dual authorization and retrospective approval require an approver to allow, deny, and delete password view requests. For a user to become an approver, that user must meet two criteria:

- The user must have a role with the **credentialsManage** privilege. Roles with this privilege are:

- Global Administrator
- Password Manager
- Operational Administrator

For more about roles and privileges, see [Identify Desired User Roles](#).

- The user must belong to a Credential Manager group that includes a Credential Manager role with the following privileges:
  - Update Password View Request Status
  - List Password View Request Summary By Approver

For example, the System Admin Group is a Credential Manager group with the necessary privileges.

To see a list of Credential Manager roles in each group, select **Credentials, Manage Credential Groups** then double-click a role in the list and view the selected privileges for that role.

### **Configure a Password View Policy That Requires Dual Authorization**

Configure dual authorization to require an administrator with an *approver* role to authorize access *before* the requester can access account credentials. Credential Manager sends an email to the requesters notifying them of the password view request decision. If the request is approved, the requester can view the password.

Enable and configure dual authorization using the following procedure.

#### **Follow these steps:**

1. Go to **Credentials, Workflow, Password View Policies**.
2. On the **Dual Authorization** tab, select the **Dual Authorization** checkbox.
3. Set the time period for View Password requests.
  - **Request must be within:** Specifies the time frame within which the password view can be requested. The default value is 14 days.
  - **Default Request Interval:** Specifies the default interval in minutes to view the password, if applicable. The default value is 60 minutes. When a user requests a password, the time between the **Request Password From** and **Request Password To** fields is set to the default request interval.
  - **Maximum Request Interval:** Specifies the maximum interval in minutes, up to which the password can be viewed, if applicable. The default value is 60 minutes.

When users request password viewing, it is for a specific time period. For example, August 8 from 9:00 to 11:00. Specify the time zone in **Global Settings, Default Preferences**.

#### **NOTE**

This time period defines when a user can retrieve and view a password. The View Password function does not initiate session management.

4. (Optional) Select **Enable One Click Approval**.  
If selected, this option allows specified approvers to approve or deny the password view request without logging in to Credential Manager. If enabled, approvers are sent an email notification whenever someone attempts to view the password. The email notification all the standard details and a URL that approves the request and a URL that denies the request. The approver can select the approve or deny URL directly from the email without logging in to PAM. If One Click Approval is *not* enabled, each approver still receives an email, but without the URLs. Instead, the approver must log in to view a list of pending requests, which are approved, denied, or expired.
5. From the **Available Approvers** list, select users and move them to the **Selected Approvers** list.
6. Select **OK**.

When a user or administrator makes a request to view the password, Credential Manager automatically sends an email notification to the approvers for that account. The notification includes the following request details:

- Name of the user submitting the request
- Account name for the requested password view
- Requested account target application
- Requested account target server
- Password view reason
- Requested timeframe (in UTC)

### **Configure a Password View Policy That Requires Retrospective Approval**

Configure retrospective approval to allow immediate emergency "break glass" access to account credentials and send a notification to administrators with an *approver* role for retrospective (after-the-fact) approval.

#### **Follow these steps:**

1. Go to **Credentials, Workflow, Password View Policies**.
2. On the **Dual Authorization** tab, select the **Retrospective Approval** checkbox.
3. (Optional) Select **Enable One Click Approval**.  
If selected, this option allows specified approvers to approve or deny the password view request without logging in to Credential Manager. If enabled, approvers are sent an email notification whenever someone attempts to view the password. The email notification all the standard details and a URL that approves the request and a URL that denies the request. The approver can select the approve or deny URL directly from the email without logging in to PAM. If One Click Approval is *not* enabled, each approver still receives an email, but without the URLs. Instead, the approver must log in to view a list of pending requests, which are approved, denied, or expired.
4. From the **Available Approvers** list, select users and move them to the **Selected Approvers** list.
5. Select **OK**.

When a user or administrator makes a request to view the password, a dialog informs them that their request is for emergency access and requires retrospective approval. If they decide to proceed, Credential Manager automatically sends an email notification and adds the request to the **My Password View Approvals** list of assigned approvers. However, because the credentials have already been accessed, the only effect of approval or denial is how the request is audited in the session logs.

For further information, see the following content:

- [Creating Custom Approvers \(Optional\)](#)
- [Process View Requests as an Approver](#)
- [View Dual Authorization Requests in the CLI](#)
- [View Retrospective Approval Requests in the CLI](#)

### **Creating Custom Approvers (Optional)**

If dual authorization is enabled, a user who is designated as an approver must grant permission to view the password. A set of preconfigured Credential Manager groups exists, which have roles with the necessary privileges to be an approver. For example, the System Admin Group contains the System Admin role, which has the required privileges for authorizing password views.

You can create a role and can add it to a Credential Manager group. Any user that is a part of the group with the new role can act as an approver.

The new role must have the following permissions:

- List Password View Request Summary By Approver
- Update Password View Request Status

In addition, an approver must have a valid email address. Their user group must also be able to access the accounts they are approving.

To create an approver role, see [Add or Modify Credential Manager Roles](#).

## Process Password View Requests as an Approver

This content describes how to process dual authorization and retrospective approval password view requests.

### Process Dual Authorization Requests

As an approver for a [dual authorization password view policy](#), you can grant, deny, or expire a password view request. You can act on a specific request only once.

When the password view request exceeds the date and time in the request, the request status changes automatically. For example, a password view request start date and time are 2012-11-19 18:06 and the end date and time is 2012-11-19 19:06. After 2012-11-19 19:06, the status of the request that is yet pending changes to Expired. The status of the request that is approved or denied changes to Approved, Expired, or Denied. The status of the request that is checked in or checked out changes to Checked In or Checked Out.

The following methods are different ways to view requests:

#### *Handle Requests from My Approval List*

##### Follow these steps:

1. Navigate to **Credentials, Workflow, My Approvals**. A list of requests appears.
2. Select a specific pending password view request and select the **VIEW** button. The **Password View Request Details** pane appears.
3. After reviewing the reason details in the email, select the appropriate option to approve, deny, or expire the request.

#### **NOTE**

You can also select multiple password view requests and then select **Approve All** or **Deny All**.

#### *Approve or Deny Requests from the Target Accounts Panel*

After you receive an email notification of a password view request, review the details in the email. Then, approve or deny the request from the Current Requests section on the **Target Accounts** panel.

#### **NOTE**

You cannot expire a password from the **Current Requests** section. You must select the entry and must select **Expire** from the **Password View Request Details** panel.

##### Follow these steps:

1. Select **Credentials, Manage Targets, Accounts**. The **Account List** panel appears with a list of current requests.
2. Take one of the following actions in the **Current Requests** section:
  - Select the green Thumbs Up icon under the **Action** column for the appropriate account.
  - Select the red Thumbs Down icon under the **Action** column for the account.
 The **Password View Request Approval** pop-up appears.
3. Select **Approve** or **Deny**.
4. Select the reason to approve the request from the drop-down list.
5. (Optional) Enter the reason description.
6. Select **Save**.
7. When you are prompted to confirm the approval, select **Yes**.

### ***Grant or Deny a One-Click Approval Request***

A password view policy might be enabled for dual authorization with one-click approval. When a person attempts to view the account password with these features enabled, Credential Manager sends an email to the approver. The approver can approve or deny the request directly from the received email without logging in to the appliance.

#### **NOTE**

The contents of the email can differ based on the email template configuration. See [Configure the Email Server and Email Templates](#).

The approver can review the reason details in the email then approve or deny the request by:

- Clicking the URL given for approving the password view request. The password view request status is updated to Approved. A web page appears with the approval confirmation message.
- Clicking the URL given for denying the password view request. The password view request status is updated to Denied. A web page appears with the rejection message.

Under the following conditions, the approver might be redirected to an error page:

- The approver is invalid or expired.
- The password view request is invalid or expired.
- The status is invalid.
- The password view request is already approved or denied.

### **Process Retrospective Approval Requests**

As an approver for a [retrospective approval password view policy](#), you can retrospectively acknowledge or decline a password view request. You can act on a specific request only once.

#### **Follow these steps:**

1. Navigate to **Credentials, Workflow, My Approvals**. A list of requests appears.
2. Select a specific pending password view request and select the **VIEW** button.  
The **Password View Request Details** pane appears.
3. After reviewing the reason details in the email, select the appropriate option to acknowledge or decline the request.

#### **NOTE**

You can also select multiple password view requests and then select **Acknowledge All** or **Decline All**.

### **Identify Extended Timeout Requirements in Password View Requests with Extended Timeout**

As an approver, you can see the connection idle timeout value that is associated with a password view request in the following locations:

- The **Timeout** column on the **My Password View Approvals** panel (**Credentials, Workflow, My Approvals**).
- The **Connection Idle Time (Minutes)** entry on the **Password View Request Details** pane

To identify a password view request seeking an [extended timeout](#), look for a value more than the default **Connection Idle Timeout** specified in the [Global Settings](#).

### **Delete a View Request Using the UI**

All password view requests with status Approved, Denied, Pending, Expired, Acknowledged, or Denied are available in the My Approval List. Any password view request that is not required can be deleted from the My Approval List with the UI.

Use the following procedure to delete a request using the UI My Approval List.

**Follow these steps:**

1. Go to **Credentials, Workflow, My Approvals**. The My Approval List Panel appears.
2. Select the check box corresponding the password view requests to be deleted. Select **Delete**.
3. When you are prompted to confirm the deletion, select **OK**.

**Delete View Requests Automatically**

You can automate the removal of password view requests using the **Password View Request Delete Interval Days** setting. For example, if you set the value of the interval for two days, the requests are deleted automatically from the list after every two days.

**Follow these steps to set the delete interval:**

1. Go to **Settings, Credential Manager, General Settings**.
2. In the **Password View Request Delete Interval Days** field, enter the number of days you want view requests removed.
3. Select **Save**.

**View Dual Authorization Requests in the CLI****Make a Request to View a Password Using the CLI**

If the password view policy specifies dual authorization, requests to view a password are sent to the approver.

In such cases, the XML command string that is returned from the operation:

- Contains a status code of 400, indicating successful operation
- Excludes all account details except a warning message indicating that the request has been forwarded for processing

**Follow these steps:**

1. Search target accounts to retrieve the target account ID:

Windows:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=searchTargetAccount ^
TargetAccount.userName=dualaccount
```

Linux:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=searchTargetAccount \
TargetAccount.userName=dualaccount
```

2. Enter your password at the prompt.

Credential Manager returns the following XML command string. Note the ID value. In this example, it is **1005**.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<TargetAccount>
<privileged>true</privileged>
<aliases />
<password>{1}3d2876d75f730fcf7b00f974816aa97b</password>
<lastUsed />
<passwordViewPolicyID>1013</passwordViewPolicyID>
<accessType />
<cacheBehavior>useCacheFirst</cacheBehavior>
<cacheDuration>30</cacheDuration>
<compoundServerList>[]</compoundServerList>
```

```

<lastVerified />
<lastViewed />
<targetApplicationID>1001</targetApplicationID>
<userName>dualaccountnew</userName>
<compoundAccount>false</compoundAccount>
<passwordVerified>false</passwordVerified>
<synchronize>false</synchronize>
<targetApplication />
<cacheAllow>true</cacheAllow>
<targetServerAlias />
<ID>1005</ID>
<Attribute.extensionType>mssql</Attribute.extensionType>
<Attribute.useOtherAccountToChangePassword>false
</Attribute.useOtherAccountToChangePassword>
<Attribute.cspm_serverkeyid>1</Attribute.cspm_serverkeyid>
<Attribute.descriptor1 />
<Attribute.descriptor2 />
<createDate>Tue Nov 16 12:44:50 UTC 2010</createDate>
<createUser>admin</createUser>
<extensionType>mssql</extensionType>
<hash>FIRqOhKpXVlsglrsroJzlyHmzH4=</hash>
<updateDate>Tue Nov 16 12:44:50 UTC 2010</updateDate>
<updateUser>admin</updateUser>
</TargetAccount>
</cr.result>
</CommandResult>

```

### 3. View the password. Use the ID provided by the output of the previous command:

Windows:

```

capam_command adminUserID=admin capam=mycompany.com cmdName=viewAccountPassword ^
TargetAccount.ID=1005 reason=Poweroutagereason reasonDetails=Recover Tuesday pm ^
PasswordViewRequest.requestPeriodStart="2010-11-16 16:58" ^
PasswordViewRequest.requestPeriodEnd="2010-11-16 17:05"

```

Linux:

```

capam_command adminUserID=admin capam=mycompany.com cmdName=viewAccountPassword \
TargetAccount.ID=1005 reason=Poweroutagereason reasonDetails=Recover Tuesday pm \
PasswordViewRequest.requestPeriodStart="2010-11-16 16:58" \
PasswordViewRequest.requestPeriodEnd="2010-11-16 17:05"

```

### 4. Enter your password at the prompt.

Credential Manager returns the following XML command string.

```

<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.warningCode>4625</cr.warningCode>
<cr.warningMessage>This account has dual authorization enabled.
A request to view the password has been e-mailed to the approvers of this account on your behalf.
</cr.warningMessage>
</CommandResult>

```

## **Grant, Deny, or Expire a Request Using the CLI**

Use the following procedure to approve or deny a password view request from the CLI using the `updatePasswordViewRequestStatus` command.

### **Follow these steps:**

1. Search target accounts to retrieve the target account ID:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=searchPasswordViewRequestByApprover
```

2. Enter your password at the prompt.

Credential Manager returns the following XML command string. Note the ID value. In this example, it is **4**.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<PasswordViewRequest>
<status>1</status>
<targetAccountID>1</targetAccountID>
<startDate/>
<endDate/>
<requestorID>3</requestorID>
<approverID>-1</approverID>
<ID>4</ID>
<createDate>Wed Sep 10 14:42:20 UTC 2008</createDate>
<createUser>req1</createUser>
<hash>RLMwHaMdENV9mlFnoSsoSOJezJw=</hash>
<updateDate>Wed Sep 10 15:42:20 UTC 2008</updateDate>
<updateUser>req1</updateUser>
<extensionType/>
</PasswordViewRequest>
</cr.result>
</CommandResult>
```

3. Change the status of the password view request to approved or denied. Use the ID provided by the output of the previous command:

Windows:

```
capam_command adminUserID=admin capam=mycompany.com ^
cmdName=updatePasswordViewRequestStatus PasswordViewRequest.ID=4 ^
PasswordViewRequest.status=approved
```

Linux:

```
capam_command adminUserID=admin capam=mycompany.com \
cmdName=updatePasswordViewRequestStatus PasswordViewRequest.ID=4 \
PasswordViewRequest.status=approved
```

4. Enter your password at the prompt.

Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<PasswordViewRequest>
<status>1</status>
<targetAccountID>1</targetAccountID>
```

```

<startDate>Wed Sep 10 15:47:00 UTC 2008</startDate>
<endDate>Wed Sep 10 16:02:00 UTC 2008</endDate>
<requestorID>3</requestorID>
<approverID>1</approverID>
<ID>1</ID>
<createDate>Wed Sep 10 14:42:20 UTC 2008</createDate>
<createUser>reql</createUser>
<hash>Yc5gR/IpPVh8evYKGipQYa9AGXU=</hash>
<updateDate>Wed Sep 10 15:47:09 UTC 2008</updateDate>
<updateUser>admin</updateUser>
<extensionType/>
</PasswordViewRequest>
</cr.result>

```

Use the following procedure to expire a password view request from the CLI using the `expirePasswordViewRequestCmd` command.

### Follow these steps:

1. Search target accounts to retrieve the target account ID:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=searchPasswordViewRequestByApprover
```

2. Enter your password at the prompt.

Credential Manager returns the following XML command string. Note the ID value. In this example, it is 4.

```

<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<PasswordViewRequest>
<status>1</status>
<targetAccountID>1</targetAccountID>
<startDate/>
<endDate/>
<requestorID>3</requestorID>
<approverID>-1</approverID>
<ID>4</ID>
<createDate>Wed Sep 10 14:42:20 UTC 2008</createDate>
<createUser>reql</createUser>
<hash>RLMwHaMdENV9mlFnoSsoSOJezJw=</hash>
<updateDate>Wed Sep 10 15:42:20 UTC 2008</updateDate>
<updateUser>reql</updateUser>
<extensionType/>
</PasswordViewRequest>
</cr.result>
</CommandResult>

```

3. Change the status of the password view request to approved or denied. Use the ID provided by the output of the previous command:

Windows:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=expirePasswordViewRequestCmd ^
PasswordViewRequest.ID=4
```

Linux:

```
capam_command adminUserID=admin capam=mycompany.com cmdName=expirePasswordViewRequestCmd \
PasswordViewRequest.ID=4
```

#### 4. Enter your password at the prompt.

Credential Manager returns the following XML command string.

```
<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
</cr.result>
```

### **Update the Approval or Denial Reasons for a Request Using the CLI**

The reasons to be populated in the Reason drop-down list while approving or denying the password view request using the GUI, can be updated using the `setSystemProperty` command.

To update the list of approval reasons, use:

```
Windows:
cspmserver_admin cmdName=setSystemProperty propertyName=viewPasswordApprovalReasons ^
propertyValues=reason1|reason2
Linux:
cspmserver_admin cmdName=setSystemProperty propertyName=viewPasswordApprovalReasons \
propertyValues=reason1|reason2
```

To update the list of denial reasons, use:

```
Windows:
cspmserver_admin cmdName=setSystemProperty propertyName=viewPasswordDenialReasons ^
propertyValues=reason1|reason2
Linux:
cspmserver_admin cmdName=setSystemProperty propertyName=viewPasswordDenialReasons \
propertyValues=reason1|reason2
```

The `|` character delimits multiple reasons.

### **View Retrospective Approval Requests in the CLI**

#### **Make a Request to View a Password Using the CLI**

If the password view policy specifies retrospective approval, requests to view a password are sent to the approver.

In such cases, the XML command string that is returned from the operation:

- Contains a status code of 400, indicating successful operation
- Excludes all account details except a warning message indicating that the request has been forwarded for processing

#### **Follow these steps:**

##### 1. Search target accounts to retrieve the target account ID:

```
Windows:
capam_command adminUserID=admin capam=mycompany.com cmdName=searchTargetAccount ^
TargetAccount.userName=breakglassaccount
Linux:
capam_command adminUserID=admin capam=mycompany.com cmdName=searchTargetAccount \
TargetAccount.userName=breakglassaccount
```

##### 2. Enter your password at the prompt.

Credential Manager returns the following XML command string. Note the ID value. In this example, it is **1005**.

```

<CommandResult>
<cr.itemNumber>0</cr.itemNumber>
<cr.statusCode>400</cr.statusCode>
<cr.statusDescription>Success.</cr.statusDescription>
<cr.result>
<TargetAccount>
<privileged>true</privileged>
<aliases />
